Introduction: Recently, liquid-liquid phase separation (LLPS) of membrane protein has been found to play a critical role in the development of tumors [1-3]. Meanwhile, Protein Kinase C and Casein Kinase Substrate in Neurons 1 (PACSIN1), a peripheral membrane protein with intrinsically disordered regions (IDRs), is associated with the prognosis of gastric cancer patients [4].

However, whether PACSIN1 could undergo LLPS and whether PACSIN1 involved in the development of gastric have not been studied until now.

Aims & Methods: Here, we aimed to investigate whether PACSIN1 could undergo LLPS and the potential role of PACSIN1 in gastric cancer. We analyzed disease free survival of gastric cancer samples from The Cancer Genome Atlas dataset. The protein sequence prediction website (Disprot - Database of Protein Disorder) was used to predict the IDRs of PACSIN1. Besides, droplet formation experiments, fluorescence recovery after photobleaching (FRAP) and cellular immunofluorescence were used to explore whether PACSIN1 could undergo LLPS. What's more, cell proliferation assay and cell migration assay were utilized to investigate the potential role of PACSIN1 in gastric cancer.

Results: In the prognosis analysis of the TCGA database, it was found that the disease-free survival rate of gastric cancer patients with high expression of PACSIN1 was significantly lower than that of patients with low expression of PACSIN1(Figure 1).

Overexpression of PACSIN1 in gastric cancer cell resulted in decreased proliferation (Figure 2A-B) and increased migration (Figure 2C-D) of gastric cancer cells. In the prediction of protein structure, it could be found that the IDRs region of PACSIN1 accounted for more than 50% (Figure 3). When fully mixed with 5% Polyethylene glycol (PEG), one of the characteristics of LLPS- droplet formation - could be observed under the microscope (Figure 4B). After the fluorescence bleaching of the droplet formed by PACSIN1 with mCherry, the fluorescence gradually recovered within a few minutes (Figure 4C). What's more, PACSIN1 formed puncta with irregular distribution in cytoplasm (Figure 4D), which also proved that PACSIN1 could undergo LLPS.

Conclusion: Overall, high expression of PACSIN1 is associated with poor prognosis of patients, and overexpression of PACSIN1 in gastric cancer cell can promote the proliferation and migration. PACSIN1 can also undergo LLPS in vitro and in vivo. Therefore, we speculate that PACSIN1 may promote the development of gastric cancer through LLPS.

AUTOMATIC DEEP LEARNING MODELS FOR GASTROINTESTINAL TUMOR DIAGNOSIS AND PROGNOSIS USING HEMATOXYLIN AND EOSIN SLIDES

J. Wang[1], S. Zhang[1], L. Wu[2,1], H. Yu[1]
[1]Renmin Hospital of Wuhan University, Wuhan, China, [2]Cambridge University, Cambridge, China

Contact E-Mail Address: wang102581@163.com

Introduction: Immunohistochemistry (IHC) is a critical tool for tumor diagnosis and treatment. However, IHC is time consuming and costly, relies on the pathologists' subjective interpretation. Deep learning has gained ground for predicting the biomarker expression on hematoxylin and eosin (H&E) staining images.

In this study, we aim to create an automatic pipeline for the construction of deep learning models to generate virtual IHC output using H&E whole slide images and validate its clinical applicability by reader study.

Aims & Methods: We obtained 134 whole-slide images (WSIs) from 73 patients at Renmin Hospital of Wuhan University and extracted 415,463 patches from H&E-stained WSIs.

Our study focused on five widely used biomarkers in pathology reports, namely anti-P40, CK-pan, Desmin, P53, and Ki-67, as recommended by the NCCN guidelines. We validated these models by using independent whole-slide images (WSIs). The number of WSIs used for each model were as follows: model-P40 (6 WSIs, 38389 Patches), model-PCK (9 WSIs, 72443 Patches), model-Ki67 (7 WSIs, 53162 Patches), model-Desmin (5 WSIs, 23974 Patches), and model-P53 (5 WSIs, 36822 Patches).

We aimed to predict these biomarkers expression in H&E WSIs and quantify the percentage of Ki-67. There are three main steps: Firstly, we employed HEMnet neural network to align the corresponding IHC and H&E WSIs, transfering the molecular labels from IHC to H&E images. Secondly, pathologists reviewed the annotations made by HEMnet and corrected HE-IHC mismatched tiles using VIA labelling platform. Lastly, the deep learning models were trained to predict positive tiles. The performance of models was assessed by sensitivity, specificity, accuracy, and the area under the receiver operating characteristic curve (AUC). To assess the ap-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

plicability of models, we randomly selected 30 cases including H&E and IHC WSIs for three pathologists to write the reports in the reader study by reading the interpretation of real IHC and AI-generated IHC.

Results: The sensitivity, specificity, accuracy, and area under the receiver operating characteristic curve (AUC) of the models for classifying positive pixels of each biomarker was: P40 (91.64%, 87.39%, 88.66%, AUC: 0.95), PAN-CK (92.40%, 89.35%, 90.81%, AUC: 0.96), Ki67 (89.63%, 86.04%, 86.77%, AUC: 0.95), Desmin (91.44%, 88.11%, 89.17%, AUC: 0.96), and P53 (75.44%,86.52%,83.04%, AUC: 0.90). The predicted Ki-67 percentage was comparable to the assessments made by expert pathologists, with a difference ranging from 7.00%±3.69%. In the reader study, compared with real-IHC pathology report, the accuracy of AI-IHC pathology report of each biomarker was: Desmin(100%,66/66), Pan-CK(98.3% , 59/60), P53(98.3% ,59/60), T-stage(84.8% .56/66), P40(96.7% ,29/30). and there is no significant difference between the quatification of Ki-67 score(*t*= 0.253 ,*P*= 0.800).

Items	Pathology report's accuracy of AI-IHC compared with Real-IHC					T test of Ki-67
	Desmin	Pan-CK	P53	T-stage	P40	
Pathologist 1	100.0% (22/22)	100.0% (20/20)	70.0% (21/30)	68.2% (15/22)	100.0% (10/10)	t= 0.475 (P= 0.637)
Pathologist 2	100.0% (22/22)	95.0% (19/20)	66.7% (20/30)	95.5% (21/22)	100.0% (10/10)	t= - 0.775 (P= 0.443)
Pathologist 3	100.0% (22/22)	100.0% (20/20)	60.0% (18/30)	90.9% (20/22)	90.0% (9/10)	t= - 0.510 (P= 0.613)
Average	100.0% (66/66)	98.3% (59/60)	98.3% (59/60)	84.8% (56/66)	96.7% (29/30)	t= 0.253 (P= 0.800)

Table. Result of Reader Study.

Conclusion: Our deep learning models have demonstrated promising performance in predicting gastrointestinal tumor biomarkers based on H&E slides. The utilization of these models can alleviate the burden of IHC staining and clinicopathological assessments.

Furthermore, these models have the potential to aid in patient grading, facilitate informed treatment decisions, and provide valuable prognostic assessments.

LOSS OF STROMAL BMP ACTIVITY DRIVES GASTRIC PATHOLOGY IN MICE

J. Wizenty[1], M. Sigal[1]

[1]Charité - Universitätsmedizin Berlin, Division of Gastroenterology and Hepatology, Medical Department, Berlin, Germany

Contact E-Mail Address: jonas.wizenty@charite.de

Introduction: The gastric epithelial gland homeostasis is driven by insufficiently characterized sub-epithelial stromal signals. Gastric stem cells in the gland base are fueled by a Wnt/Rspo^{high} niche where Bmp activity is suppressed, while terminally differentiated mucous pit cells are maintained by a BMP^{high} niche, that suppresses Wnt/Rspo activity. Infection with *Helicobacter pylori* reduces stromal and epithelial Bmp activity driving stem cell expansion. In line with this, genetic knockout of BMP activity in the epithelium leads to epithelial hyperplasia. The consequences of loss of BMP activity in the stroma on epithelial homeostasis and proliferative, regenerative, and inflammatory pathways in the interplay between stroma and epithelium are unknown.

Aims & Methods: The objective of this study was to analyze the epithelial pathology and epithelial-stromal interplay in the context of loss of BMP activity in the gastric stroma by using an inducible knockout of the BMP type 1 receptor in the stroma in mice.

Results: After two months of knockout of the BMP receptor in the gastric stroma, mice display drastic hyperplasia via stem cell expansion in the antrum and the corpus. Loss of stromal BMP signaling causes the occurrence of a bulky stroma with expanded fibroblasts and aberrant glands within the pit area, that resemble the gland base with expression of stem cell factors, high proliferation, enhanced epithelial inflammation (marked by NF-κB p65) and expression of metaplasia markers (CD44v9, Aqp5). Using scRNAseq as well as organoid and assembloid technologies we now study the mechanisms by which loss of stromal BMP affects epithelial homeostasis.

Conclusion: Collectively, our data demonstrate that alterations in stromal BMP activity can promote premalignant lesions. This model will allow us to study the underlying principles of stromal-epithelial interplay in the stomach and explore mechanistically the consequences of stromal responses observed upon *H. pylori* infection in detail.

Introduction: Human leucocyte antigen (HLA) strongly associated with autoimmune diseases. In some studies it was demonstrated, that achalasia is an autoimmune disease and associated with genetic factors.

Aims & Methods: The aim of our study was to investigate the association of genes of the HLA system in patients with achalasia and in healthy citizens of Russian Federation.

Material and methods: 140 patients with achalasia were included in this study: 75 females (55%), age from 18 to 75. The diagnosis of idiopathic achalasia was established by upper endoscopy and high resolution water-perfused manometry (MMS, Netherland). Healthy 332 volunteers from 21 to 74 y.o. (asymptomatic) were included in this study: there were 305 females.The DNA from blood samples was isolated using QIAamp DNA Blood Mini Kit (Qiagen, Germany) according to the manufacturer's recommendations. The concentration of DNA samples was measured by fluorimetric method on a Qubit 4 fluorimeter using the Qubit dsDNA BS Assay Kit (Thermo Fisher Scientific, USA). All patients underwent HLA typing by massively parallel sequencing (NGS): *HLA-A, HLA-B, HLA-C, HLA-DQB1, HLA-DRB1, HLA-DPB1*, on the platform MiSeq (Illumina, USA) v.2, Omixon. The analysis of the HLA gene sequences obtained as a result of sequencing was carried out using a computer program TypeStream Visual Software (TSV) (One Lambda, USA), and database IPD-IMGT/HLA.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The allelic variants *HLA-A*02, HLA-B*37, HLA-B*39, HLA-C*5, HLA-C*7, HLA-C*14, HLA-C*15, HLA-DRβ1*01, HLA-DRβ1*03, HLA-DRβ*08, HLA-DRβ1*13, HLA-DPβ1*06, HLA-DPβ1*11, HLA-DPβ1*05, HLA-DPβ1*15 and HLA-DQβ1*04* were evaluated equally in healthy volunteers and achalasia patients. The allelic variants *HLA-A*66, HLA-B*15, HLA-B*44, HLA-B*52, HLA-C*12, HLA-C*16, HLA-DPβ1*01, HLA-DPβ1*02, HLA-DPβ1*23, DRβ1*11, HLA-DRβ1*14, DQβ1*06* were found statistically more frequently in patients with achalasia than in healthy volunteers. The allelic variants *HLA-A*11, HLA-A*23, HLA-A*25, HLA-A*26, HLA-B*7, HLA-B*57, HLA-C*3, HLA-C*06, HLA-DPβ1*03, HLA-DPβ1*13, HLA-DPβ1*17, DRβ1*13, HLA-DRβ1*15* were insignificantly evaluated more frequently in group with achalasia than in healthy volunteers.

Conclusion: The absence of differences in some allelic variants of genes of HLA in patients with achalasia and healthy volunteers confirm that they are not specific for achalasia in Russian Federation. The statistical difference in predominance of some allelic variants of HLA system indicates, that these findings should be compare with medical history and symptoms. After that these allelic variants of genes of HLA can be consider as a prognostic factor.

Introduction: Psoriasis is a common inflammatory skin disorder following non-specific triggers such as scratching, piercing, sunburn, and chemical irritants. Involvement of immune system is widely accepted for pathogenesis studies have demonstrated importance of gut microbiota in pathogenesis of inflammatory skin diseases. Proton pump inhibitors (PPIs) and histamine-2 receptor antagonists (H2RA) are acid suppressing drugs widely used for gastrointestinal diseases, and long-term use has been reported to be associated with altered gut microbiota. This study aimed to investigate association between psoriasis and acid suppressing drugs in Korean population.

Aims & Methods: We used Korean National Health Insurance Service-National Sample Cohort (NHIS-NSC) data of 746,816 patients with upper gastrointestinal (GI) diseases between 2002 and 2013. Duration of acid suppressing drug exposure and other socio-demographic characteristics were compared between patients with and without psoriasis, and hazard ratios were estimated.

Results: Significantly larger number of patients with exposure to acid suppressing drugs had developed psoriasis compared to control cohort (46.3% vs. 33.7% respectively, $P < 0.001$). In the multivariate analysis, longer use of acid suppressing drugs and greater Charlson comorbidity index score were significantly associated with increased risk of psoriasis with an adjusted odds ratio, 1.89 (95% confidence interval, 1.66-2.17, $P < 0.001$) and 1.33 (1.17-1.51, $P = <0.001$), respectively.

Conclusion: Results from our study indicate that prolonged use of H2RA or PPI is associated with the risk of psoriasis among patients with GI diseases in Korean population. The risk was increased in dose-response trend, even after adjusting for confounding variables. Clinicians should be aware of risks associated with prolonged use of acid suppressing drugs.

CYANOCOBALAMIN INTRAMUSCULAR TREATMENT IN PATIENTS WITH CORPUS ATROPHIC GASTRITIS AND VITAMIN B12 DEFICIENCY: EFFICACY AND PREDICTORS OF INCREASED REQUIREMENT

C. Palumbo[1], F.P. Schiavone[1], L. Dottori[1], G. Cozza[1], I. Ligato[1], G. Pivetta[1], S. Scalamonti[1], E. Dilaghi[1], B. Annibale[2], E. Lahner[1]

Introduction: Corpus atrophic gastritis (CAG) is associated with vitamin B12 deficiency. Untreated vitamin B12 deficiency can lead to megaloblastic anaemia (also known as Pernicious Anaemia) and other potential serious clinical manifestations such as acute cardiocerebral events and severe neurological consequences, thus timely B12 supplementation is relevant. To date, the dosage of intramuscular B12 supplementation in CAG patients with vitamin B12 deficiency is not standardized.

Aims & Methods: The aim was to assess the efficacy of cyanocobalamin treatment (Tx) at long term follow-up and predictors of increased cyanocobalamin requirement.

A monocentric retrospective longitudinal cohort study was conducted on 190 pts (62.1% F, age 63±1 yrs) consecutively diagnosed (2007-2021) with CAG and vitamin B12 deficiency. Inclusion criteria were age >18 years, histological diagnosis of CAG (updated Sydney System), serum B12 <250 pg/ml, intramuscular cyanocobalamin supplementation, and follow-up of at least 12 mos. Demographic, clinical, biochemical, and histological data were retrospectively collected. After the diagnosis of vitamin B12 deficiency pts were first treated with TxA schedule (5000μg intramuscular cyanocobalamin every 5 days for 3 times, followed by 5000μg intramuscular every 3 mos (20000μg/yr)), and revaluated at follow up. If TxA was not sufficient to restore B12 levels, TxB was prescribed (5000μg intramuscular cyanocobalamin every 5 days for 3 times, followed by 5000μg intramuscular cyanocobalamin every 2 mos (30000μg/yr)). Primary Tx endpoint was B12 normalization. Baseline and follow-up data of pts on TxA and TxB were compared by Student's t-test. Logistic regression was performed to find out predictors of increased B12 need.

Results: Macrocytic anaemia was mild, moderate and severe in 60, 17, 14 out of 190 pts, while 94 pts had vitamin B12 deficiency without anaemia.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

TxA efficaciously corrected vitamin B12 deficiency in 130 (68.4%) pts and was maintained until longest available follow-up (41±2.4 mos). The remaining 60 (31.6%) pts, due to persistent vitamin B12 deficiency observed at 12 (6-48) mos, were switched to TxB which was then maintained until longest available follow-up (49.9±4.1 mos). At longest available follow-up, a significant increase of Hb (TxA: 12±0.2 vs 13.1±0,2; TxB: 12.1±0.4 vs 13.8±0.2, p<0,0001) and B12 (TxA: 162.9±8.6 vs 400±22.2; TxB: 142.3±11.2 vs 323.4±22.3, p<0.001) was shown in both schedules. A significant decrease of MCV was shown in TxB only (96.4± 2.1 vs 88.1±0.9,p=<0.0001). At logistic regression, switch to TxB was associated with severe intestinal metaplasia (OR10.6, IC 95% 2.6-43.0, p=0.0009) and macrocytosis at diagnosis (OR2.8, IC95% 1.1-6.9, p=0.0231), and male gender (OR 2.5, IC95% 1.1-5.7, p=0,0213), while other features such as age, severity of vitamin B12 deficiency, previous vitamin B12 therapy, concomitant iron deficiency were not significantly associated with increased need of intramuscular cyanocobalamin.

Conclusion: At long term follow-up, about 70% of pts restore vitamin B12 deficiency with 5000µg intramuscular cyanocobalamin every 3 mos, while only 30% require an increased dosage of 5000µg intramuscular cyanocobalamin every 2 mos. In particular, male pts with severe intestinal metaplasia and macrocytosis at diagnosis require a higher dosage of cyanocobalamin to obtain B12 normalization. In CAG pts with vitamin B12 deficiency regular clinical-biochemical follow-up is important to monitor efficacy of B12 treatment to restore B12 levels and to treat and prevent clinical manifestations of vitamin B12 deficiency.

Introduction: The incidence of caustic ingestion has remained stable in recent years due to its difficult prevention and limited changes in its management.

Aims & Methods: Aims:

1. To explore changes in the epidemiological and clinical characteristics of caustic ingestion over the last decades
2. To identify epidemiological risk factors of adverse outcomes.

Methods: We present data from an observational study that prospectively collected caustic ingestions in our centre since 1995 and included all adult patients whose acute episode was evaluated in the emergency department. Epidemiological data and variables related to the type of ingestion, prognostic risk factors and the adverse outcomes, defined as the need for admission to the intensive care unit, emergency surgery, patient death and oesophageal or gastric stricture development, were analysed; the results were compared for the periods 1995-2009 and 2010-2024.

Results: A total of 582 episodes of caustic ingestion were included, 305 during the first period and 277 during the second.

Epidemiological characteristics and type of ingestion were overall similar in both periods, as were the clinical, analytical, endoscopic and radiologic indicators of severity.

Adverse outcomes were also similar in the two time periods, both in the short term (comparable frequency of intensive care unit admission, need for surgery and death) and in the long term (stricture development).

The main risk groups for severe ingestions were patients older than 45 years (OR 4.3; 95%CI: 2.3-7.9) and psychiatric comorbidity (OR 5.2; 95%CI: 3.0-9.1), especially depressive syndrome (OR 7.2; 95%CI: 4.2-12.4).

Recurrent ingestions were more frequent in men (OR 1.9; 95%CI: 1.0-3.5) and psychiatric illness (OR 7.6; 95%CI: 3.5-16.5), mainly personality disorder (OR 11.0; 95%CI: 5.5-21.9).

	1995-2009	2010-2024	p value
Women	164 (53,8)	133 (48,0)	0,192
Age	44 (30)	50 (30)	0,193
Voluntary intake	154 (50,5)	121 (44,0)	0,139
pH of caustic Strong acid Weak acid Weak alkali Strong alkali	 50 (16,9) 17 (5,8) 215 (72,9) 13 (4,4)	 40 (14,7) 25 (9,2) 200 (73,3) 8 (2,9)	0,318
Psychiatric illness	155 (50,8)	119 (43,0)	0,007
Depression	112 (36,7)	75 (27,1)	0,016
Bipolar disorder	5 (1,6)	11 (4,0)	0,143
Personality disorder	28 (9,2)	20 (7,2)	0,479
Psychotic disorder	16 (5,2)	13 (4,7)	0,908
Alcohol/toxic substances consumption	23 (7,5)	26 (9,4)	0,515
Intensive care unit admission	40 (13,1)	29 (10,5)	0,391
Emergency surgery	8 (2,6)	10 (3,6)	0,655
Death	15 (4,9)	19 (6,9)	0,412
Stricture formation	11 (5,1)	8 (3,7)	0,624

Qualitative variables: absolute (relative) value, Chi-squared +/- continuity correction.
Quantitative variables: median (interquartile range), Mann-Whitney U test

Conclusion: No relevant changes were identified in the epidemiological and clinical characteristics of caustic ingestions over the last decades, nor in their evolution. The most vulnerable groups to prioritise prevention measures would be patients with psychiatric cormobility.

Disclosure: Nothing to disclose.

Introduction: Mucosa protective effects can be mediated by physical as well as by anti-inflammatory mechanisms of action. For the root extract of marshmallow (Althaea officinalis L., REAo), known to cure mild irritation of stomach/gut mucosa [1], only a physical action had been considered. Recent studies have shown that it also induces regeneration of irritated mucosa [2,3].

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Mucosal wound healing depends on the recruitment of several cell types, e.g., endothelial cells, fibroblasts, and macrophages (MΦ). Reactive oxygen species (ROS)-induced damage is associated with mucosal infiltration of activated leukocytes, such as MΦ, which produce excessive ROS and pro-inflammatory cytokines that may overwhelm the antioxidant and immune defenses of the cells and exacerbate mucosal inflammation. Additionally, fibroblasts exhibit a metabolic adaptation to control inflammation-related oxidative stress.

Aims & Methods: We aimed to investigate whether REAo has, on top of its physical effects, also anti-inflammatory/-oxidative properties in human dermal fibroblasts (NHDF), human umbilical vein endothelial cells (HUVEC), and human acute monocytic leukemia (THP-1) differentiated MΦ, critical cellular components of the gastrointestinal and oral mucosa.

The cells were pre-treated with REAo or its final formulation STW 42, containing REAo and selected excipients, followed by incubation with H_2O (pro-oxidative) or lipopolysaccharide (LPS, pro-inflammatory). Intracellular ROS were quantified with DCFDA. The releases of IL-6 and TNF-α were determined by ELISA. THP-1 cells were differentiated into MΦ with 0.1 µg/ml phorbol-12-myristate-13-acetatefor 3–5 days.

Results: Pre-treatment (24 h) of HUVEC, NHDF or THP-1-MΦ with STW 42 or REAo (100-1000 µg/ml) significantly inhibited the H_2O-induced intracellular ROS production by 30.0% to 58.7%. Whereas 24h(HUVEC, NHDF) or 48 h (THP-1-MΦ) pre-treatment with STW 42 or REAo (100-1000 µg/ml) inhibited the LPS-activated IL6 release by 25.0-67.0%. Additionally, 48 h pre-treatment of THP-1-MΦ with 50-500 µg/ml STW 42 or REAo significantly inhibited LPS-induced TNF-α release by 21.5% (50 µg/ml) to 52.0% (500 µg/ml), in comparison with LPS-treated MΦ. The observed effects of STW 42 or REAo were similar to 25-100 µM Diclofenac, which was used as an anti-inflammatory control.

Conclusion: These anti-inflammatory and antioxidant properties may support the benefit of STW 42 and its constituent REAo in patients with mucosal irritation with subsequent irritative cough or gastric complaints due to its protective/reparative effects on the mucosa.

Introduction: The relationship between disruptions in the intestinal microbiome, psychological well-being, and modern lifestyle factors in individuals with prevalent non-communicable diseases, such as atherosclerosis, has been partially elucidated but remains inadequately investigated. This raises the inquiry into the feasibility of diagnosing, preventing, and treating atherosclerosis through the measurement and adjustment of disease markers associated with intestinal microbiome, psychological state, and lifestyle indicators.

Aims & Methods: This study aims to broaden the spectrum of these markers to a degree adequate for establishing models to diagnose atherosclerosis within the alternative categories of “no atherosclerosis,” “asymptomatic atherosclerosis,” and “symptomatic atherosclerosis,” as well as by the level of associated health risks (non-significant, significant, and high). Our cohort study data were employed to fulfill this goal.

Results: We identified microbial markers from 955 gut microbiome species and other markers from 52 indicators of psychological state and lifestyle among participants. Marker properties were assessed based on their ability to distinguish between “no atherosclerosis,” “asymptomatic atherosclerosis,” and “symptomatic atherosclerosis” groups, as well as “not significant risk,” “significant risk,” and “high risk” groups. We measured their correlation with each participant’s group membership using the p-level parameter to prioritize markers, resulting in a rating for each. Eleven microbial species (including *Oxalobacter aliiformigenes, Lactobacillus acidophilus, and Bifidobacterium longum*) and six other indicators (including “feeling of slowness” and “duration of physical activity”) showed the highest scores. Cluster-type models based on these markers accurately predict group membership, with predictive accuracies ranging from 93.7% to 97.1%. This study provides novel insights into atherosclerosis-associated markers, laying a foundation for future research in this field.

Conclusion: The inclusion of microbial, psychological state, and lifestyle indicators has significantly enhanced the existing markers for atherosclerosis. These new markers have facilitated the development of models that, for the first time, enable the diagnosis of atherosclerosis within the categories of “no atherosclerosis,” “asymptomatic atherosclerosis,” and “symptomatic atherosclerosis,” as well as by the associated health risks (non-significant, significant, and high). In addition to microbial markers, these models also incorporate an individual’s psychological state and lifestyle indicators.

ESOPHAGEAL AND SALIVARY MICROBIOME RELATED WITH EOSINOPHILIC ESOPHAGITIS

M. Sasahira[1], H. Matsumoto[1], O. Handa[1], E. Umegaki[1], A. Shiotani[1], R. Inoue[2]

[1]Kawasaki Medical School hospital, Gastroenterology, Kurashiki, Japan, [2]Setsunan university, Animal Science, Neyagawa, Japan

Contact E-Mail Address: momomo0318@gmail.com

Introduction: Eosinophilic esophagitis (EoE) is a chronic, food and/or aeroallergen-mediated inflammatory disease , characterized by esophageal dysfunction and eosinophil inflammation of the esophageal mucosa. The incidence of EoE has increased in recent years, including Japan. Pathogenesis of EoE is incomplete, and the data on microbiome related with EoE are limited. The aim of this study was to identify the esophageal and salivary microbiome in patients with EoE.

Aims & Methods: Patients either with EoE or non-EOE patients with symptoms of esophageal dysfunction who underwent esophagogastroduodenoscopy(EGD) at Kawasaki Medical School hospital between April 2021 and April 2023 were enrolled. The endoscopic reference score (EREFS) is used to determine severity of endoscopic findings. EoE patients were classified as the active group, if the presence of esophageal eosinophilia greater than or equal to 15 eosinophils per high-power field were detected during the endoscopy. , Saliva and Esophageal mucous taken from esophagus using brushing samples and saliva were used to investigate microbiome in EoE patients and controls. The microbiota of samples was profiled using the Illumina MiSeq platform.

Results: Total 24 patients were enrolled including8 active EoE patients, 5 inactive EoE patients, and 11 controls.

There were no significant differences in age, PPI use, history of gastroesophageal reflux disease and *H. pylori* infection among the three groups. The comparative analysis of the taxonomic composition at the genus level among esophageal mucous samples indicated that *Streptococcus* were less abundant in the active EoE group compared to the other groups, and *Stomatobaculum* were more abundant in the inactive EoE group than in the controls. On salivary, The abundance of the genera *Megasphaera* were significantly more prevalent in the inactive EoE group than in the other groups.The abundance of the genera *Streptococcus* was negatively correlated with ERFFS scores.

Conclusion: *Streptococcus* might be involved in the pathogenesis of EOE.

Disclosure: Nothing to disclose.

Introduction: Microbiome analysis is a promising approach for the application of findings from basic research in the clinical field. However, there is an ongoing debate about the consistency of different bioinformatics analysis platforms. The lack of established standards affects the implementation of research findings.

Aims & Methods: In our study, we demonstrated that the results on the microbial composition of gastric mucosal biopsies are only slightly influenced by the efficacy of different microbiome analysis platforms. Furthermore, we investigated whether recent revisions to the International Code of Nomenclature for Prokaryotes and consequent alterations in taxonomic classification influenced the findings.

Gastric biopsy specimens were obtained from gastric cancer patients with well-defined clinical profiles (n=40), including individuals with and without *Helicobacter pylori* (*H. pylori*) infection, and from control subjects (n=39) with and without *H. pylori* infection. DNA extraction and 16S rRNA gene sequencing (V1-V2) was performed at one site, and the resulting fastQ files were distributed to five expert teams for independent analysis. Three widely used bioinformatics pipelines for microbiome analysis, namely DADA2, MOTHUR and QIIME2, were used for the analysis.

Results: The generated fastQ files exhibited no platform-dependent clustering, indicating the comparability of the sequences. Microbial diversity was slightly reduced in both GC groups and significantly reduced in the *H. pylori* positive controls. This is due to an extreme increase in the relative abundance of *H. pylori* in this group. It also follows that the samples of the *H. pylori* positive control group have a very high similarity and form the clearest cluster in the corresponding analysis. Regardless of the protocol used, *H. pylori* status, microbial diversity and relative bacterial abundance were reproducible on all platforms. Although minor differences in performance were detected and assessed, similarity analysis and bacterial enrichment assessment also yielded consistent results. The introduction of the new taxonomy only had a major impact on the *Proteobacteria* phylum, as it originally also included *H. pylori* according to the old taxonomy, but this is now assigned to the new *Campilobacterota* phylum.

Conclusion: In summary, our findings demonstrate that disparate microbiome analysis methodologies employed by independent research teams can yield comparable results from identical datasets.

Disclosure: Nothing to disclose.

GUT MICROBIOTA AND AUTOIMMUNE ATROPHIC GASTRITIS

M. Palo[1], F. Pelizzaro[2], G. Corra'[2], S. Facchin[3], E.V. Savarino[4], F. Zingone[5]

[1]University of Padua, Potenza, Italy, [2]University of Padua, Padua, Italy, [3]University of Padua, Surgical, Oncology and Gastroenterology, Padova, Italy, [4]University of Padua, Division of Gastroenterology, Department Of Surgery, Oncology And Gastroenterology, Padua, Italy, [5]University of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy

Contact E-Mail Address: fabiana.zingone@unipd.it

Introduction: Autoimmune Atrophic Gastritis (AAG) is a chronic immune-mediated condition that mainly affects the body and fundus of the stomach. AAG is often under-diagnosed due to the slow progression of the disease and a variable spectrum of symptoms. Recent data suggests a potential role of altered gastric microbiota in the natural history of AAG, due to the potential overgrowth of bacteria linked to the development of neoplastic complications (neuroendocrine tumors- NETs and gastric cancer) (1,2). Moreover, the same data hypothesizes the use of fecal microbiota as a possible non-invasive marker to diagnose and monitor AAG. Thus, we aimed to prospectively characterize the salivary and fecal microbiota of patients with AAG to provide further insights in this field.

Aims & Methods: We collected salivary and fecal samples from consecutive patients with an established diagnosis of AAG, enrolled at the Gastroenterology Unit of Azienda Ospedale Università Padova from March to June 2023 at the time of endoscopic follow-up examination. All patients needed to be off Proton-Pump Inhibitors, antibiotics, and probiotics for at least one month before enrolment. Stool samples were collected by the patients on the day of the endoscopy, transferred in a buffer solution, and stored at -20°C. Oral samples were collected through salivary commercial kits and freezed at -20°C. Both salivary and faecal samples were analyzed by BMR Genomic (Padua, Italy) that amplified the V3-V4 hypervariable ribosomal RNA region. Sequencing of the 16S rRNA gene V3- V4 region was performed using the Illumina MiSeq. Preliminary analyses were conducted on individual fecal samples compared to an internal population of healthy subjects (provided by BMR genomics) using Qiime2 tools. Shannon–Wiener index was used to calculate α-diversity and then the microbial biodiversity index (MBI) and Dysbiosis Index (DI). Mann–Whitney tests were performed to verify statistical differences in the α-diversity across AAG patients and healthy subjects.

Results: We enrolled 15 AAG patients with a mean age of ± 63 ± 11 years (9/15 females). OLGA 2 stage was reported in 10/15 patients. Sixty percent of the patients showed a MBI between 7.11 and 12.45, indicating that each sample contained phylogenetically similar species. The remaining patients have an index greater than 12.45 compared to the healthy population. More than half of the patients had dysbiosis (>0.082). The highest indices of dysbiosis were found in patients with a history of NET (n=3), gastric cancer (n=1), and previous HP- infection and OLGA 3 stage (n=1). Firmicutes, Bacteroidetes, and Proteobacteria were more frequent phyla found in the fecal samples, whereas Enterobacteriaceae and Streptococcaceae were the most common bacterial families (13/15, 87%). In particular, Klebsiella and Campylobacter pathogens genera were found in some samples. Streptococcus and Prevotella were the most abundant genera found in the salivary samples.

Conclusion: Patients with AAG were found to have a great proportion of Firmicutes and Bacteroidetes, which aligns with the literature (3,4). Moreover, a dominant of Proteobacteria, especially Enterobacteriaceae commonly associated with proinflammatory states, was found. (5) Our preliminary data showed a possible positive association between higher degrees of dysbiosis and a previous history of NET or gastric cancer.

REVIEW OF CONSECUTIVE CASES OF *CLOSTRIDIOIDES DIFFICILE* INFECTION AND ASYMPTOMATIC CARRIAGE OF TOXIGENIC *C. DIFFICILE* IN CHILDREN, OVER A 7-YEAR PERIOD

A. Desai[1,2,3], Y. Mahida[1,2,3]

[1]NIHR Nottingham Biomedical Research Centre, School of Medicine, University of Nottingham, Nottingham, United Kingdom, [2]Nottingham Digestive Diseases Centre, University of Nottingham, Nottingham, United Kingdom, [3]Translational Medical Sciences, School of Medicine, University of Nottingham, Nottingham, United Kingdom

Contact E-Mail Address: avnidesai31@gmail.com

Introduction: *C. difficile* infection (CDI) remains a significant clinical problem and has been extensively investigated in adults but by comparison is much less studied in children. Following colonisation with toxigenic *C. difficile*, clinical presentation may range from asymptomatic carriage to pseudomembranous colitis. Diagnosis of CDI can be challenging, with toxin-positive stool test (in the presence of diarrhoea) believed to reflect infection.

Aims & Methods: Our aim was to study children diagnosed with CDI and asymptomatic carriage of the organism. From 2015 - 2022, details of relevant stool test results were collected prospectively and clinical information was reviewed retrospectively. Detection of stool *C. difficile* toxin (toxin +ve) was used to imply CDI and its absence (toxin –ve), together with positive polymerase chain reaction (PCR) test for toxigenic *C. difficile* (PCR +ve) deemed to reflect asymptomatic carriage. Hospital-association was based on stool test undertaken >48 hours post-admission or within 4 weeks of discharge.

Results: Of total 113 patients, 57 [50.4%, median 11.0 (range 1-17) yrs, 31 male] were toxin +ve and were treated for CDI; 26 (45.6%) had co-existing cancer (80.8% on chemotherapy), 9 patients (15.8%) suffered from inflammatory bowel disease (IBD, 5 Crohn's disease and 3 unclassified) and 5 patients (8.77%) had had a transplant. Of the 57 CDI patients, 11 (19.3%) previously had a toxin-negative stool test result and 14 (24.6%) had a subsequent recurrence of CDI [of the latter subgroup, 7 (50%) were on chemotherapy for cancer and 2 (14.3%) had a prior transplant]. Of the 113 patients studied 48 [42.5%, 11.5 (1-18) yrs, 21 male] were PCR +ve but toxin –ve and were deemed asymptomatic carriers as they did not require treatment for CDI; 22 patients (45.8%) had co-existing cancer (all

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

on chemotherapy), 11 (23%) suffered from IBD (9 Crohn's disease) and 3 patients (6.25%) had had a transplant. There were no significant differences between the above 2 groups (CDI and asymptomatic carriers) in age, male:female ratio, co-existing cancer, IBD, current / recent antibiotics or chemotherapy. Eight [7.1%, 13.5 (9-17) yrs, 5 male] of the 113 patients studied were PCR +ve and toxin –ve but were deemed to require treatment for CDI. For all 3 groups, >84% were hospital-associated episodes and >71% were associated with the use of antibiotics.

Conclusion: A significant proportion of children with CDI and asymptomatic carriage of toxigenic *C. difficile* had co-existing cancer (majority on chemotherapy) and IBD and were predominantly hospital-associated. Some asymptomatic carriers may subsequently develop CDI and require measures to reduce this risk. Stool *C. difficile* toxin test may be <100% sensitive for diagnosis of CDI. Following initial episode of CDI, antibiotic use and chemotherapy for cancer represent significant risk factors for recurrence for CDI in children. Further research is needed to identify risk factors for CDI in children with asymptomatic carriage of toxigenic *C. difficile*.

[1]Università degli Studi di Milano, Department of Biomedical and Clinical Sciences 'Luigi Sacco', Milano, Italy, [2]ASST Fatebenefratelli Sacco, UOC Gastroenterologia ed Endoscopia Digestiva, Milano, Italy

Contact E-Mail Address: angelica.toppeta@unimi.it

Introduction: Colonization/infection with multidrug-resistant organisms (MDROs) such as methicillin-susceptible staphylococcus aureus (MSSA), methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE), extended-spectrum beta-lactamase (ESBL) producing Enterobacterales and carbapenem resistant P. aeruginosa, is an increasing problem being reported worldwide. Rectal, cutaneous and nasal swab screening allows for the detection of MDROs in asymptomatic individuals, enabling early identification and subsequent implementation of infection control measures to prevent transmission.

Aims & Methods: The aim of this study was to determine the prevalence as well as the risk factors of colonization/infection with MSSA, MRSA, VRE, ESBL producing Enterobacterales and carbapenemase producing P. aeruginosa, in patients hospitalized in gastroenterologic and oncologic and surgical unit for gastroenterologic diseases. Methods: all the consecutive patients hospitalized from May 2023 to March 2024 in the abovementioned units at admission underwent rectal swabs to identify the presence of MDROs, primarily methicillin-susceptible staphylococcus aureus (MSSA), methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE), extended-spectrum beta-lactamase (ESBL) producing Enterobacterales and carbapenemase producing P. aeruginosa. Demographic, clinical and therapeutic variables were evaluated.

Results: 242 patients were hospitalized (mean age 65,6 ± 17,8 years; 56% males). MDRO were present in 17,36% of patients (n.42). 7 % of patient tested positive for Escherichia coli ESBL+, 3.7% for Klebsiella pneumoniae ESBL+ and 2.5% for Enterococcus faecium VRE at rectal swab. 2.1% of patient tested positive at nasal swabs for MSSA, 2.1% for MRSA, 0.4% for E. coli ESBL and 0.4% for K. pneumoniae ESBL. 0.4% of patient were positive at cutaneous swab for E. faecium VRE and 0.4% for K. pneumoniae ESBL. At univariate analysis hospitalization within 1 year, ongoing treatment with PPI, ongoing steroid treatment and chronic renal failure were associated to the risk of a positive surveillance swab. At multivariate analysis only hospitalization, ongoing steroid treatment and chronic renal failure were independent predictors of colonization (table).

	Univariate	Multivariate
	OR (95% C.I.)	OR (95% C.I.)
Hospitalization within 1 year	2.4 (1.2 - 4.6)	2.2 (1.1 - 4.4)
PPI treatment	2.2 (1.1 - 4.4)	
Ongoing steroid treatment	3.7 (1.4 - 9.7)	2.9 (1.1 - 8.2)
Chronic Renal Failure	6.5 (1.9 - 22.4)	6.6 (1.8 - 24.5)

Conclusion: This research offers information on how common MDROs are among gastroenterology patients. It contributes to the existing knowledge and aids in addressing the spread of MDROs by customizing screening methods based on individual patient factors, like past hospital stay, ongoing steroid treatment and chronic renal failure.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Non-variceal upper gastrointestinal bleeding (NVUGI) represents a significant gastrointestinal disorder with elevated mortality rates (1).

Non-steroidal anti-inflammatory drugs (NSAIDs) have been firmly established as a risk factor for NVUGI, yet their precise impact on clinical outcomes remains insufficiently defined (2,3).

Conversely, proton pump inhibitors (PPIs) have shown efficacy in reducing the incidence of NVUGI associated with NSAIDs. However, the extent of their influence on the clinical outcomes of NVUGI remains inadequately substantiated. Therefore, it is necessary to study the impact of these drugs on the clinical outcomes of patients with NVUGI.

Aims & Methods: The primary objective of our study is to compare the outcomes of NVUGI patients using NSAIDs with or without PPIs against those who did not use either medication. We conducted a retrospective analysis at a Spanish tertiary hospital, encompassing NVUGI cases from 2013 to 2022. NVUGI was defined as hematemesis or melena accompanied by a two-point decrease in hemoglobin or hemodynamic instability. Key clinical outcomes included the necessity for intervention (endoscopic, radiological, or surgical) and in-hospital mortality.

Additionally, we compared baseline characteristics and pertinent clinical results such as rebleeding and delayed cardiovascular events. Statistical analysis was performed using SPSS.

Results: A total of 1200 cases were included, with 6.6% undergoing concomitant treatment with PPIs and NSAIDs, and 15.7% utilizing NSAIDs alone. Patients who took NSAIDs alone were younger (57 years vs. 66 in both other groups) and had a lower rate of comorbidities. Table 1 presents risk scores and outcome comparisons among the three groups. Statisti-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cal differences were observed, revealing lower acute mortality (9.6% vs. 7 vs. 2.8%, p=0.011) and reduced need for intervention (74% vs. 69.6 vs. 57.8%, p<0.001) in the group using NSAIDs alone. In multivariate analysis, MAP(ASH) > 2 (OR: 8, CI: 3-21, p<0.001) and ASA > 2 (OR: 4.4, CI: 1.7-11.4, p:0.002) emerged as independent risk factors for acute mortality, with an elevated MAP(ASH) score (OR: 8.8, CI: 5.9-13, p<0.001) being the sole independent factor explaining the need for intervention.

	Naive	NSAIDs and PPIs	NSAIDs without PPIs	P
ASA 3-4	596 (64,3%)	50 (63,3%)	63 (33,7%)	<0,001
MAPASH>2	448 (59,3%)	39 (65%)	52 (34,4)	<0,001
Need for intervention	691 (74%)	55 (69,6%)	108 (57,8%)	<0,001
Rebleeding	96 (10,3%)	9 (11,4%)	6 (3,2%)	0,008
Acute mortality	86 (9,6%)	5 (7%)	5 (2,8%)	0,011
Mortality at 6 months	77 (8,8%)	7 (9,3%)	7 (3,8%)	0,075
Delayed Cardiovascular event	77 (8,7%)	3 (3,9%)	4 (2,2%)	0,004
Delayed rebleeding	145 (16,4%)	15 (19,5%)	6 (3,3%)	<0,001

Conclusion: Patients abstaining from NSAIDs or those concurrently undergoing PPI therapy exhibited a higher incidence of intervention or acute mortality compared to those solely using NSAIDs. Through multivariate analysis, our study indicates that bleeding severity and baseline comorbidities, expressed by elevated MAP(ASH) scores and ASA classification, are pivotal factors influencing the clinical outcomes of NVUGI.

In summary, the use of NSAIDs or PPIs to safeguard against gastrointestinal lesions induced by these drugs did not demonstrate a discernible impact on the short-term outcomes of patients with non-variceal upper gastrointestinal bleeding.

Introduction: Esophageal varices are present in up to 40% and 85% of patients with compensated and decompensated cirrhosis, **respectively**. Endoscopic treatment of esophageal varices is used for the prevention of first variceal bleeding, treatment of active variceal bleeding, and prevention of rebleeding. Endoscopic variceal ligation (EVL) is the most common treatment. Multiple EVL sessions are often required to eradicate them. We aimed to detect factors predicting lower number of endoscopic treatments.

Aims & Methods: The study recruited all cirrhotic patients admitted to the hospital within the last two years, who have been treated for esophageal varices by EVL and achieved eradication through this endoscopic treatment. For each patient, main demographical and clinical characteristics were collected, including, etiology of cirrhosis, severity of liver disease according to Child-Pugh and MELD score and main laboratory tests. Varices were described according to the Japanese classification, and for each EVL session number of placed bands was recorded. Binomial logistic regression was used for univariate and multivariate analysis and odds ratios (OR) were calculated.

Results: A total of 31 patients (71% males, mean age 62.7±9.2) with liver cirrhosis and esophageal variceal (F2 41.9% and F3 58.1%) were included. The most frequent etiologies were alcoholic cirrhosis, non-alcoholic steatohepatitis and cryptogenic cirrhosis, in 8 (25.8%), 9 (29%) and 4 (12.9%), respectively. Esophageal Varices with Red Color Sign on Endoscopy, Cherry Red Spot (CRS), Red Wale Markings (RWM) and Hematocystic Spots (HCS), were detected in 19 (61.3%) 23 (74.2%) 5 (16.1%) patients. Only 8 patients (25.8 %) had gastroesophageal varices (GOV) while 30 subjects (96,8%) had congestive gastropathy. Concerning severity of cirrhosis, there were 13 (41,9%), 17 (54,8%), 1(3,2%) patients in Child Pugh's class A, B and C, respectively. In 14 subjects, a single session was sufficient to eradicate varices, while 9 patients required ≥3 sessions. At multivariate analysis, higher platelet count (OR=0.98, p=0.15), higher number of rubber bands (OR=0.67 p=0.16) and female sex (OR= 0.24, p=0,11) predicted the fewer number of endoscopic sessions required for eradication of varices, while at multivariate analysis, only higher platelet count demonstrated a non significative trend (OR= 0.98, p=0,07).

Conclusion: When performing endoscopic ligation of esophageal varices, the number of platelets could influence the number of endoscopic sessions to eradicate esophageal varices.

Disclosure: Nothing to disclose.

Introduction: Alcohol abuse is a significant risk factor for the development of hepatic cirrhosis, which can lead to upper gastrointestinal bleeding. In non-cirrhotic patients, alcohol has been studied as a risk factor for non-variceal upper gastrointestinal bleeding (NVUGI), particularly in cases of peptic ulcer bleeding (1).

However, the clinical impact of alcohol abuse on outcomes remains unclear. Only one retrospective study has analyzed this, finding an increased risk of rebleeding and non-significant increased mortality among alcohol consumers (2).

Nevertheless, this study included cirrhotic patients, who accounted for most of the mortality. There is currently no available data on the impact of alcohol on NVUGI outcomes in non-cirrhotic patients.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: This study aims to determine the impact of alcohol consumption on clinical outcomes in NVUGI.

We conducted a retrospective analysis at a Spanish tertiary hospital, encompassing NVUGI cases from 2013 to 2022. Alcohol abuse was defined as daily alcohol intake exceeding 20g. Key clinical outcomes included the need for intervention (transfusion, endoscopic, radiological, or surgical) and in-hospital mortality. In addition, we compared baseline characteristics and assessed both acute and delayed 6 months outcomes, including rebleeding and delayed cardiovascular events. Statistical analysis was performed using SPSS.

Results: A total of 892 cases were included. The alcohol abuse group had a higher proportion of men (95.6% vs. 64.1%, p < 0.001) and were younger (median age of 56 years vs. 66 years, p < 0.001). Non-alcohol consumers had more comorbidities and a higher ASA comorbidity risk score (58% had ASA 3 or 4 vs. 46% in the other group, p = 0.015). Additionally, the MAP(ASH) score was higher in the first group (>2 in 54.5% vs. 46.3%, p = 0.030). We did not find any other differences between groups, neither in key outcomes nor in the remaining comparisons for the acute episode. However, delayed mortality (8,2% in group 1 vs 3,1% in group 2, p=0,046) and six months cardiovascular events (8,9% vs 2,3%, p=0,011) were more frequent in the non-alcohol group. In multivariate analysis, only ASA 3-4 (OR: 4.17, CI: 1.49-11.68, p= 0.006) and MAP(ASH) (OR: 7.61, CI: 2.54-22.8, p < 0.001) were found to be independent risk factors for acute mortality.

	No Alcohol	Alcohol	p
Age	66,75	56,88	<0,001
Sex	Men 464 (61,4%)	Men 130 (95,6%)	<0,001
Chronic obstructive pulmonary disease	75 (9,9%)	13 (9,6%)	0,896
Chronic renal disease	126 (16,7%)	6 (4,4%)	<0,001
Heart faliure	91 (12%)	6(4,4%)	0,009
High blood pressure	368(48,7%)	52 (38,2%)	0,071
Diabetes mellitus	182 (24,1%)	19 (14%)	0,009
Smooking	95 (12,6%)	69 (50,7%)	<0,001
MAPASH >2	334 (54,5%)	49 (43,4%)	0,030

Conclusion: Alcohol abuse is more common among younger individuals with fewer comorbidities. This consumption does not worsen clinical outcomes in non-cirrhotic NVUGI patients, with similar rates of need for intervention or mortality. Our results indicate that only comorbidities and bleeding severity (summarized as high ASA score and MAP(ASH)) score influence the outcomes. In summary, while alcohol consumption may increase the risk of NVUGI incidence, it does not impact acute outcomes.

Introduction: Acute Upper GI bleeds (AUGIB) are common and are associated with significant mortality (1). Quick recognition, resuscitation and endoscopy improves patient outcomes (2).

Care bundles are known to improve care. The BSG 2018 AUGIB bundle was designed to standardise care. We aimed to audit management of AUGIB in two sites in North East England.

Aims & Methods: We retrospectively analysed patients who underwent endoscopy for AUGIB from May-October 2023. We surveyed junior doctors to assess knowledge and confidence in managing AUGIB.

Results: 98 patients were identified across 2 sites, the mean age was 66, and 58% were male. The AUGIB bundle was used in 10% cases.

Recognition: 83% presented to A+E with AUGIB with the remainder already inpatients. 78% presented with melaena, and 24% were suspected variceal bleeds.

Resuscitation: 100% had EWS scores, 87% received IV fluids, and 93% patients with Hb<70 received RBC transfusion.

Risk Assessment**:** Mean Glasgow-Blatchford score (GBS) was 9 for both sites. Site 1 had calculated a GBS in 65% cases, and site 2 in 88%.

	Site 1	Site 2	Overall
Variceal bleeds receiving antibiotics and terlipressin	50% (n=5)	69% (n=9)	61% (n=14)
Aspirin continued	60% (n=3)	66% (n=6)	64% (n=9)
Other antithrombotics held	100% (n=17)	91% (n=20)	95% (n=37)

Table 1: Summary of treatment

Refer: of the 98 patients 70% discussed with endoscopist within 24hours, 47% had an OGD within 24 hours, and 30% required endoscopic intervention.

Review: 84% (site1) and 63% (site 2) had PPI plan, 50% (site 1) and 36% (site 2) had antithrombotic plan.

Of the small number of patients in which the bundle was used, all received appropriate resuscitation, all had GBS completed and all had OGD within 24hours of presentation.

200 surveys were sent across sites, 61 junior doctors responded. 73% felt confident in recognising AUGIB, and 65% felt confident in management. Only 32% knew appropriate initial variceal management. 40% were unsure when to call OOH endoscopist, and only 36% knew aspirin should continue.

Conclusion: Whilst recognition of AUGIB and fluid resuscitation is good, improvement is needed for risk assessment with GBS, management of suspected variceal bleeds, and timely referral for endoscopy. More detailed endoscopy reports are needed regarding PPI and antithrombotic plans.

More education with junior doctors is needed regarding management of AUGIB, and particularly when to call endoscopist and antithrombotic decisions. It would be helpful to educate staff to improve management. A reaudit of clinical management and the junior doctor survey is planned.

AN IN-DEPTH ANALYSIS OF MORTALITY OF HOSPITALIZED PATIENTS WITH SUSPECTED NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING – DATA FROM A PROSPECTIVE REGISTRY

D. Venturi[1,2], M. Birkl[1,2], S. Bernhofer[1,2], A. Maieron[1,2,3], J. Prosenz[1,2,3]
[1]Karl Landsteiner University of Health Sciences, GI Endoscopy Quality Matters working group (GIEQM), Krems, Austria, [2]University Hospital St. Pölten, Department of Internal Medicine 2 Gastroenterology & Hepatology, St. Pölten, Austria, [3]Paracelsus Medical University, Salzburg, Austria

Contact E-Mail Address: David.Venturi@stpoelten.lknoe.at
Introduction: Non-variceal upper gastrointestinal bleeding (nvUGIB) mortality has improved but remains high. Guidelines on nvUGIB often focusing on pre- and endoscopic management. However, more data on causes of death are needed, because non-bleeding specific mortality is unlikely to be improved by interventional advances.
Aims & Methods: The aims of this retrospective analysis of a single tertiary center registry of patients with nvUGIB were to assess causes of death in patients with nvUGIB and characterize this cohort. All hospitalized patients evaluated for suspected non-variceal UGIB (i.e., patients undergoing endoscopy) at our endoscopy unit between January 2018 and October 2020, either due to presentation for nvUGIB or with a suspected bleeding episode during hospitalization for any reason, were included in a prospective registry.
Data on pre-endoscopic signs/symptoms of UGIB, epidemiological data, laboratory values, and medications were extracted from the electronic health record. Endoscopy reports were individually searched and relevant data including the most likely culprit lesion in the opinion of the endoscopist as well as respective hemostatic treatment extracted.
Results: Among 1135 patients – 41.7% women, mean age 70.4 (±15.7) years, median length of stay 8 (IQR 4;16) days – 92 (8.1%) died during hospitalization and were further analyzed. Mean age was 73.2 (±12.9) years, 44.5% were women, 36% of patients were on anticoagulation, 27% on antiplatelet therapy, and 9% on both. The median Charlson comorbidity index was 5 (IQR 3;6.8), the CHA2DS2-VASc-Score 3 (IQR 2;5).
However, the median AIMS65 score was only 2 (IQR 1;2). Median time from admission to death was 17 (IQR 6.5;30) and from endoscopy to death 11 (IQR 4;21.5) days. The most common sources of bleeding as determined by endoscopy reports were: uncertain (24%), peptic ulcer (21%), esophagitis (14%), and non-peptic ulcers (9%). Adherence to guideline-based endoscopic peptic ulcer management recommendations was 70%. Radiological intervention for bleeding was performed in 1%, surgical intervention in 8.7%. Patients who died were older (73.2 vs. 70 years, p=0.0336), had lower hemoglobin nadirs (7.1 vs. 7.8 g/dL, p<0.0001), high c-reactive protein levels (p<0.0001) and creatinine (p<0.01), had longer lengths of stay (LOS) (median LOS 17 vs. 8 days, p<0.0001), and longer times from admission to endoscopy (median 3 days vs. 1 day, p<0.0001). However, sex was not associated with mortality (p=0.58). Looking at bleeding in association with causes of death, mostly (n=55, 59.8%), bleeding was categorized as a bystander. Only 32.6% of causes of death were judged as directly due to or likely associated with the bleeding episode, and these patients had a higher AIMS65 (p=0.0301). Only 12% died due to an unmanageable bleeding (or change to best supportive care). Overall, the following major groups of causes of death were identified: malignancy (18.5%), multi-organ failure (17.4%), infection/sepsis (15.2%), bleeding-associated (15.2%), cardiovascular (13.0%), and others (23.9%).
Conclusion: UGIB mortality remains relatively high despite management advances. However, only a minority of patients die due to UGIB and even among those most deaths are related to sequelae of the bleeding instead of unmanageable bleeding. Patients who die are older, likely sicker, and suffer from many comorbidities. Based on these data, it is uncertain whether focusing on endoscopic management improvements will significantly change UGIB-related mortality. Possibly, the focus should be shifted to improving general/internal medicine or geriatric care.
Disclosure: Nothing to disclose.

Introduction: Restarting anticoagulation (AC) therapy following acute gastrointestinal bleeding (GIB) is a multidisciplinary, personalized decision. Current guidelines recommend resuming AC, though data on the optimal timing is limited.
Aims & Methods: Our aim is to assess the short-term effect of early and delayed AC therapy resumption.
We analyzed the data of the Hungarian GIB Registry (a multicenter, prospective database) between 2019-2022. Patients were included after successful management of AC-related GIB. Detailed medical and drug history, demographics, and data on the index bleeding and management (bleeding source, endoscopic, and medical therapy) were collected. 30 and 90-day rebleeding, thromboembolic (TE) complications, all-cause, and 30-day recurrent GIB or TE-related mortality were assessed in the early (≤ 7 days) and delayed (>7 days) AC resumption groups.
Results: 218 cases were analyzed. Except for the CHA_2Ds_2-VASc score (mean (SD) 5.19 (1.65) vs 4.37 (1.549); *p*=0.02), the main characteristics (e.g., age, Charlson comorbidity index, active malignancy, anamnestic previous GIB, co-medications, HAS-BLED score, hemodynamic instability, high-risk bleeding site, endoscopic intervention) were similar between the two groups. Delayed AC therapy resumption was not associated with decreased 30-day rebleeding risk (5.3% vs. 6.7%; HR = 1.26, 95%CI 0.27-5.77, *p*=0.76). Delayed resumption was not associated with a higher 90-day TE complications rate (2.1% vs. 6.6%; HR = 3.17, 95%CI 0.58-17.33, *p*=0.18). Recurrent GIB-related 30-day mortality occurred only in one case (early resumption group, 12 days after admission with index bleeding). TE-related mortality was not observed during the follow-up.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Anticoagulation resumption in the first seven days after GIB was proven to be safe, which supports the suggestion of the actual European guidelines. Further research on separated bleeding sources and types of anticoagulants is needed.
Disclosure: Authors do not have any conflict of interest to disclose.

EXPERIENCE IN THE MEDICAL TREATMENT (THALIDOMIDE, LAR OCTREOTIDE) OF PATIENTS WITH BLEEDING FROM UPPER GASTROINTESTINAL (GI) VASCULAR MALFORMATIONS RESISTANT TO ENDOSCOPIC THERAPY

B. Németh[1], G. Kiss[1], G. Pécsi[1]
[1]*Petz Aladár University Teaching Hospital, Department of Internal Medicine-Gastroenterology, Győr, Hungary*

Contact E-Mail Address: nemethbence92@gmail.com
Introduction: In the treatment of bleeding from GI vascular malformations, the priority of endoscopic hemostasis methods, particularly argon plasma coagulation (APC), is unquestionable. Until now, no effective medication-based therapy has been available as an alternative or supplemental method. Previous studies have reported on the ineffectiveness of steroids, estrogens, and progestogens. In the past decade, several promising clinical trials have been conducted regarding the use of thalidomide and long-acting-release (LAR) octreotide to reduce bleeding from vascular malformations.
Aims & Methods: At the Department of Internal Medicine-Gastroenterology of the Petz Aladár University Teaching Hospital in Győr-Moson-Sopron County, in patients who did not respond to endoscopic treatment, either.
1. Investigate the efficacy and side effects of thalidomide,
2. Investigate the efficacy and side effects of LAR octreotide in patients resistant to thalidomide treatment.

From July 2021 to February 2024, 25 patients were treated for bleeding and anemia from GI vascular malformations. In 20 patients, bleeding was stopped with 35 (1-2) APC treatments. 5 polymorbid patients (male:female= 1:4, average age ~64.6 years) required regular transfusions despite previous ~7.2 APC treatments. Their predominant underlying diseases included Banti's syndrome, autoimmune hemolytic anemia, ischemic cardiomyopathy, atrial fibrillation, Osler's disease, and autoimmune hepatitis. These 5 patients underwent a 3-month course of 100mg thalidomide per day. In patients where thalidomide was ineffective or caused side effects, LAR octreotide intramuscular injections were indicated once every four weeks at a 30mg dose. Visits, blood counts, and lab tests were conducted monthly.
Results: With thalidomide treatment, the transfusion requirement ceased in 2/5 patients. In 2/5 patients, the treatment was suspended due to ineffectiveness and side effects (deep vein thrombosis, emesis). Treatment was ineffective in 1/5 patients. In the last 3 patients, LAR octreotide treatment was also ineffective. Mild side effects (meteorism, nausea, exanthemas) were observed in these patients.
Conclusion: In the care of patients bleeding from vascular malformations resistant to endoscopic therapy,
1. Thalidomide may be an effective medication,
2. Close patient monitoring is important to filter out side effects,
3. The effectiveness of LAR octreotide cannot be determined based on the study,
4. Further follow-up studies are necessary.
Disclosure: Nothing to disclose.

PP0023

ENDOSCOPIC MANAGEMENT OF NON VARICEAL UPPER GI HEMORRAGES: OUR EXPERIENCE AS A TYPE 1 DEPARTMENT

F. Frattaroli[1], M. Varanese[1], G. Burrelli Scotti[1], M. Marchese[1], A. Antoniozzi[1], S. Pontone[1], A. Pronio[1], S. Frattaroli[1], E. Fiori[1], A. Lamazza[1]
[1]*University of Rome La Sapienza, Roma, Italy*

Contact E-Mail Address: flaminia.frattaroli@uniroma1.it
Introduction: This study aimes at evaluating the appropriate timing of endoscopic intervention in patients with non-variceal upper GI hemorrages upon admission in the emergency department and treated while on call during night shifts and public holidays. The need for blood transfusion, effectiveness of treatment, safety and reliability of endoscopic management were taken into account. We analyzed the results obtained after endoscopic treatment in terms of bleeding control, procedure-related complications, average days of hospital stay, need for second endoscopic look, surgical intervention or interventional radiology, and mortality.
Aims & Methods: From January 2019 to January 2024, 1215 patients admitted in the emergency department of Policlinico Umberto I in Rome with signs of digestive bleeding, underwent an esophagogastroduodenoscopy which demonstrated that the cause of bleeding was a non-variceal lesion of the upper digestive tract. Only adult patients aged 20 to 95 (33.3% between 60 and 80), who underwent operative endoscopic procedure were included in the study. Four hundred ninety-two patients were female (40.5%). Nine hundred sixty-three (79.3%) (963) did not undergo endoscopic therapy due to spontaneous or pharmacological resolution of the cause of bleeding while in 161 patients (16.7%) endoscopic therapy was not possible due to death caused by hemodynamic instability and underlying comorbidities. Two hundred fifty-two patients (20.7%) presented, during the endoscopic examination, signs of recent or ongoing bleeding, requiring endoscopic therapy. Eleven patients who underwent treatment (4.4%) died from complications unrelated to the procedure.
Results: Urgent EGDS, within 12 hours, was performed in 78.6% (198) of cases who presented signs of persistent hemodynamic instability, with definitive endoscopic success in 51.2% (111). Fifty-four patients (21.4%) underwent emergency intervention within 24 hours once hemodynamic stability was achieved with an endoscopic success in thirty one patients (59.1%). The average duration of the endoscopic procedure was 17 minutes. The post-procedure hospital stay was 6.5 days in 79.7% (201) of patients. All procedures were performed under deep sedation, in a dedicated operating room in the presence of the anesthesiologist. Patients who underwent a very early EGDS (<12h) had an average hospital stay, need for second look and mortality similar to that of patients treated between 12 and 24h. The single endoscopic intervention was successful in 56.4% of patients (142); 26.2% (66) underwent an endoscopic second look, 5.2% (13) a surgical procedure and 3.6% (9) interventional radiology. The overall mortality was 8.8% (22 patients).
Conclusion: In our experience, the endoscopic procedure was performed in most cases within 6-12 hours of admission in the emergency room. In light of our data and the heterogeneity of the population in urgent/emergency conditions, we can state that acting within 12-24 hours has proven to be an adequate timing for the management of non-variceal upper digestive hemorrhage, with good results in terms of haemostasias and the need for an endoscopic, surgical or radiological second look. The average hospital stay and the operating time is short and the mortality rate linked to the procedure is low. In accordance with the recommendations of the European Society of Gastrointestinal Endoscopy we believe that this timing is adequate to guarantee good long-term results. A very early EGDS <12h can be considered in patients who present signs of hemodynamic instability.
Disclosure: Nothing to disclose.

OVER-THE-SCOPE CLIP (OTSC) VS STANDARD ENDOSCOPIC APPROACH FOR PRIMARY TREATMENT OF NONVARICEAL GASTROINTESTINAL BLEEDING: SYSTEMATIC REVIEW AND METANALYSIS

Y. Dominguez-Novoa[1,2], J. Iglesias-Garcia[1,2], F. Challoukh[1], J. Lopez-Diaz[1,2], J.E. Domínguez Muñoz[1,2]
[1]University Hospital of Santiago de Compostela, Gastroenterology, Santiago de Compostela, Spain, [2]Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain

Contact E-Mail Address: yessica.dominguez.novoa@sergas.es

Introduction: Non-variceal gastrointestinal bleeding is a common condition associated with significant morbidity and mortality. Several approaches are available for primary endoscopic treatment. The standard endoscopic approach uses contact thermal methods or hemoclips with or without pre-injection of diluted epinephrine. A newer alternative is the use of an over-the-scope clip (OTSC).

Aims & Methods: The aim of our study was to evaluate the efficacy of these two modalities in the treatment of non-variceal gastrointestinal bleeding. Methods: PubMed, EMBASSE and the Cochrane Library databases were searched for multicentre randomised controlled trials comparing the efficacy of OTSC with standard endoscopic procedures for the primary treatment of non-variceal gastrointestinal bleeding published up to January 2024. The primary outcome measure was the 7-day re-bleeding rate. We also assessed the presence of persistent bleeding, 30-day rebleeding rate, length of hospital stay and mortality. A systematic review and network meta-analysis was performed for both treatments.

Results: Four trials met the inclusion criteria and were included. Regarding the 7-day rebleeding rate, OTSC showed superior efficacy compared to standard endoscopic therapy in the treatment of non-variceal gastrointestinal bleeding (RR 0.29, 95%CI 0.14-0.62). OTSC was also superior to standard endoscopic therapy in terms of re-bleeding within 30 days (RR 0.43, 95%CI 0.24-0.78). In terms of failure to achieve primary haemostasis, results were similar between the two methods, with a trend in favour of OTSC (RR 0.37, 95%CI 0.37-1.02). Finally, no differences were found in mortality (RR 0.61, 95%CI 0.25-1.51) and length of hospital stay (SMD -0.01, 95%CI -0.20-0.17).

Conclusion: OTSC significantly reduced the 7-day and 30-day re-bleeding rate compared to standard endoscopic therapy. There were no differences in mortality and length of hospital stay.

EFFICACY OF DANIS-ELLA ESOPHAGEAL STENT FOR POST-EVL ULCER BLEEDING: A SINGLE-CENTER STUDY

N.S. Malhi[1], R. Grover[1], J.S. Dhingra[1]
[1]Advanced Gastroenterology Institute (A.G.I.)-The GASTROCITI, Ludhiana, India

Contact E-Mail Address: doctorjasmeet@gmail.com

Introduction: Post-esophageal variceal ligation (EVL) ulcer bleeding poses a significant challenge in clinical practice, with various management modalities employed. However, there is a lack of established guidelines for effective management. This study aims to evaluate the effectiveness and safety of self-expandable metal SX-DANIS-ELLA (DE) stents in controlling post-EVL ulcer bleeding.

Aims & Methods: This retrospective audit focused on cirrhotic patients who underwent SEMS placement for post-EVL ulcer bleed. The study assessed bleeding control rates within 48 hours post-treatment and mortality rates within 6 weeks post-treatment

Results: Among 1025 endoscopic procedures for variceal ligation over 40 months, 1.4% (15 patients) presented with post-EVL ulcer bleed, all managed with DE stents. SEMS successfully controlled bleeding in 100% of cases at 48 hours post-procedure without the need for alternative rescue strategies. Median SEMS placement duration was eight days, with complete ulcer healing observed in 14 patients upon stent removal. However, one patient passed away within 72 hours due to decompensation. Early rebleeding within 6 weeks occurred in two (13.3%) patients which was managed with EVL. The 6-week mortality rate was notable at 20%(3 out of 15 patients). Adverse events included superficial esophageal ulcers at upper end of stent mesh in 9 patients out of 15(60%), SEMS dislocations in 3 out of 15 patients (20%) and one very deep esophageal tear with ulcer at the upper end of the stent mesh (6.6%). Two patients also had aspiration pneumonitis post procedure which was managed conservatively

Conclusion: SX-ELLA esophageal stents effectively controlled post-EVL ulcer bleeding. Despite successful bleeding control, the high mortality rate underscores the need for further strategies. SEMS dislocations highlight the complexity of this intervention and the importance of expertise in stent placement. Future research should explore the role of early transplant referral in reducing mortality following SEMS placement and improving patient outcomes

Contact E-Mail Address: cherkaoui.manal23@gmail.com

Introduction: Upper gastrointestinal bleeding is a common reason for emergency department visits. Thanks to advancements in new hemostasis techniques, morbidity and mortality rates have decreased but remain significant in most studies reported in the literature. The aim of our study is to investigate the epidemiological and evolutionary profiles of upper gastrointestinal bleeding.

Aims & Methods: This is a prospective, descriptive, and analytical study conducted over a period of 4 years from April 2020 to February 2024. Patients presenting with gastrointestinal bleeding who underwent a complete clinical examination, comprehensive laboratory tests, esophagogastroduodenal endoscopy, and immediate and follow-up care were included in our study. Patients who did not undergo esophagogastroduodenal endoscopy and those with incomplete medical records were excluded.

Results: 282 patients with gastrointestinal bleeding were included in our study. The mean age was 56.1 years (range: 20 to 90 years). The male-to-female ratio was 1.26. A history of upper gastrointestinal bleeding was noted in 41 patients (14.5%).

The presentation of upper gastrointestinal bleeding included melena with hematemesis in 93 patients (32%), melena in 68 patients (24.1%), hematemesis in 50 patients (17.7%), and rectal bleeding in 20 patients (7%).

150 patients received blood transfusions (53%), and 38 patients required admission to the intensive care unit (13% of cases). Peptic ulcer disease was the most common cause of bleeding encountered in 136 patients (48% of cases). 70 patients (24%) underwent hemostatic procedures. Total recurrence of bleeding was noted in 35 patients (12.3%): 12 patients

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

had esophageal variceal rupture (34.28%), and 8 patients had peptic ulcer disease (22%). The mean time to recurrence was 25.51 days. Ten of these patients were on anticoagulants and/or antiplatelet therapy before the bleeding episode (43%). There were 6 cases of death (2.59% of cases): 2 cases of peptic ulcer disease and 4 cases of esophageal variceal rupture. All deceased patients had experienced recurrent bleeding (100%).

Conclusion: The total recurrence rate of bleeding in our series was 2.59%. The presence of esophageal varices, the use of anticoagulant and/or antiplatelet therapy, and the absence of endoscopic treatment appear to be factors associated with recurrent bleeding. All deceased patients had experienced recurrent bleeding.

Disclosure: Nothing to disclose.

Introduction: Acute upper gastrointestinal (UGI) bleeding is a common medical emergency among the elderly. There is limited data on the management and outcomes of non-variceal UGI bleeding in the elderly in India.

Aims & Methods: We aimed to study clinical presentation, endoscopic findings, and outcomes in elderly patients with acute non-variceal UGI bleeding. All elderly patients (≥ 60 years of age) who presented with acute UGI bleed and were admitted for the same from 2021 to 2022 were retrospectively analysed. Baseline characteristics, blood transfusions before and after endoscopy, endoscopic diagnosis and therapy, AIMS65 score, complete Rockall score, and outcomes such as in-hospital re-bleeding and mortality were recorded.

Results: Of the 399 patients who had acute non-variceal UGI bleed, 309 patients aged <60 years were excluded. Of the 90 patients studied, the mean age of presentation was 69.8 ± 7.35 years, with 81.1% males. The most common presentation was melena (30%). Forty-one (45.5%) patients had a history of antiplatelet and anticoagulant use. The most common endoscopic finding was gastric ulcer (54.4%), followed by duodenal ulcer (22.2%), gastroesophageal junction ulcer (7.7%), Mallory-Weiss tear (6.6%), duodenal diverticular bleed (2.2%). The majority of ulcers were Forrest III (43.3%), followed by Forrest IIa (23.3%) and IIc (18.3%). Around 65% of patients with non-variceal UGI bleeds did not require endotherapy. Dual endotherapy was done in 25.5.5% of patients. Triple endotherapy was done in two patients. AIMS65 score was 1 in 50% of patients and 2 in 24.5% of patients. The majority (81.1%) of patients had a complete Rockall score of 3-7, indicating a moderate risk of re-bleeding and mortality. All the 90 patients were discharged without any mortality.

Conclusion: Our study showed that gastric ulcer was the most common cause of acute non-variceal UGI bleeding in the elderly, and melena was the most common presentation. Early endoscopic therapy may reduce blood transfusion requirements, in-hospital re-bleeding, and mortality.

Disclosure: Nothing to disclose.

Contact E-Mail Address: arafat4h@gmail.com

Introduction: Upper gastrointestinal bleeding is a frequent reason for consultation in the emergency room, and digestive bleeding due to rupture of esophageal varices represents the second cause in terms of frequency and can cause serious and recurrent bleeding. Recurrence of digestive bleeding due to rupture of esophageal varices (OV) is a major concern in gastroenterology and hepatology. Due to the evolution of hemostasis techniques and management strategies, the rates of recurrence, morbidity and mortality have decreased but remain significant in most studies reported in the literature.

Aims & Methods: The aim of our work is to study the epidemiological profile of hemorrhagic recurrence of esophageal varices.

This is a prospective, descriptive and analytical study, carried out over a period of 24 months from January 2022 to December 2023. we included in our study patients who had consulted for digestive bleeding due to rupture of esophageal varices and who had benefited from a complete clinical examination, a complete biological assessment, an Esophago-gastro-duodenoscopy and immediate and remote monitoring. Patients who did not benefit from an esophago-gastro-duodenoscopy and those whose files were incomplete were excluded.

Results: 90 patients presenting with digestive bleeding due to rupture of esophageal varices were included in our study. The average age is 55 years (extremes: 17 and 89 years). The M/F sex ratio is 0.8. The mode of revelation of upper digestive bleeding was melena associated with hematemesis in 10 patients (11.1%), melena in 30 patients (33.3%), hematemesis in 50 patients (55.5%).

12 (13.3%) patients required intensive care. Hemorrhagic recurrence was noted in 30 (33.3%) patients, including 11 (12.2%) early recurrence < 06 weeks, and 19 (21.1%) late recurrence after 06 weeks. For patients who had presented a recurrence, we found 18 (60%) patients with an age > 60 years, 16 (53.3%) patients with a history of ascitic decompensation, 10 (33.3%) patients with an initial large-scale digestive hemorrhage.

Conclusion: Hemorrhagic recurrence in our series was 33.3%. More frequent in elderly subjects, and with ascitic decompensation, and severe initial hemorrhage.

Disclosure: Nothing to disclose.

PP0029

RISK FACTORS OF IN-HOSPITAL MORTALITY AMONG PATIENTS WITH GASTROINTESTINAL BLEEDING AND ISCHEMIC HEART DISEASE

H. Yan[1], L. Ma[1], J. Yang[1]
[1]*West China Hospital, Sichuan University, Chengdu, China*

Contact E-Mail Address: hailin_yan@163.com

Introduction: Gastrointestinal bleeding (GIB) and Ischemic heart disease (IHD) both remain the important causes of morbidity and mortality. Patients with IHD are more likely to suffer from GIB due to the characteristics of the population, heart disease, stress state and long-term use of antithrombotic drugs[1-3].

Previous studies have found that patients with simultaneous GIB and IHD have higher mortality than that of each individual disease[4-5].

Treatment for those patients is a challenge for both the cardiologists and gastroenterologists. In order to assess the frequency of in-hospital mortality in patients with GIB and IHD, and determine the potential risk factors for this condition, we designed and conducted this single center study.

Aims & Methods: Our study assessed the hospitalized outcomes of patients with simultaneous GIB and IHD. Moreover, we explored the risk factors of in-hospital mortality in those patients.

We performed a retrospective study in West China hospital between January 2014 and December 2018. Patients diagnosed with GIB and IHD were included. The primary outcome was in-hospital mortality for all causes. Clinical and laboratory data were collected and analyzed for clinical characteristics and potential risk factors of in-hospital mortality.

Results: 574 GIB patients with IHD were enrolled in the current study, and among them 107 in-hospital deaths were observed (in-hospital mortality rate of 18.64%). The causes of death included cardiovascular death (46, 42.99%), hemorrhagic shock (10, 9.35%), severe infection (33, 30.84%), and other causes (18, 16.82%).

Patients who died were older than survivors [78（68, 82） vs. 74（65, 80）, P = 0.008], with a higher incidence of COPD (27.10% vs. 13.70%, P=0.001) and chronic renal failure (47.66% vs. 27.19%, P<0.001). Patients with a higher heart rate at admission (90 vs. 81, P=0.006), or with a course of CHD less than 3 months (53.27% vs. 32.76%, P<0.001) were more likely to die. More patients in death group received plasma infusion (24.30% vs. 7.92%, P<0.001), and present with acute coronary syndrome (53.27% vs. 38.97%, P=0.007).

Compared with survivors, patients who died showed increased peak white blood cell (WBC) count [18.75(14.35, 24.9) vs. 9.79 (7.19, 13.82) ×109/L,P < 0.001], increased peak INR [1.51 (1.21, 2.58) vs. 1.13 (1.05, 1.31),P < 0.001)], and lower minimum platelet counts [94 (52, 147) vs. 128 (83, 180)×109/L, p<0.001]. In multivariable logistic analysis, age [OR (95% CI) =1.032 (1.006-1.058), P=0.014], peak WBC count [OR (95% CI) =1.123 (1.085-1.163), P<0.001], peak INR levels [OR (95%CI) =1.220(1.061-1.402), P=0.005], and heart rate at admission [OR (95%CI) =1.015(1.002-1.028), P=0.026] were independent predictors of in-hospital mortality.

Conclusion: Patients with simultaneous GIB and IHD had a high in-hospital mortality. Age, peak WBC count, peak INR levels, and heart rate at admission were independent risk factors for in-hospital death.

UTILIZATION OF HEMOSTATIC POWDER SPRAY VERSUS STANDARD ENDOSCOPIC TREATMENT IN THE MANAGEMENT OF MALIGNANCY-RELATED GASTROINTESTINAL BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Laurel[1], Z.R. Amores[1], R.L. Galang[1]
[1]*St. Luke's Medical Center- Global City, Institute of Digestive and Liver Diseases, Taguig, Philippines*

Contact E-Mail Address: laurenceelaurel@gmail.com

Introduction: Managing tumoral bleeding poses a significant challenge for endoscopists. Traditional tools such as clips and heat-probes frequently prove inadequate in controlling stubborn bleeding caused by mucosal invasion from these tumors. Hemostatic powder sprays provide a novel solution by applying a combination of minerals and polymers directly onto the tumor surface, forming a mechanical barrier to seal the bleeding site. However, there is a scarcity of data regarding their effectiveness in treating hemorrhagic gastrointestinal neoplasms.

This study seeks to evaluate the efficacy of Hemostatic powder spray in patients suffering from gastrointestinal bleeding related to malignancies.

Aims & Methods: This study aimed to evaluate the effectiveness of Hemostatic powder spray compared to standard clinical treatment in controlling gastrointestinal bleeding originating from malignant lesions. The primary outcome measures included the combined rates of rebleeding within 30 days, while secondary outcomes encompassed the combined rates of mortality over any time period.

We gathered relevant data, an extensive search of electronic databases was conducted up to April 2024. Only randomized controlled trials (RCTs) were included in the study, focusing specifically on cases where Hemostatic powder spray was pitted against conventional endoscopic techniques for managing bleeding caused by gastrointestinal tumors.

Results: Three studies involving a total of 162 patients were included in this meta-analysis. Among them, 83 patients underwent treatment with Hemostatic spray powder alone, while 79 patients received conventional hemostatic techniques.

The pooled results of the analysis revealed that Hemostatic powder spray was associated with a lower incidence of re-bleeding beyond 30 days from the onset of treatment (odds ratio [OR] 0.36, 95% confidence interval [CI] 0.15-0.84), demonstrating a significant advantage over standard endoscopy in the management of gastrointestinal tumor bleeding (p-value 0.01).

Additionally, there was no significant difference observed in all-time mortality between the two treatment groups (OR 0.40, 95% CI 0.19-0.83, p-value 0.09).

Conclusion: Hemostatic spray powders demonstrate significant efficacy in achieving hemostasis for gastrointestinal bleeding associated with malignancies. They should be regarded as a viable alternative to conventional endoscopic methods in such cases. Subsequent research should be

IMPROVING DOCUMENTED ADVICE REGARDING ANTICOAGULANTS AND ANTIPLATELETS IN ACUTE UPPER GASTROINTESTINAL BLEEDS

E. Creed[1], V. Theis[1], K. Clark[1], S. Gurung[1], A. Motam[1], G. FarrellBinns[1]

[1]Mersey and West Lancashire Teaching Hospitals NHS Trust, Gastroenterology, Liverpool, United Kingdom

Introduction: Systemic anticoagulants are often prescribed to prevent and treat thromboembolism among other indications, yet presentations with Acute Upper Gastrointestinal Bleeds (AUGIB) in this cohort are common. Medical care bundles have been shown to improve both standards of care and patient outcomes. As a result, the British Society for Gastroenterology (BSG) created an AUGIB care bundle in 2019, and guidelines for endoscopy in patients on antiplatelets and anticoagulants in 2021. However, the former lacks definitive statements regarding resumption of antiplatelet/anticoagulant therapy, while the latter is not routinely referred to by non-Gastrointestinal specialists. It is recognised however, that resumption of antiplatelets and anticoagulants is associated with improved survival and reduced incidence of thrombotic complications. Thus, all patients should have a clear plan.

Aims & Methods: Admissions with AUGIB proceeding to endoscopy over a 6 month period were analysed. Of the 319 patients, 72 (22.5%) were taking either an antiplatelet, warfarin or a Direct Oral Anticoagulant (DOAC). Medical records were reviewed in relation to pre-procedure management of these medications, advice from the endoscopist regarding resumption (or not) of antithrombotic therapy and whether these medicines were managed appropriately thereafter.

Several interventions were then made; a change to the reporting software led to a prompt relating to antiplatelet/anticoagulant medications (though the template remains non-specific), an education campaign for post graduate doctors in training and medication guidance summaries visible in the endoscopy department.

A second 6-month review was then undertaken to evaluate if there had been any improvement in outcomes. In this time frame, 283 patients underwent endoscopic evaluation for suspected AUGIB of whom 83 (29.3%) were taking antithrombotic therapy.

Results: Results can be found in Table 1:

	Pre-Intervention	Post Intervention
Pre-procedure appropriate management	76%	81%
Documented advice on endoscopy report	35%	65%
Post procedure appropriate prescribing	68%	75%

Table 1.

A recurring theme was the discontinuation of aspirin in low-risk bleeds, and low quality medication advice given at the time of endoscopy with almost 4 in 10 reports simply stating 'continue medication'. Those without documentation resulted in further advice being sought (12.9% of cases)

Further subanalysis of the data revealed that advice was almost always documented in those presenting with major upper gastrointestinal bleeds (defined as patients presenting with haemodynamic instability). In this cohort 87.5% of patients had clearly documented advice regarding their anticoagulation or antiplatelet medication.

Conclusion: Further education to junior staff around utility of the BSG AUGIB bundle, as well as the anticoagulation guidelines is needed to improve pre and post procedure care. Further upgrades to the templates on the reporting software will also serve as prompts to the endoscopist to provide more specific advice. Human factors also need to be considered; limited advice is likely related to the high endoscopy workload pressures. Sub-analysis of the data suggests that we are better at providing more specific advice in high-risk bleeds/where endotherapy is required, reflecting that antithrombotic therapy decisions are considered by the endoscopist. Improved documentation at procedure, should translate into improved post procedure management and reduce further demands on the service.

SAFETY AND EFFICACY OF PROTON PUMP INHIBITORS IN CRITICALLY ILL PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Mostafa Al-dardery[1], M. Mohamed El-sayed[1], A. Khaled Madeeh[1], D. Osama Yehia Ibrahim[1], M. Salah mahklouf[1], N. Ahmed Kamel Ahmed[1], M. El-Samahy[2], A. Khaity[3]

Introduction: Critically ill patients are at high risk for upper gastrointestinal (GI) bleeding.[1] Proton pump inhibitors (PPIs) are commonly used for prophylaxis, but their safety and efficacy compared to histamine-2 receptor antagonists (H2 blockers) and placebo remain unclear.[1–4]

Aims & Methods: Our systematic review and meta-analysis aims to assess the safety and efficacy of PPIs for preventing upper GI bleeding in critically ill adults. We conducted a comprehensive search of Scopus, Web of Science, PubMed, and Cochrane Central for relevant randomized controlled trials (RCTs) from inception until March 2024. Data were extracted from eligible studies and pooled as mean difference (MD) for continuous outcomes and Odds ratio (OR) for dichotomous data in a random-effect model meta-analysis, using R software.

Results: Nineteen RCTs were included in this meta-analysis with a total of 62221 patients. Our study showed that PPI was superior to control in terms of GI bleeding [RR 0.55, (95% CI, 0.42 to 0.72); P = <0.01]. However, the overall effect did not favor either of the two groups in terms of ICU, mortality rate, and nosocomial infection [MD -1.45, (95% CI, -5.31 to 2.42); P = 0.4], [RR 1.04, (95% CI, 1.00 to 1.09); P = 0.07], and [RR 1.27, (95% CI, 0.98 to 1.65); P = 0.07], respectively.

Conclusion: In conclusion, our findings demonstrated a significant reduction in GI bleeding risk associated with PPI use. At the same time, we did not find a statistically significant difference between PPI and control groups regarding ICU mortality rate, overall mortality rate, or nosocomial infection rates. These findings suggest that PPIs may be effective in reducing upper GI bleeding in critically ill patients. However, further research might be necessary to definitively determine the impact of PPIs on mortality and infection risks in this population.

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the most common medical emergencies managed by gastroenterologists. Despite advances in pharmacological/endoscopic therapy, this condition is still associated with considerable morbidity/mortality.

Aims & Methods: We aimed to characterize Portuguese patients and clinical approaches in UGIB, as well as factors associated with adverse outcomes. We conducted a retrospective multicentric cohort study which included adult patients consecutively presenting UGIB at 6 participating centers over a 6-month period. Data relevant to the initial UGIB episode and for up to 30 days afterwards were collected from patient medical records. Patients' clinical information was presented using descriptive statistics. Continuous variables were described by mean ± standard deviation. Categorical data were presented as absolute numbers and percentages. Qualitative variables were compared with Chi-square and Fisher's tests. Non-normal distribution quantitative variables were compared with Mann-Whitney test. A p value < 0,05 was considered statistically significant.

Results: 600 patients presenting with UGIB were included, mostly men (58,2%, n=349) with a mean age of 71 (18-100), with multiple comorbidities and a mean Charlson comorbidity index of 5 (0-16). Antiplatelet/Anticoagulant/NSAID consumption was present in 53,5% (n=321). The primary symptoms were melena (47,2%, n=283) and hematemesis (27,3%, n=164). The median Rockall score (RS) and Glasgow-Blatchford score were 5 (0-10) and 12 (0-21), respectively. A higher RS was associated with prolonged hospitalization (p=0,03). At least one cause for UGIB was documented in 499 patients (83%). Peptic ulcer disease (PUD, 37,8%, n=192), erosive gastroduodenitis (10,0%, n=51) and gastric/duodenal angiodysplasia (6,7%, n=34) were the main bleeding causes of nonvariceal UGIB (n=507). In patients with chronic liver disease (n=93), variceal bleeding (46,2%, n=43) was the main bleeding cause, followed by PUD (19,4%, n=18). Endoscopic hemostasis was performed in 257 patients (42,8%). Combination therapy (injection therapy + thermal/mechanical therapy) was used in 122 cases. Median hospitalization time was 11 days (0-168) and admission in intensive care unit (ICU) was needed in 9,8% (n=59). Surgery for severe UGIB was performed in 2% (n=12). In-hospital rebleeding occurred in 13,3%, more frequently in chronic liver disease (p=0,02). Death occurred in 90 patients (15%), 73 from a non-bleeding related cause. Logistic regression showed that age≥65 years (p=0,02), chronic liver disease (p=0,049) and ICU admission (p=0,045) were associated with in-hospital mortality.

Conclusion: This study contributed to characterization of Portuguese patients admitted with UGIB in real clinical setting. Gastroenterologists are facing a progressively older population, with multiple comorbidities and on therapies potentially causing UGIB. Although PUD still remains the

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. most common cause of UGIB, other conditions such as angiodysplasia are becoming more frequent in clinical practice. Chronic liver disease is a risk factor for rebleeding and in-hospital mortality. The high mortality observed in this research was mainly due to decompensation of comorbid conditions rather than exsanguination, which reflects the complexity of the elderly. These patients require early risk assessment, adequate resuscitation and an attempt to identify and treat the bleeding source, which might help us to improve the management of UGIB in Portugal.

Introduction: Upper digestive hemorrhage (HDH) is a frequent reason for hospitalization in the emergency department. Schematically, they are divided into HDH of varicose origin and HDH of non-varicose origin.

Upper GI endoscopy must be performed as quickly as possible, under the best possible technical conditions.

The objective of our study is to evaluate the hemostatic endoscopic management of these hemorrhages in the emergency department.

Aims & Methods: This is a retrospective descriptive study covering a period of 26 months, from January 2022 to March 2024, and including all patients admitted in an emergency for upper digestive haemorrhage of non-variceal origin, identified during the endoscopy on-call duty at the "Médecine B" Hepato-gastroenterology and Proctology Department, CHU Ibn Sina.

All patients underwent clinical examination, blood count and oeso-gastro-duodenal fibroscopy (FOGD).

Patients admitted for HDH of varicose origin or with normal FOGD were excluded from our study.

Results: 91 cases of HDH of non-varicose origin were diagnosed out of a total of 225 cases of HDH consulting the emergency department, with a prevalence of 40.44%.

The mean age of our patients was 54.8 years (20-84 years), with a male predominance of 70.3% and a sex ratio of M/F : 2.3.

11 patients (12.08%) had a history of smoking, 11 (12.08%) had heart disease on anticoagulants, 10 (11%) had taken NSAIDs, 8 (8.79%) had nephropathy at the hemodialysis stage, and 7 (8%) were hypertensive.

The mode of externalization of HDH was melena associated with hematemesis in 26 patients (28.6%), isolated melena in 44 (48.4%), hematemesis in 16 (17.6%) and rectal discharge in 5 (5.5%).

The main etiologies of HDH of non-varicose origin revealed by FOGD were: gastro-duodenal ulcer in 73 patients (80.2%), with Forrest Ib ulcer in 9 (12.3%), Forrest IIa in 4(5.4%), Forrest IIb in 4(5.4%), Forrest IIc in 13(17.8%) and Forrest III in 43(59%).

Of the 91 patients, 15(16.48%) had esophagitis, 5(5.5%) had gastric process, 1(1.09%) had duodenal process and 8 patients (8.8%) had angiodysplasia lesions.

All patients were treated with a loading dose of injectable PPI, followed by a maintenance dose.

Endoscopic haemostasis was required in 19 patients (20.8%), of whom 8 (8.7%) benefited from injection of adrenaline serum and placement of haemostatic clips, 2 patients (2.2%) from exclusive injection of adrenaline serum, 8 patients (8.7%) from exclusive placement of haemostatic clips and one patient (1.09%) benefited from per-endoscopic surgical suturing.

The mortality rate in our study was 3.2%.

Conclusion: HDH of non-varicose origin remains dominated by ulcerative origin. Impregnation with PPIs prior to FOGD and the possibility of endoscopic haemostasis reduce the mortality rate.

Introduction: Iron deficiency anaemia (IDA) is a frequent reason for consultation with a high consumption of health resources both for its diagnosis and for its treatment.

Aims & Methods: To evaluate the characteristics of patients referred to a specialized gastrointestinal (GI) consultation for IDA without macroscopic haemorrhage and the impact of this specialized evaluation on the consumption of health resources. We performed a retrospective observational study of patients evaluated in a specialized gastrointestinal hospital consultation for IDA from January 2021 to October 2023.

Results: We evaluated 218 patients where 134 were excluded due to macroscopic haemorrhage. Finally, 84 patients were analysed, 63% were men with a median age of 73 years (range 39-93) and a median Charlson index of 6 (range 0-15). The median time from the diagnosis of IDA to the first

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

gastrointestinal visit was 46 months (range 1-161). 74% of the patients had been evaluated by another specialty previously. 43% were on antiplatelet treatment and 31% on anticoagulant treatment. The aetiology of anaemia was multifactorial in 24% (n=20) and in those with iron deficiency the most frequent cause was angiodysplasias (42%) but in up to 19% of cases the aetiology was not found despite a complete evaluation.

During follow-up, 58% required an anticoagulation switch, requiring definitive withdrawal of anticoagulation in 8% of patients. Prior to the GI consultation, only one patient was under somatostatin analogues treatment, which was subsequently started in 17 new patients. During follow-up, 12% (n=10) were included in a special management group with parallel blood test monitoring by the primary care physician for a more thoroughly monitorisation of the haemoglobin levels.

When comparing the consumption of health resources in the year before and after the GI assessment, a non-significant trend was observed towards a lower need for gastroscopies [0.87 vs. 0.65, p=0.07], but we found an statistically significant reduction in the number of colonoscopies [0.88 vs. 0.40, p<0.001].

We also observed a significant increase in the mean haemoglobin [10.6 g/dL vs. 12.1 g/dL, p<0.001] without statistically significant differences in the number of blood transfusion [2.82 units vs. 2.30 units, p=0.21] or intravenous iron therapy [1.44 g vs. 1.50 g, p=0.74] before and after the GI assessment respectively. A significant reduction in emergency department visits was also observed [0.79 vs. 0.43, p=0.002] as in hospital admissions [0.46 vs. 0.23, p=0.004] related to anaemia or its complications.

During follow-up, 12 patients died (none due to haemorrhage or anaemia), resulting in a cumulative mortality incidence of 6.7 deaths per 100 patients/year.

Conclusion: Multimorbid patients with iron deficiency anaemia benefit from the care of a specialized digestive consultation which is associated with a decrease in the use of health resources.

VARIATION IN GASTRODUODENAL FUNCTION TESTING IN CLINICAL PRACTICE: RESULTS FROM AN INTERNATIONAL SURVEY

S. Kindt[1], A. Fikree[2], M. Fox[3]

[1]UZ Brussels, Gastro-enterology and Hepatology, Brussel, Belgium, [2]University College Hospital NHS Trust, Dept. of Gastroenterology, London, United Kingdom, [3]Klinik Arlesheim & Zürich University, Center for integrative Gastroenterology, Arlesheim, Switzerland

Contact E-Mail Address: sebastien.kindt@uzbrussel.be

Introduction: Gastric emptying scintigraphy (GES) is an accepted standard for gastroduodenal function (GDF) testing, while various other investigations are available for the assessment of dyspeptic symptoms. However, in the absence of guidelines, it remains uncertain which test one should favour.

Aims & Methods: This study examined variation in GDF testing between centres to establish the status of current practice. A web-based questionnaire assessing availability, standard operating procedures and interpretation of 15 different GDF testing techniques was distributed among specialist practitioners via professional organizations. Availability, indication, meal-related characteristics and standard operating procedures (SOP) were compared.

Results: Fifty-nine complete responses (57 clinical practice, 86% tertiary care) were included from 28 countries. Eleven (19%) respondents referred more than 10 patients for further testing monthly. Accessibility for clinical practice were as follows: 100% gastroscopy, 91% measurement of gastric emptying (79% by GES; 19% gastric emptying breath testing (GEBT); 5% SPECT), 39% intragastric pressure measurements (IGP), 33% pyloric Endoflip (PE), 30% gastric MRI, 19% nutrient drinking challenge (NDC), 18% gastric ultrasound (US), 18% motility capsule (MC) and 16% antroduodenal manometry (AM). Other techniques were available to less than 15% of the respondents. In clinical practice, meal-related dyspeptic symptoms and chronic unexplained nausea and vomiting (CUNV) represented the main indications for GE studies as compared to epigastric pain, burning or discomfort (GES: 70% and 94% vs. 20%, p<.00001; GEBT: 100% and 100% vs. 0%, p<.001), Similar results were present for PE (73% and 93% vs. 33%, p=.002), NDC (100 and 82 vs. 27%, p=.0006). MC (33% and 67% vs. 0%, p=.05), AM (28% and 75% vs. 25%, p=.11), MRI (75% and 88% vs. 38%, p=.09) and IGP (33% and 33% vs. 0%, p=.15) By contrast, US was indiscriminately performed (57% and 71% vs. 57%, p=.82).

There was a large heterogeneity in the type of meal and meal quantity used for each test as well as between tests. Symptoms were recorded by only half the respondents during GES and MRI, with higher percentages for other testing modalities. Variation in the specific symptoms included in questionnaires was present.

Conclusion: GES is widely available in clinical practice. Meal-related symptoms and CUNV represent the main indications for GDF testing in clinical practice. A large variation in the availability of GDF testing and SOPs exists between centres. This hampers clinical interpretation, data transfer between centres and research collaboration. These findings emphasise the need for an international co-operation effort at standardisation.

BREAKING BARRIERS IN FUNCTIONAL DYSPEPSIA – A SYSTEMATIC REVIEW AND META-ANALYSIS ON DUODENAL TIGHT JUNCTION PROTEIN EXPRESSION

R. Farcas[1], S. Grad[1], A. Ismaiel[1], D.-C. Leucuta[1], P. Stefan-Lucian[1], D.L. Dumitrascu[1]

[1]Iuliu Hatieganu University of Medicine and Pharmacy, 1 2nd Department of Internal Medicine, Cluj-Napoca, Romania

Contact E-Mail Address: radufr@gmail.com

Introduction: Disruptions in tight junction (TJ) protein expression leading to duodenal epithelial barrier impairment may contribute to increased intestinal permeability, potentially playing a role in functional dyspepsia (FD) pathophysiology. Currently published studies evaluated the role of several TJ proteins in FD patients with inconsistent results. Therefore, we conducted this systematic review and meta-analysis to evaluate the duodenal mucosal expression of several TJ proteins in FD.

Aims & Methods: We performed a systematic electronic search on PubMed, EMBASE, and Scopus using predefined keywords. Diagnosis of FD by ROME III or ROME IV criteria was considered acceptable. Full articles satisfying our inclusion and exclusion criteria were included. The principal summary outcome was the mean difference (MD) of several TJ proteins in FD patients and control subjects. The study aimed to find if patients diagnosed with functional dyspepsia have lower gene expression of intestinal TJ proteins compared to healthy subjects.

Results: A total of 8 and 5 studies were included in our qualitative and quantitative synthesis, respectively, with a total population of 666 participants, out of which 420 were FD patients. No significant differences were observed between FD patients and controls in the expression of claudin-1

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. (-0.102 [CI 95% -0.303,0.099]), claudin-2 (0.161 [CI 95% -0.134,0.456)], claudin-3 (0.278 (CI 95% -0.280,0.837]), claudin-4 (0.045 [CI 95% -0.264,0.354]), ZO-1 (-0.221[CI 95% -0.683, 0.241]), ZO-2 (-0.070 [CI 95% -0.147,0.007]), ZO-3(-0.129 [CI 95% -0.376, 0.118]), B-catenin (-0.135 [CI 95% -0.484,0.214]), E-cadherin (-0.083 [CI 95% -0.229,0.063]), and occludin (-0.158 [CI 95% -0.409, 0.093]).

Conclusion: The expressions of all evaluated proteins including claudin-1, claudin-2, claudin-3, claudin-4, ZO-1, ZO-2, ZO-3, B-catenin, E-cadherin, and occludin did not significantly differ between FD patients and controls. However, due to the limited number of included studies, results should be interpreted with caution.

Contact E-Mail Address: cedric.vandebruaene@kuleuven.be

Introduction: Functional dyspepsia (FD) is a common gastrointestinal disorder, comprising postprandial distress syndrome, PDS, with meal-related symptoms, and epigastric pain syndrome, EPS, with meal-unrelated symptoms. In a pilot study in PDS patients, the 6-food elimination diet was able to provide symptom relief (1). Using confocal laser endomicroscopy (CLE), acute disruption of the duodenal epithelium in response to food protein administration can be observed (2). This assessment may have the potential to identify food components that should be the target of an elimination diet treatment approach.

Aims & Methods: Aim: To evaluate the acute effect of food administration on duodenal mucosal integrity in FD patients and to determine whether visualized alterations are associated with changes in mucosal permeability or markers of mast cell activation ex-vivo.

Methods: In 17 Rome IV FD patients (8 PDS, 1 EPS, 8 overlap PDS/EPS), classic allergy to nutrients was excluded by specific serum IgE tests. Index upper GI endoscopy (EGD) was followed at least 2 weeks later by a second EGD with CLE. Duodenal mucosa was visualized at baseline and after consecutive administration of egg white, soy, milk, wheat, lyophilized fish and shellfish and nuts solutions through the working channel in a randomized order. In those with reaction to one of the first 2 administered food solutions, an additional CLE was scheduled. Serum was obtained at baseline and 30 minutes after occurrence of acute mucosal alterations. Biopsies were obtained at index EGD and after acute alterations to measure transepithelial electrical resistance (TEER) in Ussing chambers. Tryptase levels in biopsy supernatants after 1h and following 24h incubation were assessed. Data are reported as mean ± SEM. Comparisons were done using two-sided t-tests. P-value <0.05 is considered significant.

Results: 29 CLE exams were carried out in 17 patients (age 35±3.7y, f16, BMI 22±0.7 kg/m^2). In 90% of exams (*n=26)*, acute alterations were visible only after food exposure, while in 10% (*n=3),* these were already present at baseline. Twelve patients (71%) showed alterations on CLE after exposure to one of the first 2 food components and underwent a second CLE procedure. Highest percentage of acute alterations was observed after soy administration (6/11 exposed). In the table, distribution of reactions per food is presented. After acute alterations, there was no difference in serum tryptase compared to baseline (4.52µg/L±0.6 vs. 4.72µg/L±0.6, p=0.21), nor did TEER change compared to baseline (28±0.9 Ωxcm^2 vs 28±1.6 Ωxcm^2, p=0.25), nor did tryptase content alter in biopsy supernatants, both after 1h and 24h compared to baseline (0.23µg/g±0.04 vs. 0.28µg/g±0.07, p=0.15 and 1.66µg/g±0.44 vs. 1.06µg/g±0.33, p=0.60).

Observations	Number of exams with exposure	Number of acute alterations	% of acute alterations per food item
Baseline	29	3	10
Milk	8	2	25
Nuts	12	4	33
Soy	11	6	55
Wheat	7	3	43
Fish	10	2	20
Egg white	8	3	38

Table. Number of examinations with exposure and alterations per specific food components.
All patients had a baseline visualization during CLE examination.

Conclusion: In FD patients without IgE mediated classical allergies, CLE visualized a high rate of acute food induced mucosal alterations. These acute responses were not associated with altered permeability, a rise in systemic tryptase, or release of tryptase from biopsy supernatants. Mechanisms underlying acute mucosal alterations and its impact on elimination diet efficacy needs further investigation.

GENDER GAP IN THE TREATMENT OF FUNCTIONAL DYSPEPSIA? DATA FROM THE GERIATRIC POPULATION

J. Worbs[1], E. Complido[1], O. Kelber[1], K. Nieber[2], K. Kraft[3]

Introduction: Functional gastrointestinal disorders (FGIDs) are more prevalent in female than in male patients [1,2]. This triggers the question whether this is also reflected in medical care, especially also in self-medication, where often botanicals are used. A potential source of data to address this question is the PhytoVIS study, a pharmacoepidemiological study conducted in Germany in more than 20,000 patients taking herbal medicinal products.

Aims & Methods: To have a large and homogenous data base for a gender-related evaluation, records for a clinically proven herbal medicinal product (HMP) often used in FGIDs, STW 5 [3,4], were evaluated to uncover potential gender-related differences in the pharmacotherapy of FGIDs.

Results: 1513 records were evaluated, 71 % of them from females and 29 % from males, i.e. a 4 % higher proportion of females compared to the overall population of the PhytoVIS study. Main criterium for the evaluation was the Clinical Global Impression Scale – Efficacy (CGI-E). No major differences between females and males were found, apart that women perceived a minimally better effect of the therapy. The reported symptoms were differentiated into symptoms associated with functional dyspepsia (FD), irritable bowel syndrome (IBS), or symptoms that can be associated with both. As far as the records allow a differentiation, no gender differences could be observed. This applies also to the perceived efficacy, the tolerability and the onset of action.

Conclusion: So, while there are differences in the prevalence of FGIDs in women and men, there are no therapeutically relevant pharmacoepidemiological differences in patients with functional gastrointestinal diseases treated with a medicinal product indicated in these diseases, so suggesting that there is no gender gap in this highly relevant therapeutic field.

ACTIVATING TRANSCRIPTION FACTOR 3 ASSOCIATED WITH NAUSEA IN GASTROPARESIS PATIENTS - A WHOLE GENOME SEQUENCING STUDY

H. Bai[1], S. Smieszek[1], J.L. Carlin[1], C. Xiao[1], G. Birznieks[1], C. Polymeropoulos[1], M.H. Polymeropoulos[1]

Contact E-Mail Address: baihm_steven@hotmail.com

Introduction: Gastroparesis is a severe medical condition characterized by delayed gastric emptying and symptoms of nausea, vomiting, bloating, fullness after meals, and abdominal pain. Thus far, little is known about the underlying genetic risk factors for nausea in gastroparesis patients. We explored the association of genetic variants with nausea severity in a set of WGS data from a clinical gastroparesis study.

Aims & Methods: Blood samples were obtained from adults with a diagnosis of diabetic or idiopathic gastroparesis, having evidence of delayed gastric emptying, and moderate to severe nausea, daily average nausea score of >2.5, at least one episode of vomiting, PAGI-SYM nausea score of ≥2 at screening, and controlled blood glucose levels. WGS was conducted with 30x read depth using whole blood samples. Nausea score was assessed from a daily symptom dairy with a range from 0 mild to 5 severe. GWAS using linear model was conducted on variants with MAF ≥0.01 with adjustment of the subject's age, sex, BMI, etiology, and the first 3 PCs.

Results: Variant clusters from multiple genes are significantly associated with baseline nausea score at p=1e-5 level. Among the top scoring variants are loci within ATF3, PP2D1, CNTN4, BMP2, ABL1, CTNNA3 and KIF6. Interestingly, upon comparing our results with a published transcriptomic analysis that included both diabetic and idiopathic gastroparesis subjects, we found that ATF3 and BMP2 were overlapping with genes differentially expressed in both diabetic and idiopathic gastroparesis when compared with controls. ABL1 was however differentially expressed in diabetic cases whereas CNTN4 was differentially expressed in idiopathic controls. We expanded the analysis with single gene tests which shows that ATF3 is significant especially for MAF>0.05 variants (SKAT p=0.02). The top variant in ATF3 is rs79151334 (beta= 0.68, p=5.76e-6), whose minor allele associates with higher nausea score.

Conclusion: Additionally, we report new potential associations CTNNA3, PP2D1, and KIF6 as well as a cluster of variants between CDH2 and MIR302F, that associated with baseline nausea score. Among those, both CTNNA3 and CDH2 encode cadherin related proteins, suggesting this type of junction could play a role in the underlying mechanism.

HOW MANY SUBJECTS WITH SEVERE DISORDERS OF GUT-BRAIN INTERACTION HAVE AN INTOLERANCE OF GLUTEN WHEN A DOUBLE-BLIND GLUTEN EXPOSURE IS PERFORMED?

N. Smith[1], A. Do[1], B. McKillen[1], T. Fairlie[1], N.A. Koloski[1], K. Duncanson[2], N.J. Talley[3], A. Shah[1], G.J. Holtmann[1]

Contact E-Mail Address: nxjsmith@gmail.com

Introduction: Approximately 50% of patients with disorders of gut-brain interaction (DGBI) report intolerance of wheat products [2]. While dietary gluten restrictions would be a feasible approach to managing gastrointestinal symptoms, in DGBI patients with gluten-related symptoms, there are challenges in relation to compliance and even adverse long-term effects of a gluten and wheat-free diet.

Aims & Methods: This study aims to test the feasibility of a double-blind gluten exposure test and determine the rate of patients with DGBI who respond with a change of symptom severity after exposure to gluten.

From a cohort of 70 consecutive patients referred to our Integrated Care Clinic for patients with complex DGBI, 35 agreed to participate in a double-blind gluten exposure test. This test was aligned with the gluten exposure test outlined in the Salerno criteria [1].

After exclusion of coeliac disease (endoscopy and serology), a seven-week gluten-free run-in, patients received one week of encapsulated gluten (8 g per day) or identical placebo. Each week with daily gluten exposure or placebo exposure was separated by one week of washout. Gluten and placebo were administered in a double-blind randomised fashion. The Structured Assessment of Gastrointestinal Symptoms (SAGIS) score was used at baseline before commencing the gluten exposure test and at the end of every week to assess changes of gastrointestinal symptoms.

Results: 34 patients completed the challenge test, of whom seven initially had self-reported symptoms associated with gluten or wheat consumption. Only one of these seven patients responded to gluten exposure with a >25% increase of the SAGIS score. 16 out of 34 patients (47 %, 95% CI 30-65) reported improved gastrointestinal symptoms while on a gluten-free diet.

Overall, 2 of the 34 patients (5.9%, 95% CI 0.7-20.0) showed a deterioration of symptoms during the gluten challenge week, while 8 patients (23.5%, 95% CI 10.8-41.2) reported a reduction of the symptoms while exposed to placebo. No effects of gluten exposure on extraintestinal symptoms were observed.

Conclusion: A standardised, double-blind gluten exposure test is suitable in the routine clinical setting to rule out gluten intolerance in patients with self-reported gluten sensitivity. Overall, gluten exposure is rarely associated with an increase of gastrointestinal symptoms in patients with DGBI. Self-reported non-celiac wheat sensitivity is a poor predictor for developing symptoms during double-blind gluten exposure.

EFFECTS OF DA-9701 (MOTILITONE) ON GASTRIC EMPTYING, BLOOD GLUCOSE REGULATION, AND OXIDATIVE STRESS IN DIABETIC RATS

M. Kim[1], C.I. Sohn[2], Y.m. Song[3]
[1]Asan Medical Center, Ulsan University School of Medicine, Department of Gastroenterology, Seoul, South Korea, [2]Department of Internal Medicine, Sungkyunkwan University Kangbuk Samsung Hospital, Seoul, South Korea, [3]Sungkyunkwan University Kangbuk Samsung Hospital, Institute of Medical Research, Seoul, South Korea

Contact E-Mail Address: daneel0717@naver.com

Introduction: Diabetes is associated with a variety of gastrointestinal disorders, including altered gastric emptying, which can be rapid, slow, or transient.

These changes can significantly influence gastrointestinal symptoms and potentially impact blood glucose levels. DA-9701 (motilitone), a known prokinetic agent derived from *Corydalis* tuber and *Pharbitis* seed, is employed in Korea to manage functional dyspepsia due to its noted anti-inflammatory and gastrointestinal motility-enhancing effects. This study aims to investigate the potential of DA-9701 in addressing altered gastric emptying and glycemic control in diabetic rats, thereby validating its broader clinical utility.

Aims & Methods: Diabetes mellitus was induced in rats by streptozotocin injection. Post-diabetes development, rats received oral administration of DA-9701 daily for two weeks. Evaluations included serum glucose levels, gastric emptying rates for liquids and solids, plasma insulin levels, and serum malondialdehyde concentration. Immunoblot assays assessed the expression of c-Kit, the *Ogg1* gene, and phosphorylated extracellular signal-regulated kinase (p-ERK).

Results: Diabetic rats exhibited blood glucose levels three to four times higher than nondiabetic control rats at weeks 3 and 4. Gastric emptying, initially accelerated by week 2 and persisting until week 4, was linked to increased interstitial cells of Cajal (ICC) activity driven by hyperglycemia-induced oxidative stress. The expression of c-Kit, an ICC marker, was elevated in the gastric tissues of diabetic rats by weeks 3 and 4 but reduced following two weeks of DA-9701 administration. Oral administration of DA-9701 (6 mg/kg) not only normalized gastric emptying but also improved blood glucose levels through increased serum insulin concentrations by weeks 3 and 4. Oxidative stress markers, including *Ogg1*, p-ERK, and serum malondialdehyde concentrations, initially upregulated, were reduced post-treatment.

Conclusion: Two weeks of DA-9701 treatment attenuated accelerated gastric emptying and reduced elevated blood glucose levels in diabetic rats. Normalized gastric emptying contributed to improved glucose homeostasis by reducing oxidative stress. Additionally, an unexpected increase in serum insulin levels post-treatment suggests that DA-9701's regulatory effects extend beyond gastric dynamics to direct modulation of blood glucose. These findings underscore DA-9701's significant potential in managing both gastrointestinal dysfunction and glucose control in diabetes mellitus.

ASSESSMENT OF VAGAL NERVE INJURY THROUGH SHAM FEEDING

T. Li[1], S. Billings[1], T.A. Woodward[1], B. Lacy[1]
[1]Mayo Clinic Florida, Gastroenterology, Jacksonville, United States of America

Contact E-Mail Address: li.tian@mayo.edu
Introduction: Vagal nerve injury may lead to symptoms of nausea, vomiting, abdominal discomfort, and bloating. Be it by injury or an infiltrative process, vagal nerve function is difficult to assess. Measuring pancreatic polypeptide (PP) following a sham meal may serve as a reasonable surrogate marker of vagal nerve function. PP is released in response to eating and may correlate with slow gastric emptying.
Our aim is to assess vagal nerve integrity using sham feeding with measurement of PP, in addition to evaluating the relationship of symptoms with PP levels and gastric emptying.
Aims & Methods: This was a retrospective study of patients who underwent a sham feeding study at Mayo Clinic Florida from 2018 to 2023. We collected demographic and clinical data, sham feeding results, the indication for the study, and gastric emptying data. A 50 % increase in PP level within 30 mins compared to baseline after sham feeding was considered normal. A gastric emptying scan was classified as delayed if <75% of the material emptied at 4 hours.
Results: 29 patients were included (58.6% women) with a mean age of 57.3 years. Most patients were white (n=24), and the mean BMI was 27.9 kg/m^2. The most common reason to request a sham feeding study was abdominal pain (7, 24.1%), gastroesophageal reflux (GER) (6, 20.7%) and chronic nausea and vomiting (6, 20.7%). The main GI symptoms were nausea and vomiting (13, 44.8%) and diarrhea (11, 37.9%). The average weight loss from the onset of symptoms was 31 lb. 24 of 29 included patients had a history of abdominal surgery, with hiatal hernia repair (HHR) and HHR with Nissen fundoplication being the two most common surgeries (5, 17.2%). 20 of 29 studied patients (69.0%) had an abnormal sham feeding study and 48.1% of the patients who underwent gastric empty studies were found to have delayed gastric emptying. The mean baseline PP level of normal vs abnormal was 102.88 pg/mL and 226.4 pg/mL, respectively (p=0.21). The mean peak PP level of normal vs abnormal was 195.22 pg/mL and 245 pg/mL, respectively (p=0.68). Among the 20 patients with an abnormal sham feeding study, ten had delayed gastric emptying. Symptoms of nausea and vomiting were found to have a robust correlation with a positive sham feeding result (12, 92%), compared with gastric emptying scintigraphy (8, 61.5%). There was no correlation between sham feeding result with symptoms of abdominal pain and GER. The care after apparent vagus nerve injury required significant medical resources, including an average of 3.5 visits and 5.7 tests per patient to evaluate key GI symptoms.
Conclusion: Sham feeding is an underused method to measure vagus nerve injury. It is safe and easy to perform. PP levels measured during sham feeding were consistently abnormal in patients with predominant symptoms of nausea and vomiting after foregut surgery while the correlation between gastric emptying measured using scintigraphy and gastroparesis symptoms was not significant. Interestingly, there was limited correlation between scintigraphy gastric emptying results and outcomes of sham feeding. Our research highlights the significant medical and financial burden evaluating patients with symptoms after foregut surgery. Larger prospective studies are needed to better quantify the relationship between PP levels and gastric emptying in patients with prior foregut surgery who remain symptomatic.
Disclosure: Nothing to disclose.

Introduction: Autonomic neuropathy affecting multiple organs is a common and severe complication of diabetes[1]. Neuropathy of the enteric nervous system and the regulatory autonomic nerve fibers can affect the entire gastrointestinal tract, causing mild to severe gastrointestinal symptoms[2]. The correlation between gastrointestinal symptoms and underlying pathophysiology is generally weak, so objective assessment is important to guide treatment[3-5]. Methods for direct evaluation of enteric neuropathy are not yet available in clinical practice. Hence, gastrointestinal transit times and contractile activity are used as proxies for enteric autonomic dysfunction[6,7]. Panenteric gastrointestinal assessment is considered essential, yet suitable methods are generally inaccessible, and diagnosing diabetic gastroenteropathy often causes significant challenges[4,8]. It is unknown whether measures of extraintestinal autonomic function can reflect diabetic gastroenteropathy and whether these measures could serve as supplementary diagnostic tools.
Aims & Methods: We aimed to assess 1) whether gastrointestinal symptoms are associated with motility measures and 2) whether gastrointestinal symptoms/motility measures are associated with extraintestinal autonomic markers. We included 81 persons with type 1 or type 2 diabetes (65% female, mean age 54) with gastrointestinal symptoms and either symptoms or signs of autonomic neuropathy. The Gastroparesis Cardinal Symptom Index (GCSI) and the Gastrointestinal Symptom Rating Scale (GSRS) were used to assess gastrointestinal symptoms. The wireless motility capsule assessed panenteric transit times and motility indices. Cardiovascular reflex tests performed with the VAGUS device and the cardiac vagal tone assessed with the eMotion Faros device estimated cardiovascular autonomic neuropathy, while the SUDOSCAN evaluated sudomotor function.
Results: Proximal gastrointestinal symptoms were positively associated with the gastric motility index (GCSI: 1.18 (1.04 - 1.35), *p*=0.01; GSRS: 1.15 (1.03 - 1.29), *p*=0.02; median ratio (95%CI)), while only satiety reflected gastric emptying time (1.24 (1.03 - 1.49), *p*=0.02). Diarrhea was associat-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ed with decreased small bowel transit time (0.93 (0.89 - 0.98), *p*=0.005), while constipation was associated with prolonged colonic transit time (1.16 (1.03 - 1.31), *p*=0.02). Gastrointestinal symptoms increased with the degree of abnormal cardiovascular reflex tests (GCSI: 0.67 (0.16 - 1.19), *p*=0.03; GSRS: 0.87 (0.30 - 1.45), *p*=0.01; mean difference (95%CI)) but not with motility measures. Cardiac vagal tone and sudomotor function were not associated with gastrointestinal markers.

Conclusion: Gastrointestinal and extraintestinal autonomic measures were not associated. However, proximal gastrointestinal symptoms were associated with the gastric motility index and cardiovascular reflex tests. Hence, the latter may contribute to evaluating whether proximal gastrointestinal symptoms are autonomically derived.

PHARMACOLOGICAL ACTIVITY OF A HERBAL PREPARATION AND ITS INDIVIDUAL HERBAL EXTRACTS ON GASTRIC MOTILITY IN FUNCTIONAL DYSPEPSIA

M.-R. Piqué-Borràs[1], J. Röhrl[1], M. Mennet-von Eiff[2], G. Künstle[1]
[1]Weleda AG, Preclinical Research and Development, Arlesheim, Switzerland, [2]Weleda AG, Research and Development Pharma, Arlesheim, Switzerland

Contact E-Mail Address: mpiqueborras@weleda.ch

Introduction: This study investigates the pharmacological activity of Amara-Drops, a traditional herbal remedy used for gastrointestinal dysmotility, and its nine individual herbal extracts on fundus accommodation, a characteristic aspect of functional dyspepsia. Impaired fundus accommodation after food intake can lead to symptoms such as epigastric pain and vomiting, yet its etiology remains poorly understood.

Previous studies have demonstrated that the extract of Amara-Drops relaxes guinea-pig fundus stomach, potentially mediated by M2 muscarinic receptor inhibition, though the exact mechanism and responsible individual extracts were not investigated.

Aims & Methods: Our study aimed to explore the mechanisms of action of Amara whole extract and its constituent extracts (*Artemisia absinthium Herba*, *Centaurium erythraea Herba*, *Cichorium intybus Planta tota*, *Gentiana lutea Rhizoma*, *Juniperus communis Summitates*, *Achillea millefolium Herba*, *Peucedanum ostruthium Rhizoma*, *Salvia officinalis Folium* and *Taraxacum Planta tota*) on fundus accommodation, both *ex vivo* and *in vitro*.

Dry extracts were obtained from the commercial product Amara-Drops or from the individual ethanolic tinctures. Guinea-pig fundus muscle strips were prepared and set up in organ baths in a circular orientation to study the relaxation effect of the whole extract (94.4–1,000 µg/mL) or vehicle, with or without Carbachol-induced contraction. To elucidate whether M2 or M3 muscarinic receptors were involved in the relaxation effect, guinea-pig fundus was pretreated with J-014129, an antagonist of M3, followed by addition of whole extract or three selected individual extracts. Furthermore, binding and antagonist activities on muscarinic M3 and M2, and opioid µ (OP1) receptors expressed in CHO-K1 cell line were assessed for the whole extract and/or individual extracts.

Results: Exposure of the whole extract to guinea-pig fundus muscle strips induced significant relaxation at the highest concentrations tested ($p<0.001$). Significant relaxation was observed in Carbachol-contracted muscle strips ($p<0.05$), regardless of J-014129 pretreatment, suggesting potential modulation of the M2 receptor.

In vitro studies revealed the whole extract bound to M3, M2 and OP1 receptors (IC_{50}: 380, 294 and 55 µg/mL, respectively), with selective M2 and OP1 receptor activity impairment (IC_{50}: 219 and 304 µg/mL, respectively) *via* inhibition of their respective reference agonist activity.

M3 receptor activity was not affected. *Juniperus communis*, *Salvia officinalis*, and *Peucedanum ostruthium* extracts showed M2 receptor inhibition (IC_{50}: 32, 20, and 21 µg/mL, respectively), with only *Peucedanum ostruthium* extract binding to M2 receptor (IC_{50}: 137 µg/mL) and significantly relaxing Carbachol-contracted muscle strips, irrespective of J-014129 pretreatment ($p<0.001$).

However, *Juniperus communis* and *Salvia officinalis* did not show M2 receptor binding nor relaxation effects. Furthermore, *Gentiana lutea*, *Juniperus communis*, *Artemisia absinthium*, and *Centaurium erythraea* extracts inhibited OP1 receptor activity (IC_{50}: 42, 25, 22 and 104 µg/mL, respectively).

Conclusion: These data highlight the potential of the medicinal product Amara-Drops, particularly its *Peucedanum ostruthium* extract, in modulating fundus accommodation by inhibiting M2 receptor activity.

Further investigations are needed to elucidate relaxation mechanisms through OP1 receptor inhibition. Nevertheless, this study provides a promising molecular basis for the efficacy of Amara-Drops in improving impaired fundus accommodation in functional dyspepsia.

Introduction: Esophageal dysphagia and retrosternal chest pain are considered the typical manifestations of major esophageal motility disorders (mEMD). High Resolution Manometry (HRM) is the gold standard for the diagnosis of mEMD.

However, in real clinical practice patients are referred for HRM due to several non-typical esophageal symptoms and the rate of EMD among those patients is largely unknown.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: Aim of our study was to search for mEMDs prevalence among patients with typical symptoms and compare them with patients referred for non-typical symptoms.

We retrospectively collected epidemiological, endoscopic (available in 263/302), barium swallow (available in 176/302) and manometric data from consecutive patients referred for HRM in our center from 1/2020 to 12/2023. Atypical symptoms for which patient were referred for HRM included; heartburn, regurgitation, globus, oropharengeal dysphagia and epigastric pain.

Patients with a previous diagnosis of mEMDs/scleroderma/EoE, referred for pre-surgical evaluation for Gastroesophageal Reflux Disease (GERD) or submitted to gastro-esophageal surgery were excluded. Endoscopic data suggestive of an mEMD were considered esophageal dilation, solids/liquids/saliva in the lumen and difficulty to pass the scope through the Lower Esophageal Sphincter (LES), while delay in barium transit from Esophagus to the stomach, esophageal dilation and bird-like LES appearance as barium swallow were considered findings compatible to mEMD.

Results: We included 302 patients (M/F: 147/155, mean age: 56±17 years). Typical symptoms were reported by 234 (77.2%) patients, while only atypical in 68 (22.8%). Main referral symptom was; esophageal dysphagia: 176 (58.3%), chest pain: 42 (13.7%), heartburn: 27 (8.9%), regurgitation: 25 (8.3%), globus/oropharengeal dysphagia/epigastric pain: 32 (10.8%). Diagnosis of mEMDs in HRM was set in 175/302 (57.9%) and was statistically more common when typical symptoms existed (163/233, 69.9% vs 12/78, 15.4%, p<0.001).

HRM diagnosis among patients with mEMDs are given in table 1. Among patients with a diagnosis of mEMD in HRM, endoscopic data compatible to mEMDs were statistically more common among patients with typical symptoms, though barium swallow data were not (103/149, 69.1% vs. 4/10, 40%, p=0.037 and 110/116, 94.8% vs. 9/9, 100%, p=0.633 respectively).

HRM diagnosis of mEMD among patients with compatible either barium swallow or endoscopic findings was found in a statistically increased rate among patients with typical symptoms (134/145, 92.4% vs. 10/19, 52.6%, p<0.001). We should point that among 43 patients with non-typical symptoms and normal endoscopy and barium swallow study only 1 (2.3%) had a mEMD diagnosis by HRM.

HRM diagnosis	Total cohort (n=175)	Typical symptoms (dysphagia-chest pain) (n=163)	Non-typical symptoms (n=12)
Achalasia	143 (81.7%)	135(82.8%)	8 (66.7%)
Type I	6/143 (4.2%)	5/135 (3.7%)	1/8 (12.5%)
Type II	134/143 (93.7%)	127/135 (94.8%)	7/8 (87.5%)
Type III	3/143 (2.1%)	3/135 (2.2%)	0
Esophago-Gastric Junction Outflow Obstruction	21 (11.4%)	18 (11.0%)	2 (16.6%)
Diffuse Esophageal Spasm (DES)	3 (1.7%)	3 (1.8%)	0
Hypercontractile Esophagus	1 (0.6%)	1 (0.6%)	0
Absent peristalsis	8 (4.6%)	6 (3.7%)	2 (16.6%)

Conclusion: More than half of patients referred for HRM will be diagnosed with mEMD, rate significantly increased when typical symptoms, as dysphagia or chest pain, are reported. Achalasia, more specifically type II, is in general the most commonly diagnosed mEMD. Absence of compatible endoscopic or barium swallow findings make mEMDs diagnosis, in the absence of typical symptoms, almost impossible.

Disclosure: Nothing to disclose.

PP0049

THE EFFECT OF BOLUS VOLUME, VISCOSITY AND SENSORY TRP STIMULANTS ON THE UPPER ESOPHAGEAL SPHINCTER AND PHARYNGEAL MOTILITY IN HEALTHY [JL1] ADULTS MEASURED WITH HIGH-RESOLUTION IMPEDANCE MANOMETRY

M. Martínez-Guillén[1,2], P. Clavé[1,2], M. Bolívar-Prados[1,2], E. Palomera[1], N. Tomsen[1,2], D. Españo[1,2], A. Raventós[1,2], L. Mundet[1,2], T.B Karunaratne[1,2], S. Carrion[1,2]

Introduction: Introduction: High-resolution impedance manometry (HRIM) is now an important tool in the study of upper esophageal sphincter (UES) function and pharynx propulsion in patients with oropharyngeal dysphagia. Our aim was to study the effect of volume, viscosity and sensory TRP stimulants using HRIM in healthy adults.

Aims & Methods: Methods: We present a cross-sectional, controlled, quasi-experimental study in 14 healthy volunteers (median age 33 years) studied by high-resolution solid-state probe manometry of 30 unidirectional pressure channels and 6 circumferential channels at the UES with 16 impedance channels. Duplicate boluses of 5, 10 and 20 mL of 4 viscosities (50, 250, 800 and 2,000 mPa·s) and a duplicate bolus of 5 mL of TRP stimulants with the same 4 viscosities were administered. UES relaxation (UES-IRP), UES opening (UES Max Admittance), flow resistance (hypopharyngeal pressure at nadir impedance (PNadImp) and pharyngeal propulsive forces (peak pharyngeal pressure (PeakP) and pharyngeal contraction integral (PhCI) were assessed. The analysis was performed using SwallowGateway® software.

Results: Results: Bolus volume increase at different viscosities caused a) increase in UES integrated relaxation pressure (UES-IRP $p < 0.05$), b) increase in UES opening (UES Max Admittance $p < 0.05$), c) increase in flow resistance (PNadImp) at 800 and 2,000 mPa·s ($p < 0.005$) and d) increase in pharyngeal propulsion at 2,000 mPa·s (PhCI ($p < 0.05$) with no significant increase with other viscosities or at the PeakP level in all of them.

Viscosity increase at different volumes showed:

a) Increase in UES integrated relaxation pressure (UES-IRP $p = 0.004$) majority at higher volume boluses (10 and 20 mL),

b) increase in UES opening (UES Max Admittance $p < 0.05$ at 5 and 10 mL),

c) no changes in bolus resistance (PNadImp (20 ml) $p > 0.05$) and;

d) no changes in pharyngeal forces (PeakP $p > 0.05$ and PhCI $p > 0.05$).

TRP stimulants increased the UES-IRP ($p < 0.011$) and UES Adm ($p < 0.001$) and had no effect on pharyngeal contraction forces or bolus flow resistance.

Conclusion: Conclusions: In healthy adults without dysphagia, increasing volume has a significant effect on UES with an improvement on opening with less relaxation, increased flow resistance and increased pharyngeal propulsive forces. In contrast, increasing bolus viscosity and adding TRP stimulants impairs relaxation with improvement on the aperture of the UES with no effect on pharyngeal propulsive forces and flow resistance.

Introduction: Treatment of non-obstructive esophageal dysphagia (NOD) should consider not only the primary condition, but also its impact on patients' daily function, their perception and surgical risk. Between surgical, endoscopic, and medical therapies, there is a wide range of choices, most without well-established indications or outcomes.

Aims & Methods: This is an ongoing prospective multicentric study to evaluate the real-life approach to NOD in 7 centers, by comparing the efficacy of different treatments [per-oral endoscopic myotomy (POEM), botulinic toxin (BT), pneumatic dilation (PD), optimization of proton-pump inhibitors (PPI) and expectant], through the Eckardt, EuroQol-5D (TTO and VAS) and PROMIS GI Disrupted Swallowing (PDS) scores.

Results: According to Chicago V4, it included 97 esophagogastric junction (EGJ) outflow disorders, 24 spastic motility disorders, 38 hypomotile disorders and 91 dysphagia with normal manometry. Fifty-seven (22.8%) patients were submitted to therapy.

Forty-three (44.3%) patients with EGJ outflow disorders were treated (31 POEM, 5 BT, 2 PD, 1 surgical and 4 medical). In contrast to untreated, treated patients showed better differences in Eckardt, PDS and EuroQol-5D VAS scores (p-values <0.005) after 6 months.

PPI was introduced and/or optimized in five (13.2%) patients with hypomotile disorders. There were no differences in Eckardt, EuroQol-5D and PDS at 6-months in treated or untreated patients.

Three (12.5%) patients with spastic motility disorders were treated (2 BT and 1 calcium-channel blocker). Both treated and untreated showed no differences in Eckardt or EuroQol-5D scores at 6 months.

Regarding dysphagic patients with normal manometry, medical treatments were optimized in 6 patients (6.6%), without any differences in Eckardt and EuroQol-5D scores at 6-months. Interestingly, the PDS showed a better difference at 6 months in untreated patients (p-value <0.001).

Conclusion: Apart from EGD outflow disorders, which have well-established treatment options, real-life approach of NOD is heterogeneous and showed no clear benefit. To improve clinical results, specialized clinics must be created.

Disclosure: Nothing to disclose.

Contact E-Mail Address: andremascarenhasmd@gmail.com

Introduction: Dysphagia is a common condition with consequences surpassing the physical dimension and extending to the patient's psychological, personal, and professional life. However, when referring to non-obstructive esophageal dysphagia (NOD) and motility disorders, data is still scarce.

Aims & Methods: Our study consists in a prospective and multicentric evaluation of the severity of dysphagia and its impact on quality of life, that was measured with the Eckardt, EuroQol-5D (TTO and VAS) and PROMIS GI Disrupted Swallowing (PDS) scores, in patients with NOD and underlying motility disorders. We included 373 individuals (250 with NOD and 123 without dysphagia).

Results: Among patients with NOD, 97 had esophagogastric junction (EGJ) outflow disorders on manometry according to Chicago V4.0, 24 spastic motility disorders, 38 hypomotile disorders and 91 normal motility. Compared with non-dysphagic individuals, dysphagic patients had significantly worse scores of both EuroQol-5D and PDS (p-values <0.001).

Among esophageal motility disorders, Eckardt score was significantly different between groups (p-value <0.001) as determined by ANOVA. Specifically, it was significantly higher in EGJ outflow disorders (mean of 5.2), when compared to spastic motility disorders (mean of 3.3) or dysphagic patients with normal motility (mean of 3.2).

With respect to Patient-reported outcomes, PDS score was statistically different between groups (p-value 0.003), being higher in the EGJ outflow disorders (mean T-score of 64.1) when compared to hypomotiity disorders (mean of 60.2) and dysphagic patients with normal motility (mean of 60.3).

Regarding patient-reported quality of life, there were no differences between groups in terms of EuroQol-5D TTO or VAS score (p-value of 0.156 and 0.368, respectively).

Conclusion: Our findings highlights the impact of NOD on the quality-of-life of patients. Although physician and patient reported symptoms' severity were worse on EGJ outflow disorders, overall quality of life seems equally affected among all esophageal motility profiles.

Disclosure: Nothing to disclose.

PP0052

ASSESSING ANTRO-DUODENAL MANOMETRY PATTERNS IN PATIENTS WITH HYPERMOBILE EHLERS-DANLOS SYNDROME WITH GASTROINTESTINAL SYMPTOMS

K. Sweerts[1], Z. Mujagic[2], D. Keszthelyi[2], J.M. Conchillo[3]
[1]Maastricht University, Gastroenterology & Hepatology, Maastricht, Netherlands, [2]Maastricht University Medical Center, Gastroenterology & Hepatology, Maastricht, Netherlands, [3]Maastricht UMC, Gastroenterology, Maastricht, Netherlands

Contact E-Mail Address: daniel.keszthelyi@maastrichtuniversity.nl

Introduction: Hypermobile Ehlers-Danlos syndrome (hEDS) is a hereditary non-inflammatory disorder of connective tissue laxity characterized by joint hyperextensibility in association with musculoskeletal symptoms. The prevalence of gastrointestinal (GI) symptoms, such as abdominal pain, nausea, and constipation is high in hEDS. Research on the relationship between EDS and GI symptoms has mostly been restricted to disorders of the gut-brain axis, whereas the relationship between hEDS and GI dysmotility remains to be clarified.

Aims & Methods: This study aimed to explore antro-duodenal manometry (ADM) patterns in patients with hEDS presenting with GI symptoms.

In a prospective open-label study, patients with hEDS and GI symptoms presumed to be the results of GI dysmotility underwent a 6-hour high resolution ADM. The manometry tracings were analyzed by two investigators (KS and JC) independently. Antral contraction frequency (contractions per minute) < 1.0 was considered as antral hypomotility. Pylorospasm was defined as isolated pyloric pressure waves within 60 minutes postprandial. The following neuropathic enteric patterns were scored: presence of retrograde peristalsis, bursts, clustered contractions, and absence of phase III contractions. Abnormal ADM was defined as having antral hypomotility and/ or pylorospasm and/ or neuropathic enteric patterns.

Results: Fifty patients (48 women, mean age 30.4 ± 11.1 yrs.) were included. At baseline, 74% of patients were dependent on enteral feeding and the mean BMI was 20.4 ± 4.4 kg/m^2.

Overall, ADM tracings with one or more abnormal patterns were identified in 53% of patients. Antral hypomotility and pylorospasm were detected in 29% and 15% of patients, respectively. Neuropathic enteric patterns were only seen in 17% of patients. In all cases, no more than one neuropathic pattern was identified. Among the observed neuropathic enteric patterns, 15% of patients showed retrograde peristalsis, 13% absence of phase III contractions, and 2% bursts. Clustered contractions were not identified in this cohort.

Conclusion: Hypermobile Ehlers-Danlos patients presenting with gastrointestinal symptoms showed low numbers of abnormal ADM patterns. In particular, enteric dysmotility was observed in only a small minority of cases. Antroduodenal dysmotility therefore does not appear to be a principle pathomechanism in the majority of hEDS cases studied. Further research is needed to understand the mechanisms that underlie GI symptom generation in this population.

Disclosure: Nothing to disclose.

Contact E-Mail Address: jan.tack@kuleuven.be

Introduction: Nausea and vomiting are prevalent in gastroparesis (GP) and may persist in some patients with GP (pNVGP) despite treatment with prokinetics/antiemetics. There is scarce evidence at the population level on the demographic and clinical characteristics and disease experience of patients with pNVGP.

Aims & Methods: A retrospective study was conducted using Optum Market Clarity, a large US database comprised of claims and electronic health records (EHR) that is linked at the patient level and has customised fields developed by Natural Language Processing from unstructured clinical notes (e.g., GP-specific symptoms, gastric emptying testing). The pNVGP cohort was defined as: all GP diagnoses from claims/EHR during the study period (01Jan2008–30Sep2020, 1st documented GP Dx date in EHR/claims as the index date), with encounters for ≥5 years pre- and ≥1 year post-index in study period; received ≥14 cumulative days' supply of prokinetics and/or antiemetics pre- and/or post-index; and still reported nausea/vomiting ≥28 days after treatment at encounters.

Results: Of 207,704 patients identified with GP (45% diabetic [DG], 45% idiopathic [IG], 10% other causes), 25,654 met the criteria for pNVGP (57% DG, 31% IG, 12% other; mean±SD age at index 51.3±16.6 years; 75% female; 80% Caucasian; mean Charlson Comorbidity Index score 2.6). Prior to index, abdominal pain (61%), nausea (50%), nausea and vomiting (42%) and vomiting (39%) were the most commonly reported symptoms for pNVGP patients. Prokinetic/antiemetic use was frequent during 1-year pre-index (71% of pNVGP patients) and increased during 1-year post-index (85%). Ondansetron (53% of pNVGP patients pre-index, 66% post-index) and metoclopramide (13% pre-index, 32% post-index) were the most frequently used.

% Patients who received prokinetics*/antiemetics**	Diabetic GP (n=14,509)	Idiopathic GP (n=7962)	Other GP (n=3183)	Total pNVGP (n=25,654)
1 yr pre-index, 1 yr post-index	73%, 87%	66%, 82%	76%, 84%	71%, 85%

*e.g., metoclopramide, azithromycin; **e.g, ondansetron, diphenhydramine, lorazepam

Conclusion: In this study, a sizable subcohort of patients with GP had pNVGP despite the use of prokinetics/antiemetics. pNVGP occurs more often in diabetic GP, and often with abdominal pain. Patients with pNVGP had persistent unmet needs.

THE EFFICACY OF THE FUNCTIONAL LUMEN IMAGING PROBE (FLIP) PROCEDURE IN A COHORT OF PATIENTS WITH DYSPHAGIA

C. Maradey-Romero[1,2], A. Albshesh[1,2], O. Saukhat[2,3], D. Carter[1,2]
[1]Department of Gastroenterology, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, [2]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel, [3]Department of Radiology, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel

Contact E-Mail Address: Carlucha239@yahoo.com

Introduction: Functional lumen imaging probe (FLIP) is an adjunctive test indicated in the evaluation of the esophagogastric junction and esophageal motility, especially in those with an inconclusive diagnosis during esophageal high-resolution manometry (HRM) such as esophagogastric junction outflow obstruction (EGJOO) or absent contractility per Chicago Classification v4.0 (CCv4.0), and in patients that are unable to perform a HRM.

Aims & Methods: Our study aimed to evaluate the efficacy of the FLIP procedure in establishing diagnosis in a cohort of patients who underwent assessment due to dysphagia, who were either diagnosed with EGJOO or absent contractility according to CCv4.0, or were unable to perform HRM.

Our study population consisted of patients who were evaluated by FLIP due to dysphagia between March 2023 and April 2024. All patients had completed an upper gastrointestinal endoscopy and HRM per CCv.4.0. Additionally, most patients underwent further evaluation with a timed barium esophagram (TBE).

Results: We included 58 patients (52% female, median age 62.5 years) in the study cohort. Most patients (67.24%) referred to the FLIP procedure had a prior failed attempt to perform a HRM or had an inadequate test. 46.5 % of all patients had an abnormal FLIP procedure. Of those, 15 patients had EGJOO with absent contractile response compatible with achalasia (55.5 %) and another 5 patients had a confirmed diagnosis of EGJOO on FLIP (18.5 %). Of those patients who had a FLIP procedure performed due to abnormal esophageal manometry findings per CCv4.0 (n=19), 8 patients were diagnosed with EGJOO (42.1%), 5 had absent contractility (26.3 %), 4 had a hypercontractile esophagus (21 %) and 2 had ineffective esophageal motility (10.5 %). 60 % of the patients diagnosed with EGJOO by FLIP were offered an achalasia-targeted treatment (pneumatic dilation (6), POEM (4), Heller myotomy (1) and Botox injection (1)), while the rest were treated conservatively.

Additionally, TBE was performed in 55% of patients with an abnormal FLIP procedure and the result was pathological in about half of them. Furthermore, in 70% of patients the diagnosis of EGJOO during FLIP was correlated to a delayed esophageal clearance on TBE.

Conclusion: FLIP is a useful tool in the assessment of dysphagia in patients who have an inconclusive diagnosis per CCv4.0, either EGJOO or absent contractility, as well as in patients who are unable to perform a HRM.

PREDICTING OUTCOMES OF G-POEM USING BODY SURFACE GASTRIC MAPPING: EARLY RESULTS FROM A TERTIARY CENTRE

H. Ayubi[1], C. Varghese[2], S. Thrumurthy[3], A. Haji[3], B.H. Hayee[1]
[1]King's College Hospital, Endoscopy and Gastroenterology, London, United Kingdom, [2]University of Auckland, Department of Surgery, Auckland, New Zealand, [3]King's College Hospital, London, United Kingdom

Contact E-Mail Address: homira.ayubi@gmail.com

Introduction: Gastroparesis (GP) is a poorly understood condition with current diagnostic tests lacking disease specificity. Gastric per oral endoscopic myotomy (G-POEM) has emerged as a promising treatment for refractory gastroparesis, however up to a third of patients fail to have an improvement in their symptoms.

Aims & Methods: We assessed the ability of Gastric Alimetry®, a new, non-invasive test of gastroduodenal function to enhance patient selection for G-POEM. Data was collected from patients with suspected GP (based on symptoms and scintigraphy), being worked up for G-POEM at Kings College Hospital between November 2022 and September 2023 (REC: 22/LO/0802). G-POEM success was defined as <1 point reduction in GCSI score. Descriptive comparisons were used to explore predictors of improvements in gastroparesis cardinal symptom index (GCSI).

Results: 11 patients were assessed (8F, median age 40 interquartile range 32.5-49.5). GCSI scores significantly improved after G-POEM (median difference -1.03, IQR 0.50). Aetiologies of gastroparesis included 5 (45.5%) diabetic, 4 (36.4%) idiopathic, and 2 other aetiologies. Gastric Alimetry spectral analysis showed 2 (18.2%) with high frequencies, 2 (18.2%) with neuromuscular dysfunction (low rhythm stability and/or low amplitude), and 7 (63.6%) with normal spectral metrics. Symptom profiles followed a continuous pattern in 4 (36.4%), sensorimotor in 2 (18.2%), post-gastric in 1 (9.1%) and meal-induced in the remainder (36.4%). High frequency phenotype was associated with treatment failure (2/2, 100%), and neuromuscular phenotype was associated with success (2/2, 100%). The change in GCSI score after G-POEM was significantly lower in the high frequency group compared to the group average (median difference -0.18, IQR 0.18; p = 0.03).The average frequency and rhythm index was 2.9 (0.1) cycles per minute (cpm) and 0.4 (0.2) respectively among responders vs 3.2 (0.4) cpm 0.6 among non-responders.

Conclusion: Gastric Alimetry® is a new, non-invasive test of gastric function with provisional utility in differentiating disease mechanisms in patients with suspected GP. Early data suggests biomarkers for gastric autonomic dysregulation (high slow wave frequencies) were associated with reduced response to G-POEM. Further data are eagerly anticipated to validate these findings and develop more sophisticated predictive models for G-POEM outcomes.

Disclosure: Nothing to disclose.

ROUTINE X-RAY CONTRAST STUDY FOLLOWING PERORAL ENDOSCOPIC MYOTOMY (POEM) DOES NOT PREVENT POSTPROCEDURAL COMPLICATIONS – SINGLE CENTER RETROSPECTIVE ANALYSIS

M. Vojtko[1], M. Ďuriček[2], M. Demeter[2], P. Banovcin[3], J. Vnučáková[1]
[1]Jessenius Faculty of Medicine, Comenius University, Clinic of Internal Medicine-Gastroenterology, Martin, Slovakia, [2]Jessenius Faculty of Medicine, University Hospital in Martin, Clinic of Internal Medicine - Gastroenterology, Martin, Slovakia, [3]Jessenius Faculty of Medicine, Comenius University, Department of Gastroenterology, Martin, Slovakia

Contact E-Mail Address: marek.vojtko98@gmail.com

Introduction: Peroral endoscopic myotomy has become the mainstay of treatment of achalasia. Oral feeding has been initiated if no submucosal leak of the contrast fluid was detected on the X-ray contrast study which was performed the following day after the procedure. However, as major adverse events are rare, and in case of their occurrence, are rarely asymptomatic, it has become unclear whether routine X-ray contrast study is necessary. In our center we have been performing POEM procedures since 2015 and initially routinely performed X-ray contrast study. However,during the course of time it has become unavailable and we were forced to initiate oral feeding diet based on our clinical decision. We adopted a protocol of the initiation of oral liquids on the 2 nd postoperative day (or later in case of suspected complication). We therefore compared these two strategies in terms of periprocedural and postprocedural complications rate and the length of the hospital stay.

Aims & Methods: This is a retrospective analysis of the single high-volume center. We evaluated (1) the rate of peri- and postprocedural complications and (2) length of the hospital stay in patients hospitalized for POEM for esophageal achalasia in 2015-2023. We separately evaluated the "X-ray subgroup" (oral feeding was initiated after X-ray that was performed the day after the procedure) and the "clinical decision subgroup" (oral feeding was initiated on the 2 nd postoperative day).

Results: We analyzed a total number of 274 POEM procedures (129 males, 145 females), mean age was 52,3±16 years. 102 patients (37.2%) received X-ray contrast study after the procedure, in 169 patients (62.8%) the initiation of oral feeding was based on clinical decision. The mean time of the hospital stay was 7.2±2.9 vs. 6.5±1.4 days in the X-ray group and in the clinical decision group, resp. (p<0.004).

In the X-ray group we detected complications in 8 patients (7.7%). 5 were periprocedural (mucosal perforation or aspiration during intubation), were solved during the procedure and did not lead to the extension of the hospital stay. There were postprocedural complications in 3 patients. In one case submucosal leak was detected on X-ray contrast study the following day after the procedure due to loosened clip in the mucosal entry and was solved by placing additional clips. In one case patient presented with bleeding from the mucosal entry after discharge. In one case the patient developed mediastinitis that led to the extension of the hospital stay. In the clinical decision group we detected complications in 10 patients (5.9 %), 9 of them were periprocedural (mucosal perforation or aspiration during intubation), 8 of which were solved during the procedure by endoscopic clipping and did not lead to the extension of the hospital stay, 1 required surgery. In one case of postprocedural complication perforation with pleural effusion was detected on CT scan and required surgical intervention that led to the extension of the hospital stay.

Conclusion: Our analysis shows that severe complications after POEM are rare. In the X-ray subgroup there was only single postprocedural event in which X-ray was helpful in its early detection (1%). In the clinical decision subgroup there was also only single event that could have been identified on the X-ray (0.6%). The length of the hospital stay in the clinical judgement group was significantly shorter than in the X-ray group. This can be attributed to the improvement of overall experience with the management of the POEM patients as X-ray contrast has become unavailable after performing c.a. 100 POEM procedures.

Contact E-Mail Address: Jesse.Carlin@vandapharma.com

Introduction: Tradipitant is a novel NK1R antagonist studied in diabetic and idiopathic gastroparesis. This report presents the analysis from the open-label arm of a multicenter, randomized, double-blind, placebo-controlled study (VP-VLY-686-3301) assessing the efficacy of tradipitant in relieving symptoms of gastroparesis.

Aims & Methods: N=531 idiopathic and diabetic gastroparesis patients with delayed gastric emptying received open label 85mg tradipitant BID for 12 Weeks. Nausea was assessed using the 5-point Gastroparesis Core Symptom Daily Diary. An exposure response analysis was performed to control for low drug exposure. We used a threshold of ≤140ng/ml tradipitant blood concentration at any visit to classify participants in the High (n=309) and Low (n=218) PK Populations.

Results: Patients improved the average nausea score significantly from baseline after 12 weeks tradipitant (improvement of -1.01 vs 2.14 at baseline, p<0.0001). A significant improvement was also seen in the percent of nausea free days (an addition of 51.76% of days for tradipitant vs. 19.62% at baseline, p<0.0001).

Patients in the High PK group significantly improved average nausea score compared to the Low PK group at Week 12 (improvement of -1.19 vs -0.78, p<0.0001). A significant improvement was also seen in the percent of nausea free days (an addition of 35.6% of days for High PK versus 22.6% for Low PK, p=0.0002).

Conclusion: Tradipitant demonstrated statistically significant improvement from baseline in average nausea severity and percentage of nausea-free days in this 12 week open label study in both idiopathic and diabetic gastroparesis subjects. Additionally, a strong exposure response in nausea improvement was observed when comparing subjects with high drug exposure vs low drug exposure.

EXPOSURE-RESPONSE ANALYSIS OF OPEN LABEL TRADIPITANT IN IDIOPATHIC GASTROPARESIS IN STUDY VP-VLY-686-3301

J.L. Carlin[1], C. Polymeropoulos[1], M. Fisher[1], P. Moszczynski[1], G. Johannsen[1], C. Xiao[1], G. Birznieks[1], M.H. Polymeropoulos[1]
[1]Vanda Pharmaceuticals, Inc., Research & Development, Washington, United States of America

Introduction: To assess the exposure response of NK-1 receptor antagonist tradipitant in the reduction of gastroparesis symptoms in patients with idiopathic gastroparesis in the open label arm of phase 3 study (VP-VLY-686-3301).

The four etiologies of gastroparesis are diabetic, post-surgical, drug-induced, and idiopathic. The idiopathic etiology of gastroparesis is least common, presenting in about 11.3% of patients, which amounts to about 90,000 patients in the United States. Standards set by the FDA define a rare disease or condition as one that affects less than 200,000 people in the United States. This establishes idiopathic gastroparesis as a rare condition, as well as one with a high unmet need for treatment. Patients with gastroparesis have decreased quality of life associated with severe and chronic symptoms and no treatment is currently approved for idiopathic gastroparesis specifically. Tradipitant previously demonstrated efficacy in idiopathic gastroparesis in reducing gastroparesis symptoms in a phase 2 study (VP-VLY-686-2301).

Aims & Methods: The open label arm of Study 3301 enrolled n=531 idiopathic and diabetic gastroparesis patients with delayed gastric emptying, moderate to severe nausea, and at least 1 vomiting episode. Patients received 85 mg tradipitant twice a day for 12 weeks. Nausea was assessed daily using the 5-point Gastroparesis Core Symptom Daily Diary (GCSDD). Overall gastroparesis symptoms were assessed every 2 weeks in clinic using the Gastroparesis Cardinal Symptom Index (GCSI).

An exposure response analysis was performed on a subgroup of patients to control for low drug exposure. We used a threshold of ≤140ng/ml tradipitant blood concentration at any visit to classify participants in the High (n=309) and Low (n=218) PK Populations. Results were further stratified to compare average nausea severity and gastroparesis symptoms at baseline nausea severity scores of ≥2 and ≥2.5 for Low (n=129 and n=89, respectively) and High (n=170 and n=110, respectively) PK subgroups.

Results: Patients in the High PK subgroup had statistically improved nausea severity at Week 12 compared to the Low PK subgroup (-1.19 vs. -0.78, respectively; p<0.0001), including at baseline nausea severity scores of ≥2 (-1.61 vs. -0.98, respectively; p<0.0001) and ≥2.5 (-1.77 vs. -1.03, respectively; p<0.0001). The High PK subgroup also had statistically significant improvement in nausea-free days at Week 12 compared to Low PK (+35.65% vs. +22.56%, respectively; p=0.0002), including at baseline nausea scores of ≥2 (+36.36% vs. 18.15%, respectively; p=0.0002) and ≥2.5 (+33.44% vs. 14.11%, respectively; p=0.0009).

Conclusion: A significant exposure response was seen in idiopathic gastroparesis patients receiving open label tradipitant for 12 weeks. Patients with higher blood levels of tradipitant significantly improved in average nausea severity and in endpoints measuring overall gastroparesis symptoms compared to subjects with low drug blood levels.

SOLID AND LIQUID GASTRIC EMPTYING SCINTIGRAPHY WITH GASTRIC ALIMETRY ADDS DIAGNOSTIC VALUE IN ASSESSING CHRONIC GASTRODUODENAL SYMPTOMS

W.J. Wang[1,2], D. Foong[2], S. Calder[3], V. Fernandes[4], V. Ho[2,5], G. O'Grady[3,6,7], G.J. Holtmann[1,8,9,10]
[1]Princess Alexandra Hospital, Department of Gastroenterology and Hepatology, Brisbane, Australia, [2]Western Sydney University, School of Medicine, Sydney, Australia, [3]Alimetry Ltd, Auckland, New Zealand, [4]Lumus Imaging, Sydney, Australia, [5]Campbelltown Hospital, Department of Gastroenterology and Hepatology, Sydney, Australia, [6]The University Of Auckland, Department of Surgery, Auckland, New Zealand, [7]The University Of Auckland, Auckland Bioengineering Institute, Auckland, New Zealand, [8]The University of Queensland, Faculty of Medicine, Brisbane, Australia, [9]Translational Research Institute, Brisbane, Australia, [10]AGIRA (Australian Gastrointestinal Research Alliance) and the NHMRC Centre of Research Excellence in Digestive Health, Brisbane, Australia

Contact E-Mail Address: william.wang3@health.qld.gov.au

Introduction: Solid gastric emptying scintigraphy (GES) is used to assess gastric motility by measuring the transit of a radioactively labelled solid meal, however it can be non-specific and insensitive by itself. Liquid gastric emptying scintigraphy provides an additional modality of motility testing using a similar process with a liquid meal. Gastric Alimetry is a non-invasive test that measures gastric electrophysiological activity through body surface gastric mapping (BSGM) and validated symptom profiling[1].

Aims & Methods: This study aimed to assess the additional diagnostic value of performing liquid GES and Gastric Alimetry in addition to solid GES alone.

Patients with chronic gastroduodenal symptoms underwent simultaneous solid GES and Gastric Alimetry, comprising of a 30-minute baseline recording followed by a 99mTC-labelled egg meal, and 4-hour postprandial recording. Patients would also have a glucose liquid GES study on a different date. Delayed emptying was defined as greater than 10% retention at 4 hours for solid GES and more than 50% retention at 2 hours for liquid GES[2,3].

Gastric Alimetry spectral metrics were referenced to normative ranges that included principal gastric frequency (cpm), Gastric Alimetry Rhythm Index (GA-RI) and BMI-adjusted amplitude[4].

Results: 36 patients with chronic gastroduodenal symptoms were prospectively recruited (30 female, median age 38.0 years, median BMI 24.6 kg/m^2). 10 (27.8%) patients had delayed solid GES whilst 7 (19.4%) patients had delayed liquid GES. 9 (25.0%) patients had abnormal Gastric Alimetry spectral metrics.

Combining solid and liquid GES detected an abnormality in 13 (36.1%) patients which was further enhanced when combined with Gastric Alimetry, detecting an abnormality in 17 (47.2%) of patients.

Of those 13 patients with either a delayed solid or liquid GES, 38.5% of them had abnormal Gastric Alimetry spectral metrics (3 High Frequency, 1 Low Rhythm Stability, 1 High Amplitude) while those with a normal solid and liquid GES had abnormal spectral metrics in 17.4%.

Conclusion: Combining solid and liquid GES with Gastric Alimetry detected a higher yield of motility abnormalities than solid GES alone. GES and Gastric Alimetry assess different aspects of gastric function with further studies required to understand their complementary roles as biomarkers in clinical practice to help tailor therapy.

COMPREHENSIVE ASSESSMENT OF GASTROINTESTINAL SYMPTOMS IN PEDIATRIC PATIENTS: INSIGHTS FROM INITIAL OUTPATIENT CONSULTATIONS USING THE PSAGIS

K. Hammer[1], B. Majcher[1], U. Anwar[2], J. Hammer[2]
[1]St. Anna Kinderspital, Abt. für Gastroenterologie, Wien, Austria, [2]Medical University Vienna, Vienna, Austria

Contact E-Mail Address: johann.hammer@meduniwien.ac.at

Introduction: Exploring paediatric gastrointestinal (GI) diseases is a dynamic medical challenge. Children and adolescents present with unique symptoms that require careful assessment. These can range from mild discomfort to indicators of serious disease. The initial outpatient visit is crucial for diagnosis and treatment planning.

Understanding the nature and spectrum of these symptoms is crucial for improving paediatric care.

Aims & Methods: We aimed to improve the understanding of GI disorders in paediatric patients, utilising the recently validated paediatric (p)SAGIS questionnaire, which provides an unbiased assessment of symptoms. From February 2016 to January 2023, all consecutive patients attending the outpatient GI clinic at St. Anna Kinderspital, Vienna, Austria, underwent a standard work-up to arrive at a final diagnosis.

In addition, and independently, the patients and/or their caregivers completed the pSAGIS for standardised symptom assessment on the day of their appointment before meeting the paediatrician. pSAGIS consists of 21 GI-related questions (assessment of type and 5 severity grades within the previous week) to arrive at five symptom groups (abdominal pain, diarrhea, constipation, dysphagia, and dyspepsia).

Pain was considered clinically relevant if the score was at least 1 (moderate pain) and severe if the score was ≥2. Data were analyzed for functional bowel disorder (FBD) versus organic GI disease (OD), with a p-value <0.05 considered significant.

Results: 1481 outpatients completed the pSAGIS questionnaire at their initial consultation. Patients were then followed up to establish a final diagnosis. 775 patients were diagnosed with organic disease, 441 patients were diagnosed with functional bowel disease, and 265 subjects were healthy or had a non-GI diagnosis or could not be definitively diagnosed.

In the whole group, abdominal pain was reported by 405 patients (27.3%) and severe pain by 140 patients (9.5%). 185 patients with organic disease (23.9%) but 199 patients with FBD (45.1%) reported abdominal pain (p>0.001), severe pain was reported by 42 (5.4%; OD) and 54 (12.2%; FBD) patients, respectively (p<0.001). Pain was reported as the main symptom by 105 OD patients (13.5%) vs. 113 FBD patients (25.6%) (p<0.001). Pain was present but not the main symptom in 64 (8.3%; OD) and 65 (14.7%; FBD) patients, respectively (p>0.01). Of the latter, 14 (1.8%; OD) and 18 (4.1%; FBD) patients reported severe pain.

Conclusion: Our study provides a comprehensive insight into paediatric gastrointestinal symptoms using the paediatric SAGIS questionnaire. The stark contrast in the prevalence of abdominal pain between patients with organic disease and functional bowel disorders underscores the complex landscape of paediatric GI problems. In particular, the high incidence of severe pain in functional bowel disorders challenges conventional perceptions of these disorders. Recognising pain as a prominent symptom in both organic and functional cases is critical for effective management. The findings underscore the critical role of standardised assessment tools, such as the pSAGIS questionnaire, in delineating the nuanced spectrum of paediatric GI symptoms and ultimately informing more targeted and comprehensive care strategies.

DIFFERENCES IN GASTRIC FLUID MICROBIOTA BETWEEN POSTPRANDIAL DISTRESS SYNDROME AND EPIGASTRIC PAIN SYNDROME

K.J. Lee[1], G.H. Lee[1]
[1]Ajou University Hospital, Gastroenterology, Suwon, South Korea

Contact E-Mail Address: kjl@ajou.ac.kr

Introduction: Dysbiosis of gut microbiota has recently been suggested to be implicated in the pathophysiology of functional dyspepsia (FD). However, qualified studies on the gastric microbiota in FD patients are lacking, and it is unclear whether there are differences in gastric microbiota between the subgroups of FD.

Aims & Methods: Our aim of the present study was to compare the diversity and composition of gastric fluid microbiota between postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS) in patients with FD. Eighteen patients with FD who met the Rome IV criteria and 12 age- and gender-matched healthy controls who had no chronically recurrent abdominal symptoms with absence of past or present *Helicobacter pylori* (HP) infection participated in the study. Gastric fluid was obtained from the subjects after an overnight fast, using a sterilized tube inserted into the stomach through the working channel of the endoscope. DNA was extracted and quantified from the samples. Samples from 15 FD patients (83.3%) and 6 healthy controls (50%) were adequate for analysis. The V3 and V4 region of 16S rRNA gene was amplified and sequenced using the MiSeq™ platform (Illumina, San Diego, USA).

Results: The microbiota diversity indices did not significantly differ in FD patients without HP infection, compared with healthy controls. There were no significant differences in the microbiota diversity and composition at the phylum level between PDS patients and healthy controls, and between EPS patients and healthy controls. At the genus level, the relative abundance of *Centipeda* was significantly increased in patients with PDS, whereas that of *Massilia, Acinetobacter, Enterococcus, Bacteroides, and Blautia* was significantly decreased in patients with PDS. In patients with EPS, the relative abundance of *Collinsella, Holdemanella and Paraprevotella* was significantly increased, whereas that of *Massilia* was significantly decreased. At the species level, the relative abundance of *Prevotella intermedia, Veillonella tobetsuensis, Neisseria subflava, and Centipeda*

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

periodontii was significantly increased in patients with PDS. The relative abundance of *Clostridium leptum, Clostridium perfringens, Alistipes ihumii, Collinsella aerofaciens, Eubacterium ventriosum, Holdemanella biformis, Klebsiella aerogenes, Paraprevotella clara, Sphingomonas olei, and Sutterella wadsworthensis* was significantly increased in patients with EPS.

Conclusion: Although the diversity of gastric fluid microbiota is not different between PDS and EPS subgroups, there are differences in their composition between PDS and EPS. Further investigation is needed to determine whether those differences in the composition of gastric fluid microbiota are cause or effect.

Introduction: Esophageal dysphagia is a common complaint in daily clinical practice. After excluding structural and motility disorders, it may be related to functional disorders, which are challenging to diagnose and manage, leading to high health care utilization and both patient and physician dissatisfaction.

Aims & Methods: This is a prospective multicentric 6-months follow-up study to characterize dysphagic patients with normal esophageal motility, in terms of epidemiology and clinical aspects, focusing on patient-reported outcome measures, and evaluate their evolution at 6-months.

Results: From 2021-2024, 91 patients were recruited, 78.0% female, with a median age of 65 years [22-88]. Of these, 27.5% (n = 25) suffered from rheumatologic or endocrinologic disorders, and 56.0% were previously exposed to medical therapies.

Dysphagic symptoms had a median duration of 3 years [1-31], with a median Eckardt of 3 [0-9], PROMIS GI Disrupted Swallowing (PDS) of 60.4 [40.3-84.1], EuroQol-5D TTO of 0.592 [-0.055-1] and VAS of 70 [0-100].

Compared to non-dysphagic participants (n=123), these patients had significantly worse Eckardt, EuroQol-5D and PDS scores (p-values <0.001).

Compared to esophageal motility disorders (Chicago V4.0), the Eckardt and PDS scores in this group were significantly lower when compared to EGJ outflow disorders (p-value <0.001 and 0.003), without differences regarding EuroQol-5D.

Regarding gastroesophageal reflux, 24 (26.4%) patients had a positive GERD-Q questionnaire and 3 had an objective GERD diagnosis. Even though, compared to motility disorders, this score was significantly lower in this group when compared to EGJ outflow disorders (p-value 0.001).

Medical treatments (PPI, amitriptyline) were optimized in 6 patients (6.6%), without any differences in Eckardt or EuroQol-5D scores at 6-months. However, at 6-months, the PDS improved in untreated patients (p-value <0.001).

Conclusion: Non-obstructive dysphagia with normal esophageal motility has a negative impact on quality of life. However, symptoms tend to have a favorable course independently of treatment, therefore mandating a holistic management.

Disclosure: Nothing to disclose.

PP0063

THE PREVALENCE OF NAUSEA IN EASTERN AND WESTERN SECONDARY AND TERTIARY CARE FUNCTIONAL DYSPEPSIA

B. Broeders[1], F. Carbone[2], C. Van de Bruaene[3], T. Vanuytsel[4], J. Tack[5], AEGIS working group

[1]KU Leuven, Chronic diseases and metabolism, Ku Leuven, Belgium, [2]UZ Leuven, TARGID, Leuven, Belgium, [3]Van de Bruaene Cedric, Gastroenterology, Leuven, Belgium, [4]KU Leuven, Department of Gastroenterology, Leuven, Belgium, [5]University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium

Contact E-Mail Address: bert.broeders@kuleuven.be

Introduction: According to the ROME IV criteria, functional dyspepsia (FD) can be subdivided into PDS (postprandial distress syndrome) with meal-related symptoms such as early satiation and postprandial fullness and EPS (epigastric pain syndrome) with meal-unrelated complaints such as epigastric pain or burning. Nausea can also co-exist in FD but the literature is poor in reporting whether this symptom is mainly triggered by meal ingestion.

A recent global epidemiology study of gastroparesis-like symptoms showed that the prevalence of nausea or vomiting, in combination with postprandial fullness or early satiation varies between continents.[1]

Aims & Methods: This study aims to compare the difference in prevalence rates of nausea within each FD subgroup between western and eastern secondary and tertiary care centers. Adult patients with disorders of gut-brain interaction (DGBI) recruited in 9 western and 7 eastern secondary and tertiary care facilities between the ages of 18 and 70 years completed the Enhanced Asian Rome IV questionnaire (Asian European Gastrointestinal Symptoms cohort or AEGIS). The western centers were located in Belgium, Bulgaria, France, Israel, Italy (2x), Slovakia, Sweden and The United Kingdom while the eastern centers were located in Australia, China, Iran, Japan, Malaysia and Singapore (2x).

FD patients were divided into PDS, EPS and PDS-EPS overlap (OVP) subgroups. Patients were furthermore classified as having nausea when this symptom was reported at least once per week. The questionnaire EARQ4 questionnaire was also used to address the relationship between nausea and food intake.

Patients were asked how often they experienced nausea, whether nausea was triggered or worsened by meal intake, how often nausea occurred after a meal and if so, how soon after a meal nausea started. A comparison of the prevalence of nausea and meal-related nausea was made between

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

eastern and western patients and among FD subgroups. Continuous variables are reported as median (IQR) and compared with a Kruskal-Wallis test. Categorical variables were compared using a Pearson Chi-square test.

Results: Of the 1074 DGBI patients that completed the survey, 483 were classified as having FD (59.4% PDS, 27.5% EPS, 13.0% PDS-EPS overlap). FD patients from eastern (N=202) and western sites (N=281) had a similar body mass index (22.5 (19.6-25.7) vs. 21.3 (19.7-25.4) kg/m^2) and age (39.0 (29.0-55.0) vs. 38.0 (26.0-54.0) years). Eastern sites included significantly more female patients than western sites (43 % vs. 17.5%, p<0.001). PDS and EPS patients from eastern sites had significantly less nausea than PDS and EPS patients from western sites (17.9% vs. 46.3% and 6.8% vs. vs 40.5% respectively, both p<0.001). The majority of FD patients with nausea experienced meal-related nausea with no difference between eastern and western sites (63.9% vs. 73.7%). In PDS patients with nausea, nausea was significantly more triggered or worsened by a meal (72.4%) than in PDS-EPS overlap and EPS (48.6% and 35.3% respectively; p<0.001). All groups reported that meal-related nausea started mostly (> 85%) within 60 minutes after the meal.

Conclusion: In contrast to previous literature, we found that western PDS and EPS patients report nausea more frequently than eastern PDS and EPS patients. In both eastern and western patients nausea was mostly meal-related. Meal-related nausea is more common in PDS than in PDS-EPS overlap and EPS patients. Further research is needed to investigate the role of ethnic factors in the pathophysiology of nausea in functional dyspepsia.

Introduction: Functional abdominal pain disorders (FAPDs), linked to brain-gut interaction disturbances, are common in childhood, with a prevalence of 3-16%. They are classified based on the Rome IV criteria, involving persistent gastrointestinal symptoms due to abnormal enteric system functioning without organic issues. Childhood stress and anxiety are linked to FAPDs. Psychotherapy aims to educate patients and families about pain triggers and uses cognitive-behavioral therapy extensively.

Aims & Methods: To discuss different characteristics of patients with FAPDs and identify triggering factors for stress/anxiety. Moreover, to analyze the role of various treatment options, including mind-targeted therapies as a treatment.

This prospective cohort study included all patients who were referred to the Pediatric Gastroenterology and Hepatology Outdoor Department at Children's Hospital Lahore due to chronic abdominal pain and subsequently diagnosed with FAPDs based on Rome IV criteria after excluding organic causes over a period of 18 months. Patients were screened for stress by the clinical psychologist using perceived stress scores after excluding organic causes. The role of various treatment options, including mind-targeted therapies, was studied in patients with different FAPDs. They were reassessed for symptom improvement or resolution at a 4-week follow-up by both gastroenterologists and clinical psychologists.

Results: This study included 300 patients aged 4-16 years, of any gender and economic background, using consecutive non-probability sampling. The overall mean age was 9.848 ± 2.6879 years, with 171 female (57%) & 129 male (43%) patients. 245 patients (81.7%) were diagnosed with an organic cause for chronic abdominal pain based on various clinical and biochemical parameters. Commonest cause was gastritis 83 (27.7%) followed by celiac 59 (19.7%), chronic pancreatitis 32 (10.7%), Abdominal TB 22 (7.3%), UTI 17(5.7%), IBD 16 (5.3%), Choledochal cyst 9 (3%), Cholelithiasis 5 (1.7%), Hydatid cyst 2 (0.7%). In total 55 (18.3%) were diagnosed with functional GI disorders based on Rome IV criteria. Among them, Functional Abdominal Pain, not otherwise specified accounted for 21 cases (38.18%), followed by functional dyspepsia 19 (34.54%), irritable bowel syndrome 10 (18.18%), and abdominal migraine with 5 cases (9.09%).The age range of patients diagnosed with FAPDs spanned from 7.5 to 15 years, with a median age of 12 years. There were 34 females (61.8%) compared to 21 males (38.2%). 60% of them were from urban areas. Various triggers for stress were identified: financial issues (69.1%), followed by family conflict (58.2%), family member illness (18.2%), single parents/broken families (16.4%), exam failure (16.4%), abuse/bullying (12.7%), family member death (9.1%), frequent punishment at home (5.5%), sibling rivalry (3.6%), and frequent punishment at school (1.8%). The perceived stress scores were categorized as low (0-13) for 7 (12.7%), moderate (14-26) for 45 (81.8%), and high (27-40) for 3 (5.5%) patients before treatment. Among them, 43.3% received psychotherapy, followed by 25.5% receiving psychotherapy along with symptomatic treatment, 16.4% symptomatic treatment, 9.1% psychotherapy along with antidepressant, and 5.5% receiving only antidepressant. Patients with a moderate stress score were given psychotherapy alone in 48.9% of cases. Post-treatment perceived stress scores improved to low in 40 patients (72.7%) (p<0.001).

Conclusion: Functional GI disorders, with stress or masked depression, need assessment for better child welfare, as healthy psyche fosters resilience.

Introduction: Disorders of gut brain interaction (DGBIs) is a group of diseases with relatively high prevalence. One of the most common is functional dyspepsia. It has been repeatedly reported that university students tend to have higher prevalence of this disease than general population. Study at medical school is associated with high degree of stress and this could be accumulated during the passing years. As many other factors could affect the symptomatology, the best way to test this hypothesis is to perform a prospective cohort study following one particular group of students over the years.

Aims & Methods: The aim of this study is to evaluate the prevalence of symptoms of functional dyspepsia in selected cohort overtime. This is a prospective, observational study. The observed group were students of medicine from their 1st to 3rd year of study. Acquisition of the data was performed by questionnaires. The diagnosis was made by using ROME IV criteria for DGBI. Additional information was obtained from STAX1 and STAX2 validated questionnaires (STAI-X1 shows how the patient feel while answering the questionnaire (anxiety as a state) and STAI-X2 is based on how the patient feel overall (anxiety as a personality trait)) and Beck depression inventory. The measurement was performed in the middle of the school year, every October (2021 to 2023).

Results: Initially 121 students from first year agreed to participate in the study and filled out the questionary. Subsequently the response rate for 2nd year was 67.8 % and for 3rd 73%. The symptoms of Functional Dyspepsia were present in 14.9% of participants from 1st year, 13.4% from 2nd year and 14.6% from 3rd year. The cumulative cohort average of STAX 1 was 45.5 points for 1st year, 46.5 points for 2nd year and 46.2 points for 3rd year. The cumulative cohort average of STAX 2 was 47.7 points for 1st year, 46.2 points for 2nd year and 46.8 points for 3rd year. The cumulative cohort average of Beck depression inventory was 8.7 points for 1st year, 8.8 points for 2nd year and 8.4 points for 3rd year. The rate of smoking was 7.4 % of participants from 1st year, 13.4% participants from 2nd year and 14.6% from 3rd year.

Conclusion: The results of this prospective cohort observational study shows that the symptoms of Functional Dyspepsia are highly prevalent among medical students and this varies only insignificantly over time. The probands in average showed no signs of depression however the average levels of anxiety and stress were high during all 3 years. This could be associated with significant rise of smokers within the cohort during the observation period.

Introduction: The prevalence of functional dyspepsia (FD) and gastroparesis in diabetic patients remains unknown. A high prevalence of gastroparesis has been reported in diabetic patients reaching up to 5%.[1] However, recent consensus specified the symptom pattern for gastroparesis, with nausea and/or vomiting as predominant symptoms, now defined as "gastroparesis-like symptoms" (GPLS).[2] The global prevalence of GPLS has been estimated to reach only 1.2% in diabetic patients, but type 1 and type 2 diabetes were not assessed separately.[2]

Aims & Methods: We aimed to assess the prevalence and burden of FD and GPLS in primary care patients with diabetes, comparing patients with type 1 and type 2 diabetes. An online survey was addressed to diabetic patients through general practitioners and diabetic patient associations. The survey included the Rome IV questionnaire and the Patient Assessment of Gastro-Intestinal Disorders-Symptom Severity Index (PAGI-SYM) for upper gastro-intestinal symptoms. Anxiety, depression, somatization, and quality of life were also assessed by specific questionnaires (Generalized Anxiety Disorder GAD-7, Patient Health Questionnaire PHQ-9, PHQ-15, and PAGI-QoL questionnaires respectively).

	Type 1 diabetes (n=146)	Type 2 diabetes (n=68)	p value
Age	39 (29–51)	60 (50–67)	<0.001
Sex (female)	99 (67.8%)	35 (51.4%)	0.02
Functional dyspepsia	18 (12.3%)	10 (14.7%)	0.66
PDS	17 (11.6%)	10 (14.7%)	0.52
EPS	3 (2.1%)	3 (4.4%)	0.38
Gastroparesis-like symptoms	3 (2.1%)	6 (8.9%)	0.03
GAD-7 (Anxiety)	4 (1–6)	3 (0–7)	0.80
PHQ-9 (Depression)	3 (1–7)	3 (1–10)	0.05
PHQ-15 (Somatization)	7 (3.3–10)	8 (4–13)	0.10
PAGI-SYM	6.5 (1–8.8)	9.5 (2–35.5)	0.009
PAGI-QoL	6 (0–15.3)	10 (3–38)	0.003

Results: A total of 216 patients completed the questionnaires, among which 146 had type 1 diabetes, and 68 had type 2 diabetes, (2 patients did not know their type of diabetes). The median age of the population was 56 (50-61) years old, with 134 female patients (61.8%). The prevalence of FD was 13.0% with no difference between the 2 groups. The prevalence of GPLS reached 4.2% and was significantly higher in patients with type 2 diabetes (8.9% vs 2.1%; p=0.03). The burden of upper gastro-intestinal symptoms and their impact on quality of life was higher in type 2 dia-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

betes patients with higher PAGI-SYM and PAGI-QoL scores while anxiety and somatization were not different between type 1 and type 2 diabetes patients (see Table). Overall, patients with GPLS had higher anxiety (9 vs 3; p=0.003), depression (12 vs 3; p=0.001) and somatization scores (16 vs 6; p<0.001) than patients without. Compared to patients with FD without GPLS, GPLS patients had numerically higher but not statistically different scores for symptom severity (51 vs 28; p=0.46), anxiety (9 vs 7; p=0.29), depression (12 vs 7; p=0.07), somatization (16 vs 11.5; p=0.16) and quality of life scores (52 vs 24; p=0.16).

Conclusion: This study confirms that the prevalence of GPLS seems to be higher in diabetic patients compared to available population data, especially in patients with type 2 diabetes. The impact of the symptoms was similar to the impact of FD in this population. Further studies are required to assess the prevalence of delayed gastric emptying in diabetic type 1 and 2 patients with GPLS.

GASTROESOPHAGEAL REFLUX DISEASE AND FUNCTIONAL DYSPEPSIA ARE ASSOCIATED WITH CAPSAICIN COUGH SENSITIVITY IN SEVERE ASTHMA

T. Kamiya[1], K. Ito[2], Y. Kanemitsu[2], M. Shikano[3], E. Kubota[3], A. Niimi[2]

[1]Nagoya City University Graduate School of Medical Sciences, Department of Medical Innovation, Nagoya, Japan, [2]Nagoya City University Graduate School of Medical Sciences, Department of Respiratory Medicine, Allergy and Clinical Immunology, Nagoya, Japan, [3]Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Nagoya, Japan

Contact E-Mail Address: kamitake@med.nagoya-cu.ac.jp

Introduction: Functional dyspepsia (FD) is one of the most prevalent functional gastrointestinal disorders. It is well known that asthma can complicate gastroesophageal reflux disease (GERD), and sensory nerve dysfunction is related to the pathophysiology of asthma and GERD. However, the relationship between FD and asthma has not been extensively examined yet. The capsaicin receptor transient receptor potential vanilloid 1 (TRPV1) is a non-selective ion channel, which can be activated capsaicin, acid (pH<6.5), and heat etc. TRPV1 channels are highly expressed in sensory nociceptive and visceral nerve fibers and are involved in inflammatory pain and hyperalgesia signaling. TRPV1 is found to be expressed in both airway epithelium and sensory neurons of the gastrointestinal tract, as previously reported. In addition, several studies have shown increased gastrointestinal sensory sensitivity to capsaicin in patients with FD.

Aims & Methods: The aim of this study was to clarify the physiological associations between GERD, FD, and asthma. Fifty-two patients with severe asthma who were performed capsaicin cough sensitivity (C-CS) test were analyzed. Clinical characteristics C-CS were compared between patients with and without comorbid GERD or FD. C-CS was evaluated by C5 (concentration of inhaled capsaicin that induced five or more coughs), and C5<2.44 uM was defined as heightened C-CS. GERD was diagnosed based on the presence of the typical reflux symptoms of heartburn and/or acid regurgitation, which occurred more than twice a week prior to proton pump inhibitor (PPI) therapy. FD was diagnosed using the Rome IV criteria, which are defined as chronic and recurrent epigastric pain or postprandial distress, and no other organic disease that could have caused these symptoms.

Results: A total of 52 patients with severe asthma were eligible for this study. Twenty-two out of 52 patients had GERD comorbidity, and 15 out of them had FD comorbidity. Thirteen GERD patients showed heightened C-CS, while nine patients showed normal C-CS. Compared to the GERD (-) group, the GERD (+) group had a significantly lower threshold value of C5. Lower C2 and C5 thresholds were found in the FD (+) group than in the FD (-) group, and heightened C-CS was more prevalent in the FD (+) group than in the FD (-) group. Patients who had a heightened C-CS were more likely to experience GERD and FD than those who had a normal C-CS.

Effects of comorbidities on C-CS in patients with severe asthma

		Heightened C-CS	Normal C-CS	p value
FD	n=15	11	4	0.003
GERD	n=22	13	9	0.04

Conclusion: These results suggest that FD, as well as GERD, and severe asthma are functionally linked by the interaction of sensory nerves between the airways and the upper gastrointestinal tract. TRPV1 may be involved in the pathophysiology of both GERD, FD, and asthma.

Disclosure: Nothing to disclose.

Introduction: Prucalopride, a 5-HT4 agonist approved for the treatment of refractory chronic constipation has been shown to reduce oesophageal acid exposure in healthy volunteers (Kessing BF, 2014) and improve oesophageal motility in gastroesophageal reflux (GER) patients with ineffective oesophageal motility (Lei W-Y, 2018). To date, no studies have evaluated its effect in patients with dysphagia and oesophageal dysmotility.

Aims & Methods: Our aim was therefore to evaluate the effect of prucalopride on dysphagia symptoms and to assess which, if any, motility or GERD diagnosis influenced outcome in patients with gastroscopy negative dysphagia. Clinical records, together with oesophageal high-resolution

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

manometry (HRM) and available 24hr pH-monitoring (pH-MII) reports of patients referred for dysphagia to a single Neurogastroenterology Clinic between April 2017 and March 2024 were retrospectively reviewed. All patients had a previous negative gastroscopy with oesophageal biopsies, were not responsive to PPIs and were prescribed prucalopride as an add-on treatment at the initial dosage of 1 mg/daily with the possibility to increase to 2 mg/daily after one week in case of no response. A standardized template was used to collect clinical data and patient-reported response to treatment. Clinical response was defined as a self-reported improvement in dysphagia symptoms associated with a reduction in Eckardt score of at least one point. Data are expressed as median (QR).

Results: Thirty-five patients [median age 62 (28) years; 19 (54%) female] were included. Mean duration of follow-up was 12 (19) months. Twenty-two (63%) patients responded to Prucalopride with a significant improvement in the Eckardt score before to after treatment [3.5 (2.3) vs 1 (1.8); p<0.001)]. Six patients (27.3% of responders) responded to 1 mg, with the rest increasing to 2mg/daily. Response was maintained for a median of 14.5 (16) months.Thirteen (37.1%) patients did not respond, of which four (11.4%) experienced adverse events (diarrhoea, headache, abdominal pain) leading to an early treatment discontinuation. In these patients the Eckardt score did not change before to after the treatment [3 (3) vs 3.5 (2.3), respectively; p=0.85)]. None of the clinical (data not shown) or key manometric parameters were associated with treatment response [median basal distal contractile integral 283 (425) vs 340 (470)mmHg/s/cm; p=0.71 and median integrated relaxation pressure 6.2 (8) vs 8.4 (9.4) mmHg; p=0.13 in responders and non-responders, respectively]. However, there were trends for more patients with absent contractility to be non-responders, and more patients with EGJOO to be responders to prucalopride. Normal acid exposure time and number of reflux events were associated with a positive response to treatment (Table 1).

Oesophageal Manometry	Non-Responders (n=13)	Responders (n=22)	p-value
Ineffective Oesophageal Motility (%)	7 (53.8%)	9 (40.9%)	0.46^
Oesophago-gastric junction outflow obstruction (%)	0 (0%)	5 (22.7%)	0.13^
Absent contractility (%)	5 (38.5%)	4 (18.2%)	0.24^
Other diagnoses (%)	1 (7.7%)	4 (18.2%)	0.63^
AET	14.2 [20.3]	1.4 [4.1]	0.06+
Mean number of acid refluxes	46 (107)	12 (15.5)	<0.01
Pathological AET (>6%)	11 (84.6%)	10 (45.4%)	0.03^

Table 1 – HRM and pH-monitoring characteristics of responder and non-responder patients at baseline.
+Mann-Whitney's U tests
^Fisher's Exact Test
Abbreviations: AET=acid exposure time

Conclusion: Our study suggests Prucalopride might be a well-tolerated and useful treatment for dysphagia in patients with dysmotility disorders, mainly in the absence of pathological reflux. However, prospective randomized controlled studies are needed to confirm these data.

Disclosure: Nothing to disclose.

DIFFERENCES IN MEDICAL CARE SATISFACTION OF PATIENTS WITH "*FUNCTIONAL*" VS "*ORGANIC*" ESOPHAGEAL DISEASES: ITALIAN VALIDATION OF THE PPRS-SF QUESTIONNAIRE AND ITS APPLICATION IN CLINICAL ROUTINE PRACTICE

C. Soldaini[1], L. Ruggiero[1], A. Sellitti[1], A. Caloro[1], L. De Leo[1], A. Santonicola[1], P. Iovino[1]
[1]University of Salerno, Gastrointestinal Unit, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Baronissi, Italy

Contact E-Mail Address: carlo.soldaini@outlook.com

Introduction: Patient-physician relationship (PPR) plays a center role in modern health care, especially within gastrointestinal (GI) medical practice, where patients affected by non-structural disorders (better described as disorders of gut-brain interaction or DGBI) tend to report a low satisfaction towards their medical care. In 2017 Kurlander et al. developed and validated a Patient-Physician Relationship Scale (PPRS), a questionnaire used in patients affected by Irritable Bowel Syndrome (IBS) to assess their degree of medical care-satisfaction. The original PPRS was later shortened and simplified by Drossman et al. in 2021 by creating a PPRS-SF (short form), consisting in a 12-item questionnaire.

Aims & Methods: The aims of this study were to validate the PPRS-SF in Italian and to administer it to both patients with functional and organic esophageal diseases, in order to highlight the differences in patient-physician relationship between the two categories.

The process of validation to Italian language of the PPRS-SF questionnaire was carried out following a standardized forward-backward procedure and each step was overseen by an independent clinical monitor assigned by the Rome Foundation itself. The Italian version of the PPRS SF was successfully administered to 50 Eosinophilic Esophagitis (EoE), 53 Achalasia (Ach), 48 Gastroesophageal Reflux Disease (GERD) and 44 esophageal DGBI patients (affected by functional dysphagia or functional heartburn).

Results: In esophageal DGBI and GERD, the degree of patients' satisfaction was significantly lower, if calculated as a total summation, compared to that of EoE and Achalasia patients.. Between a minimum score of -36 and a maximum of +36, the mean PPRS-SF "Italian version" score for patients with EoE was 30.20 (±9.78), for patients with Ach 23.78 (±19.9); for patients with GERD 20.46 (±16.03); for esophageal DGBI 17.91 (±18.41). Moreover, there was a significant difference in PPR between younger patients (under 50 years old), who reported a score of 27.1 (±12.29) and older patients (over 50 years old), reporting a score of 20.16 (±19.72).

Conclusion: This study validated the Italian version of the PPRS-SF questionnaire and showed that the patients' diagnosis together with other factors such as their age, can affect the quality of the PPR. In particular, patients with DGBI and older patients reported lower scores than the ones with organic diseases and the younger ones, respectively. Further studies are necessary to confirm these results.

Disclosure: Nothing to disclose.

INVESTIGATING INAPPROPRIATE PROTON PUMP INHIBITOR USE IN PRIMARY CARE PATIENTS

J. Scheepers[1], F. Carbone[1,2], K. Van den Houte[1], J. Tack[1,2]
[1]KU Leuven, Translational Research Center for Gastrointestinal disorders, Leuven, Belgium, [2]UZ Leuven, Department for Gastroenterology and Hepatology, Leuven, Belgium

Contact E-Mail Address: janne.scheepers@kuleuven.be

Introduction: Increasing concerns arise regarding inappropriate proton pump inhibitor (PPI) use in terms of indication and dosage, impacting healthcare budgets and posing possible risks and drug interactions. It was estimated that up to 70% of PPI use may not medically indicated, however, the characteristics of this population of patients have not been described (1,2).

Aims & Methods: We aim to describe demographic and clinical profiles of primary care PPI users who lack a strict medical indication.

General practitioners included long-term PPI users without strict medical indication in the study. Demographic characteristics, duration and dosage of PPI use, and medical history (e.g. upper endoscopy findings, H. pylori status and previous attempts to stop PPI) were registered. Patients completed questionnaires assessing gastrointestinal symptoms (PAGI-SYM) and psychosocial co-morbidities (depression, somatization, and anxiety using respectively PHQ-9, PHQ-15, GAD-7). For this analysis, patients were categorized by: (I) initial indication for PPI therapy (GERD with low-grade esophagitis, dyspepsia, non-gastric symptoms) and (II) PPI dose (healing or maintenance). Statistical significance ($p<0.05$) was assessed using one-way ANOVA, student's T-test, and Fisher's exact test. Results are shown as mean±SD.

Results: Out of 482 recruited patients on long-term PPI therapy, 42% reported failed previous attempts to discontinue PPI therapy. Main indications for PPI initiation were low-grade reflux esophagitis (26%), functional dyspepsia (18%), uninvestigated reflux symptoms (13%), uninvestigated dyspepsia (10%), peptic ulcer (2%) and mixed causes (18%, e.g. polymedication, cough, hoarseness,….). A history of H. pylori infection was present in 9% of patients. Patients exhibited on average low somatization, no depression, and no anxiety (Table).

	Nausea/ vomiting (PAGI-SYM) mean score ± SD	Postprandial fullness/ early satiety (PAGI-SYM) mean score ± SD	Bloating (PAGI-SYM) mean score ± SD	Upper abdominal pain (PAGI-SYM) mean score ± SD	Lower abdominal pain (PAGI-SYM) mean score ± SD	Heartburn/ regurgitation (PAGI-SYM) mean score ± SD	Depression (PHQ-9) mean score ± SD	Somatization (PHQ-15) mean score ± SD	Anxiety (GAD-7) mean score ± SD
Total (n=482) Mean age 61 ± 14 y.o. 58% female BMI 27.9 ± 4.6 kg/m²	0.4 ± 0.7	1.1 ± 1.1	1.7 ± 1.6	1.0 ± 1.2	0.7 ± 1.2	0.9 ± 1.0	4.6 ± 4.6	8.8 ± 5.1	5.0 ± 5.0
GERD (n=167) Mean age 60 ±14 y.o. 59% female BMI 27.5 ± 4.7 kg/m²	0.3 ± 0.7	1.1 ± 1.0	1.6 ±1.5	0.8 ± 1.7	0.6 ±1.1	0.9 ± 1.0	3.9 ± 3.9	8.2 ± 4.8	4.2 ± 4.7
Dyspepsia (n= 126) Mean age 60 ± 15 y.o. 63% female BMI 28.0 ± 4.6 kg/m²	0.4 ± 0.6	1.3 ± 1.2	2.0 ± 1.6	1.1 ±1.2	0.8 ± 1.2	0.9 ± 1.1	5.5 ± 5.0	9.8 ± 5.3	6.1 ± 5.1
Non-gastric (n=55) Mean age 64±11 y.o. 65% female BMI 27.8 ± 4.1 kg/m²	0.4 ± 0.7	1.1 ± 1.2	1.3 ± 1.5	0.8 ± 1.4	0.5 ± 1.1	0.6 ± 0.9	4.5 ± 4.7	8.3 ± 4.6	3.9 ± 3.6

There were no differences in age and sex among cohorts on healing (n= 80, 62% female, mean age 61 ± 13 y.o.) or maintenance PPI dose (n=362, 58% female, mean age 61 ± 14 y.o.). However, those on healing doses had a significantly higher BMI (29.2 ± 4.9 vs 27.6 ± 4.4 kg/m², $p=0.003$) and reported higher scores on all PAGI-SYM subscales (NS), with a significantly higher score on the postprandial fullness & early satiety subscale (average score of 1.4 ± 1.3 vs. 1.1 ±1.0, $p=0.030$). There were no significant differences in psychosocial co-morbidities between patients on healing or maintenance PPI doses (all $p>0.05$).

Sex, age, and BMI were similar among subgroups based on the initial reason for PPI therapy. Patients in whom PPI therapy was initiated for dyspepsia had significantly higher bloating scores than those with reflux or non-gastric symptoms ($p=0.011$). Furthermore, dyspepsia patients exhibited significantly higher somatisation ($p=0.015$), depression ($p=0.007$), and anxiety ($p=0.002$) compared to reflux symptom patients.

Conclusion: A large subset of patients with prolonged PPI intake lacking a strict medical indication have unsuccessfully attempted to stop PPI usage. The patients who are long-term on healing doses have a significantly higher BMI and more severe postprandial distress syndrome symptoms. Psychosocial co-morbidity is significantly higher in patients in whom PPIs were started for dyspeptic symptoms. These characteristics are relevant when considering attempts to deprescribe PPIs in primary care.

HIGH-RESOLUTION VIDEO MANOMETRIC ASSESSMENT OF DYSPHAGIA POST FUNDOPLICATION

V. Perananthan[1,2], M. Richards[2], R.E Burgell[1], G. Hebbard[2]

Introduction: Post-fundoplication dysphagia is common and can occur in up to 65% of patients[1]. Following anti-reflux surgery, the oesophago-gastric junction (OGJ) is an anatomically complex and dynamic area which is subject to mechanical stress, herniation and slippage. Upper gastrointestinal endoscopy and barium oesophagrams are the most commonly ultilised diagnostic modalities. High-resolution video manometry (HRVM) is an alternative and potentially superior technique as it allows for physiological assessment with high-resolution manometry (HRM) with simultaneous fluoroscopic views help delineate anatomy, location of the fundoplication and better appreciate hernias. We aimed to characterise modes of dysphagia post-fundoplication with HRVM.

Aims & Methods: We conducted a retrospective observational study over 62 months until March 2023. HRVM performed on patients with ongoing dysphagia post-fundoplication were selected from a HRVM database and modes of dysphagia were assessed.

Results: 501 patients had HRVM over 62 months of which 32 patients had dysphagia post-fundoplication. Median integrated relaxation pressure (IRP) was greater than 15mmHg in 9 patients (27.3%). HRVM was normal in 8 (25%), The causes of dysphagia post-fundoplication included pseudo-achalasia with oesophogo-gastric junction outflow obstruction (OJ-GOO) due to a tight wrap in 9 (28.1%), ineffective oesophageal motility in 8 (25%), para-oesophageal hernia due to slippage of wrap in 3 (9.4%), non-achalasia oesophageal dysmotility disorders (i.e. hypercontractile oesophagus and distal oesophageal spasm) in 2 (6.3%) and new diagnosis of Type 2 achalasia in 2 (6.3%). Post fundoplication complications accounted for 12 (37.5%) and an underlying oesophageal motility disorder was diagnosed in 12 patients (37.5%).

Conclusion: Whilst iatrogenic causes of dysphagia due to fundoplication itself were commonly seen, underlying oesophageal motility disorders

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. were also identified in an equally large proportion of patients. Whether this reflects post-surgical motility disturbance or missed pre-morbid dysmotility is unclear. Nevertheless, these results highlight the importance of oesophageal manometry prior to anti-reflux surgery.

COMPARISON OF ANXIETY AND DEPRESSION FREQUENCIES IN ROMA IV FUNCTIONAL DYSPEPSIA SUBGROUPS: A CROSS-SECTIONAL OBSERVATIONAL STUDY FROM TURKEY

S. Demirbaş Yüceldi[1], M. Sadeçolak[2], A. Bilgili[2], M. Tozlu[2], A.T. Eminler[2], M.I. Uslan[2]

Contact E-Mail Address: selmademirbas@yahoo.com

Introduction: Different pathophysiological mechanisms are thought to play a role in functional dyspepsia (FD) subgroups defined by Rome IV criteria. However, many more studies are needed to determine whether a better separation of pathophysiological mechanisms, so a better therapy choice, can be obtained with the Rome IV subgrouping. This study aims to investigate the difference in psychopathological comorbidities between the FD subgroups defined by the Rome IV criteria. We hypothesized that anxiety and depression would be risk factors differently for each functional dyspepsia subgroup according to Roma IV criteria.

Aims & Methods: This is a cross-sectional observational study conducted at a tertiary gastroenterology center in Turkey between December 2022 and April 2023. Dyspeptic patients, aged over 18 years old referred for an upper gastrointestinal endoscopy were recruited. Participants were asked to fill out the Rome IV gastroduodenal questionnaire along with the Hospital Anxiety and Depression Scale. FD subgroups were defined using the Rome IV criteria. Hospital Anxiety and Depression Scale was used to assess the anxiety and depression of participants. All statistical analyses were conducted using SPSS version 23.0.The p-value of <0.05 was accepted as statistically significant.

Subgroups	PDS N:59	Overlapping N:37	EPS N:21	Total N:117
Depression n(%)	25 (37.9%) p>0.05	9 (30%) p>0.05	7 (33.3%) p>0.05	41 (35%)
Anxiety n (%)	26 (39.4%) *p<0.05	7 (23.3%) p>0.05	2 (9.5%) *p<0.05	35 (29.9%)

FD, functional dyspepsia; PDS, postprandial distress syndrome; EPS, epigastric pain syndrome

Table 1. Anxiety and depression frequencies among FD Rome IV subgroups.

Results: Of 424 dyspeptic participants, FD was identified in 117 (27.5%) patients. There were 66 (56.4%) PDS (postprandial distress syndrome), 21 (18%) EPS (epigastric pain syndrome), and 30 (25.6%) overlapping cases. Depression was detected in 35% of FD patients; in 37.9% of the PDS subgroup, 30% of the overlapping subgroup, and 33.3% of the EPS subgroup; There was no difference between the groups (p:0.622). Anxiety was detected in 29.9% of FD patients; in 39.4% of the PDS subgroup, 23.3% of the overlapping subgroup, and 9.5% of the EPS subgroup; detected more frequently in PDS subgroup than in EPS and overlapping subgroups (p:0.022) (Table 1). The frequency of anxiety was significantly higher in patients with postprandial fullness and early satiation symptoms according to those without symptoms (35.8% vs. 15.6%, p:0.035; 44.7% vs. 23.9% p:0.027, respectively).

Conclusion: PDS subgroup, postprandial fullness, and early satiety symptoms were more associated with anxiety, according to the EPS subgroup undd epigastric pain symptom. Evaluating this patient groups in this respect and providing the necessary support can accelerate the recovery process of the patient. It seems reasonable to assume that anxiolytic drugs are of benefit in especially the PDS subgroup. Further studies assessing psychological factors and treatment strategies for FD Rome IV subgroups are required to confirm the relationship of subgroups with depression and anxiety.

ESOPHAGEAL SAMPLING AFTER FOOD IMPACTION; PREJUDICE AFFECTS CLINICAL PRACTICE…

T. Voulgaris[1], T. Alexopoulos[1], J. Vlachogiannakos[1], D. Kamberoglou[1], A. Koutsoumpas[1], K. Papaxoinis[1], P. Fytili[1], G. Papatheodoridis[1], G. Karamanolis[1]

Contact E-Mail Address: georgekaramanolis@yahoo.co.uk

Introduction: Epidemiological studies have shown that Eosinophilic Esophagitis (EoE) is most commonly observed among young males with atopic background. Data have pointed out that approximately half of young patients presenting with bolus impaction will have EoE as a causative factor. According to guidelines, in patients with bolus impaction, EoE should be searched, by esophageal sampling, irrespective of patients age, sex or endoscopy findings.

Aims & Methods: Aim of our study was to elucidate if clinicians in an academic hospital in Greece cohere to guidelines or if epidemiological and endoscopic data precludes them from esophageal sampling.

We included 134 consecutive patients presented with bolus impaction

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

during a 6-year period (1/18-12/23). We excluded patients with a history of; esophageal stenosis, esophageal/gastric cancer esophageal motility disorders, metastatic disease, bone-foreign body ingestion, caustic agent ingestion, esophagogastric surgeries. We further excluded 34 patients with endoscopical evidence of another disease that could explain patients' symptoms. Epidemiological, endoscopical and histological data were collected and analyzed.

Results: We finally included 100 patients (M/F: 71/29, mean age 55±23 years old). A history of previous bolus impaction without biopsy sampling was reported by 35 (26.1%), while 12 (9%) reported history of dysphagia before the impaction episode. During the endoscopy 36 had endoscopic findings suggestive of EoE and 64 (47.8%) a normal Endoscopy. Biopsies were obtained by 47/100 (47%). In the univariate analysis, sampling was correlated, in a statistically significant way, with male sex, age <65 years old, endoscopic signs compatible to EoE and a history of previous bolus impaction or dysphagia. Though in the multivariate analysis only endoscopic findings and age were observed, in a statistically significant way, to affect clinicians decision to obtain biopsies. EoE was diagnosed in 33/47 (70.2%). In the univariate analysis EoE diagnosis was significantly correlated with age <65 years, male sex and the existence of compatible endoscopic findings but not with a history of previous bolus impaction or dysphagia. In the multivariate analysis only age <65 was independently correlated with EoE diagnosis. (Table)

Factor	Biopsy sampling among patients with Bolus impaction (patients without endoscopic findings other than EoE that could explain patients symptoms)			EoE diagnosis among patients with Bolus impaction		
		Univariate p	multivariate p		Univariate p	Multivariate p
Younger than 65	44/71 62%	<0.001	0.002 OR: 0.951 95% C.I.: 0.922-0.982	33/44 75%	0.041	0.038 OR: 0.931 95% C.I.: 0.870-0.996
65 and older	3/29 10.3%			0/3 (0%)		
Male	41/71 57.7%	0.001	0.231 OR: 0.441 95% C.I.: 0.116-1.683	31/41 76.5%	0.047	0.968 OR:1.064 95% C.I. :0.052-21.887
Female	6/29 20.7%			2/6 33.3%		
Findings compatible to EoE	32/36 88.9%	<0.001	<0.001 OR: 21.836, 95% C.I.: 3.994-115.956	27/32 84.3%	0.031	0.062 OR: 7.536 95% C.I.: 0.900-63.101
Normal endoscopy/ other findings	15/64 23.4%			6/15 40.0%		
History of previous bolus impaction or dysphagia	22/33 66.7%	0.010	0.493 OR: 1.690, 95% C.I.: 0.376-7.592	16/22 72.7%	0.555	
Yes	25/67 37.3%			19/25 76.0%		
No						

Conclusion: According to our study, esophageal biopsies are obtained in <50% of patients with a bolus impaction episode. Age and endoscopic evidence supportive of EoE seem to drive clinicians decision to obtain esophageal biopsies after a bolus impaction episode. EoE is more commonly observed in young male patients with bolus impaction.

Disclosure: Nothing to disclose.

Introduction: The Swiss Eosinophilic Esophagitis Cohort Study (SEECS) is a national prospective cohort for adults with eosinophilic esophagitis (EoE) that was established in 2015 with the aim of improving quality of care considering EoE's increased incidence. The SEECS allows for documentation of EoE's natural history, patients' quality of life (QoL) and monitoring of treatment efficacy and safety. It also aims to promote clinical and translational research projects with the availability of standard operating procedures (SOPs) for the submission of scientific protocols. The first cohort update was published in 2017.

Between 2020 and 2022, paper questionnaires were gradually replaced by fully electronic data capture using Research Electronic Data Capture (REDCap) software. We aim to provide a second update of the cohort, eight years after its launch.

Aims & Methods: The SEECS includes adult patients (age ≥18 years) with EoE, gastro-esophageal reflux (GERD) and healthy controls (HC) using strict eligibility criteria in line with the most recent guidelines. Upon inclusion and follow-up (typically once a year), patients and physicians complete questionnaires in REDCap which are available in German, French, and English.

Patients reported outcomes (PROs) and biologic activity are assessed all on the same day using validated instruments (EEsAI PRO for symptoms; EoE-QoL-A for QoL; EREFS for endoscopic activity; modified EoE-HSS for histologic activity). The SEECS biobank includes biosamples (blood samples, esophageal biopsies) from patients with EoE, GERD, and HC.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: As of July 2023, the SEECS includes 778 patients [716 (92%) with EoE, 29 (3.8%) with GERD, and 33 (4.2%) HC; 559/778 (71.9%) are male]. Mean age±SD (years) according to diagnosis is as follows: EoE 41.9±12.9, GERD 53.6±16.4, HC 51.7±17.2. Mean diagnostic delay for the EoE group is 89.6±96.2 months. Concomitant GERD is found in 200 patients (27.9%) of the EoE cohort. Concomitant allergic disorders (asthma, rhinoconjunctivitis, neurodermitis) are present in 500 patients (74.4%) with EoE. At inclusion, 694 (96.9%) of EoE patients have an ongoing treatment [orodispersible budesonide tablet: 290 patients (41.8%); budesonide/fluticasone syrup: 281 patients (40.5%); PPI: 162 patients (23.3%); elimination diets: 103 patients (14.8%); esophageal dilation at last visit: 166 patients (23.9%)]. Esophageal biopsies are available from 525/778 (67.5%) patients including 468 EoE patients (65.4%).

Conclusion: Our findings are in line with the available literature on EoE's natural history. To our knowledge, the SEECS is the only national cohort for EoE adult patients that includes both GERD and healthy controls with their biosamples. Data capture is based on validated instruments and is fully electronic using REDCap. The SEECS offers up-to-date epidemiologic data on EoE and promotes research projects.

Introduction: Eosinophilic oesophagitis (EoE) is a rare, chronic, inflammatory disorder with few approved treatments. Thymic stromal lymphopoietin (TSLP) is a pro-inflammatory epithelial cytokine. *TSLP* genetic variants are associated with EoE risk, and oesophageal TSLP mRNA and protein levels are elevated in patients with active EoE. Tezepelumab, a human monoclonal antibody approved for the treatment of severe asthma, specifically binds to and blocks the activity of TSLP.

Aims & Methods: This analysis aimed to determine whether TSLP-mediated gene expression changes are enriched in patients with EoE to understand whether tezepelumab could be a potential treatment for EoE. Gene signature analyses were performed to generate TSLP gene lists from two independent transcriptomic data sets obtained from: 1) bronchial brushings at week 28 from patients with moderate-to-severe, uncontrolled asthma, treated with tezepelumab in the phase 2 CASCADE study (NCT03688074); and 2) human myeloid dendritic cells (mDCs) treated *ex vivo* with recombinant TSLP for 24 hours. Using these TSLP gene lists, gene set variation analyses were performed on publicly available gene expression data from oesophageal biopsies in healthy individuals and patients with chronic oesophagitis, active untreated EoE, inactive treated EoE (responsive to swallowed topical corticosteroids [STCs]) and active treated EoE (unresponsive to STCs).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The TSLP gene lists comprised 18 upregulated genes and 32 downregulated genes in bronchial brushings from CASCADE, and 183 upregulated and 161 downregulated genes in human mDCs. The TSLP gene scores from bronchial brushings were elevated in patients with active EoE, untreated and unresponsive to STCs, compared with healthy individuals (upregulated genes: $p \leq 0.05$ and $p \leq 0.001$, respectively; downregulated genes: $p > 0.05$ and $p \leq 0.01$, respectively). The TSLP gene scores from human mDCs were elevated in patients with active EoE, untreated and unresponsive to STCs, compared with healthy individuals (upregulated genes: $p \leq 0.05$ and $p \leq 0.01$, respectively; downregulated genes: $p \leq 0.05$ and $p \leq 0.001$, respectively). In both data sets, compared with patients who had inactive treated EoE, TSLP gene scores were elevated in patients with active treated EoE that was unresponsive to STCs (upregulated genes: $p < 0.001$; downregulated genes: $p \leq 0.05$ [bronchial brushings] and $p \leq 0.0001$ [human mDCs]). These data support clinical evaluation of tezepelumab in the treatment of EoE, which is being conducted in the ongoing phase 3 CROSSING study (NCT05583227). CROSSING is a double-blind, placebo-controlled study that will evaluate the efficacy and safety of tezepelumab in approximately 360 patients (12–80 years old) with symptomatic and histologically active EoE. Patients will be randomized (1:1:1) to receive one of two dose options for tezepelumab or placebo subcutaneously every 4 weeks for 52 weeks. The study includes an optional 24-week active treatment extension period in which patients previously receiving placebo will be re-randomized to receive one of the two tezepelumab doses. The co-primary endpoints are to assess the effect of tezepelumab on symptom improvement and histologic response.

Conclusion: Gene lists indicative of elevated TSLP activity were enriched in patients with active EoE (untreated or unresponsive). These data suggest that blocking TSLP with tezepelumab may be a therapeutic option for EoE. The efficacy and safety of tezepelumab in patients with symptomatic and histologically active EoE are being assessed in the ongoing CROSSING study.

Introduction: Eosinophilic esophagitis (EoE) is a chronic inflammatory disorder restricted to the esophagus that predominates in males (male:female ratio being around 3:1). The impact of patient sex on the onset, diagnosis and progression of EoE has been barely evaluated, with some reporting no or minor differences (1) while others discovered relevant changes between men and women regarding symptomatology, endoscopic findings and molecular signature (2,3).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: The study aims to assess potential disparities in EoE presentation and phenotype at the moment of diagnosis, as well as to evaluate whether sex determines difference in disease progression and response to therapy. This is a cross-sectional, multicentre study that includes patients diagnosed with EoE from the EoE CONNECT registry. Demographical and clinical data were obtained from patients recruited at 37 hospitals in 4 European countries. Data extraction was conducted on March 21st, 2024.

Quantitative (age, diagnostic delay, dysphagia symptom score, EREFS endoscopic scale, peak of eosinophils per high power field, number of previous endoscopies, and number of endoscopic dilations) and qualitative (age by groups, phenotype, country, presence of fibro-stricturing findings, atopies, treatments and symptoms) variables were compared. Statistical significance was established for p<0.05.

Results: Data from 2,976 patients (76% males) were retrieved, with no difference in female proportions among countries. Mean±SD age at diagnosis was higher for females (34.8±15.6 *vs* 32.7±14.8 years, p=0.007), with no differences in diagnostic delay or number of previous endoscopies before diagnosis. Proportion of women diagnosed with EoE at 60 year or older age was twice compared to men (6.4% *vs* 3.1%, p<0.001). Abdominal (6.6% *vs* 4.4%, p=0.023) and epigastric (10.6% *vs* 8.1%, p=0.047) pains, heartburn (27.9% *vs* 22.0%, p=0.003) and dysphagia (79.7% *vs* 73.3%, p=0.001) were significantly more frequent in females; food bolus impaction predominated in males (59.5% *vs* 50.1%, p<0.001). Symptoms intensity measured with the Dysphagia Symptom Score was higher in female patients (6.9±3.8 *vs* 6.3±4.1, p=0.003).

Endoscopic features of fibrosis (rings and/or strictures) at baseline endoscopy predominated in males (61.0% *vs* 51.4%, p<0.001). Accordingly, overall EREFS score and its fibrotic sub-score (2.6±1.7 *vs* 2.3±1.6 and 1.0±1.0 *vs* 0.8±1.0, respectively, p<0.001), and mixed/stricturing phenotypes were more commonly found in male compared to female patients (25.0% *vs* 19.3%, p=0.002). Peak eosinophil count was higher in females (median 50 *vs* 42 cells/HPF, p=0.005).

No differences were found for first-line treatment choice and effectiveness of anti-inflammatory therapies between men and women. In addition, 126 patients underwent 215 endoscopic dilatation procedures overall, which were slightly more common among male patients (4.5% *vs* 3.4%, p=0.187). In contrast, the median number of dilation procedures was higher in female compared to male EoE patients (2 *vs* 1; p=0.001).

Regarding concomitant atopies, no differences were noted in the prevalence of rhinitis, conjunctivitis and asthma according to sex. However, atopic dermatitis was more common in women (21.7% *vs* 17.8%, p=0.028).

Conclusion: Sexual dimorphism exists in EoE, as observed in other immune-mediated diseases. Despite symptoms severity scored slightly higher in females, EoE in male patients appeared earlier, more commonly with food bolus impaction and with fibro-stricturing endoscopic features at diagnosis.

RESULTS FROM DOSE ESCALATION IN RESOLVE, AN ONGOING PHASE 1B/2A DOSE-ESCALATION STUDY OF EP-104GI (EXTENDED-RELEASE FLUTICASONE PROPIONATE INTRA-ESOPHAGEAL INJECTION) FOR EOSINOPHILIC ESOPHAGITIS

J. Helliwell[1], A. Malone[1], M. Kowalski[1], A. Bredenoord[2], N.Q. Nguyen[3], H.H. Ko[4], C. Dobek[1], A. Litke[1], V. Peck[1], M. Webb[1], E.S. Dellon[5]

Contact E-Mail Address: amalone@eupraxiapharma.com

Introduction: Eosinophilic esophagitis (EoE) is a chronic, immune-mediated disease characterized by inflammation, influx of eosinophils and esophageal remodeling. Therapy for EoE includes swallowed/topical corticosteroids, dupilumab, proton pump inhibitors, and dietary elimination; but these are not always effective.

EP-104GI is an extended-release fluticasone propionate (FP) intra-esophageal injection being developed as a novel treatment for EoE. It consists of polymer-coated FP crystals that release drug locally via diffusion at a pre-defined rate to reduce peak concentrations and prolong the therapeutic window. Preclinical work in pigs has demonstrated that EP-104GI remains at injection sites for at least 6 weeks (duration of the study), with FP spreading 2-4 cm into the surrounding tissue.

Aims & Methods: RESOLVE (NCT05608681) is a Phase 1b, multicenter, open-label, 3+3 design dose-escalation study to evaluate the safety, tolerability, pharmacokinetics, and efficacy of EP-104GI in patients with EoE.

The starting dose of EP-104GI consisted of 1 mg injected at each of 4 sites in 4 quadrants over 2 circumferential areas in the esophagus (4 mg total dose). Dose escalations increase the dose per site and/or number of sites; the second and third cohorts received 1 mg and 2.5 mg respectively at each of 8 sites; the fourth cohort received 2.5 mg at 12 sites (8, 20, and 30 mg total doses).

After a single administration of EP-104GI in these cohorts, participants are assessed for up to 24 weeks. Additional cohorts are planned to evaluate greater dose per injection site and/or increased number of injections with a longer duration of follow-up.

Assessments include Peak Eosinophil Count (PEC) from esophageal biopsies at 16 sites, patient-reported symptom outcomes including the Straumann Dysphagia Index (SDI) and Likert scales for dysphagia and odynophagia, and plasma concentrations of FP. Adverse events (AEs) and laboratory tests including serum glucose and cortisol are assessed.

Results: Cohort 1-3 safety observations include mild-moderate AEs; the majority not related to EP-104GI. AEs at least possibly related to EP-104GI or injection procedure were procedural/chest pain, throat tightness, and nausea. Glucose levels post-dose have remained stable. Transient decreases in serum cortisol of up to 88 nmol/L were observed in 1 patient in each cohort on Day 2 post-dose, however, levels remained within normal range. There have been no symptoms of adrenal insufficiency.

Response data from Cohorts 1 and 2 (Table 1) demonstrate a decrease from baseline in symptom scores at Weeks 12 and 24. Reduction in mean PEC has been observed in all patients in Cohort 2, with a trend indicating that increasing the total dose of EP-104GI results in a more consistent reduction in PEC at the 16 biopsy sites assessed.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 	Cohort 1 (1 mg × 4 sites, total 4 mg)	Cohort 2 (1 mg × 8 sites, total 8 mg)
Mean change from baseline (CFB) in Straumann Dysphagia Index (0-9) at Weeks 12 and 24	-4.0, -4.0	-2.7, -3.3
Mean CFB in Dysphagia (0-10) at Weeks 12 and 24	-4.0, -5.0	-4.3, -4.0
Mean CFB in Odynophagia (0-10) at Weeks 12 and 24	-2.0, -3.0	-5.7, -4.3
Mean CFB in PEC at Weeks 4 and 12 (cells/hpf from 16 sites)	No reduction observed	-26%, -44%
Mean plasma concentration of FP at 2 hours post-dose (pg/mL)	4.3	11.2

Table 1: Patient-reported symptom outcomes, peak eosinophil count (PEC), and plasma fluticasone propionate (FP) after a single dose of EP-104GI.

Conclusion: A novel diffusion-based localized delivery of FP via EP-104GI injection into the esophagus is feasible and safe in patients with EoE in this initial escalating dose cohort study. Initial efficacy data show improvement in symptom outcomes and histological findings which may increase with dose. These findings support the potential for extended intervals of at least 6 months between injections. Recruitment is ongoing.

PERSISTENT DYSPHAGIA IN STRICTURE-FREE EOSINOPHILIC ESOPHAGITIS IN HISTOLOGICAL REMISSION: EFFECTIVENESS OF EMPIRICAL DILATION

L. Cini[1], B. Marinoni[2], M. Coletta[3], G. Aldinio[1], N. Siragusa[1], M. Vecchi[4], R. Penagini[5]

[1]Università degli studi di Milano / Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [3]Università degli Studi di Milano Dept. of Gastroenterology, Milan, Italy, [4]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico University of Milan, Milan, Italy, [5]Università degli Studi di Milano, Department of pathophysiology and transplantation, Milan, Italy

Contact E-Mail Address: laura.cini@unimi.it

Introduction:

It is known that not all patients with eosinophilic esophagitis (EoE) in histological remission also achieve clinical remission. Several reasons have been postulated among which decreased esophageal compliance without apparent stricture at endoscopy is particularly appealing, but no data are so far available on effectiveness of empirical dilation.

Aims & Methods: Aim of our study was to investigate this topic. A retrospective analysis with prospectively collected data has been conducted on all EoE patients without stenotic features at endoscopy (i.e. no R3/S1 according to EREFS) in whom histological remission with drug and/or diet has been induced in a single referral Center from July 2018 to December 2023. All patients who had not achieved concurrent remission of dysphagia and/or bolus impaction were empirically dilated. At least 6 months of follow-up after remission was needed for inclusion. Demographic, clinical and endoscopic data were compared between patients who needed dilation and those who did not.

Results: A total of 33 patients aged 40; 30-51 yrs (median; IQR range), 23 men, were included. PPI was the main treatment (76% of pts). Nineteen of them (group 1) achieved clinico-histological whereas 14 (group 2) achieved histological remission only and underwent empirical dilation to 15-17 mm with no complications after which clinical remission was achieved in 13 of them. A second dilation was needed in 2 patients at 25 and 31 months respectively, in order to maintain remission. EREFS score at histological remission, but not at diagnosis, was higher in group 2 vs 1 (p=0.02, see table) and was accompanied by a higher % of patients with rings (R1 or R2), 78 vs 37 (p=0.04). A lower % of group 2 patients was treated with topical steroids, 7 vs 26 (p=NS).

	Group 1 (n=19)	Group 2 (n=14)
Age, yrs	37;28-46	44;22-55
Sex, male n (%)	12(63)	11(79)
Symptom duration, months (*)	46;23-102	36;19-77
I-SEE at diagnosis (**)	4;3-5	5;2-6
EREFS at diagnosis	2;1-2	2;0-3
EREFS at histological remission	1;0-2	2;1-2 #
Duration of follow-up, months	12;7-54	20;10-43

(*) up to histological remission, (**) I-SEE= Index of severity of EoE (1), # p=0.02 vs group 1

Conclusion: In our cohort of stricture free EoE patients achieving histological remission, over 40% still had residual obstructive symptoms which were relieved by empirical esophageal dilation in most, suggesting high relevance of decreased esophageal compliance. Prospective multicenter data with use of FLIP are warranted in order to assess if topical steroids are more effective than PPIs in reversing remodeling and avoiding dilation.

PREDICTIVE HISTOLOGICAL FEATURES OF PROTON PUMP INHIBITOR RESPONSE IN UNTREATED EOSINOPHILIC ESOPHAGITIS PATIENTS

M. Machín Delgado[1], V. Roales Gómez[1], M.J. Fernández Aceñero[1], M. Suárez Solís[1], C. Rodríguez Carrillo[1], Y. Altuzarra Ranedo[1], J. Sánchez César[1], I. Cacho Soblechero[1], C. López Martínez[1], C. Ciriza de los Ríos[1], J.L. Mendoza Hernández[1]
[1]Hospital Clínico San Carlos, Madrid, Spain

Contact E-Mail Address: mariamacdel@gmail.com

Introduction: Eosinophilic esophagitis (EoE) is an immunoallergic disease of increasing prevalence whose clinical manifestations are due to dysmotility resulting from eosinophil-mediated inflammation. The goal of treatment is the clinical, endoscopic and histological response, with discordant data on predictive criteria.Historically, histological response has been assessed with the intraepithelial eosinophil count until the validation of the Histological Score System (HSS), which includes microabscesses and eosinophilic degranulation, lamina propria fibrosis, intraepithelial lymphocytosis and spongiosis.

Aims & Methods: Our aim is to identify histological features in baseline esophageal biopsies at diagnosis that are predictive of response to proton pump inhibitors (PPI), first line treatment.

A retrospective cohort study, approved by the Ethics Committee of the Hospital Clínico San Carlos, was designed that included incident patients with diagnostic criteria for EoE evaluated between January and December 2022. They underwent a baseline gastroscopy and another after a cycle of PPIs at high doses. After 8-12 weeks induction, two cohorts were established: responders to PPI (PPI-REE) and non-responders (non PPI-RRE). Clinical and endoscopic data were collected from reports, and biopsies were reviewed by expert pathologists after anonymisation of the patient cohort.

	Proximal esophagus			Distal esophagus		
Histologic variable	PPI-REE	Non PPI-REE	p value	PPI-REE	Non PPI-REE	p value
Predominance of eosinophils on epithelial surface	3 (6.4%)	2 (11.1%)	0.611	0	0	n. a.
Basal cell hyperplasia	36 (70.6%)	11 (61.1%)	0.458	50 (74.6%)	19 (73.1%)	0.878
Eosinophilic microabscesses	9 (17.3%)	7 (31.8%)	0.218	18 (27.3%)	12 (37.5%)	0.303
Eosinophil activation (degranulation)	16 (31.4%)	18 (81.8%)	<0.001	38 (56.7%)	25 (78.1%)	0.038
Submucosal lamina propria fibrosis	16 (76.2%)	9 (100%)	0.286	33 (97.1%)	11 (100%)	0.015
Intraepithelial lymphocytosis	10 (19.85%)	1 (4.8%)	0.158	13 (20%)	5 (15.6%)	0.602
Spongiosis	9 (17.6%)	17 (77.3%)	<0.001	25 (37.3%)	29 (93.5%)	<0.001
Papillary elongation	7 (53.8%)	1 (14.3%)	0.158	17 (77.3%)	5 (41.7%)	0.062

Results were analysed using IBM SPSS Statistics v.26, with $\chi 2$ or Fisher's exact test for qualitative variables and Student's t-test or non-parametric Mann-Whitney U test for quantitative variables. A binary logistic regression model was used to analyse the association between cohorts and each individual variable, with a significant p-value of 0.005 accepted.

Results: 99 patients with EoE were included, 32 in the non-PPI-REE cohort (32.3%) and 67 in the PPI-REE cohort (67.7%), with no differences in baseline characteristics or endoscopic variables. Histological analysis (Table 1) shows that spongiosis, regardless of location, eosinophilic degranulation in the proximal esophagus and fibrosis of the lamina propria in the distal esophagus are predictive factors for non-response to PPI. However, in multivariate analysis, only the presence of spongiosis, regardless of location, was significant (p 0.021 proximal [95% CI 0.030-0.756] and 0.016 distal [95% CI 0.008-0.611]).

Conclusion: EoE is a growing entity. Being able to predict the response to PPIs at diagnosis would allow clinical improvement and early reduction of inflammation, reducing progression to the fibrostenotic phenotype.

According to our results, we consider it important to universalise the HSS, highlighting the importance of identifying spongiosis, easily identifiable histological changes with low interobserver variability and without additional cost, which could predict the absence of response to PPIs, with patients able to benefit from swallowed corticosteroids or exclusion diets from diagnosis. However, studies with greater power should confirm these data.

Disclosure: Nothing to disclose.

Introduction: Until a few years ago, there existed only off-label medical treatment options for eosinophilic esophagitis (EoE) such as proton pump inhibitors (PPI) or swallowed topical corticosteroids (STC) with various formulations and ingredients. Since the approval of a budesonide orodispersible tablet (BOT), the first biological agent (Dupilumab) has been approved by the EMA and FDA, and another budesonide oral suspension has been received approval by the FDA recently. Currently, many phase 3 trials with different drugs are running, resulting in various treatment options in the next years. However, data about patients' perspectives are lacking. We therefore aimed to assess patients' awareness, beliefs and restrictions to medical treatment options in EoE

Aims & Methods: We developed a web-based survey using SurveyMonkey and sent a questionnaire comprised of 47 questions about patients' preferences regarding medical treatment options to patients with established EoE in Switzerland, Austria and Germany.

Results: A total of 56 patients (64% male, 66% with other atopic diseases) from Switzerland (64%), Austria (34%) and Germany (2%) answered the questionnaire. A swallowed topical therapy was ranked first (71% of patients) in terms of patient's preference followed by a subcutaneous therapy every 4 weeks (21.4%) and by an oral therapy with systemic effect (7%). Although one third do not have reservations against long-term medical therapy, nearly half of patients (42%) are skeptical about long-term treatment and 65% are afraid of adverse events. However, a third of patients are not aware that STC are locally effective medications with nearly no systemic effect. Furthermore, 48% of patients believe that physicians underemphasize adverse events of medication. Nearly all patients understand the importance of not only treating symptoms but also inflammation (85%).

Conclusion: Patients with EoE prefer topical agents over other available routes of administration. Patient education should be carried out to address reservations about long-term treatment.

Disclosure: Falk Pharma, Sanofi (both consultency meetings).

RISK FACTORS FOR ORAL AND ESOPHAGEAL CANDIDIASIS DURING BUDESONIDE TREATMENT IN EOSINOPHILIC ESOPHAGITIS PATIENTS

I. Spinelli[1], M. Parmigiani[1], F. Fianchi[1], A. Aruanno[1], F. Castri[1], F.R. Ponziani[1], G. Ianiro[1], A. Gasbarrini[1]

Introduction: Eosinophilic esophagitis (EoE) is a chronic and progressive disease characterized by eosinophil-predominant inflammation of the esophagus. First-line therapy is represented by topical corticosteroids with anti-inflammatory effects, in particular budesonide orodispersible tablets (BOT). Their efficacy and safety are nowadays well established, but very low number of patients develop oral and esophageal candidiasis.

Aims & Methods: The aim of the study is to evaluate risk factors for the development of oral and esophageal candidiasis during budesonide therapy in eosinophilic esophagitis patients. To date, these data have not still been studied. A retrospective study was conducted to include all EoE patients in therapy with BOT referred to Fondazione Policlinico Universitario A. Gemelli IRCCS between March 2022 and November 2023. Prevalence, localization, and time of presentation of candidiasis were evaluated. Histological findings, in particular eosinophilic count in gastroscopy before BOT therapy were analyzed. Concomitant treatment with proton-pump inhibitors (PPI) and its dosage were reviewed. In addition, each case of discontinuation of BOT for disabling candidiasis was studied.

Results: A total of 52 EoE patients in BOT therapy, 44 males and 8 females, were included in the study. 7 patients (13%) developed oral and/or esophageal candidiasis, in particular 6 patients (85%) during induction phase (1 mg bid) and 1 patient (15%) during early maintenance phase (0.5 mg bid). All these 7 patients presented peak eosinophil count >35/HPF before corticosteroid treatment, with mean count of 46 eos/HPF. 4 patients (57%) of this group were in concomitant PPI therapy at 40 mg per day or more dosage. 3 patients (42%) presented recurrent and severe oral candidiasis inducing discontinuation of treatment.

Conclusion: Oral and esophageal candidiasis is a well-known side effect of budesonide orodispersible tablets in eosinophilic esophagitis. Our results suggest that consistent eosinophilic count (> 35/HPF) and concomitant PPI therapy could represent risk factors in developing mycosis in EoE patients. According to literature, major esophageal inflammation, PPI-induced elimination of the gastric acid barrier and corticosteroid immunosuppression are the main mechanisms leading to oral and esophageal candida colonization. Concomitant use of PPI during BOT treatment in eosinophilic esophagitis should be carefully evaluated, especially in patients with elevated eosinophilic count.

COMPARATIVE PHARMACOKINETICS, SAFETY, AND TOLERABILITY OF A SINGLE DOSE OF CENDAKIMAB IN HEALTHY CHINESE AND US PARTICIPANTS

Y. Chen[1], C. Xue[2], L. Liu[2], S. Peng[1], J. Rojo[3], W. Kang[2], S. Basdeo[3], B. Wang[2], Y. Qin[2], B. Yang[2], C. De Oliveira[3], K. Yu[3], M. Thomas[3], B. Murthy[3], P. Zhang[3]

Introduction: Eosinophilic esophagitis (EoE) is a chronic and progressive Type 2 inflammatory disease with a significant unmet need for effective and safe long-term targeted therapy. Cendakimab (CEN) is a recombinant, humanized, high-affinity, neutralizing monoclonal antibody that binds to interleukin 13 (IL-13) thereby blocking interaction with its receptors, IL-13Rα1 and IL-13Rα2. CEN is currently under clinical development for the treatment of EoE.

Here, we present the results of 2 phase 1, randomized, single-center, single-dose trials assessing the pharmacokinetics (PK), safety, and tolerability of CEN in healthy Chinese (NCT05638282) and US (NCT05337345) populations.

Aims & Methods: In the China study (NCT05638282), healthy participants (age, 18–55 years; body mass index [BMI], 18.0–28.0 kg/m^2; weight, ≥50.0 kg) were sequentially assigned to 2 groups. Participants in each group were randomized 5:1 to receive: group 1, single-dose CEN 360 mg subcutaneous (SC) via 1 injection (n=10) or placebo (n=2), and group 2, single-dose CEN 720 mg SC via 2 injections (n=10) or placebo (n=2). All doses were administered in the abdomen using an autoinjector (AI). In 1 of 4 groups of the US study (NCT05337345), healthy participants (age, 18–55 years; BMI, 18.0–30.0 kg/m^2; weight, ≥40.0 kg) received single-dose CEN 360 mg SC via 1 injection in the abdomen using an AI (n=32). Data from groups that received CEN via AI are presented here. The PK parameters assessed in both studies were maximum observed serum concentration (C_{max}), time of C_{max} (T_{max}), area under the concentration-time curve from time 0 to time of the last quantifiable concentration (AUC_{0-T}), AUC from time 0 to infinite time (AUC_{∞}), terminal elimination half-life ($T_{1/2}$), apparent total body clearance (CL/F), and apparent volume of distribution of terminal phase (Vz/F). Safety and tolerability were also evaluated.

Results: Demographic characteristics were generally similar in the China and US studies, eg. median BMI was 23 and 26 kg/m^2, respectively. In the China study, following SC doses of 360 and 720 mg, the absorption of CEN was slow, with a median T_{max} of 96 and 143 hours; mean $T_{1/2}$ was 565 and 535 hours, and Vz/F was 11.8 and 10.7 liters, respectively (*Table*).

The geometric mean C_{max}, AUC_{∞}, and AUC_{0-T} increased in a dose-proportional manner between the 360 and 720 mg CEN doses. Antidrug antibodies (ADAs) were detected in 50% of participants in each of the 360 and 720 mg CEN groups, with a low titer in most of them.

Results for the 360 mg AI group from the China study were consistent with those of the 360 mg AI group in the US study. ADAs were detected in 16% of the participants in the US study. In both studies, the ADA response did not impact the safety or PK of CEN, and CEN (360 mg or 720 mg) was well tolerated with no deaths, serious adverse events (AEs), or discontinuations due to an AE.

Conclusion: Single-dose 360 mg or 720 mg SC CEN was safe and well tolerated in all healthy participants. CEN PK was generally dose-proportional for C_{max} and AUC from 360 mg to 720 mg. Overall, the PK, tolerability, and safety profiles of a single dose of 360 mg SC CEN in the China study were consistent with those observed in the US study, supporting the use of similar doses across both populations.

ANALYSIS OF CLINICAL RESPONSE IN ADULTS WITH EOSINOPHILIC ESOPHAGITIS: PROSPECTIVE COHORT AT A UNIVERSITY HOSPITAL IN CHILE

C. von Muhlenbrock[1], J. Venegas[1], P. Nuñez[1], J. Achondo[1], N. Pacheco[1], K. Herrera[1], F. Castro[1], R. Quera[1]
[1]Universidad de los Andes, Gastroenterology, Santiago, Chile

Contact E-Mail Address: christianvon@uandes.cl

Introduction: Eosinophilic esophagitis (EoE) is a chronic, immune-mediated inflammatory disease that affects the esophagus. In Chile and Latin America, its epidemiology is unknown.

Aims & Methods: The aim of this study is to describe the clinical, endoscopic, and histological characteristics of adult patients diagnosed with EoE. Prospective cohort of patients seen at the Digestive Diseases Center, diagnosed with eosinophilic esophagitis and undergoing one follow-up endoscopy. Endoscopic classification was performed using the Eosinophilic Esophagitis Endoscopic Reference Score (EEERS), and histological response was defined as fewer than 15 eosinophils (Eos) per high-power field. Descriptive statistics (median and interquartile range) were used for sample characterization, considering the non-normal distribution of the sample evaluated by the Kolmogorov-Smirnov test. The Chi-square test was used for the analysis of nominal (categorical) or ordinal data. The Wilcoxon test was used for the comparison of histological and endoscopic results, while the Mann-Whitney U test was used for the analysis of medical treatment. Statistical software SPSS® v.29 and GraphPad Prism 8.3.0 were used. Values of $p < 0.05$ were considered statistically significant.

Results: Eighty-five patients aged between 17 and 77 years old (Median=36 years) were included, with 75.3% being male. The median age at symptom onset was 31 years and at diagnosis was 34 years. The most frequent reason for consultation was dysphagia (54%), and the most common concomitant immune-allergic diseases were allergic rhinitis (38%) and asthma (29%). Women had more frequent autoimmune comorbidity, peripheral eosinophilia, and food allergies but had a lower eosinophil count and endoscopic score. Regarding treatment, 55% were on PPI therapy and 40% on mixed treatment. In terms of clinical outcomes, patients at admission had a median score of 4 for EREFS and 30 eosinophils/field on biopsy eosinophil count. At follow-up, a significant decrease was observed in both endoscopic and histological (biopsy) parameters ($p < 0.001$), with medians of 0 for each indicator, respectively. Moreover, regarding the influence of treatment type (PPI or mixed) on endoscopic or histological response, it was observed that both treatments are equally effective: patients on PPI therapy showed a 72% histological improvement and an 89% endoscopic response, while patients on mixed treatment showed a 77% and 85% improvement, respectively (p=ns).

Conclusion: This is the first patient cohort in Latin America to our knowledge with EoE. Characteristics are similar to those described in international groups. Women exhibited more frecuent autoimmune comorbidity, peripheral eosinophilia, and food allergies but had a lower eosinophil count and endoscopic score. We did not observe differences among the various therapeutic regimens.

Disclosure: None.

PP0085

TREATMENT PATTERNS AND DISEASE PROGRESSION AMONG PATIENTS WITH EOSINOPHILIC OESOPHAGITIS IN EUROPE: A REAL-WORLD STUDY

U. von Arnim[1], F. Zerbib[2], T. Pela[3], A. Radwan[4], J.A Jacob-Nara[3], B.P. Raphael[4], R.C. Parikh[5], F. Bello[5], G. Le-Bagousse-Bego[6], R.B. Thomas[4], S.T. Tilton[3]
[1]University Hospital, Department of Gastroenterology, Hepatology, and Infectious Diseases, Magdeburg, Germany, [2]CHU de Bordeaux, Centre Médico-Chirurgical Magellan, Hôpital Haut-Levêque, Department of Gastroenterology, Université de Bordeaux, INSERM CIC 1401, Bordeaux, France, [3]Sanofi, Cambridge, MA, United States of America, [4]Regeneron Pharmaceuticals, Inc., Sleepy Hollow, NY, United States of America, [5]RTI Health Solutions, Research Triangle Park, NC, United States of America, [6]Sanofi, Chilly-Mazarin, France

Contact E-Mail Address: Ulrike.vonArnim@med.ovgu.de

Introduction: Eosinophilic oesophagitis (EoE) is a chronic, progressive type 2 inflammatory disease. Proton-pump inhibitors (PPIs), swallowed topical corticosteroids (STCs), and elimination diets have been used as standard treatments for EoE patients. However, the real-world evidence (RWE) highlighting disease burden in Europe are limited.

Aims & Methods: To assess disease burden and treatment patterns among adolescent and adult patients with EoE in real-world practice.

Medical records were retrospectively reviewed for patients (aged ≥12 years) who were newly diagnosed with EoE between 1 January 2009 and 31 December 2019 (index) in Germany, France, Spain, and the United Kingdom. Patients with a peak eosinophil (eos) count (PEC) of ≥15 eos/hpf within 90 days of the index date and ≥1 follow-up endoscopy within 24 months of the index date were included. Demographics, clinical features, treatment patterns, and health outcomes were assessed from the 12-month pre-index period to the last medical record entry or death. Disease progression was assessed via physician-defined (based on symptoms, endoscopy findings, histology, need for dilation, and food impaction) and proxy-reported outcomes (dilation performed, strictures, dysphagia, evidence of food impaction, treatment initiation in treatment-naïve patients and switching/augmentation).

Results: Overall, 385 patients were included, with 70.1%–78.1% being male; the mean age was 27.8 to 33.9 years. At EoE diagnosis, the PEC was 35.3–46.1 eos/hpf, the endoscopic appearance of the oesophagus was abnormal in 73.7%–85.6% of patients, and dysphagia was present in 59.8%–82.8% of patients. Most of the patients across all 4 countries were treated with PPIs (61.5%–91.8%), STCs (56.7%–82.3%) and elimination diets (41.4%–55.2%) after EoE diagnosis. Of the patients with available data, abnormal histology (≥15 eos/hpf) was reported in 44.8%–72.0% of patients during the first 5 years after EoE diagnosis. The abnormal endoscopic appearance of the oesophagus was observed in 34.6%–83.3% of patients after approximately 2 years of EoE diagnosis and dysphagia was present in 10.2%–25.0% of patients after 4 years of EoE diagnosis across all 4 countries. While physician-defined disease progression occurred in 6.1%–16.1% of patients, 19.4%–35.1% of patients experienced proxy-reported outcomes of potential disease progression (including oesophageal dilation performed in 10.8%–21.7% of patients) after EoE diagnosis. An

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. overview of patient and clinical characteristics at EoE diagnosis and treatment patterns and disease progression (physician-defined and proxy-reported) after EoE diagnosis across Germany, France, Spain, and the United Kingdom is provided in the *Table*.

Patient and clinical characteristics at eosinophilic oesophagitis diagnosis	Germany (N=96)	France (N=99)	Spain (N=97)	United Kingdom (N=93)
Male, n (%) / Age, years, mean (standard deviation)	78.1 / 32.0 (14.9)	72.7 / 27.8 (13.4)	70.1 / 32.2 (14.1)	72.0 / 33.9 (13.5)
Peak eosinophil count/ high-power field, mean (standard deviation)	35.3 (29.1)	39.5 (46.3)	46.1 (41.7)	43.3 (56.7)
Treatment patterns and disease progression (physician-defined and proxy-reported) after eosinophilic oesophagitis diagnosis				
Proton-pump inhibitors, n (%)	59 (61.5)	87 (87.9)	89 (91.8)	62 (66.7)
Swallowed topical corticosteroids (e.g., fluticasone budesonide), n (%) / Systemic (oral) corticosteroids, n (%)	79 (82.3) / 24 (25.0)	76 (76.8) / 7 (7.1)	55 (56.7) / 8 (8.3)	55 (59.1) / 4 (4.3)
Dietary modifications or eliminations, n (%)	53 (55.2)	41 (41.4)	46 (47.4)	41 (44.1)
Physician-defined disease progression, n (%)	12 (12.5)	6 (6.1)	7 (7.2)	15 (16.1)
Proxy-reported disease progression, n (%) / dilation performed, n (%)	26 (27.1) / 20 (20.8)	31 (31.3) / 16 (16.2)	34 (35.1) / 21 (21.7)	18 (19.4) / 10 (10.8)
Overall disease progression (Physician-defined OR Proxy-reported), n (%)	33 (34.4)	34 (34.3)	36 (37.1)	30 (32.3)

Table.

Conclusion: Adolescent and adult patients with EoE chronically experienced substantial disease burden. A subset demonstrated disease progression, perhaps underrecognised despite treatment with PPIs, STCs, and elimination diets. Hence, successful EoE management may include proactive disease monitoring, treating underlying pathophysiology and prescribing maintenance therapies to achieve long-term clinical remission.

Contact E-Mail Address: mario.ricchiuti0411@gmail.com

Introduction: Eosinophilic esophagitis (EoE) is a chronic Th-2 mediated inflammatory disease, closely associated with comorbid allergic disorders, including atopic dermatitis (AD). Studies show that EoE is associated with atopic disease but the prevalence of EoE symptoms in patients with atopic conditions is unknown. To date, a single retrospective study involving 80 atopic patients has shown that the prevalence of dysphagia in atopic patients without a known history of EoE is higher than the control population, while it failed to find a significant association between dysphagia and atopic eczema [1].

Therefore, in our study we evaluated the prevalence of dysphagia in a population of patients severe with atopic dermatitis, candidates to biological therapy, in order to consider the possibility of screening these patients for comorbid EoE.

Aims & Methods: Consecutive patients with moderate to severe AD referred to our tertiary care center from January to October 2023 were prospectively screened. Based on AD severity and phenotypic manifestation and comorbidities, patients were referred to systemic therapy with cyclosporine (CsA), biological drugs (dupilumab, tralokinumab) or JAK inhibitors (upadacitinib, abrocitinib, baricitinib). The presence of dysphagia was evaluated by using the self-administered Eosinophilic Esophagitis Score Activity Index (EEsAI). This score uses seven PRO (patient reported outcome) items that are used to assess characteristics of dysphagia, behavioral adaptations to living with dysphagia and pain while swallowing. The presence of other atopic disorders and esophageal symptoms was also recorded. Questionnaires were collected and analyzed at the gastroenterology department, while the dermatology consultant was blinded from the questionnaire results. Data are presented as mean±SD.

Results: 147 patients (85 M, 42.7±23) successfully completed the form. The prevalence of dysphagia in the population was low (7 patients, 4.7%). The prevalence of other atopic conditions was similar in dysphagia and non-dysphagia patients (42 vs 40%). Patients reporting dysphagia were more likely to have heartburn (28.5 vs 7.1%, p=0.043), while other esophageal symptoms did not differ. Based on clinical evaluation by a single experienced dermatology consultant (clinical phenotype of AD, AD severity and comorbidities), patients were assigned to either receive CsA (8 pts, 4 M, 41.7±18y), dupilumab (42 pts, 27 M, 39.6±21y), tralokinumab (21 pts, 11 M, 46.2±12.5y), or Jak inhibitors (76 pts, 43 M, 43±23y). The prevalence of dysphagia was significantly higher in the Dupilumab group as compared to other therapies (19 vs 1.9%, p=0.01), while other esophageal symptoms were comparable between the two groups.

Conclusion: We observed that the overall prevalence of dysphagia is relatively low in severe AD patients. However, we found a higher likelihood of complaining of dysphagia in the subset of patients who were candidate to treatment with Dupilumab. Due to the reported augmented risk for atopic patients to develop EoE, screening AD patients complaining of dysphagia before initiating biologic treatment is pivotal to prevent EoE under-diagnosis and under-treatment. Better characterizing the relationship between AD and EoE and a multidisciplinary approach to atopic patients will facilitate the optimal management to both conditions.

"THE PATH2 TASK FORCE": REAL-LIFE EXPERIENCE FROM A MULTIDISCIPLINARY TEAM APPROACH FOR EOSINOPHILIC ESOPHAGITIS

M. Ricchiuti[1], M. Pesce[1], A. Cefaliello[1], V. Catapano[1], M. Falco[1], M. Flaminio[1], M. Napolitano[1], A. Detoraki[1], M. Maniscalco[1], E. Cantone[1], G. Sarnelli[1]
[1]Univers. of Naples ´'Federico II', Dept. Clinical Medicine and Surgery, Naples, Italy

Contact E-Mail Address: mario.ricchiuti0411@gmail.com
Introduction: Eosinophilic esophagitis (EoE) is a Th2-related disease characterized by dysphagia and food impaction. EoE has been associated with several other atopic disorders, supporting the knowledge that it may represent a late manifestation of the so-called "atopic march". However; in everyday clinical practice, allergic comorbidities are rarely objectivized by means of specialist consultations and often rely on patients' self-reporting. This bears the risk of not fully recognizing the burden of Th2-related pathology, since EoE patients may outgrow some of the allergic diseases presenting during childhood; or, conversely, they could underestimate the presence and severity of Th2-diseases. To this aim, a multidisciplinary task-force involving multiple specialists was established at our university hospital, in order to systematically investigate newly referred EoE patients.
Aims & Methods: This is a cross-sectional observational study, involving consecutive EoE patients that were referred to our tertiary center from January 2022. We prospectively collected data about patients' clinical history, specifically recording the presence of Th2-related comorbidities. Each patient underwent an esophagogastroduodenoscopy with differential esophageal biopsies. After reaching a conclusive diagnosis of EoE, patients were referred to dermatology, ear, nose and throat specialist (ENT) for rhinofibroscopy, immunologist (performing prick test, as necessary) and respiratory consultant for spirometry.
Results: 40 EoE patients were included (34M, age 31±12 years), with a mean age of onset of 23±16 years. A clinical history of Th2-comorbidities was reported by 90% of the overall population with rhinitis being the most prevalent comorbidity (77.5%), while no patient reported Chronic Rhinosinusitis with Nasal Polyps (CRwNP). Asthma, food allergy and atopic dermatitis (AD) were reported in 15 (37.5%), 14 (35%) and 9 (22.5%) patients, respectively. Following the consultations, the presence of asthma, food allergy and AD did not significantly differ (37.5 vs 30%, 35 vs 45% and 22.5 vs 20%), since only 3 patients reporting a history of asthma did not confirm the diagnosis at spirometry and one patient with a history of AD had dermographic urticaria. On the contrary, following ENT consultation, 6 patients with rhinitis received the diagnosis of CRwNP (0 vs 15%, p=0.01). Overall, nearly 60% of patients had two comorbid Th2 disorders besides EoE and 25% of the whole population of EoE patients had 3 or more.
Conclusion: Our results clearly support the need for a multidisciplinary team approach to investigate the burden of Th2-related pathology in EoE patients. In our hands, the prevalence of Th2-related comorbidities was as high as 97.5% of EoE patients and up to 63% of our population had 2 or more allergic disorders. Furthermore, CRwNP is frequently under-reported and properly diagnosed only following rhinofibroscopy. This is further from being irrelevant when managing EoE patients. Indeed, it may guide the most appropriate choice of therapy by targeting multiple atopic manifestations at the same time, since many Th2-related diseases share common pathophysiological mechanisms and treatment.
Disclosure: Nothing to disclose.

RETROSPECTIVE ANALYSIS OF DIAGNOSIS OF EOSINOPHILIC OESOPHAGITIS IN A TERTIARY CENTRE

Y.J. Chew[1], K. Maqbool[1], A.M. Thant[1], A.K. Kurup[1]
[1]University Hospitals of North Midlands, Stoke-on-trent, United Kingdom, [2]Royal Stoke University Hospital, Dept. of Gastroenterology, Stoke on Trent, United Kingdom

Contact E-Mail Address: khawaja.maqbool@uhnm.nhs.uk
Introduction: Eosinophilic Oesophagitis (EOE) has a mean estimate of 63 new cases per 100,000 in the Western World and is in increasing prevalence[1]. It must be considered as a differential diagnosis amongst patients presented with dysphagia and food bolus obstruction. British Society of Gastroenterology (BSG) guideline recommends that patients undergoing endoscopy should have oesophageal biopsies taken if they have endoscopic signs associated with EOE or symptoms of dysphagia or food bolus obstruction with normal looking oesophagus. At least six biopsies should be taken from at least 2 different anatomical sites within the oesophagus for diagnosis of EOE[2]. (GDG recommendation).
Aims & Methods: A single-centre, retrospective analysis of patients presenting for an oesophagogastroduodenoscopy (OGD) with an indication of dysphagia or food bolus obstruction and coded as oesophagitis over the past 5 years was performed. The study was undertaken at a tertiary NHS Hospital Trust in West Midlands which provides hospital services for approximately 900,000 people[3].
Data was then collected for demographics, sedation, macroscopic findings, quality and location of biopsies as well as histology. This is measured against BSG recommendations.
Results: In total, 31 patients were included. 68% of patients were male and the mean age was 53 (range 14-90) 35% (n=11) had pharyngeal anaesthesia only, 16% (n=5) had midazolam and pharyngeal anaesthesia, 35% (n=11) had midazolam and fentanyl and 6% (n=2) had general anaesthesia (GA). Both patients who had GA were 14 and 15 years old. In terms of macroscopic findings, 61 % (n=19) had normal findings, 19% (n=6) had oesophagitis, 10 % (n=3) had EOE changes and 3% (n=1) had benign stricture with the same number for achalasia and tertiary contraction. 81% (n=25) had biopsies taken from at least 2 different anatomical sites and 32% (n=10) had more than 6 biopsies taken in total. There were 29 % (n=9) patients with a histological diagnosis of EOE, 29% was normal, 29% (n=9) had inflammation, 6% (n=2) had gastric metaplasia, 3% (n=1) had basal hyperplasia with 7-8 eosinophils per high-power field (HPF) and 3% (n=1) had basal hyperplasia with lymphocytic infiltration. In all patients with EOE, the histopathological report explicitly documented the presence of >15 eosinophils per HPF.
Conclusion: Our data suggest that our practice for diagnosis of EOE falls short of national recommendation, both in the number of anatomical sites and the number of biopsies taken. In terms of histopathology, we have adhered to the recommended diagnostic criteria of >15 eosinophils per HPF. Further work must be done to improve awareness and adherence to the guidelines for the diagnosis of this treatable condition.

ESOPHAGEAL BIOPSY SAMPLING AMONG PATIENT WITH DYSPHAGIA. TO BITE OR NOT TO BITE?

T. Alexopoulos[1], T. Voulgaris[1], J. Vlachogiannakos[1], D. Kamberoglou[1], A. Koutsoumpas[1], K. Papaxoinis[1], P. Fytili[1], G. Papatheodoridis[1], G. Karamanolis[1]
[1]*National and Kapodistrian Unversity, Laiko General Hospital, Department of Gastroenterology, Athens, Greece*

Contact E-Mail Address: georgekaramanolis@yahoo.co.uk

Introduction: Dysphagia is a very common symptom and entities such as Eosinophilc Esophagitis (EoE) or an esophageal motility disorder can be its basis. A controversy among guidelines when approaching a patient with dysphagia exists, as it is mandated to obtain esophageal sampling when EoE is sought but is not a prerequisite for motility disorders diagnosis. Therefore, the necessity of esophageal sampling is based on endoscopists' assessment.

Aims & Methods: Aim of our study was to search for factors driving clinicians to obtain esophageal biopsies among patients with dysphagia. Secondary aim was to search for the incidence of EoE and factors correlated with EoE diagnosis among patients with dysphagia.

We included consecutive patients presented with dysphagia during a 6-year period (1/2018-12/2023). We excluded patients with a history of; esophageal stenosis, esophageal motility disorders, metastatic disease, EoE, esophageal/gastric cancer, carcinoma that could impair esophageal motility, bone/food impaction, caustic agent ingestion, esophagogastric surgeries as also severely immune-compromised patients (HIV, recently transplanted).

Furthermore, 58 patients were excluded as they showed endoscopic evidence of another disease that could explain patients' symptoms. Epidemiological, endoscopy and histological data were collected and analyzed.

Results: We included 63 patients (M/F: 29 (46.0%)/34 (54.0%), mean age 64±19 yrs). A history of dysphagia > 6 months was reported by 51 (80.9%), while <6 by 11 (19.1%). During the endoscopy; 7 (11.1%) had findings supportive of EoE, and 56 (89.9 %) had normal endoscopy. Biopsies were obtained by 30/63 (47.6%).

Significant higher rates of biopsy sampling were seen among patients <65 years old and with endoscopic EoE signs, while dysphagia duration and sex did not affect sampling. In the multivariate analysis only age, but not endoscopic findings compatible to EoE, drove clinician decision to obtain biopsies. (Table)

We were able to retrieve the histology report of 29/30 patients. EoE was diagnosed in 4/29 (13.8%). All patients with EoE were male (4/14, 28.6% vs female 0/15, 0% p=0.042). Existence of compatible endoscopic signs (3/6, 50% vs normal endoscopy 1/23, 4.3% p=0.020) was correlated with EoE diagnosis but age (<65 years old 4/22, 18.7% vs <65 year old 0/7, 0% p=0.307) and longstanding dysphagia (4/25, 16% vs female 0/4, 0% p=0.533) were not.

Factor	Biopsy sampling among patients with Dysphagia (patients without endoscopic findings other than EoE that could explain patients symptoms)		
		Univariate p	multivariate p
Younger than 65 years 65 years and older	25/35, 75.4% 5/28 17.9%	<0.001	<0.001 OR: 0.092, 95% C.I.: 0.025-0.339
Male Female	12/29 41.4% 18/34 52.9%	0.450	
Findings compatible to EoE Normal endoscopy/other findings	7/7 100% 23/56 41.1%	0.004	0.099 OR: 21.327, 95% C.I.: 18,298-35.474
history of dysphagia <6 months history of dysphagia>6 months	5/11 45.5% 25/52 48.1%	0.989	

Conclusion: Clinician obtain esophageal biopsies in less than 50% of patients with dysphagia. Endoscopic findings supportive of EoE and most importantly age seem to drive their decision. The rate of EoE among patients with dysphagia and esophageal sampling is not negligible and is more commonly observed in young males with longstanding dysphagia and compatible endoscopic findings.

Disclosure: Nothing to disclose.

ENDOSCOPIC INDICATORS OF INSULIN RESISTANCE: ASSOCIATIONS WITH EROSIVE ESOPHAGITIS AND REGULAR ARRANGEMENT OF COLLECTING VENULES (RAC)

H. Hong[1], H.T. Lee[1], J.-y. Seo[1]
[1]*Bundang Jesaeng General Hospital, Gastroenterology, Seongnam-si, South Korea*

Contact E-Mail Address: whoim1020@nate.com

Introduction: With the increasing westernization of lifestyles, there has been a significant rise in obesity, leading to a growing interest in metabolic syndrome and insulin resistance. Identifying indicators of insulin resistance through endoscopic findings could be valuable in assessing a patient's systemic metabolic status. Thus, we conducted a retrospective study to explore the association between endoscopic findings and insulin resistance.

Aims & Methods: We retrospectively investigated the patients who underwent screening endoscopy at Bundang Jesaeng General Hospital between February and June 2023. We excluded patients who were not tested for insulin resistance. Insulin resistance was defined using Homeostatic Model Assessment for Insulin Resistance ($HOMR_{IR}$), with a value above 1.9. We also assessed the *Helicobacter pylori (H. pylori*) status using rapid urease test, and history of previous eradication into current infection, non-infection, and past infection. To ensure balanced variables between the two groups, we performed propensity score matching (1:2 ratio) based on age and *H. pylori* status. Multivariate analysis was performed to investigate the association between the endoscopic features and insulin resistance.

Results: Following propensity score matching, we selected 210 patients with insulin resistance and 420 patients without insulin resistance were selected. In baseline characteristics, age and *H. pylori* status were balanced between the two groups. Prior to propensity score matching, endoscopic findings including erosive esophagitis, RAC (regular arrangement of collecting venules), atrophy, and diffuse redness appeared to be significant associated with insulin resistance. However, after matching, only erosive esophagitis remained significantly associated with insulin resistance. Furthermore, the severity of erosive esophagitis showed positive correlation with the degree of insulin resistance, as indicated by increased $HOMA_{IR}$. Multivariate analysis demonstrated that erosive esophagitis (OR 1.81, p = 0.010) significantly raised the risk of insulin resistance while RAC was associated with a lower risk of insulin resistance (OR 0.68, p = 0.032).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our study showed an obvious correlation between insulin resistance and erosive esophagitis, as well as RAC among the endoscopic findings.

Moreover, we observed a proportional relationship between the severity of erosive esophagitis and the degree of insulin resistance. Multivariate analysis showed that erosive esophagitis and RAC were significantly associated with the insulin resistance.

These findings suggest that individuals with erosive esophagitis and without RAC should undergo metabolic evaluation to assess their insulin resistance status. Further research is warranted to explore the underlying mechanisms and potential implications of these associations.

THE EPIDEMIOLOGY AND SYMPTOMATIC CHARACTERISTICS OF REFLUX ESOPHAGITIS SUBGROUPS BASED ON THE LYON 2.0 CONSENSUS: A POPULATION-BASED STUDY

K. Wang[1], L. Duan[2], N. Hu[2], Z. Liu[3]

[1]Peking University Third Hospital, Department of Gastroenterology, Beijing, China, [2]Peking University Third Hospital, Beijing, China, [3]Peking University Third Hospital, Gastroenterology, Beijing, China

Contact E-Mail Address: wangkun55555@sina.com

Introduction: Reflux esophagitis (RE) can present typical symptoms, atypical symptoms or asymptomatic. The proportions and epidemiology characteristics of these three symptomatic patterns of RE has not been clarified. The Lyon 2.0 consensus provides new conclusive criteria for RE diagnosis and adjusts the symptom spectrum. Thus, the RE subgroups were redefined.

Aims & Methods: The aim of this study was to clarify the prevalence and symptomatic characteristics of RE subgroups based on the update Lyon 2.0 consensus in a Chinese population. An Endoscopic Screening for Esophageal Cancer in China (ESECC) randomized controlled trial was initiated in Hua County in January 2012, a gastroesophageal reflux disease (GERD) database was constructed. This data was reviewed to analyze the subgroups of RE based on the Lyon 2.0 consensus. RE were divided into three subgroups: typical reflux symptoms (TSRE), atypical symptoms (ASRE) and asymptomatic RE (ARE). The rest esophagitis was inconclusive-GER esophagitis. Chi-square test was used for differences between groups.

Results: In this study, 2916 residents were enrolled. 271 (9.29%) participants had esophagitis, among them, 143 (4.87%) fulfilled the conclusive RE diagnosis based on the Lyon 2.0 consensus. In RE, 97 (67.83%) was TSRE, 11(7.69%) was ASRE and 35 (24.48%) was ARE. 115 esophagitis belonged to inconclusive-GER esophagitis group. The age (≥60 years), male sex, Body Mass Index (BMI) (≥24 kg/m^2), and smoking were risk factors for TSRE. Smoking was also a risk factor for ARE (OR [95%CI]:4.521 (1.448, 14.113)).

Conclusion: This population-based study reported that 9.29% of residents had erosive esophagitis. The point prevalence rate of RE was 7.75%, according to the updated Lyon 2.0 consensus. ARE LA-B and non-RE EE are common. Smoking is a risk factor for ARE. The findings of this study can be beneficial in the diagnosis, prevention, and establishing the screening system for RE. A well-designed screening strategy and long-term follow-up study should be conducted for ARE and non-RE EE in the future.

Introduction: Gastroesophageal reflux disease (GERD) is a prevalent digestive disorder characterized by the symptoms of heartburn and regurgitation. In recent years, the epidemiological characteristics of GERD have been studied due to its increasing prevalence and associated issues.

Aims & Methods: In the current study, we aimed to evaluate the prevalence of GERD among the Prospective Epidemiological Research Studies (PERSIAN) Guilan Cohort study (PGCS) population. This cross-sectional study was conducted on the PGCS population in Guilan, Iran. Demographical data and clinical characteristics of individuals were recorded, and a specialist applied the diagnosis of GERD. The association between variables and GERD was evaluated using SPSS version 17 based on a significant level <0.05.

Results: Out of 10520 participants, 5633 were female, and the mean age of individuals was 51.52±8.9 years. The prevalence of GERD was 13.2% and it was most prevalent among females. The frequency of GERD was higher in unemployed individuals, individuals with a higher level of education, body mass index (BMI), higher waist-hip ratio (WHR), and a lower level of physical activity. In addition, patients with a higher number of underlying diseases, a history of hypertension, and the use of non-steroidal anti-inflammatory drugs (NSAIDs) had a higher prevalence of GERD (P<0.05). The multivariate analyses revealed that females, urban residents, and individuals with higher levels of education had greater odds of GERD (P<0.05). Moreover, with the increase in the number of underlying diseases, the odds of having GERD increased (P<0.001).

Conclusion: Our findings showed factors such as female gender, higher level of education, urban residency, and higher number of underlying diseases were associated with increased risk of GERD. Identifying the associated factors will allow specialists to better diagnose and control the GERD.

Contact E-Mail Address: pedronunesml@gmail.com

Introduction: The incidence of esophageal adenocarcinoma has been increasing in Western countries, with gastroesophageal reflux (GERD) and Barrett's esophagus (BE) being important risk factos for such diagnosis. In Portugal, the current prevalence of reflux esophagitis and BE is unknown, and the aim of this study is to clarify these points.

Aims & Methods: A multicenter cross-sectional study including 13 national digestive endoscopy units, involving patients who underwent upper endoscopy from January to March 2024.

Results: 6320 patients were included (57% female, mean age 58). Reflux esophagitis was identified in 1105 patients (17% of the exams, 54% male, mean age 57) (Los Angeles Grade A 10.1%; B 5.6%; C 1.1%; D 0.4%) and 46 with BE (0.7% (95%CI 0.05-1%), 67.4% male, mean age 59 years), with only 4 (0.06% of the total) having 3 cm or more of extension.

The prevalence of BE was higher in the Lisbon region (1.35% vs 0.5%, p<0.05), with no difference in the prevalence of reflux esophagitis. Among patients who underwent endoscopy for GERD symptoms, 38% had erosive esophagitis (p<0.05 vs the rest of the population).

Among patients with esophagitis and BE, 27% and 39%, respectively, underwent endoscopy for symptoms and/or surveillance related to GERD (vs 11.6% of the rest of the population, p<0.05), with a prevalence of BE in patients with GERD of 2.3% (95%CI 2.1-2.5%, p<0.05 vs the rest of the population). Male gender was a risk factor for grade C/D esophagitis and BE (p<0.05).

Conclusion: Erosive esophagitis is common in Portugal, particularly in patients undergoing endoscopy for GERD symptoms. However, the prevalence of BE, particularly long segment BE, remains low compared to other Western countries, despite similar values of reflux esophagitis. This trend may be reversing in Lisbon with a higher prevalence of BE. Further studies are necessary to better understand these differences.

Disclosure: Nothing to disclose.

Introduction: Gastro-esophageal reflux disease (GERD) is a multifactorial disease that manifests in patients with different degrees of anti-reflux barrier impairment. GERD significantly impacts quality of life despite the fact that symptom burden may not always correlate with disease severity. Precise pathophysiologic evaluation can identify patients with actionable GERD who may benefit from anti-reflux surgery or escalation of medical therapy.

The Milan Score, a novel high-resolution manometry (HRM) metric, numerically quantifies the degree of anti-reflux barrier disruption[1]. While the Milan Score has been proven to predict pathologic GERD, its ability to distinguish non-severe from severe GERD and to identify patients with a higher grade of anti-reflux barrier disruption requires further study.

Aims & Methods: A database of prospectively collected data from a cohort of patients undergoing HRM and pH-study for persistent GERD symptoms was queried. Using Lyon 2.0 consensus, pathologic GERD was defined as AET >6%, grade B-C-D esophagitis or Barrett's esophagus on endoscopy. Severe reflux was defined as AET >12%, DeMeester score >50, grade C-D esophagitis or Barrett's esophagus[2].

Demographic, HRM and pH data were extracted, classified and compared between groups with varying GERD severity (no GERD, non-severe GERD, severe GERD). The Milan Score integrates the main manometric parameters related with the pathophysiology of GERD (ineffective esophageal motility, esophago-gastric junction (EGJ) contractile integral, EGJ morphology and straight leg raise maneuver response).

In order to simplify the use of the Milan Score, risk rates have been classified into six categories, from extremely unlikely to extremely likely. A cumulative odds ordinal logistic regression was run to determine the independent effect of HRM variables on reflux severity. The ability of the Milan Score to predict severe reflux was assessed, as well as its association

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. with the pH-study criteria proposed by Lyon 2.0 as adjunctive evidence for pathologic GERD (>80 reflux episodes, mean nocturnal baseline impedance (MNBI) <1500 W or positive reflux-symptom association).

Results: Among 603 patients enrolled (median age 49.9 years, median body mass index (BMI) 25.3 Kg/m^2, 50.5% males), 124 (20.6%) had non-severe and 142 (23.5%) had severe GERD. Non-severe and severe GERD patients had similar demographic and clinical characteristics, but were significantly different from the no-GERD group (Table). On univariate analysis, presence and size of hiatal hernia, Milan Score and Milan Score categories were significantly different among the groups (p <0.001). On ordinal logistic regression, hiatal hernia size and Milan Score category were found to be independent predictors of GERD severity (OR 1.28, 95% CI, 1.04-1.57, p=0.018 and OR 2.92, 95% CI, 2.47-4.45, p=<0.001 respectively). A significantly higher Milan Score (p <0.001) was found in patients with >80 reflux episodes, MNBI <1500 W, positive reflux-symptom association and any criteria of severe GERD.

	Total (n=603)	No GERD (337)	Non severe GERD (n=124)	Severe GERD (n=142)	p-value
Female, n (%)	282 (49.5)	178 (56.2)a	54 (45.4)a,b	50 (37.3)b	<0.001
Age, (years)	49.9 (14.6)	48.6 ±15.9 a	51.4 ± 13.5 a,b	52.0 ± 14.2 b	0.044
BMI, (Kg/m^2)	25.3 (5.8)	24.7 ± 23.8 a	25.9 ± 5.6 b	26.3 ± 5.1b	<0.001
PPI use, n (%)	450 (79.8)	232 (73.9)a	105 (89.7)b	113 (85.0)b	<0.001
PPI non responders, n (%)	139 (30.6)	88 (37.4)a	31 (29.2)a,b	20 (17.7)b	0.002
EGD hiatal hernia, n (%)	327 (59.2)	145 (47.9)a	84 (71.8)b	98 (74.2)b	<0.001
EGD Esophagitis, n (%)	168 (30.6)	60 (19.9)a	42 (36.2)b	66 (50.0)b	<0.001

Conclusion: Hiatal hernia size and Milan Score assessed at HRM are independent factors associated with severe GERD. The Milan Score is significantly higher in patients with pathologic adjunctive pH-impedance metrics and in patients with severe GERD.

Introduction: Gastroesophageal Reflux Disease (GERD) is a common condition diagnosed by endoscopy and/or pH monitoring. However, only high-resolution manometry (HRM) provides detailed assessment of the pathophysiology underlying reflux mechanisms and GERD symptoms. While it is widely accepted that esophago-gastric junction (EGJ) type 3 is a strong predictor of GERD, EGJ type 2 is less clearly implicated in GERD pathogenesis[1]. This study aimed to investigate the clinical and physiological characteristics of patients with EGJ type 2 and to identify HRM variables that predict GERD in this category of patients.

Aims & Methods: 535 patients with suspected GERD who underwent HRM and reflux monitoring were retrospectively analyzed. Patients were divided into three groups based on EGJ morphology (type 1, 2, or 3). Clinical data, HRM parameters, and reflux study results were compared among groups. The Milan Score[2], a novel metric that integrates ineffective esophageal motility (IEM), EGJ-contractile integral (EGJ-CI), EGJ morphology and straight leg raise (SLR) response, was applied to the EGJ type 2 group to identify patients at higher risk of developing GERD. Pathologic GERD was defined as AET >6% on pH-impedance monitoring and/or stricture, Barrett's esophagus or Los Angeles grade B, C or D, or at endoscopy. As previously demonstrated, a Milan Score of 137 (risk rate 50%) or higher was considered pathologic. Receiver operating characteristic (ROC) analysis was performed to determine Milan score prediction of GERD within patients with EGJ type 2 morphology.

Results: Patients with EGJ type 3 had the highest rate of GERD diagnosis, followed by EGJ type 2 and type 1 (p <0.001). HRM showed differences in EGJ-CI, proportion of patients with IEM and positive SLR response among groups (p <0.001). Reflux monitoring revealed a stepwise increase in AET from type 1 to 3 (5.1±7.3 vs. 8.3±11.1 vs. 12.2±11.3, p <0.001). A pathologic

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Milan Score identified two subgroups of patients within the EGJ type 2 group: patients with a score below 137 resembled type 1, while those with a score of 137 or higher resembled type 3 in terms of pH monitoring characteristics (*Table*). On ROC analysis the area under the curve was 0.858, and the optimal threshold to identify pathologic GERD in this group was 137 points (sensitivity 77.3%, specificity 87.7%).

	EGJ type 1 (n=277)	EGJ type 2 with MS<137 (n=93)	EGJ type 2 with MS≥137 (n=85)	EGJ type 3 (n=80)	P-value
AET (%), mean (SD)	5.1 (7.3)[a]	3.9 (5.8)[a]	13.2 (13.3)[b]	12.2 (11.1)[b]	<0.001
4%<AET<6%, n (%)	35 (12.6)	14 (15.1)	7 (8.2)	6 (7.5)	0.305
AET > 6%, n (%)	72 (26.0)[a]	12 (12.9)[a]	69 (81.2)[b]	62 (77.5)[b]	<0.001
DeMeester score, mean (SD)	21.7 (30.3)[a]	15.7 (23.2)[a]	55.0 (53.0)[b]	45.3 (39.5)[b]	<0.001
Total reflux ≥80, n (%)	37 (13.4)[a]	12 (12.9)[a]	24 (28.2)[b]	25 (31.3)[b]	<0.001
MNBI <1500 Ω, n (%)°	36 (21.8)[a]	11 (20.0)[a]	35 (66.0)[b]	39 (59.1)[b]	<0.001
PSPW <50%, n (%)°	54 (32.7)[a]	18 (32.3)[a]	39 (75.8)[b]	51 (77.2)[b]	<0.001

Conclusion: Our data suggests that EGJ type 2 encompasses a wide spectrum of disease severity. The Milan Score with a cut-off of 137 may help to identify patients with EGJ type 2 who are more likely to demonstrate pathologic GERD on reflux monitoring.

Introduction: Dietary and lifestyle recommendations are the cornerstones of the treatment of GERD. However, the evidence of the efficacy of those recommendations is lacking. We performed a retrospective analysis of the GISTAR study[1] participants evaluating the symptoms of GERD and dietary and lifestyle parameters developing a tool for predicting GERD symptoms based on the aforementioned criteria.

Aims & Methods: The aim of the study was to analyse the factors pointing to GERD symptoms through the use of data mining and decision tree classifier.

Methods: GERD diagnosis was evaluated using a self-assessment questionnaire[2]. Dietary, demographic and lifestyle data were collected within the GISTAR study protocol[1]. 3340 40-64 year old participants from the GISTAR study were included in the analysis. 1670 of them did not have GERD symptoms. 41 attributes describing demographic, lifestyle, and dietary habits were used for these respondents to induce a decision tree classification model using Orange Data Mining software[3].

Results: Fried potatoes including French fries were the most predictive factor of GERD symptoms (65.3% with symptoms; 1516 from 2321), especially for females (82.6%; 1048/1228). This was more pronounced in the group who consumed sweets once per week (87.2%, 950/1090). In males, who consumed fried potatoes, the next most important factor was the consumption of sweets (46.3%, 431/930).

For participants who didn't consume fried potatoes (14.6%; 147/1008), 1-3 cups of green tea (37.9%; 66/174) and male gender (71.4 % 20/28) were predictors of GERD symptoms.

The accuracy of the decision tree model was: sensitivity (74.8%), precision (75.6%), specificity (75.9%) and AUC (0.841%).

Conclusion: Fried potatoes, female gender and consumption of sweets are the risk factors predicting the diagnosis of GERD. None of the lifestyle factors were displayed as significant.

IMPAIRED MUCOCILIARY CLEARANCE IN LARYNGOPHARYNGEAL REFLUX DOES NOT REFLECT THE AMOUNT OF GASTROESOPHAGEAL REFLUX

Introduction: Gastroesophageal reflux is responsible for various extresophageal symptoms that are commonly labelled as laryngopharyngeal reflux (LPR). These mostly include cough, throat clearing, globus sensation and hoarseness. The pathophysiological link between reflux and symptoms likely includes direct effect of the refluxate on the upper airways epithelium and reflex that is initiated by stimulation of the afferent nociceptive fibres in the distal esophagus by acidic gastroesophageal reflux.

Arguably, the relationship between reflux and laryngopharyngeal symptoms might involve other, yet not well explored mechanisms. In our previous research we found that LPR patients have impaired mucociliary clearance of the respiratory epithelium of the upper airways. This could contribute to the inflammation persistence and the presence of symptoms.

We therefore aimed to determine whether any parameter of the reflux burden as detected by 24-hour pH/impedance correlates with ciliary beat frequency (CBF), the major quantifiable aspect of mucociliary clearance.

Aims & Methods: Consecutive patients with LPR confirmed by off PPI 24-hour pH/impedance had a sample of the ciliated epithelium obtained from the nose using a cytology brush. Nasal CBF was analysed using a digital high-speed video microscope and the dedicated software application Ciliary Analysis (NI LabVIEW). Healthy volunteers without either esophageal or extraesophageal reflux symptoms served as a control group. Both patients' and healthy volunteers' group were without any airway inflam-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. mation at least 3 months prior to the evaluation and were at least 10 days of PPI therapy. Maximal, minimal, and the median value of the CBF (Hz) was obtained. We performed correlation analyses between the acid exposure time (AET), number of reflux episodes, mean nocturnal baseline impedance (MNBI) in all impedance segments (Z1-Z6) and CBF values.

Results: 32 patients with LPR confirmed by 24-hour pH/impedance that had positive reflux symptom index (RSI>13) were included in the final analysis. Of them, 12 patients had confirmed by positive acid exposure time (AET>6%) and/or abnormal number of reflux episodes (>80). Firstly, we confirmed our previous observations that LPR patients had lower CB frequency (median value) compared to the healthy individuals (6,37±2,17 vs. 10,9±1,9; p<0.0001). Separate analysis of patients with proven GERD showed no CBF difference from the remaining (pH negative patients) (6,26±2,53 vs. 6,43±1,94; p=0,42). Secondly, we performed correlation analysis between AET/number of reflux episodes and CBF. We found no significant correlation between reflux burden and median value of CBF (N=32, R=-0.18, p=NS and R=0.05, p=NS for AET and number of refluxes, resp.). Thirdly, we performed correlation analyses between CBF and MNBI values of all impedance segments. Indeed, correlation analysis between median CBF and MNBI Z1-Z6 showed no significant correlations (N=32, R=-0.16, 0.09, 0.28, 0.01, 0.14 for Z1, Z2, Z3, Z4, Z5, Z6, resp., resulting in p=NS in all segments).

Conclusion: pH positive LPR patients had no difference in CBF values from the remaining (pH negative) patients. Reflux burden in the esophagus as determined by pH recording does not seem to be related to ciliary beat frequency. We observed no significant correlation between the MNBI values in any impedance segment and the median CBF value. Further research should be performed to determine the putative mechanism between the impairment of CBF and reflux.

Introduction: Gastro-oesophageal reflux disease (GORD) is a common disorder with a prevalence of 10-20%. It occurs from disruption of the gastro-oesophageal flap valve (GFV) and/or a diaphragmatic abnormality causing a hiatus hernia (HH). Transoral incisionless fundoplication (TIF2.0) using the EsophyX device (Endogastric solutions) is an endoscopic treatment for GORD, which recreates the GFV through a partial 270º wrap. Prospective trials show the procedure is safe and effective and is recommended in North American guidelines, yet the experience of TIF is limited in Europe.

Aims & Methods: We conducted a UK-based, retrospective, cohort study to determine the safety and efficacy of TIF2.0. Patients undergoing TIF2.0 by a single operator were identified and analysed between 2019-2023. Patient demographics, reflux assessments (GERD-HRQL, endoscopy, pH testing), and procedural details were recorded. Primary outcomes were technical success and clinical response defined as complete (off regular anti-acid therapy) or partial (reduction from baseline in anti-acid therapy, GERD-HRQL score, and/or physiological parameters) without the need for revision. Secondary outcomes were adverse events and changes in reflux parameters measured by Wilcoxon signed-rank test. A p-value <0.05 was significant.

Results: In total, 81 patients underwent TIF2.0 with 92.0% on oral anti-acid therapy. Median age was 51 (IQR 37-64), 23 (28.4%) were female, and the median ASA grade was 1 (IQR 1-2). A HH was present in 84.6% with an average size of 1.9cm (SD 0.5). The average acid exposure time (AET) was 8.9% (SD 4.1; n=61). The clinical outcomes are summarised in table 1. Technical success was 97.5% (n=79) with an average procedural time of 38.0 minutes (SD 10.3), and 1-day (IQR 1) inpatient stay. The device could not pass the cricopharynx in two patients despite routine balloon dilatation. Over 15.5 months of median follow-up (IQR 7-24), 55% had a complete response, and 71.7% partial response. On logistic regression analysis, no variables were predictive of response. Among those with paired pre-/post-testing, the average GERD-HRQL score reduced significantly (33.9 ±18.6 to 9.1 ±9.2; P<0.001) as well as the average AET (8.9 ±4.1 to 5.1 ±4.0; P=0.005) post-procedure. Procedure or device-related adverse events occurred in 12.2% (n=10), which were all managed conservatively. The single perforation was delayed and managed with intravenous antibiotics and endoscopic vacuum therapy. Seven patients underwent a revisional procedure, including two surgical fundoplications, with 83.3% due to recurrent HH.

Procedure time in minutes (SD)	38.0 (7.2)
Technical success (%)	79 (97.5)
Inpatient stay (IQR)	1 (1)
Complete response*	33 (55.0)
Partial response†	43 (71.7)
Follow-up in months (IQR)	15.5 (7-24)
Repeat procedure (%)	7 (8.6)
Adverse events (%)‡	10 (12.2)

IQR – interquartile range; ; SD – standard deviation
* Off all regular anti-acid therapy (respondents during follow-up: n=60)
† Reduction from baseline in anti-acid therapy, symptomatology based on HRQL-GERD questionnaire, and/or physiological parameters (respondents during follow-up: n=60)
‡ Mucosal injury (n=1), chest infection (n=3), perforation (n=1), leak/collection (n=1), bleeding (n=1), dysphagia (n=2), admission for nausea and vomiting (n=1).

Table 1 - Clinical outcomes among patients undergoing Transoral Incisionless Fundoplication 2.0

Conclusion: TIF2.0 is associated with technical success in 97.5%, clinical response in 71.7%, and significant improvements in GERD-HRQL and AET. Recurrent HH is a frequent cause of failure showing the importance of patient selection and/or need for concomitant HH repair.

INDEPENDENT MEDICAL EDUCATION SIGNIFICANTLY IMPROVES PHYSICIANS KNOWLEDGE, CONFIDENCE AND COMPETENCE REGARDING THE LONG-TERM MANAGEMENT OF REFLUX AND DEPRESCRIBING PROTON PUMP INHIBITORS

J. Duffey[1], A. Piazza[2], K. Reid[2], G. Griffiths[2], P.J. Kahrilas[3], A.P. Hungin[4]
[1]Medscape Global Education, Clinical Strategy, London, United Kingdom, [2]Medscape Global Education, London, United Kingdom, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, United States of America, [4]Newcastle University, UK, Medicine, Stockton-on-Tees, United Kingdom

Contact E-Mail Address: kreid@webmd.net

Introduction: Proton pump inhibitors (PPIs) are widely prescribed open-ended fashion, but in an estimated 25-82% of patients this may be inappropriate.[1, 2] Chronic PPI use is associated with an increased risk of specific adverse events including pneumonia, dementia, and osteoporotic fractures although no causal relationships have been established.[3] However, recent surveys have found that among physicians who regularly prescribe PPIs, a considerable proportion were unfamiliar with deprescribing strategies.[2] Here, we assessed whether an 30-minute online independent medical education activity could improve primary care physicians' (PCPs) and gastroenterologists' knowledge, confidence and competence regarding the long-term management of reflux and PPI deprescribing.

Aims & Methods: Educational effect was assessed using a repeated-pairs design with pre-/post-assessment. Three multiple choice questions assessed knowledge, and one question assessed confidence. Statistical tests to assess significance included: Paired samples t-test for overall average number of correct responses and confidence. McNemar's test for individual questions and learning objectives (P <.05). Cohen's d estimated the effect size impact on number of correct responses (<.20 modest, .20-.49 small, .59-.79 moderate, ≥.80 large).

Results: From a total of 3422, there were 359 assessment completers. Overall, there were highly significant and impactful knowledge gains for both groups of physicians (PCPs P <.001, Cohen's d = 0.87; Gastroenterologists P <.001, Cohen's d = 1.02). For PCPs, the highest relative proportional change in knowledge was for the extent of PPI overuse and misuse at 161% with 38% of physicians improving their knowledge (P<.001). Whilst for gastroenterologists the highest relative proportional change was seen regarding the implications of PPI overuse at 277% with 37% of physicians improving knowledge following the activity (P<.001). Significant increases in physician competence in best practice in PPI deprescribing were found (P<.001 for both), despite high baseline levels of competence. A considerable proportion of PCPs (51%; confidence shift 69%; P <.001) and gastroenterologists (39%; confidence shift 52%; P <.001) increased their confidence regarding their ability to use appropriate management strategies to reduce or discontinue a patient's use of PPI therapy.

Conclusion: Online medical education significantly improved physicians' knowledge, confidence and competence regarding the extent and implications of PPI overuse and best practice in the long-term management of reflux and PPI deprescribing. As PPI prescribing is prevalent and long-term use is common, it is important that physicians understand appropriate indications and implications associated with over and long-term use and are also able to undertake clinically appropriate deprescribing approaches.

PATIENT-REPORTED OUTCOMES OF VONOPRAZAN IN CHINESE REFLUX ESOPHAGITIS PATIENTS: A REAL-WORLD, OBSERVATIONAL STUDY

Y. Xiao[1], Z. Xue[2], X. Li[3], Q. Song[4], L. Xie[5], M. Chen[1]
[1]The First Affiliated Hospital, Sun Yat-Sen University, Guang Zhou, China, [2]The Second Affiliated Hospital of Wenzhou Medical University, Wen Zhou, China, [3]Henan Provicial People's Hospital, Gastroenterology, Zheng Zhou, China, [4]Takeda Pharmaceutical Company, Shang Hai, China, [5]Takeda Pharmaceutical Company, BeiJing, China

Contact E-Mail Address: qi.song@takeda.com

Introduction: Reflux esophagitis (RE) is a common, chronic disorder characterised by the mucosal break with symptoms such as heartburn and/or acid regurgitation. Patient-reported outcomes (PROs) offer more comprehensive access to the symptoms and impact on RE, which is a widely used treatment option that is effective from the patient's perspective. Vonoprazan is a novel potassium competitive acid blocker, approved in China for treating RE since 2019. Here, we present the PROs of vonoprazan in Chinese RE patients.

Aims & Methods: VIEW (NCT04501627) is a multicenter, single-arm, prospective, observational, real-world study to evaluate the safety and effectiveness of Vonoprazan. The subgroup analysis of VIEW was designed to assess the effectiveness of vonoprazan in patients with endoscopically confirmed RE. All patients were treated with 20 mg vonoprazan orally q.d. for 4 weeks (continued for 8 weeks if the patient did not show any beneficial effects) followed by a safety follow-up for 2 weeks.

All the patients were assessed for symptomatic relief by PROs which included patient symptom diary (percentages of patients with complete relief of heartburn, nocturnal heartburn, regurgitation, and nocturnal regurgitation) and GERD questionnaire (GerdQ) scores.

Results: Out of 1040 endoscopy-confirmed RE patients, 935 (89.90%) patients were with mild RE (LA grade A/B) and 105 (10.09%) patients were with severe RE (LA grade C/D). For all RE patients with heartburn, night-time heartburn, regurgitation, and night-time regurgitation at enrollment, the percentages of patients with complete symptomatic relief during the first one-week of treatment were 35.1%, 47.2%, 29.5%, and 43.6% respectively; while during first two-weeks of treatment, the respective percentages were 60.7%, 71.3%, 52.3%, and 65.0%.

Higher percentages were observed in patients with complete night-time heartburn or night-time regurgitation. Among subgroups, severe RE patients exhibited marginally higher percentages than mild RE patients (severe RE: 44.9%, mild RE: 33.7%), (severe RE: 52.2%, mild RE: 46.5%), (severe RE: 39.7%, mild RE: 28%) (severe RE: 47.1%, mild RE: 43.1%) during first one-week of treatment. A similar trend of symptomatic relief in severe RE patients was observed during the first two-weeks of vonoprazan treatment compared to mild RE patients (Table 1).

The proportion of patients without typical GERD symptoms increased by 36.9% (95% CI: 32.79, 41.10), 36.7% (95% CI: 32.29, 41.09) and 39.3% (95% CI: 26.84, 51.78) for all RE, mild RE and severe RE patients, respectively, at week 4 compared to baseline. The total change in GerdQ scores from baseline to week 4 (mean (SD)) were −1.7 (2.76) (95% CI: −1.85, −1.48) in

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Contact E-Mail Address: josephcooney@doctors.org.uk

Introduction: Gastro-oesophageal reflux disease (GORD) affects 25% of adults and impairs quality of life. Initial treatment is with lifestyle change and acid suppression however up to 1/3 will be refractory or intolerant to medical therapy. The Stretta procedure is an endoscopic treatment delivering radiofrequency energy around the gastro-oesophageal junction (GOJ). Whilst it can improve symptoms and reduce oesophageal acid exposure (AET) its mechanism of action is not fully understood. EndoFLIP is a device to measure GOJ distensibility (DI) and calcitonin gene related peptide (CGRP) is a neuropeptide marker for sensory afferents involved in GORD hypersensitivity - it is not known whether Stretta alters these factors and whether they are linked to normalisation of AET and symptoms.

Aims & Methods: This prospective study aimed to assess the effect of Stretta on UGI physiological parameters (LES pressure, IRP, DCI, AET, GOJ DI), mucosal CGRP presence, and symptom scores, by performing the following tests before and 6-months after Stretta:

Gastroscopy, EndoFLIP, HRM, ambulatory pH testing, oesophageal biopsies analysed using immunohistochemistry (IHC) for CGRP, and symptom questionnaires (Hull airway reflux, Reflux Symptom Index, Hospital Odynophagia Dysphagia, Reflux Disease, GERD-QOL).

Authors were blinded during analysis. Statistical analysis using SPSS with paired t-test for parametric data, Wilcoxon-signed rank test for non-parametric data, Pearson and Spearman tests for correlations. Ethical approval (IRAS 296193, NCT 05238636).

Results: 30 pts – 13F:17M, aged 22-71y (med. 55y).

		Pre-Stretta (Median, IQR)	Post-Stretta (Median, IQR)	Mean % delta (95% CI)	p value
EndoFLIP (40ml)	GOJ diameter (mm)	11.7 (8.4-13.5)	12.6 (10.4-14.8)	15.6 (3.7-27.5)	0.053
	Median pressure (mmHg)	34.9 (29.0-49.3)	37.3 (21.6-51.2)	1.3 (-9.7-12.3)	0.820
	GOJ distensibility index (mm2/mmHg)	3.1 (1.5-4.2)	4.5 (2.2-6.6)	71.1 (22.1-120.0)	0.014
HRM	Mean basal LES pressure (mmHg)	16.7 (7.8-28.6)	21.3 (9.3-33.3)	19.9 (-19.9-59.3)	0.758
	Median IRP (mmHg)	5.0 (3.1-10.0)	4.6 (2.5-7.9)	-16.5 (-51.0-18.0)	0.758
	Mean DCI (mmHg/s/cm)	1372.1 (306.0-2404.0)	1239.9 (369.8-2341.0)	3.4 (-29.5-36.2)	0.494
pH	Overall AET (%)	9.9 (6.4-14.8)	6.6 (3.0-14.3)	-19.2 (-44.3-5.8)	0.037
	DeMeester Score	43.3 (22.3-61.7)	27.4 (9.4-47.2)	-33.6 (-56.8 - -10.5)	0.012
IHC	% papillae with CGRP (10µm)	5.7 (4.0-9.7)	9.3 (6.0-17.8)	73.0 (-6.9-152.8)	0.071

Tests before and 6 months after Stretta:

48.5% pts felt Stretta was "very" or "somewhat" helpful.

Statistically significant (SS) improvements were seen in Hull (p=0.029) and RSI (p=0.028) scores.

AET normalised for 31% however there were no SS correlations between symptom scores and AET (p>0.05).

SS negative correlation between GOJ DI and LES pressure both before (r =-0.5, p = 0.017) and after (r=-0.5, p=0.012) Stretta.

No SS correlations between GOJ DI, GOJ diameter, LES pressure, IRP vs AET (p>0.05).

SS positive correlation between the percent change in GOJ DI pre/post Stretta with the percent change in DeMeester score (r= 0.4, p=0.03).

CGRP was most prevalent in the lower oesophagus (mean 12.0% papillae), vs middle (6.8%) and upper (7.3%). There was a mean increase of 73% post stretta but this was not SS and did not correlate with symptom scores, GOJ DI nor AET.

Conclusion: The normalisation of AET in 31% is consistent with published meta-analysis (30%). There was a non-significant trend towards increased basal LES pressure without a reduction in GOJ DI. This suggests the mechanism of action of Stretta may not be related to changes in GOJ compliance. There was SS improvement in laryngopharyngeal symptoms (Hull, RSI) suggesting these pts may benefit most from Stretta, although this was not supported by concurrent improvement in AET. CGRP presence within mucosal papillae was not affected, suggesting that this neuropeptide is not involved and that Stretta may not alter oesophageal sensitivity.

KNOWLEDGE, ATTITUDES, AND PRACTICES AMONG DOCTORS MANAGING OF GASTROESOPHAGEAL REFLUX DISEASE IN A SRI LANKAN SETTING

N. Wickramasinghe[1], D.G. Wickramasinghe[2], A. Thuraisingham[3], N.M. Devanarayana[4]
[1]Faculty of Medicine, University of Colombo, Physiology, Colombo, Sri Lanka, [2]Faculty of Medicine, University of Colombo, Surgery, Colombo, Sri Lanka, [3]Ministry of Health, Sri Lanka, Colombo, Sri Lanka, [4]Faculty of Medicine, University of Kelaniya, Physiology, Kelaniya, Sri Lanka

Contact E-Mail Address: nilanka@physiol.cmb.ac.lk

Introduction: While the global prevalence of GERD ranges from 5% to 25%, in Sri Lanka, it is slightly higher at 25.3%. There are no Sri Lankan guidelines for management of GORD despite it been a relatively common condition.

However, there is a lack of studies in Sri Lanka documenting the current management practices for GERD among doctors both primary and specialized.

Aims & Methods: This study aims to give an insight about the Sri Lankan doctor's point of view in managing GERD.

A self-administered questionnaire designed to gather information on medication prescription, lifestyle advice given, investigations, and personal experiences and beliefs was used. MBBS doctors working as primary care doctors, consultant general physicians/ general surgeons/ gastroenterologists as well as trainees in the fields, attached to the National Hospital of Sri Lanka, Colombo South Teaching Hospital, Colombo North Teaching Hospital, and the College of General Practitioners, Sri Lanka were approached consecutively.

Data analysis was conducted using SPSS-28.

Results: Of the 100 participants recruited, 57 were male while the average age was 35 years. The average duration of practice as a doctor was 11 years, ranging from 1 to 50 years. A significant proportion of doctors reported personally experiencing reflux and regurgitation (n=62, 62.0%).

In the first presentation of heartburn or reflux, the majority of doctors prescribed proton pump inhibitors (PPIs) (n=92,92.0%), followed by domperidone (n=67,67.0%), antacid syrups (n=42, 42.0%), H2 receptor blockers (n=37, 37.0%), antacid tablets (n=27,27.0%), antidepressants and anxiolytics (n=11,11.0%). Prescription at the second presentation showed a similar trend except for H2 receptor blockers taking precedence while only 3 doctors prescribed triple therapy. Only 46.0% advised the patients to come for a follow-up, and the mean follow-up period was 2 weeks, with n=88,88.0% of the patients presenting.

Most doctors referred/ utilized upper gastrointestinal (GI) endoscopy (n=96,96.0%), while upper GI manometry (n=13,13%) and pH impedance studies (n=4,4.0%) were referred at specialist level.

Most doctors reported advising their patients (n=88,88.0%) on lifestyle changes, such as avoiding food that causes GERD symptoms (n=91,91.0%), weight loss (n=71,71.0%), reducing mental stress (n=70,70.0%), and other lifestyle modifications. Spicy food (n=86,86.0%), oily food (n=93,93.0%), wheat-based food(n=50,50.0%), and bread (n=52,52.0%), were the types of food most commonly advised against.

The majority 73% of doctors co-prescribed PPIs for patients on multiple other medications and 36% co-prescribed PPIs when NSAIDs were prescribed (n=64,64.0%).

Only 52.0% were satisfied with their management while 19% believed that anti-reflux surgery was a good option for managing GERD.

Conclusion: According to this study a majority of physicians prescribe proton pump inhibitors (PPIs) as the first-line treatment for GERD, followed by other medications such as domperidone and antacids. Lifestyle modifications, including dietary changes and stress reduction, are commonly advised. Upper GI endoscopy is the most preferred investigation method. Despite advising patients to avoid wheat and bread, many physicians report patients experiencing symptoms from these foods only sometimes or less. Overall, physicians are generally satisfied with their management of GERD and do not consider surgery as a treatment option.

Education programs and seminars on the management of GERD is recommended to ensure optimal patientcare.

DOES MUCIN EXPRESSION PHENOTYPE OF BARRETT'S ADENOCARCINOMA AFFECT THE RISK OF LYMPH NODE METASTASIS?

Y. Iwaya[1], T. Tomoaki[1], Y. Kou[1], H. Ikeuchi[1], H. Sawaguchi[1], S. Kako[1], A. Hirayama[1], T. Okamura[1], T. Nagaya[1], M. Iwaya[2]

Contact E-Mail Address: yiwaya@shinshu-u.ac.jp

Introduction: Superficial Barrett's adenocarcinoma (BAC) is a rare disease in Japan, and its clinicopathological characteristics are not well-defined. As a result, indications for endoscopic treatment have not been determined.

Aims & Methods: A histopathological study was performed to investigate whether there is a relationship between risk factors for lymph node metastasis and the mucin expression phenotypes of BAC. We conducted a retrospective analysis of a database comprising consecutive patients with superficial BAC treated by endoscopic or surgical resection. Immunohistochemical analysis was performed using the antibodies of MUC5AC, MUC6, MUC2, and CD10 to determine the classification of mucin expression phenotype.

Results: A total of 74 BAC lesions in 68 patients (54 males, median age 69 years) were identified. Mucin expression classification showed gastric (64%, complete gastric 24%, predominantly gastric 39%), intestinal (34%, complete intestinal 14%, predominantly intestinal 20%) or null (3%) phenotypes. Surgical treatment was performed in 30 patients, including additional treatment after ESD, and lymph node metastasis was observed in 4 patients (13%). Compared to the intestinal phenotype group, patients with gastric phenotype BAC had an almost significantly higher rate of lymphovascular invasion (38% vs 16%, P=0.06) and poorly differentiated component (23% vs 4%, P=0.09). All 4 lymph node metastasis-positive cases were in the gastric phenotype group (P=0.28).

Conclusion: Although our study did not show a direct relationship between the risk of lymph node metastasis and mucin expression phenotype of BAC, it did suggest BAC with gastric phenotype may be more likely to have lymphovascular invasion and poorly differentiated component. The endoscopic-specific findings of BAC with gastric phenotype are unknown. However, some specific endoscopic findings of gastric phenotype in gastric cancer are well-known, such as intralobular loop pattern or vessels within epithelial circle pattern. If we see such findings in BAC, due to a possible higher risk of lymphovascular invasion or poorly differentiated components, we should perform ESD rather than piecemeal EMR to obtain en-bloc tissue specimens for detailed pathological evaluation.

SAFETY AND EFFICACY OF CRYO-ABLATION ON BARRETT ESOPHAGUS: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Papaefthymioy[1], A. Telese[1], B. Norton[1], P. Gkolfakis[2], M. Duku[1], A. Murino[1], G. Johnson[1], C. Murray[1], R.J. Haidry[1]
[1]Cleveland Clinic London, Gastroenterology, London, United Kingdom, [2]Konstantopouleion General Hospital of Nea Ionia, Hepatogastroenterology Unit, Second Department of Internal Medicine, Propaedeutic, Research Institute and Diabetes Center, Medical School, National and Kapodistrian University of Athens, Attikon University General Hospital, Athens, Greece

Contact E-Mail Address: Andrea.Telese@nhs.net

Introduction: Barrett esophagus (BE) represents a pre-malignant condition of the esophagus and current guidelines favor endoscopic eradication therapy (EET). After endoscopic resection for visible neoplastic lesions, field ablation of the residual BE is advised to mitigate the risk of metachronous neoplasia. Cryoablation was introduced as an endoscopic ablative option for BE during the last decade with growing data on outcomes and interest in potential lower adverse events that established ablative techniques.

Aims & Methods: This systematic review and meta-analysis aimed to summarize the existing data regarding safety and efficacy of Cryoablation on BE treatment. A systematic literature search in Medline, Cochrane and Scopus databases was performed until November 2023 for full papers. Safety was considered as the primary outcome, interpreted as the overall rate of procedure related adverse events. Secondary outcomes included post-Cryoablation stricture development, and the complete eradication rates of intestinal metaplasia (CEIM) and dysplasia (CED). In case of heterogeneity, a sub-analysis based on the used device was performed for the primary outcome. Random effects model was used and the results were reported as percentages for pooled rates with 95% Confidence Intervals (95%CIs).

Results: Ten full-paper studies (471 patients; 80.3% men; mean age 62.2-69) were eligible for analysis. The mean BE length, based on Prague classification, was C0-2M2-5. Regarding the primary outcome, the overall adverse events rate was 19.7% (95%CI: 14-25.4; I^2=60.66%), although they were mild in the vast majority. Strictures warranting treatment were developed in 30 patients, representing 4.4% (95%CI: 1.8-7.1; I^2=61.18%). Four studies provided results on CED, yielding a rate of 94.6% (95%CI: 90.1-99.1; I^2=61.06%) whereas CEIM was assessed in six studies, reporting a rate of 90.1% (95%CI: 82.3-97.9; I^2=87.92%). Given the high heterogeneity in all outcomes, a sub-analysis including studies on focal Cryoablation was performed, revealing a similar rate of adverse events [16.5% (95%CI: 11.1-21.8)] with lower heterogeneity and non-significant heterogeneity (I^2=47.7%).

Conclusion: Cryoablation is a safe procedure with initial data showing a potentially low rate of esophageal strictures and comparable rates of dysplasia and BE eradication when compared to other ablative technologies. High-quality prospective studies including comparisons with established ablation techniques are warranted.

PP0105

BILE ACIDS IN SALIVA AS POSSIBLE NON-INVASIVE DIAGNOSTICS OF BARRETT'S ESOPHAGUS

S. Konecny[1,2], J. Dolina[1,2], V. Dosedelova[3], M. Lastovickova[4], P. Kuban[3]
[1]University Hospital Brno, Department of Internal Medicine and Gastroenterology, Brno, Czech Republic, [2]Masaryk University, Faculty of Medicine, Brno, Czech Republic, [3]Institute of Analytical Chemistry of the Czech Academy of Sciences, Department of Bioanalytical Instrumentation, Brno, Czech Republic, [4]Institute of Analytical Chemistry of the Czech Academy of Sciences, Department of Environmental Analytical Chemistry, Brno, Czech Republic

Contact E-Mail Address: stefankonecny@gmail.com

Introduction: Bile acids are a group of steroid compounds essential for lipid digestion. However, when bile acids are refluxed into the stomach and the esophagus during the so called duodenogastroesophageal reflux, they can have a detrimental effect on the esophageal epithelium and cause pathological changes of esophageal tissue, e.g., Barrett's esophagus (BE). The levels of bile acids in saliva could therefore serve as possible biomarkers for the diagnostics of BE.

Aims & Methods: We focused on optimization of saliva sampling methods for further analysis of bile acids. Three sampling methods were compared, i.e. sampling with Salivette sampler, Salivette Cortisol sampler and simple spitting. Then we performed quantification of 11 selected bile acids (unconjugated, glycine-conjugated) in saliva from 10 healthy volunteers and 10 BE patients by ultra-high-performance liquid chromatography coupled to triple-quadrupole tandem mass spectrometry. Moreover, high resolution MS (Orbitrap-MS) was utilized for identification of new bile acids in saliva.

Results: The results showed a clear advantage of simple spitting compared to the Salivette samplers. The median concentration of bile acids in saliva from healthy volunteers was generally below 1 nmol L −1 and approximately 2 nmol L −1 in saliva from patients with BE. The determined concentrations of bile acids in saliva are in the same range as previously reported. Levels of most bile acid were significantly higher ($p < 0.05$) in saliva from patients than in saliva of healthy volunteers. The most distinctive differences were found in levels of glycolithocholic acid, chenodeoxycholic acid, hyocholic acid and the sum of bile acids. Taurocholic acid, taurochenodeoxycholic acid and taurodeoxycholic acid were identified in a pooled saliva sample. To the best of our knowledge, this is the first time taurine-conjugated bile acids were detected in saliva. Moreover, glycine-conjugated dihydroxy-bile acid sulfate was detected and identified. Sulfate-conjugated bile acid, specifically glycochenodeoxycholate-3-sulfate, was previously detected only in one metabolomic study.

Conclusion: Saliva from BE patients contained higher levels of almost all bile acids, and the patients with BE could be distinguished from healthy volunteers by principal component analysis. In untargeted analysis taurine-conjugated bile acids were identified in saliva for the first time. The number of subjects in this preliminary study is low as we wanted to pinpoint a possible application for the analysis of bile acids in saliva, but not to complete a large clinical study, that will be conducted in future research, also including the taurine-conjugated bile acids.

CLINICAL EVALUATION OF CRYOBALLOON ABLATION FOR BARRETTS OESOPHAGUS: A UK FIRST MULTI-CENTRE EXPERIENCE

N. Aslam[1], J. Gertner[1], M. Duku[2,2], J. Britton[3], Y. Ang[4], V. Sehgal[1]
[1]University College London Hospitals, London, United Kingdom, [2]Cleveland Clinic London, London, United Kingdom, [3]Northern Care Alliance, Salford, United Kingdom, [4]Salford Royal NHS Foundation, Dept. of gastroenterology, Salford, United Kingdom

Contact E-Mail Address: n.s.aslam1@icloud.com

Introduction: The Cryoballoon Focal Ablation System (CbFAS) (Pentax Medical Inc) is an innovative device designed for the endoscopic ablation of Barrett's-related neoplasia. This system has been shown to provide advantages such as reduced stricture rates and improved patient tolerance compared to the conventional standard of care, radiofrequency ablation (RFA).

We report early outcomes from a prospective UK first multi-centre registry of consecutive patients who underwent Cryoablation for the endoscopic eradication (EET) of Barrett's-related neoplasia.

Aims & Methods: Patients were prospectively enrolled from two tertiary referral centres for Barrett's Oesophagus (BE). Inclusion criteria included patients with a BE segment no longer than 5cm with histologically-proven dysplasia on biopsy or endoscopic resection specimens suitable for EET of BE after MDT review. Cryoablation sessions were conducted at 3-month intervals until endoscopic eradication was complete. The standardised protocol involved administering 8 seconds per ablation for all enrolled patients with the CbFAS. Our primary outcome was complete eradication of BE. Secondary outcomes included the number of ablations performed, adverse events, device malfunction, stricture rate, patient tolerance, and endoscopist satisfaction which was evaluated using a 10-point Likert scale (1=poor, 10=excellent).

Results: Between January 2020 and December 2023, a total of 16 patients (35 treatment sessions) were treated. The median BE length was C0M2. Complete eradication of BE was achieved in 89% (8/9) of patients who had completed treatment. No instances of device malfunction or intraoperative adverse events were recorded. A stricture rate of 12.5% (2/16) was observed, both of which were successfully managed through endoscopic dilatation. All patients were recorded as tolerating the procedure well with sedation. The median endoscopist satisfaction score was 9 (+/- 2.4) with only one recorded instance of difficulty attributed to balloon positioning.

Conclusion: These preliminary results from the UK cryoablation registry suggest that cryoablation with the CbFAS is a safe and effective therapy for BE-related dysplasia. The stricture rate appears to be comparable to that observed with RFA and similar studies. With the planned enrolment of further centres and suitable patients, this registry will further enhance our understanding of the long-term efficacy and safety profile of cryoablation using the CbFAS.

Disclosure: Nothing to disclose.

Contact E-Mail Address: a.m.van.der.waaij@umcg.nl

Introduction: Patients with Barrett's esophagus (BE) have an increased risk of developing esophageal adenocarcinoma (EAC) and therefore surveillance is necessary. However, lesion detection with high-definition white light endoscopy (HD-WLE) and narrow-band imaging (NBI) is hampered by high miss rates. Previous phase II studies have confirmed the great potential of quantitative fluorescence molecular endoscopy (qFME) in combination with topically administered fluorescent tracers for lesion detection in BE.

However, incubation time after topical tracer administration prolongs the procedure time by five minutes. In this ongoing clinical study, oral administration of bevacizumab-800CW, targeting vascular endothelial growth factor A (VEGFA), and cetuximab-800CW, targeting epidermal growth factor receptor (EGFR), is evaluated to improve both lesion detection and the clinical implementation of qFME.

Aims & Methods: A total of 30 patients with BE scheduled for a diagnostic and/or therapeutic endoscopy will be included. First 5 – 10 patients receive 4.5 mg and/or 9 mg oral bevacizumab-800CW before qFME. Subsequently, five patients will be included who receive 4.5 mg cetuximab-800CW orally before the diagnostic endoscopy, before their therapeutic endoscopy they receive a dose of 9 mg.

The patients drink the tracer in two sips in an upright position ten minutes before qFME. qFME consisted of *in vivo* fluorescence signal visualization and quantification by multi-diameter single fiber reflectance / single fiber fluorescence (MDSFR/SFF) spectroscopy measurements on the mucosa. Additionally, biopsies are collected from non-dysplastic Barrett tissue and (suspected) dysplastic tissue and *ex vivo* analysis will be performed.

Results: Nine patients received 4.5 mg and/or 9 mg bevacizumab-800CW and five patients received 4.5 mg cetuximab-800CW. Oral administration of both tracers was well tolerated by all patients. No incubation time is needed after oral administration after the procedure. A higher fluorescence signal was seen in all visible lesions in vivo. 16 out of 17 endoscopically visible lesions were detected by qFME with bevacizumab-800CW or cetuximab-800CW and were pathologically confirmed to be dysplastic. We will conduct further analysis to evaluate target-to-background ratios and/or contrast-to-noise ratios *in vivo*. Additionally, quantitative *in vivo* fluorescence based on MDSFR/SFF spectroscopy will be assessed.

Conclusion: Our preliminary results show that qFME with oral administration of bevacizumab-800CW and cetuximab-800CW is feasible and, compared to topical administration, seems promising for shortening the procedure time, while remaining adequate in lesion detection.

After completion of the cetuximab-800CW cohort, the optimal dosis and tracer will be determined and compared to combined administration of both tracers. Lastly, depending on what achieves the best *in vivo* results,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. HISTONE CHAPERONES IN ESOPHAGEAL CARCINOMA: CAUSAL INSIGHTS AND PROGNOSTIC BIOMARKERS THROUGH MULTI-DIMENSIONAL ANALYSIS

B. Xia[1], Y. Liu[1], J. Yang[1]
[1]West China Hospital of Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

Contact E-Mail Address: xbh0715@163.com

Introduction: Esophageal carcinoma (EC) is an aggressive cancer with poor outcomes, often stemming from disrupted cellular regulators that enhance malignancy[1]. Although histone chaperones are crucial in maintaining genomic and cellular integrity and have been implicated in various solid tumors, their definitive causal roles and therapeutic potential in EC are yet to be fully determined[2].

Aims & Methods: Our study aims to elucidate the causal roles of Histone Chaperone-Related Genes (HCRGs) in EC and assess their potential as prognostic markers and therapeutic targets.

We utilized datasets from TCGA-Esophageal carcinoma, GSE53624, and genome-wide association study data from ebi-a-GCST90018841. We began our analysis by identifying HCRGs linked to EC prognosis through univariate Cox regression. We then used unsupervised cluster analysis on EC samples from the TCGA-EC dataset to identify distinct clusters and subsequently isolated differentially expressed genes (DEGs) within these clusters and compared to normal controls. This identified common DEGs, which were further analyzed using expression quantitative trait loci (eQTL) data to perform a two-sample Mendelian Randomization (MR) analysis, with EC as the outcome. This analysis, enhanced by sensitivity analysis and MR Steiger filtering, helped identify candidate genes whose expression patterns were consistent with their MR properties.

These candidate genes were used to classify EC samples into high and low expression groups, identifying genes with significant survival differences. A prognostic nomogram incorporating clinical features and these genes' expression levels was developed to predict three-year survival probabilities.

Additionally, we performed functional and pathway enrichment analyses to explore the biological processes these genes influence and assessed the immune microenvironment. Validation efforts included immunohistochemistry on EC patient tissues and molecular assays in EC cell lines, confirming the clinical relevance and biological impacts of our findings and highlighting potential diagnostic and therapeutic strategies.

Results: We identified eight key HCRGs in the TCGA-EC dataset, significant for predicting EC prognosis. Analysis revealed 1,742 common DEGs, categorized into 9 risk factors and 17 protective factors via two-sample MR. Among these, ADORA2B and SAPCD2 stood out as crucial hub genes, strongly influencing survival outcomes.

A developed nomogram incorporating pathological stage, nodal classification, and expression levels of these two genes demonstrated good predictive accuracy for three-year survival (AUC=0.749). Immunophenotyping linked ADORA2B with increased dendritic cells and decreased Tregs, while SAPCD2 was associated with higher M0 macrophages and lower Tregs, indicating their influence on the immune landscape in EC.

Clinically, increased expression of ADORA2B and SAPCD2 correlated with adverse outcomes, confirmed by qPCR and immunohistochemistry in paired EC tissues (n=63). Functional studies in cell lines (KYSE150, TE-9) showed ADORA2B's overexpression enhanced cell proliferation, G1/S transition, and migration, altering key proteins like PCNA, CDK4, and cadherins, confirming its oncogenic role in EC.

Conclusion: This study elucidates the causal roles of histone chaperones in EC, identifying ADORA2B and SAPCD2 as risk factors and prognostic biomarkers based on the integrated analysis of transcriptome analysis, MR, clinical sample evaluation, and molecular experiments.

Contact E-Mail Address: aichanelemrabott@gmail.com

Introduction: Plummer-Vinson syndrome is a rare entity that associates dysphagia, iron deficiency anemia, and cervical esophageal membrane. Our work aimed to describe the clinical profile and to specify the predictive factors of degeneration in patients with Plummer-Vinson syndrome associated with esophageal cancer and to show interest in endoscopic surveillance.

Aims & Methods: It was a retrospective descriptive and analytical study over 30 years (1993-2023) including all patients treated and followed up for Plummer-Vinson syndrome and who presented esophageal cancer. Data collection and statistical analysis were performed by SPSS version 20.0 software.

Results: Out of the 160 patients treated for Plummer-Vinson syndrome, 15 patients had associated esophageal cancer resulting in a prevalence of 9.37%. The median age was 50.6 years with extremes of 28 and 74 years, with a sex ratio of M/F = 2/13. The interval between the diagnosis of Plummer-Vinson syndrome and the appearance of cancer was 8 years +/- 7.4.

All our patients with associated cancer had dysphagia with weight loss, odynophagia in 92.9% (n=13), clinical anemia syndrome in 59 %(n=8), and upper gastrointestinal bleeding in 10%(n=1). All patients had hypoferritinemia with a median value of ferritin 6.2µg/l.

The location of the Plummer-Vinson ring was at the level of the Killian triangle at 46%(n=7) and the upper third of the esophagus at 54%(n=8).

The location of the cancerous process at the level of Killian's triangle was in 46% of cases (n=7), and the location at the level of the upper third of the esophagus was in 19.7%(n=3). In 33.3% of cases (n=5) in the middle third. It was squamous cell carcinoma in all cases.

Surgical treatment was initiated in 14% of cases (n=2), radio-chemotherapy in 72% (n=11) and refusal of treatment in 14% of cases (n=2). Two patients progressed well with the disappearance of dysphagia, 10 patients died between 5 months and 5 years of cancer progression, and the rest of the patients could not be followed up.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In multivariate analysis, the statistically significant predictive factors for the degeneration of Plummer-Vinson syndrome were: Age>50.6 years (OR= 2.37, p=0.003 CI=1.875-4.236), Ferritinemia <6.2 µg/l (OR=3.02, p=0.001 CI=0.977-12. 516) and location of the ring at the level of the Killian triangle (OR=1.140, p=0.001 CI=1.057-1.229). Gender and dysphagia did not appear to be associated with degeneration with (p=0.26) and (p=0.35) respectively.

Conclusion: Plummer-Vinson syndrome is a precancerous lesion requiring endoscopic surveillance. In our series, the prevalence was 9.37%. Malignant transformation of this ring at the level of the triangle of Killian was present in 46% of cases. The predictive factors of degeneration were advanced age, low ferritinemia, and the location of the ring in the mouth of Killian.

PP0110

PREDICTION OF ADDITIONAL TREATMENT AFTER ESD IN EARLY ESOPHAGEAL CANCER – ASSOCIATION WITH LESION SIZE

J.H. Yoon[1], G.H. Kim[1], D.H. Jung[1], J.C. Park[1], S.K. Lee[1], Y.C. Lee[1], S.K. Shin[1]

[1]Severance Hospital, Seoul, South Korea

Contact E-Mail Address: YJIHOON89@yuhs.ac

Introduction: ESD is considered as a first-line treatment for early esophageal cancer. Although ESD is expanding its area and replacing surgery, it has complication risk that cannot be ignored and often lead to subsequent surgery or chemoradiation. Currently, in early esophageal cancer, ESD is indicated in the absence of definite SM invasion, but it is difficult to differentiate this by EGD or EUS at the time of diagnosis.

In this study, we aimed to determine the additional indications for selecting ESD candidates based on factors that can be easily identified at diagnosis.

Aims & Methods: We retrospectively analyzed the data of a total 244 cases of patients who underwent esophageal ESD or modified EMR (e.g. precutting EMR, cap-assisted EMR) for dysplasia of the esophagus from 1 center between January 2006 and October 2023 and were diagnosed with esophageal cancer at the final pathology report. Among them, the cases whose final pathology report suggested the need for additional treatment were further analyzed. The indication for additional treatment included SM invasion, vertical margin positive, lymphovascular invasion (LVI), and perineural invasion (PNI). To identify the risk factors associated with additional treatment, we performed multivariable analysis using the logistic regression model. Factors included in the analysis were baseline patient characteristics, endoscopic findings, and pathological findings of the endoscopic resection specimen.

The longest diameter in the final specimen was used as the size of the lesion, and the morphology of the lesion was referred to the gross endoscopic findings at the time of diagnosis.

Results: Of the 244 total cases, the mean age was 65.6 and 219 (89.75%) cases were male. There were 74 cases (30.33%) suggesting indications for additional treatment, which included SM invasion (65 case), vertical margin positive (10 case), LVI (23 case), PNI (0 case), respectively. Regarding lesion size, the number of cases exceeding 15mm, 20mm, 25mm, and 30mm were 98 (40.16%), 45 (18.44%), 27 (11.07%), and 22 (9.02%), respectively. On multivariable analysis, lesion size greater than 15mm was a significant independent risk factor for additional treatment (OR = 2.234, 95% CI 1.127–4.426, p=0.021). Additionally, cutoff sizes greater than 15mm (such as 20mm, 25mm, 30mm), elevated morphology, and moderate or poorly differentiated cell type were also independent risk factors for additional treatment.

	Univariable analysis			Multivariable analysis *		
Predicting factor	OR	[95% CI]	p-value	OR	[95% CI]	p-value
Size						
>=15mm	1.947	[1.123-3.376]	0.018	2.234	[1.127-4.426]	0.021
>=20mm	2.291	[1.181-4.446]	0.014	2.582	[1.145-5.823]	0.022
>=25mm	2.692	[1.197-6.054]	0.017	3.227	[1.225-8.498]	0.018
>=30mm	3.812	[1.551-9.373]	0.004	4.699	[1.604-13.762]	0.005

*Table 1. Multivariable analysis of possible predictor for additional treatment**

adjusted for morphology, and cell type.

Conclusion: Our study suggests that lesion size can be used as an independent risk factor to predict the need for additional treatment after endoscopic resection of early esophageal cancer. However, when applying this size factor, there is a discrepancy between the microscopic size in the resection specimen analyzed in this study and the size measured during the endoscopic procedure. Nevertheless, assuming that the discrepancy is not significant, it seems that superficial esophageal cancer measuring 15mm or more on endoscopy may be recommended for surgery or chemoradiation rather than ESD. Future studies with larger numbers of patients and adjustment for this discrepancy are expected to provide more powerful results.

Disclosure: Nothing to disclose.

Introduction: Endoscopic resection (ER) is widely accepted as the standard treatment for superficial esophageal squamous cell carcinoma (ESCC). In contrast, many old patients, especially 80 years or older, may die as a result of other diseases soon after ER. Therefore, the investigation of clinical outcomes and identification of prognostic factors of patients 80 years or older undergoing ER are clinically important because these findings may inform decision-making regarding the suitability of ER.

Aims & Methods: This study aimed to identify such clinical outcomes and prognostic factors. We retrospectively evaluated the short and long-term outcomes and prognostic factors of 87 patients 80 years or older undergoing ER for ESCC at two cancers between April 2012 and March 2021. We also evaluated the relationships of patient characteristics (sex, age, Eastern Cooperative Oncology Group-performance status; ECOG-PS, American Society of Anesthesiologists physical status; ASA-PS, prognostic nutritional index; PNI, Charlson comorbidity index; CCI) and overall survival rate using the Kaplan-Meier method and a Cox proportional hazards regression model.

Results: The median age of the patients was 82 years, and male was 76 patients (87.4%). The background factors were ECOG-PS 0-1 in 81 patients (93.1%) and a median CCI of 3. As short-term outcomes, 79 patients (90.8%) were curative resections (pT1a-M, V0 and Ly0), 9 patients (10.3%) had adverse events occurred (pneumonia was the most common: 4.6%),

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and no treatment-related deaths occurred. As long-term outcomes, 34 patients died; however, only two patients died due to ESCC. The 3-year overall survival rates and the 5-year overall survival rates were 81.4% and 71.6%, respectively. CCI≥4 (hazard ratio 4.75, 95% CI: 2.03-11.10) was identified as an independent prognostic factor.

Conclusion: The short-term outcomes were good. In contrast, as the long-term outcomes, the overall survival rates of patients with CCI≥4 were poor. The decision to perform ER for patients with CCI≥4 should be carefully considered because follow-up without ER is possible.

Disclosure: Nothing to disclose.

Introduction: Radiation therapy (Rth) remains an integral part of the multifactorial management of breast cancer (BC). Some reports suggest an increased risk of secondary esophageal cancer (SEC) following Rth for BC, but wide-ranged populational studies on this topic are scarce. We conducted this nationwide registry-based study to analyze the incidence, prognosis, and timing of SEC within BC survivors.

Aims & Methods: We used two high-volume national databases (the National Health Fund Registry and the National Cancer Registry) to identify adult patients with a confirmed diagnosis of primary BC who received oncological treatment either with or without Rth between 2009 and 2019. Those patients were followed-up for the diagnosis of SEC until December 2023. The Fine-Gray competing risk regression models were used to determine and compare the cumulative incidence of SECs in both groups. We applied the Kaplan–Meier method to calculate the 5-year overall survival rates (OS) for SECs in both subsets of BC patients.

Results: We screened 194,598 patients with primary BC, of which 128,625 (66.1%) with available treatment data were included in the final analysis (mean age 61±13yrs.; 99% females). Of these, 89,078 (69%) received Rth within the treatment regime (post-Rth BC) and 39,547 (31%) did not receive Rth (no-Rth BC). The 10-year cumulative incidence of SEC within the post-Rth BC group was 0.06% (95%CI, 0.04%-0.09%), as compared to 0.02% (95%CI, 0.01%-0.04%) within the no-Rth group (Gray test *P*=.005). In a competing risk model, having received Rth was associated with a >2.5-fold increase in the risk of developing SEC relative to no-Rth BC patients (HR 2.67, 95%CI, 1.27-5.65, *P*=.010). The median time to SEC occurrence after Rth completion was 3.7 years (interquartile range [IQR], 1.3-6.6). Squamous cell cancers constituted 89% of SECs in the post-Rth BC group, which was higher than within the no-Rth BC group, of which 73% were SCCs. The prognosis of post-Rth SECs was as poor as for no-Rth SECs, with 5-year OS of 23% (95%CI, 14%-37%) and 13% (95%CI, 4.4%-36%), respectively; *P*=0.3.

Conclusion: Radiotherapy significantly increases the risk of SECs in BC survivors, although the cumulative incidence of this unfavorable event is low. These results raise awareness of SEC after RTH for breast cancer.

Disclosure: Nothing to disclose.

COMPARISON OF RESTAGING ACCURACY BETWEEN ENDOSCOPIC ULTRASOUND AND POSITRON EMISSION TOMOGRAPHY IN PATIENTS WITH ESOPHAGEAL CANCER ACHIEVING PATHOLOGICAL COMPLETE RESPONSE AFTER CONCURRENT CHEMORADIOTHERAPY

M.-L. Han[1], Y.-J. Kuo[1]

[1]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan

Contact E-Mail Address: minglun@ms18.hinet.net

Introduction: Endoscopic ultrasound (EUS) and positron emission tomography (PET) have been widely recognized as valuable imaging modalities for tumor-node-metastasis (TNM) staging and treatment decision-making in patients with esophageal cancer. However, the accuracy of EUS and PET in esophageal cancer patients following neoadjuvant concurrent chemoradiotherapy (CCRT) remains inconsistent. Our objective was to conduct a comparative study between EUS and PET to evaluate their accuracy in staging post-CCRT patients who underwent resection surgery and were diagnosed with tumor complete remission.

Aims & Methods: The subjects of this study comprised patients diagnosed with esophageal squamous cell carcinoma and treated with CCRT before surgery at National Taiwan University Hospital (NTUH). Data were collected from May 1, 2007, to May 31, 2022, from a database of 828 esophageal cancer patients who underwent both EUS and PET before and after CCRT, and subsequently underwent resection surgery with pathologically complete response, resulting in a total of 231 patients. After excluding 14 patients who did not receive CCRT, 217 patients were enrolled for further study. The analysis focused on the T and N stages of esophageal cancer as reported by EUS and PET before and after CCRT, correlating clinical stages with pathologic stages. Using pathological diagnosis as the criterion standard, the sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of EUS and PET were calculated. Patients who did not receive EUS or PET before CCRT and those who did not receive EUS or PET after CCRT (n=87) were excluded, resulting in a final inclusion of 128 cases for analysis.

Results: Among the 128 recruited patients, the overall accuracy of EUS for T-stage was 6.3%, while PET exhibited an accuracy of 13.3%. For N-stage, the accuracy of EUS was 20.3%, whereas PET demonstrated an accuracy of 33.6%.

Conclusion: In post-CCRT esophageal patients who achieved complete pathological remission, PET exhibited superior accuracy compared to EUS for both T and N staging; however, neither modality attained satisfactory levels of accuracy.

Introduction: Transnasal endoscopy by ultrathin endoscope with image-enhanced endoscopy and high image quality has contributed greatly to the diagnosis of superficial cancers of the pharynx due to its ease of use. Its role in the diagnosis of p16-positive pharyngeal carcinoma which is closely associated with HPV infection, and has been recently reported to be increasing, is not clear.
Aims & Methods: We retrospectively investigated the clinical, pathological and endoscopic features of the cases of oropharyngeal cancer at our hospital, who underwent upper gastrointestinal endoscopy in the period between January 2019 to December 2023. All pathological specimens were stained with p16 immunohistochemistry.
(Study 1) Patient background, age, history of alcohol consumption and smoking, and the presence of multiple primary cancers in other organs were compared between the p16-positive oropharyngeal squamous cell carcinoma (p16+OPSCC) group and the p16- negative squamous cell carcinoma (p16-OPSCC) group.
(Study 2) The endoscopic features of the p16+OPSCC lesions were compared with those of the p16-OPSCC lesions.
Results: Sixty patients were included in this study, with a male/female ratio of 48:12 and a mean age of 63.7 years. The mean age of the female patients was 58.5 years, which was significantly younger than that of the male patients (65.0 years).
(Study 1) The p16+OPSCC group consisted of 25 patients with a male/female ratio of 19:6 and a mean age of 58.3 years, and the proportion of female patients was higher than that of the p16-OPSCC group (35 patients, 29:6, 67.5 years). The number of patients without a history of alcohol consumption nor smoking was significantly higher in the p16-OPSCC group (11 and 6, respectively), and 6 patients (24%) had neither. Multiple primary cancers were more frequent in the p16-OPSCC group (17 cases, 49%) than in the p16+OPSCC group (3 cases,12%), mainly found in the hypopharynx and the esophagus.
(Study 2) p16-OPSCC lesions showed brownish areas (BAs) with dotted vasodilatation under narrow band imaging, whereas p16+OPSCC lesions had a unique appearance of subepithelial mass-like, enlarged tonsil-like, or submucosal mass-like with ulceration or nodular elevation. These lesions were accompanied by BA in only 8 cases (32%), and in some cases, the lesions were difficult to even detect by transnasal endoscopic observation.
Conclusion: p16+OPSCC is a new clinical entity that may affect young patients who are not at risk for alcohol consumption and smoking. Our study showed that the endoscopic features of the tumor are not appropriate for BA-based diagnosis. Gastrointestinal endoscopists need to renew their awareness of the disease.
Disclosure: Nothing to disclose.

THE USE OF PROTON PUMP INHIBITORS AMONG ADULTS IN NORWAY – A NATIONWIDE DRUG UTILIZATION STUDY

S. Molnes[1], O. Spigset[2,3], L. Sagatun[1,2], Ø. Salvesen[4], R. Fossmark[2,5]
[1]St.Olavs Hospital, Department of Gastroenterology and Hepatology, Trondheim, Norway, [2]Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Trondheim, Norway, [3]St.Olavs Hospital, Department of Clinical Pharmacology, Trondheim, Norway, [4]Norwegian University of Science and Technology, Unit of Applied Clinical Research, Department of Public Health and Nursing, Faculty of Medicine and Health Science, Trondheim, Norway, [5]St. Olavs Hospital, Centre for Obesity Research, Clinic of Surgery, Trondheim, Norway

Contact E-Mail Address: sveinungm@gmail.com
Introduction: The use of proton pump inhibitors (PPIs) has increased in many Western countries over the past decades. This may reflect the increasing prevalence of symptoms of gastroesophageal reflux disease (GERD) and prophylactic PPI use against gastroduodenal ulcers and haemorrhage induced by non-steroid anti-inflammatory drugs (NSAIDs) or acetylsalicylic acid. However, increasing PPI use against functional or uninvestigated dyspepsia and other inappropriate prescription have previously been documented and may also have contributed to the observed increase in PPI use. In this study we describe the change in incident and prevalent PPI use over time and the indication for prescription.
Aims & Methods: Nationwide data were retrieved from the Norwegian Prescription Database (NorPD) and consisted of information about dispensed prescription drugs. The study population consisted of all adults with at least one PPI prescription during the study period from 2009 to 2022. PPIs were defined by their ATC codes A02BC01 – C05 in addition to M01AE52, which is an esomeprazole and naproxen combination product. Prevalent PPI use was defined as the period covered by the defined daily doses (DDD) in each prescription. The indications for prescription were defined by ICPC or ICD-10 codes depending on whether PPI was prescribed in primary care or secondary health care. National data from the Norwegian Patient Registry (NPR) on all upper endoscopies performed during the study period were combined with NorPD data and it was assessed whether incident PPI users, defined as no PPI dispensal for two years, had undergone an upper endoscopy 180 days before or after incident PPI use.
Results: The use of PPI increased from 58.1 mill DDD in 2009 to 166.9 mill DDD in 2022, i.e. 15700 DDD/1000 and 38700 DDD/1000 persons. The absolute increase in DDDs was driven by a 3.5-fold increase in esomeprazole and a 5-fold increase in the use of pantoprazole.
The prevalence of PPI use increased from 3.5% in 2009 to 9.9% in 2022. The incidence of PPI use increased from 2.85% in 2011 to 5.42% in 2022.
In 2009 the dominant indications in primary and secondary health care, respectively, were esophageal disease and GERD (72.5% and 10.7% of DDDs), gastric ulcer (3.3% and 0.46% of DDDs), duodenal ulcer (0.86% and 0.21% of DDDs), while prescriptions with no reimbursement diagnosis constituted 10.2% of DDDs. In 2022 the dominant indications were esophageal disease and GERD (57.6% and 4.7% of DDDs), musculoskeletal disorders and pain (7.1% and 0.39% of DDDs and in combination with naproxen), prophylaxis against gastroduodenal ulcer (4.8% and 0.95% DDDs), while prescriptions with no reimbursement diagnosis constituted 5.2% of the DDDs.
There were 2.27 mill cases of incident PPI use in the study period and the proportion of PPI users that underwent upper endoscopy around treatment start decreased from 25.3% in 2009 to 11.1% in 2022. In patients with esophageal disease or GERD combined the proportion examined by upper endoscopy fell from 41.4% to 27.1%, while in patients without a reimbursement diagnosis the proportion fell from 19.2% to 6.9%.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this nationwide study a 2.8-fold increase in prevalent PPI use was observed during the 14-year study period. This was caused by an absolute increase in PPI use against esophageal disease and GERD as well as prophylaxis in patients given ulcerogenic comedication. The proportion of incident PPI use investigated by upper endoscopy was halved.

PP0116

EPIDEMIOLOGY OF PROTON PUMP INHIBITOR PRESCRIPTION IN THE CZECH REPUBLIC

J. Cyrany[1], M. Vysoudil[2], J. Jarkovsky[2,3], S. Sembera[1], P. Moravkova[1], S. Rejchrt[1], I. Tachecí[1]
[1]Charles University, Medical Faculty and University Hospital Hradec Kralove, 2nd Dept. of Internal Medicine - Gastroenterology, Hradec Kralove, Czech Republic, [2]Institute of Health Information and Statistics of the Czech Republic, Praha, Czech Republic, [3]Institute of Biostatistics and Analyses, Medical Faculty, Masaryk University, Brno, Czech Republic

Contact E-Mail Address: jiri.cyrany@fnhk.cz
Introduction: Proton pump inhibitors (PPIs) are one of the most frequently prescribed drugs with high risk of the over-prescription.
Aims & Methods: Objective: to find potential sources of the over-prescription by analysis of prescription policy and its evolution in time by means of descriptive statistics
Methods: Analysis from the National Registry of Reimbursed Health Services (2010-2022) was performed targeting reimbursed prescription of ATC group A02BC (PPIs) and A02BA (H2 receptor blockers) with respect to the age of patient and prescribing specialist.
Results: More than 300 million defined daily doses (DDD) of antisecretory drugs were prescribed in 2022; PPIs represent the vast majority (296.2 million, 99 %). This volume rose 2.6 times during the 13 years span, the speed of rise is slowing but still 2.4 % yearly.
PPI were prescribed to 1.314 million of patients in 2022 and this number also rose 1.5 times for 13 years. 48 % of PPI users in 2022 were seniors over 65 years, majority of patients treated by PPIs was in 7th decade of life (24 %), while it was 6th decade till 2018 - age of patients rose in the observed period. PPI was prescribed to more than 12 % of the overall population in 2022, but to 29 % of senior population over 65 years of age!
Vast majority of PPI prescription (in DDD) is realized by general practitioners (GP, 67.8 %). The highest proportion of non-GP prescription (95.5 million DDDs) is realized by: gastroenterology (26.9 %), internal medicine (19.2 %), cardiology (9 %), rheumatology (6.1 %) and ENT (ears-nose-throat, 5.4 %). While overall PPI prescription (in DDD) rose 2.6 times during the last 13 years; higher increment was reached by ENT (18.7 times), allergology/immunology (5.7 times), pneumology (4.4 times); cardiology (4 times) and rheumatology (3.1 times).
Conclusion: Global volume of PPI prescription is overwhelming and covers almost a third of senior population. The rise during 13 years was 2.6 times in DDD and 1.5 times in the number of patients; and probably approaches the plateau. GPs are responsible for longstanding maintenance prescription and realize more than 2/3 of the volume. Prescription by specialist probably mirrors rather introductions of prescription. Prophylactic co-prescription with antithrombotic agents and NSAIDs can be responsible for increase in cardiology and rheumatology. Excessive increase of prescription in ENT (and to less extent pneumology and allergology/immunology) is probably to the account of extraesophageal reflux (EER). Routine long-term prescription of PPI for EER (which has no unequivocal diagnostic criteria so far) is a matter of debate because profit was proven dominantly in patients with simultaneous "classical" gastroesophageal reflux symptoms (1,2). EER can be a target population for de-prescribing strategies.

EVALUATING GASTRIC FUNCTION AND ENDOSCOPIC CHARACTERISTICS IN CORONARY ARTERY DISEASE PATIENTS POST-PERCUTANEOUS CORONARY INTERVENTION

G. Sobirova[1], J. Uzokov[2], B. Alyavi[2], M. Karimov[2], A. Abdullaey[2]

Introduction: The relationship between coronary artery disease (CAD) and gastrointestinal function post-percutaneous coronary intervention (PCI) is complex and multifaceted.
Aims & Methods: This study aims to investigate the implications of CAD on gastric function and endoscopic characteristics in patients following PCI, providing insight into potential clinical interventions that could improve outcomes. A longitudinal study encompassed 116 patients with CAD post-PCI, with a mean age of 62.4 ± 12.5 years and 55% male representation. These patients were observed over a mean duration of 2.3 ± 1.5 years. Comprehensive assessments included cardiac function evaluation via echocardiography and biomarker analysis, alongside detailed gastric function tests (gastric emptying studies, pH monitoring) and endoscopic examinations to identify morphological changes in the gastric lining. Statistical analysis involved the use of independent t-tests and chi-squared tests for baseline comparisons, with paired t-tests and the Wilcoxon signed-rank test applied to assess changes over time. The Cox regression model was employed to determine the impact of altered gastric function and endoscopic findings on the prognosis of CAD patients, adjusting for age, gender, and baseline cardiac function.
Results: Our study identified significant gastric functional impairments in patients post-PCI, including delayed gastric emptying and increased gastric acidity ($p<0.01$). Endoscopic findings revealed a higher prevalence of gastritis and gastric erosions in this cohort compared to the general population ($p<0.05$). These gastric alterations were associated with poorer cardiac function and increased incidence of adverse cardiac events. Cox regression analysis further highlighted that specific gastric dysfunctions, particularly delayed gastric emptying and severe gastritis, significantly predicted worse cardiac outcomes (HR=2.3, 95% CI: 1.4-3.8, $p=0.001$), after controlling for conventional risk factors. This study sheds light on the notable impact of CAD and PCI on gastric function and morphology, underscoring the bidirectional relationship between heart disease and gastrointestinal health. The findings suggest that the stress and systemic inflammation associated with CAD and the intervention process itself may contribute to gastric dysfunction. Addressing these gastric issues through targeted therapies could potentially mitigate some of the adverse cardiac outcomes observed in this patient population.
Conclusion: The presence of impaired gastric function and specific endoscopic changes in CAD patients post-PCI underscores the need for a holistic approach to patient care, integrating cardiovascular and gastroin-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. EARLY GASTRIC CANCER IN CENTRAL NORWAY 2001 TO 2016 – A POPULATION-BASED STUDY

C. Kvamme[1], T. Stillingen[1], A.D. Sandø[2,1], P. Mjønes[3,1], E.A. Bringeland[2,1], R. Fossmark[1,4]
[1]Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Trondheim, Norway, [2]St.Olavs Hospital, Department of Gastrointestinal Surgery, Trondheim, Norway, [3]St.Olavs Hospital, Department of Pathology, Trondheim, Norway, [4]St. Olavs Hospital, Centre for Obesity Research, Clinic of Surgery, Trondheim, Norway

Contact E-Mail Address: reidar.fossmark@ntnu.no
Introduction: Early gastric cancers (EGC) are confined to the gastric mucosa and submucosa irrespective of lymph node metastases. The proportion of gastric cancers diagnosed at an early stage varies considerably between Western countries but is low compared to countries with a screening program for gastric cancer. The majority of EGC patients have been treated with surgical resection including standard lymphadenectomy in Western countries. In contrast, Asian countries have treated larger proportions of EGC with endoscopic submucosal dissection (ESD) followed by estimation of risk of lymph node metastases based on histopathological characteristics. The aim of the present study was to characterize EGCs in Central Norway before ESD was an available treatment option. Furthermore, we aimed to assess histopathological characteristics associated with lymph node metastases and long-term survival in our cohort of EGC patients.
Aims & Methods: The study was a retrospective population-based study using patients identified from the Norwegian Cancer Registry and Norwegian Patient Registry (NPR). The annual number of gastroscopies was retrieved from NPR. 1205 patients were diagnosed with gastric cancer from 2001 to 2016, a period when gastrectomy with a modified D2 resection was standard treatment. In accordance with Western diagnostic criteria, patients with carcinoma in situ were not included. Patients who received neoadjuvant chemotherapy and histologically ypT0 or ypT1 were excluded to study only chemo naïve (true) EGC. Histopathological specimens were re-examined and eCura score risk stratification was calculated. Finally, long-term survival and cause of death were assessed.
Results: Of the 1205 patients with gastric cancer 88 (7.3%) had EGC. The number of gastric cancers declined (p=0.010), but the relative proportion of EGC was unchanged during the study period despite a doubling of annual gastroscopies at a national level during the study period. Patients with EGC had median age 77 (43-91) years vs. 74 (21-99) years for non-EGC controls. EGCs were more often of the Lauren intestinal type (p<0.001) and were more often localized in the antrum or corpus. Eighty-three patients underwent surgical resection and eight (9.0%) of these had N+ disease. An eCura score could be calculated for 79 EGCs. A significant proportion (9.4%, n=5) of the patients with a low risk eCura had lymph node metastases, whereas further exclusion of tumours with histological ulceration or SM2 invasion in a post-hoc analysis identified a N0 cohort (n=36). Recurrence of cancer was diagnosed in seven (8.1%) patients after a median time of 29 (14-124) months from the EGC diagnosis. Fifty-five (62.5%) EGC patients died during follow-up, whereof 43 (78.2%) deaths were unrelated to EGC, seven (12.7%) died of cancer recurrence and five (9.1%) died from postoperative complications. Median survival for EGC patients was 117.1 months (95% CI 99.8-134.3) and 5-year overall survival 75%. Approximately half of deaths related to cancer recurrence (3 of 7) occurred more than five years after the EGC diagnosis.
Conclusion: EGCs constituted a minor but constant proportion of gastric cancers despite a considerable increase in gastroscopies. In this historic cohort with formal gastric resection for EGC, 9.0% had pN+ disease. Low risk eCura score alone was insufficient to predict pN0 disease whereas additional exclusion of patients with histological ulceration or SM2 infiltration identified a pN0 cohort. Long-term follow-up of more than five years is needed to assess EGC related mortality.
Disclosure: Nothing to disclose.

Introduction: Trisomy and tetrasomy 18 are genetic aberrations characterized by the presence of one or two additional copies of chromosome 18 within a subset or in the entirety of cellular components. This genomic anomaly is a prevalent karyotypic irregularity in extra nodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma), which is a type of lymphoma that originates from mucosa-associated lymphoid tissue in various organs, including the stomach, lungs, eyes, and thyroid. In previous investigation, we examined 146 patients with MALT lymphoma of the stomach who underwent FISH analysis for t (11, 18) translocation[1]. However, the importance of trisomy and tetrasomy 18 in gastric MALT lymphoma is not fully understood because of the lack of long-term patient monitoring focused on genetic abnormalities. Therefore, in this study, we extended our investigation by tracking the same cohort of patients for an additional period exceeding 5 years to analyze the long-term prognosis of patients with gastric MALT lymphoma harboring trisomy/tetrasomy 18.
Aims & Methods: The objective of this study was to clarify the long-term prognosis of patients with gastric mucosa-associated lymphoid tissue (MALT) lymphoma with additional copies of *MALT1*. In this multicenter retrospective study, we enrolled 145 patients with gastric MALT lymphoma who underwent fluorescence in situ hybridization (FISH) analysis to detect t (11;18) translocation.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The patient cohort was divided into three groups: Group A (n=87), comprising individuals devoid of the t (11;18) translocation or extra *MALT1* copies; Group B (n=27), encompassing patients characterized by the presence of the t (11;18) translocation; and Group C (n=31), including patients with extra *MALT1* copies. The clinical outcomes in each cohort were collected. Over the course of a mean follow-up of 8.5±4.2 years, one patient died of progressive MALT lymphoma, while 15 patients died due to etiologies unrelated to lymphoma. The progression or relapse of MALT lymphoma was observed in 11 patients: three in Group A, two in Group B, and six in Group C. In Groups A, B, and C, the 10-year overall survival rates were 82.5%, 93.8%, and 86.4%, respectively, and the 10-year event-free survival rates were 96.1%, 96.0%, and 82.9%, respectively. The event-free survival rate in Group C was significantly lower than that in Group A. However, no differences were observed in the 10-year event-free survival rates among individuals limited to stage I or II_1 disease (equivalent to excluding patients with stage IV disease in this study, as there were no patients with stage II_2), with rates of 98.6%, 95.8%, and 92.3% for Groups A, B, and C, respectively.

Conclusion: The presence of extra copies of *MALT1* was identified as an inferior prognostic determinant of event-free survival.

EFFECT OF DIETARY ANIMAL PROTEIN ON DEVELOPING GASTRIC CANCER CONSIDERING *HELICOBACTER PYLORI*: MULTI-CENTER PROSPECTIVE STUDY

S.W. Jeon[1], S.Y. Nam[1]
[1]*Kyungpook National University, Internal Medicine, Daegu, South Korea*

Contact E-Mail Address: sw-jeon@hanmail.net

Introduction: Dietary animal protein effect on gastric cancer (GC) taking *Helicobacter pylori* status into account has rarely been reported and has therefore been investigated in this study.

Aims & Methods: GC patients and healthy subjects were prospectively registered by 6 hospitals from October 2016 to December 2018. Multivariate analysis adjusted for many epidemiological factors (Model I) and additionally *H. pylori* (Model II) was conducted to investigate dietary protein effect on GC. Dietary animal protein groups included red meat, processed meat, white meat, eggs, and fishes.

Results: A total of 5,535 subjects (1,629 GCs) were enrolled. In Model I, red meat, fish, and eggs showed non-linear associations. Two serving/week for red meat, 1 serving/week for fish, 2-3 serving /week for egg was associated with the lowest risk of GC. Both low (aOR, 1.33) and high intake (aOR, 1.49) of red meat were associated with increased risk of GC. Both low (aOR, 1.76) and high intake (aOR, 1.74) of fish were associated with increased risk of GC. Both low (aOR, 3.07) and high intake (aOR, 1.33) of egg were associated with increased risk of GC. High intake of processed meat was associated with GC (adjusted odd ratio [aOR], 1.78; 95% CI, 1.27-2.49). Frequent intake of white meat was associated with GC risk (aOR, 1.67 for 1 serving/week, 2.15 for 2 servings/week, and 4.16 for ≥3 servings/week). In model II, these non-linear or positive association were sustained. Sub-analysis by sex showed similar association in both men and women.

Conclusion: Dietary animal proteins had non-linear or positive association with GC after adjusted for *H. pylori.* Nonlinear relationships of some food groups with GC suggests modest intake of such foods may reduce GC risk.

Disclosure: No COI.

SURVIVAL AMONG PATIENTS CURED FROM GASTRIC ADENOCARCINOMA COMPARED TO THE BACKGROUND POPULATION

W. Leijonmarck[1], F. Mattsson[1], J. Lagergren[1,2]
[1]*Karolinska Institutet, Department of Molecular medicine and Surgery, Stockholm, Sweden,* [2]*King's College London, School of Cancer and Pharmacological Sciences, London, United Kingdom*

Contact E-Mail Address: wilhelm.leijonmarck@ki.se

Introduction: It is unknown if gastric adenocarcinoma survivors have longer, shorter, or similar survival compared to the background population. This knowledge could contribute to evidence-based monitoring strategies, healthcare recommendations, and information for patients and families.

Aims & Methods: We aimed to help clarify if the survival among survivors of gastric adenocarcinoma is different from the corresponding background population. This population-based cohort study included all patients who underwent gastrectomy for gastric adenocarcinoma between 2006-2015 in Sweden and survived ≥5 years after surgery who did not later die from tumour recurrence. They were followed up until death, postoperative year 10, or end of study period (31 December, 2020). The observed survival was divided by the expected survival, yielding relative survival rates with 95% confidence intervals (CIs) using the life table method. The expected survival was derived from the entire Swedish population of the corresponding age, sex, and calendar year. Data came from medical records and nationwide registers.

Results: The survival among all 733 gastric adenocarcinoma survivors was shorter than the expected. The reduction in relative survival increased for each follow-up year, from 98.7% (95% CI: 97-100.5%) year 6 to 90.9% (95% CI: 86.7-95.2%) year 10. The decline in relative survival was more pronounced among patients who had gastrectomy in earlier calendar years (88.4% [95% CI: 83.0-93.9%] year 10 for years 2011-2015), shorter education (87.9% [95% CI: 80.1-95.7%] year 10 for education ≤9 years), more comorbidities (82.5% [95% CI: 68.2-96.7%] year 10 for Charlson comorbidity score ≥2), and no neoadjuvant therapy (87.7% [95% CI: 81.9-93.5%] year 10).

Years after gastrectomy	Alive at the beginning of each year	Observed survival in % (95% CI)	Expected survival in %	Relative survival in % (95% CI)
6	733	94.5 (92.9-96.2)	95.7	98.7 (97.0-100.5)
7	625	89.0 (86.6-91.3)	92.0	96.7 (94.1-99.2)
8	537	85.1 (82.4-87.8)	88.9	95.8 (92.7-98.8)
9	444	80.3 (77.2-83.5)	86.0	93.4 (89.8-97.1)
10	350	75.8 (72.2-79.3)	83.3	90.9 (86.7-95.2)

Conclusion: Gastric adenocarcinoma survivors seem to have poorer survival than the corresponding background population, particularly in certain subgroups.

Disclosure: Nothing to disclose.

KEY INDICATORS FOR GLOBAL GASTRIC CANCER ENDOSCOPIC SCREENING PROGRAMS: A SYSTEMATIC REVIEW AND META-ANALYSIS

J. Wang[1], X. Zhou[1], Y. Du[1]
[1]*Changhai Hospital, Naval Medical University, Department of Gastroenterology, Shanghai, China*

Contact E-Mail Address: wangjiayue829@163.com

Introduction: Discrepancies in gastric cancer (GC) mortality reduction are evident across global GC screening programs. Specifically, the reduction brought by endoscopic screening nearly doubled in Japan and Korea compared with China.

Despite studies indicating that economic status, screening methods, and public health awareness may influence screening efficiency, there is no comprehensive study that has summarized and compared the outcomes of available screening programs and identified factors potentially influencing the cancer-preventive effects.

Aims & Methods: Here we present data, including response to invitation, uptake of endoscopy screening and cancer screening positivity, of global GC screening programs. By pooling three key indicators throughout screening process, including endoscopic compliance rate, GC detection rate and early diagnosis rate, we conducted a meta-analysis of global GC endoscopic screening programs, in order to compare the outcomes of available screening programs and identify possible influencing factors.

PubMed, Embase, Web of Science, and Scopus were searched for relevant articles published until September 20, 2023. Original articles providing enough information to calculate the indicators in the general screening population were included.

Pooled random effect estimates of the indicators were computed, and further subgroup analysis stratified according to study period, country or region, setting, screening interval, education level and socioeconomic status was conducted. This study was registered with PROSPERO (CRD42023464921).

Results: 90 studies (59 reported endoscopic compliance rate, 68 reported GC detection rate and 33 reported GC early diagnosis rate) were included. Overall, the rates of endoscopic compliance, GC detection, and early-cancer diagnosis were 46.94% (95%CI 41.35-52.53%), 0.62% (95%CI 0.46-0.80%), and 61.41% (95%CI 51.42-71.40%), respectively.

Subgroup analysis demonstrated a gradual increase in endoscopic compliance and a counterintuitive decline in GC detection rate over time. Stratified by countries, the three indicators in Japan (51.05% [37.06-65.05%] for endoscopic compliance rate, 0.89% [0.55-1.31%] for GC detection rate, and 78.98% [68.83-87.66%] for GC early diagnosis rate) and Korea (49.78% [38.77-60.80%] for endoscopic compliance rate, 1.07% [0.05-3.38%] for GC detection rate, and 69.84% [61.51-77.57%] for GC early diagnosis rate) were significantly higher in China (39.68% [31.84-47.52%] for endoscopic compliance rate, 0.51% [0.33-0.74%] for GC detection rate, and 51.35% [36.33-66.37%] for GC early diagnosis rate).

The highest endoscopic compliance and GC detection rate was reported in hospital, while GC early diagnosis rate was higher in community and health checkup. Screening programs with 2-3 years intervals, public health campaigns, higher education levels, and socioeconomic status showed higher compliance. Screening programs based on new endoscopic techniques generally reported higher GC detection and early diagnosis rates.

Conclusion: Among high-incidence countries for GC, China lags behind Japan and Korea regarding endoscopic compliance rate, GC detection rate and early diagnosis rate. Screening settings, intervals, campaigns, education and socioeconomic stratum may affect endoscopic compliance, while GC detection and early diagnosis rates are mainly influenced by screening settings and endoscopic techniques. In the future, continuous monitoring of quality control indicators should be applied in GC screening programs and the screening strategy should be adjusted accordingly to improve screening effectiveness.

Disclosure: Nothing to disclose.

Introduction: In recent years, as the rate of *Helicobacter pylori (H. pylori)* infection has declined, the number of *H. pylori*-related gastric neoplasms (HpRGNs) has decreased. Although the number of *H. pylori*-naïve gastric neoplasms (HpNGNs) is estimated to be small compared to that of HpRGNs, the exact prevalence has not been unknown. Therefore, the effectiveness of screening by esophagogastroduodenoscopy (EGD) in cohorts with low *H. pylori* infection rate has not been revealed.

Aims & Methods: The aim of this study is (1) to determine age-related HpNGN prevalence by using a large-scale Japanese cohort and (2) to develop the optimal EGD screening strategy to detect HpNGNs in terms of screening efficiency.

Database of EGD for health checkup from 12 institutions in Japan between 2016 and 2022 was retrospectively reviewed. Detailed information on identified HpNGNs was investigated; age, sex, pathological diagnosis (pure signet ring cell carcinoma (PSRCC), gastric adenocarcinomas of the fundic gland type (GA-FG), foveolar gastric adenoma-raspberry type (FGA-raspberry type), and undifferentiated type cancer), lesion size, lesion depth, lymphovascular invasion, and presence of lymph node metastasis, and EGD images. EGD images of patients who underwent multiple EGDs in the past were followed retrospectively for changes in tumor size. Tumor growth speed, missing rate, age-related HpNGNs prevalence, and detection threshold size were calculated from database.

A virtual cohort of 100,000 births in the first year and thereafter reflecting the Japanese fertility trend was constructed based on these parameters. In this virtual cohort for 70 years of follow-up, tumor detection rates and

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

number-need-to-test (NNT) for PSRCC, GA-FG, and undifferentiated cancers at different EGD screening start ages (40, 45, and 50 years) and screening intervals (2, 5, and 10 years) were compared.

Results: A total of 519,368 EGD cases were initially screened and 113 HpNGN lesions were detected in 108 patients (0.021%). HpNGN was found in all generations from 20s to 80s (0.011-0.028%). The age-related prevalence varied widely by HPNGN type; the prevalence of PSRCC was highest (0.022%) in 60s, but the prevalence of GA-FG gradually increased after the age of 50 and was not detected in people under 40. Additionally, undifferentiated cancer was discovered in people in their 30s and 50s, but not in people over 60. Tumor characteristics were analyzed for the construction of the simulation model by investigating the 97 of those lesions (34 PSRCC cases, 26 GA-FG cases, 30 FGA-raspberry type cases, and 7 undifferentiated type cases). The tumor growth rate was 2.5 mm/year for PSRCC, 2.7 mm/year for GA-FG, 1.2 mm/year for FGA-raspberry type and 11.7 mm/year for undifferentiated carcinoma. The missed rate was 46.1% for PSRCC, 65.2% for GA-FG, 56.5% for FGA-raspberry type and 17.0% for undifferentiated type. Among the strategies with detection rates of 50% or higher in the virtual cohort, the NNT of the 5-year interval screening strategy starting at age 45 years was the lowest for all tumor types (PSRCC 4.89, GA-FG 9.92, undifferentiated cancer 4.69). By adopting this strategy, most of HpNGNs were detected in less than 20 mm in size and the deep submucosa invasion rate was less than 30%.

Conclusion: A large-scale Japanese cohort demonstrated that prevalence of HpNGN was very low (0.021%). Mathematical simulation modeling revealed that the strategy of screening every 5 years starting at age 45 was most efficient to detect HpNGN.

DIFFERENT SURVIVAL RATES OF PATIENTS WITH GASTRIC CANCER DEPENDING ON AGE AND SEX: A LARGE-SCALE STUDY

Y. Choi[1], N. Kim[1,2], J.H. Lee[1], Y. Kim[1], J.-H. Kim[1], H.H. Jo[1], Y.K. Jun[1], H. Yoon[1], C.M. Shin[1], Y.S. Park[1], D.-H. Lee[1,2]

Introduction: The sex differences in the incidence of gastric cancer have been well known. However, uncertainty still exists in terms of prognosis of GC. For example, the US SEER data reports a significantly better prognosis in females than in males, but the prognosis is better in males than in females in Korean Central Cancer Registry data. Roles of molecular markers and gut microbiota as new prognostic factor are emerging recently, but few studies seem to try to reveal sex differences.

Aims & Methods: In this background, we aimed to analyze the differences in GC characteristics according to sex in Korean patients, mainly focused on survival. This was a single-center retrospective study. A total of fifteen thousand patients diagnosed with GC at the Seoul National University Bundang Hospital between 2003 and 2023 were included. Clinicopathological characteristics, histologic types, survival rates with age- and stage-stratification, and associated risk factors were analyzed. Information related to death was cross-verified using medical record review and data from the National Statistical Office.

Results: The ratio of males and females was about 2:1, and there was no differences in stage between sexes. Female patients were significantly younger than males, had more gastric body cancers and tumors with diffuse type or poorly differentiated histology. Females underwent less endoscopic treatment and more surgery, and tumors with microsatellite instability was more common in females, while mutation of p53 was less common. In histological types according to Lauren classification, diffuse type histology was more common in younger patients in both males and females. The proportion of intestinal type GC increased with age, but the proportion increased rapidly in males while increased gradually in females. In Cox multivariate regression analysis for GC-related death, older age, proximal tumor location, diffuse type histology and advanced tumor stage were risk factors. In terms of survival, overall and GC-specific survival did not show significant differences between sexes in the analysis of the total population. However, sex differences in survival reversed with age, that younger females under 50 showed survival disadvantages, but the survival became similar in 50s, and older females over 60 showed survival advantages in both overall and GC-specific survival. Furthermore, in the stratification analysis according to the stage, there were no significant differences in stages I to III. But, stage IV female patients showed significant survival disadvantages. In subgroup analysis of stage IV patients, the differences between males and females in median survival were two months, and female patients were significantly younger and had a higher proportion of diffuse type GC than male patients, which shows aggressive feature and is related to poorer survival.

		Total (N=1,924) (%)	Male (n=1,282) (%)	Female (n=642) (%)	p
Median survival (mo)		10	11	9	0.022
Age (mean±SD)		61.59±14.25	62.41±13.23	59.96±15.97	0.001
Age (in diffuse type patients, mean±SD)		54.55±14.71	56.43±14.29	52.26±14.91	0.001
Lauren classification	Intestinal	554 (48.0)	438 (56.7)	116 (30.4)	<0.001
	Diffuse	574 (49.7)	315 (40.7)	259 (68.0)	
	Mixed / Indeterminate	26 (2.3)	20 (2.6)	6 (1.6)	

Conclusion: Significant differences in survival between sexes were observed with stratification analysis, although sex itself was not an independent prognostic factor. These age-dependent changes are thought to suggest the effect of sex hormones. These differences should be considered in clinical practice and later research in terms of tailored medicine.

Introduction: Serum pepsinogens (PGs) are the biomarkers for atrophic gastritis and severe gastric inflammation.

Aims & Methods: The aim of this study was to validate the role of PGs in gastric cancer (GC) screening. 1,705 gastric neoplasms (1,287 GC and 418 gastric adenoma (GA)) and 21,425 controls (total 23,130) were enrolled.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. PGs and anti-*Helicobacter pylori* (HP) antibody were measured. Area under the curve and receiver operating characteristic curve were calculated to identify the optimal cutoff values for PGs. Multivariate logistic regression and risk stratification were conducted by combining each PG value and anti-HP antibody in GC subtypes.

Characteristics		Total (23,130) (%)	Control (21,425) (%)	Gastric Adenoma (418) (%)	GC (1,287) (%)	p	Intestinal-GC 762 (%)	Diffuse-GC (489) (%)	p
Sex	Female	8,897 (38.5)	8,358 (39.0)	134 (32.1)	405 (31.5)	<0.001	175 (23.0)	219 (44.8)	<0.001
	Male	14,233 (61.5)	13,067 (61.0)	284 (67.9)	882 (68.5)		587 (77.0)	270 (55.2)	
Age (mean)		54	54	63	62	<0.001	64	55	<0.001
HP status	Negative	8,119 (35.1)	7,857 (36.7)	54 (12.9)	208 (16.2)	<0.001	137 (18.0)	61 (12.5)	0.008
	Positive	15,009 (64.9)	13,566 (63.3)	364 (87.1)	1,079 (83.8)		625 (82.0)	428 (87.5)	
	Missing	2 (0.0)	2 (0.0)	0 (0.0)	0 (0.0)		0 (0.0)	0 (0.0)	
PG series (ng/mL)	PGI	52.1 (28.8)	52.4 (27.9)	40.3 (38.85)	50.6 (50.2)	<0.001	44 (42.65)	60.2 (56.75)	<0.001
	PGII	11.2 (10.8)	11.0 (10.3)	12.9 (11.7)	17.5 (19.2)	<0.001	16 (16.63)	21.2 (21.0)	<0.001
	PGI/II ratio	4.6 (2.6)	4.8 (2.6)	3.0 (2.4)	2.9 (2.3)	<0.001	2.9 (2.4)	2.9 (2.1)	0.328

GC, gastric cancer; HP, *Helicobacter pylori*; PG, pepsinogen.

Results: PGII ≥21 ng/ml was associated with the risk of GA (odds ratio (OR) 1.38, p<0.001), GC (OR 2.77, p<0.001), diffuse-type GC (DGC) (OR 4.26, p<0.001), especially, early-stage DGC (OR 7.11, p<0.001). When GC risk was assessed by combining each PG value and HP antibody, OR showed significance between categories, and even stepwise increment from HP negative to positive and from each PG value negative to positive after adjustment with other confounding GC risk factors.

Conclusion: Each PG value combining HP test can be used as a screening test for high risk subjects with GC, and especially the combination of PGII≥21ng/ml and positive HP status in young female was related to high risk of early-stage DGC.

Disclosure: Nothing to disclose.

Contact E-Mail Address: d.sun@erasmusmc.nl

Introduction: Gastric cancer (GC) often presents at advanced stages with high rates of metastasis and poor clinical outcomes. Identification of groups at a high-risk of GC could facilitate screening in countries with a low GC incidence. Current understanding of which groups in the Netherlands are at an elevated risk is limited.

Aims & Methods: Our aim was to identify such high-risk groups, based on individual-level population data on migration status and socioeconomic status (SES). Patient data from the Netherlands cancer registry were linked to demographic data of Statistics Netherlands in the period 2010-2022. GC incidence rates in the 14 largest immigrant populations were compared to those born in the Netherlands. Odds ratios (ORs) were computed per birthplace and corrected for age, sex and SES. Additionally, we investigated GC risk among second-generation immigrants and by SES.

Results: A total of 21,299 GC patients were recorded in the Dutch cancer registry between 2010 and 2022. Immigrant populations at a significantly higher GC risk compared to the general population were identified (Table 1). These include people born in Bosnia-Herzegovina (OR: 2.42), Turkey (OR: 2.22), Afghanistan (1.92), China (OR: 1.92), Surinam (1.68), Morocco (1.63), and the Dutch Antilles (1.61). Low SES increased the odds of developing GC, with an OR of 1.48 in individuals with the lowest SES compared to those with the highest SES. Still, first-generation migrants remained at a higher risk when adjusting for SES. Second-generation migrants did not have a significantly higher risk of developing GC.

Birth place	All	Afghanistan	Turkey	Bosnia-Herzegovina	China	Morocco	Surinam	Iran	Poland	Netherlands	Iraq	Belgium	United Kingdom
Gastric Cancer (GC)	10.10	21.09	20.11	19.46	17.28	17.17	12.68	12.49	9.10	8.43	8.25	6.66	6.23
Non-cardia GC	4.87	13.1	12.28	13.51	11.95	10.87	8.86	8.11	5.64	3.89	4.99	4.15	2.62
cardia GC	3.10	5.16	3.20	2.99	2.64	3.14	1.27	2.01	0.40	2.76	1.87	2.00	1.72
Other GC	2.13	2.82	4.63	2.96	2.68	3.16	2.55	2.38	3.06	1.78	1.39	0.51	1.89

Table 1: Age-standardized incidence rates per 100,000 for immigrants from selected countries in the Netherlands in the period 2010-2021.

Conclusion: Individuals born in countries with a high GC incidence remain at an elevated risk despite migration to a low-risk region, likely due to prior infection of *H. pylori*. Potential benefits of targeted *H. pylori* test-and-treat in immigrant populations should be explored in clinical and modelling studies. Primary caregivers should be cognizant of high-risk immigrant and socio-economic groups, facilitating the early detection of cancer within these vulnerable populations.

Introduction: Autoimmune atrophic gastritis (AAG) leads to significant changes in the gastric mucosa, including hypo-achlorhydria and increased gastrin (G) levels, providing proliferative *stimuli* on the gastric mucosa (1-5).

Aims & Methods: The aim of our study is to evaluate the occurrence and characteristics of gastric polyps in AAG patients across six tertiary centers in Italy. We conducted a multicentric, cross-sectional study from January to June 2023, prospectively enrolling consecutive patients diagnosed with AAG, from January 2000 to June 2023, who underwent at least one endoscopy. Data on demographics, clinical history, biochemical profiles, serological data, and endoscopic and histopathological findings were collected.

	AAG overall population (#612)	AAG patients without lesions (#390)	AAG patients with non-NEN polyps (#162)	AAG patients with gNENs (#108)
Sex, female (%)	452 (73.9)	280 (71.6)	280 (71.6)	78 (72.2)
Age (years), median (IQR)	66 (54–74)	61.5 (51-70)	70 (58.7-76.2)	70 (58.7-76.2)
APCA positivity, n (%)	496 (81)	386 (99.1)	125 (77.2)	76 (70.4)
Current smokers, n/n available (%)	48/185 (21.8%)	13/96 (13.5%)	13/96 (13.5%)	13/96 (13.5%)
PPI treatment, n/n available (%)	48/137 (25.9%)	29/98 (29.6%)	7/41 (17.1%)	10/41 (24.4%)
OLGIM, n (%)	II: 245 (40)	II: 144 (37)	II: 63 (39)	II: 60 (56)
OLGA, n (%)	II: 325 (53)	II: 179 (46)	II: 92 (57)	II: 76 (70)
Chromogranin A (ng/mL), median (IQR)	153 (75.5-269.3)	139 (68-221)	139 (68-221)	160 (86.9-251.5)
Gastrin (pg/mL), median (IQR)	667 (336.5-1156.5)	589.0 (281.8–1071.5)	688 (425.8–1200)	874 (362.5-1335)

Conclusion: This study represents the largest multicentric cohort of AAG patients, highlighting the significant presence of gastric polyps, including gNENs and various non-endocrine types including a not negligible proportion of patients who showed gastric adenocarcinoma. These results emphasize the importance of proactive endoscopic monitoring and comprehensive histopathological evaluation in patients with AAG, to effectively identify and manage these different gastric lesions.

Introduction: In autoimmune atrophic gastritis (AAG), immune-mediated morpho-functional changes in gastric mucosa lead to hypo-achlorhydria and subsequent hypergastrinemia. This stimulates gastric enterochromaffin-like (ECL) cell proliferation, escalating the risk of type I gastric neuroendocrine neoplasms (gNENs). Yet, longitudinal studies on the AAG-type I gNENs association are still scanty.

Aims & Methods: Our study aims to assess in a multicentric cohort of AAG patients, the frequency and the characteristics of type I gNENs.

We conducted a multicentric, cross-sectional study from January to June 2023, prospectively enrolling consecutive patients diagnosed with AAG, from January 2000 to June 2023, who underwent at least one endoscopy. Data on demographics, clinical history, biochemical profiles, serological

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

data, and endoscopic and histopathological findings were collected.

Results: The study included 612 patients with AAG [444 (75.2%) female, median age 66 (IQR 54-73) years]. At enrollment, 355 (58.1%) patients had ECL cell hyperplasia. Over a median follow-up of 4 (IQR 2-7) years, and after a median number of two upper GI endoscopies per patient, and a median disease duration of 7 (IQR 3-8) years, 108 patients showed 125 gNENs, corresponding to an incidence rate of 0.051 person-years. All the gNENs were well-differentiated. In 22 (18%) cases Ki 67 was not available; of the remaining 103, 86 (68.8%) cases were G1, 17 (13.6%) were G2, all of which with a Ki-67 < 10%; no G3 lesions were observed. 119 (95.2%) gNENs were located in the body/fundus. The median size was 5 (IQR 3-10) mm. 79 (73.1%) patients underwent endoscopic removal, 10 (9.2%) gastrectomy, 12 (11.1%) somatostatin analog therapy due to multifocal/recurrent disease, and 7 (6.5%) were only monitored. Patients with AAG and gNENs had significantly higher gastrin levels compared to patients without gNENs [median 874 pg/mL (IQR 362.5-1335) vs 581.5 pg/mL (IQR 281.8-1071.5), p=0.014]. However, there were no significant differences in proton-pump inhibitor use, OLGA and OLGIM stages, H. pylori status, and notably, circulating chromogranin A levels.

	AAG patients with gNENs (#108)
Sex, female (%)	78 (72.2)
Age (years), median (IQR)	68 (57-75.8)
APCA positivity, n (%)	76 (70.4)
Current smokers, n/n available (%)	19/57 (33%)
PPI treatment, n/n available (%)	10/41 (24.4%)
OLGIM, n (%)	II: 60 (56)
OLGA, n (%)	II: 76 (70)
Chromogranin A (ng/mL), median (IQR)	160 (86.9-251.5)
Gastrin (pg/mL), median (IQR)	874 (362.5-1335)

Conclusion: Type I gNENs are a relevant complication in patients with AAG. Elevated circulating gastrin levels are linked to their occurrence, with hypergastrinemia acting as a driver for abnormal proliferation of gastric ECL cells. Regular endoscopic surveillance and thorough histopathological examination are crucial in patients with AAG, serving as a key strategy for early diagnosis and treatment of gNENs.

Introduction: Programmed cell death ligand-1 (PD-L1) is known to negatively regulate T-cell activation. Immune checkpoint inhibitors (ICIs) such as nivolumab and pembrolizumab have prolonged survival in gastric cancer (GC) as well as malignant melanoma and lung cancer.

Aims & Methods: The aim of this study was to investigate the affecting factors on the expression of PD-L1 in GC tissue in the Korean population in terms of clinicopathological variables.

Total 216 patients with GC who underwent PD-L1 immunohistochemistry (22C3) were prospectively enrolled at Seoul National University Bundang Hospital from March 2018 to February 2024. Positive PD-L1 expression was defined as a CPS score of 5 or higher. Univariate and multivariate analysis was performed.

Results:

		Univariate analysis		Multivariate analysis	
Variables		**OR (95% CI)**	***p* value**	**OR (95% CI)**	***p* value**
EBV infection	EBV negative	Ref.		Ref.	
	EBV positive	8.54 (1.59-158.42)	**0.043**	14.01 (2.23-278.16)	**0.019**
Tumor location	Non-cardia	Ref.		Ref.	
	Cardia	2.78 (1.18-7.35)	**0.026**	4.97 (1.17-16.08)	**0.005**
TNM stage	Stage I	Ref.		Ref.	
	Stage II,III, or IV	1.38 (1.00-1.92)	**0.049**	1.61 (1.09-2.42)	**0.018**

Table.Univariate and Multivariate analysis for affecting factors on PD-L1 expression.

Multivariate regression (Table) showed some few significant associations between PD-L1 expression and specific factors. EBV infection shows a strong effect in both univariate (odd ratio [OR] 8.54, 95% confidence interval [CI] 1.59-158.42, *p*=0.043) and multivariate analysis(OR 14.01, CI 2.23-278.16, *p*=0.019). Cardia portion involvement shows a significant correlation in both univariate (OR 2.78, CI 1.18-7.35, *p*=0.026) and multivariate analysis(OR 4.97, CI 1.71-16.08, *p*=0.005). And higher TNM stage also remains significant in both univariate (OR 1.38, CI 1.00-1.92, *p*=0.049) and multivariate analysis (OR 1.61, CI 1.09-2.42, *p*=0.018).

Conclusion: EBV infection, cardia involvement, and higher TNM stage were independent factors influencing PD-L1 expression.

Disclosure: Nothing to disclose.

Introduction: FAP is a disorder characterized by an autosomal dominant mutation of the APC gene. Duodenal adenomas are indeed found in 60–90% of patients with FAP. Gastric polyps in FAP patients are found in 30–100% of cases and most of them are fundic gland polyps. Some patients have a neoplastic phenotype (low grade/high grade dysplasia or adenocarcinoma). Shimamoto et al. tried to explain this condition: they subdivided the APC gene into six groups (from A to F), each one corresponding to a codon range, and evaluated the phenotypic correlation for each of these regions. They found an association between APC variants in codons 1398– 1580 (Region E) and neoplastic gastric and duodenal lesions.

Aims & Methods: The aim of our pilot study is to investigate the correlation between the different APC mutations and the presence of neoplastic gastric and duodenal phenotype in our case series of FAP patients.

We analysed 37 patients followed by our center for an average of 10 years: the APC gene was subdevided into six groups (from A to F) according to Shimamoto er al, each one corresponding to a codon range, and we studied the correlation between genotype and phenotypic manifestation of gastric and duodenal lesions according to their clinical history.

Results: We collected two patients with a mutation in region E: both developed gastric polyposis with low grade dysplasia (LGD) and high grade dysplasia (HGD) lesions of the duodenum. We also observed that two out of the three patients with mutation in region D (1250–1398) progressed to gastric cancer and duodenal cancer respectively. In Shimamoto's study region B (454–1020) appears to be associated with a low risk of developing gastric lesions and a moderate risk of duodenal polyposis (Spigelman ≥ III), while our analysis shows that two (out of 12) of the patients mutated in this region developed gastric cancer and two developed duodenal cancer. In our case series two patients had the mutation at the promoter level of the APC gene, and this correlates with GAPPS (Gastric Adenocarcinoma and Proximal Polyposis of the Stomach): a newly discovered disease that has a very high risk of gastric adenocarcinoma typically without duodenal polyps.

Region (tot pt)	Gastric LGD	Gastric HGD/AC	Spigelman ≥ 3	Duodenal HGD/AC
A (11)	4	0	4	0
B (12)	4	1	3	2
C (5)	4	0	2	0
D (3)	1	1	2	1
E (2)	2	0	2	2
F (2)	0	0	1	0
B1 APC promoter (2)	2	0	0	0

Conclusion: Currently there are no precise guidelines for upper gastro-intestinal tract endoscopy based on genetic mutations. This pilot study highlights the need for further research to establish an evidence based consensus.

FEASIBILITY AND SAFETY OF ENDOSCOPIC RESECTION VIA SNARING FOR GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE

H. Yamazaki[1], Y. Kano[1], E. Yamabe[1], H. Eida[1], S. Kuwabara[1], M. Kanamori[1], I. Toshifumi[1], S. Banjoya[1], N. Tomita[1], T. Kimura[1], K. Furuta[1], S. Nagae[1], N. Takeuchi[1], Y. Kimoto[1], K. Ono[1], Y. Minato[1], K. Ohata[1]

[1]NTT Medical Center Tokyo, Department of Gastrointestinal Endoscopy, Tokyo, Japan

Contact E-Mail Address: hiroyama90@hotmail.com

Introduction: Gastric adenocarcinoma of the fundic gland type(GA-FG) originates from the deeper mucosal layer, and predominantly occurs in the upper gastric region. Endoscopic submucosal dissection (ESD) in the upper region often results in a perpendicular approach and can be technically challenging. On the other hand, most GA-FG are relatively small, and snaring resection such as hybrid ESD and endoscopic mucosal resection with a cap-fitted pan endoscope (EMRC) may offer efficacy. However, the safety and feasibility of snaring resection for GA-FG remain unclear.

Aims & Methods: We retrospectively analyzed 77 cases of GA-FG endoscopically resected between August 2013 and April 2024 at NTT Medical Center Tokyo. Cases were categorized into two groups: (i) ESD group (lesions resected by ESD, n=54) and (ii) Snaring group (lesions resected by hybrid ESD or EMRC, n=23), and treatment outcomes were compared between the two groups.

Results: There was no difference in gender between the two groups. Patients in the snaring group were significantly younger (median age 62.0 vs 56: p<0.05), and the lesions were significantly smaller (median tumor size 5.0 vs 4.0mm: p<0.05). The majority of lesions in both groups were located in the upper gastric region. The two groups had no significant differences in en bloc resection rate, rate of submucosal invasion, lymphovascular invasion, vertical/horizontal margin positivity rate, or R0 resection rate. However, the snaring group exhibited a shorter procedure duration (29.5 vs 12.0 minutes; p<0.05), and reduced hospital stay duration (7.0 vs 5.0 days: p<0.05) compared to the ESD group. Adverse event rates were not significantly different between the two groups. Submucosal tissue was present in 100% of snaring group specimens, with a median resected submucosal layer thickness of 667.0μm (IQR: 527.9-797.2).

	ESD group N=54 lesions	Hybrid ESD/EMRC group N=23 lesions	P
Procedure time, min, median (IQR)	29.5 (18.0-50.0)	12.0 (7.0-21.5)	<0.05
En-bloc resection, no. (%)	54 (100%)	23 (100%)	1
Tumor size, mm, median (IQR)	5.0 (3.0-8.0)	4.0 (2.9-5.0)	<0.05
Depth of Invasion, no, (%)			
M/SM1	48 (90.6%)	19 (95.0%)	
SM2	5 (9.4%)	1 (5.0%)	0.06
Lymphovascular invasion, no(%)	3 (5.7%)	1 (5%)	1
R0 resection (%)	46 (86.8%)	18 (90.0%)	1
Hospitalization period, day, median (IQR)	7.0 (5.3-7.0)	5.0 (5.0-5.5)	<0.05

Conclusion: Despite comparable rates of en bloc resection, positive vertical margin, and adverse events, the snaring group exhibited significantly shorter procedure time and hospital stay durations. All snaring group specimens contained submucosal tissue, with the resected submucosal layer thickness exceeding 500μm. Endoscopic resection by snaring might be a safe and feasible approach for resection of GA-FG.

VALIDATION OF YPSTAGE AND CONSTRUCTION OF "YCSTAGE" AFTER PREOPERATIVE CHEMOTHERAPY IN GASTRIC CANCER

E. Bando[1], Y. Matsumoto[1], K. Takahashi[1], T. Hattori[1], S. Inoue[1], Y. Koseki[1], K.-i. Furukawa[1], K. Fujiya[1], Y. Tanizawa[1]
[1]Shizuoka Cancer Center, Division of Gastric Surgery, Suntogun, Japan

Contact E-Mail Address: e.bando@scchr.jp
Introduction: In the eighth edition of the TNM classification, clinical stage (cStage) and pathological stage after neoadjuvant chemotherapy (ypStage) were newly defined for gastric cancer. However, cStage after prior chemotherapy (ycStage) has not yet been defined.
Aims & Methods: This study aimed to validate ypStage and construct ycStage after preoperative chemotherapy in gastric cancer from the viewpoint of survival outcomes. One hundred-eighty-seven patients who planned to undergo gastrectomy with curative intention after preoperative chemotherapy were enrolled. Survival outcomes stratified by ypStage and ycStage was evaluated. ycStage was evaluated by extrapolating TNM cStage. In addition, macroscopic type, tumor size, histological type, and tumor marker (CEA/CA19-9) after chemotherapy were selected as other prognostic factors. These staging system and variables were evaluated by univariate and multivariable analysis. Harrell's concordance index (C-index: time dependent area under the curve) was used to evaluate predictive ability.
Results: Gastrectomy was not performed in 14 patients (7.5%) due to incurable factors during operation. Remaining 173 patients underwent surgery. Residual tumor was R0: 148 cases (85.5%), R1: 17 cases (9.8%), R2: 19 cases (4.6%), respectively. ypStage: The survival distribution of ypStage was assessed in 173 patients who underwent gastrectomy. The 5-year survival rates (ysr) for ypStage I (n = 36), II (n = 55), III (n = 60), and IV (n = 22) were 82.3%, 76.5%, 42.7%, and 14.1%, respectively. There were significant differences between II/III (P=0.001) and between III/IV (P=0.009), respectively. There was a tendency for there to be a difference in survival between I/II (P=0.087). The C-index of ypStage was 0.713 (standard error: se=0.027). ycStage constructed by ordinal TNM factor: The survival distribution of ycStage, ycT, and ycN was assessed in all 187 patients. The 5-ysr for ycStage I (n = 12), II (n = 39), III (n = 90), and IV (n = 46) were 54.7%, 57.5%, 61.0%, and 40.6%, respectively. The predictive ability was poor with C-index of 0.533 (se=0.031). The 5-ysr for ycT1 (N=9): 66.7%, ycT2 (N=16): 64.2%, ycT3 (N=27): 60.6%, ycT4 (N=135): 52.0%, respectively. There were no significant differences between ycT1/2 (P=0.734) and between ycT2/3 (P=0.872). The 5-ysr for ycN0 (N=55): 45.9%, ycN1 (N=55): 59.3%, ycN2 (N=54): 68.2%, ycN3 (N=23): 36.4%, respectively. The survival outcomes among cN0, cN1 and N2 are completely reversed. Other preoperative prognostic factors: In univariate analysis histological type (P=0.703), macroscopic type (P=0.125), and CA19-9 (P=0.296) were not significant prognostic factors, but tumor size [<80mm (n=117): 5-ysr; 64.6% vs. ≥80mm (n=70): 34.2%, P<0.001] and CEA [(negative (n=152): 5-ysr; 59.2% vs. positive (n=35): 33.0%, P<0.001)] were significant prognostic factors. Multivariate Cox proportional hazard model selected tumor size (P<0.001) and CEA (P=0.007) as independent prognostic variables. Construction of proposal ycStage: A new proposal stage was constructed from the results of multivariate analysis. ycStageI: size<80mm and CEA-negative, ycStageII: size<80mm and CEA-positive, ycStageIII: size≥80mm and CEA-negative, ycStageIV: size≥80mm and CEA-positive. The 5-ysr for new proposal ycStage I (n = 94), II (n = 26), III (n = 52), and IV (n = 15) were 71.3%, 54.0%, 37.0%, and 20.0%, respectively. The C-index of new proposal ycStage was 0.662 (se=0.029). It is significant higher value than that of ycStage constructed by ordinal TNM factor.
Conclusion: The predictive ability of the ypStage, on the basis of TNM factors, considered favorable. However, survival separation was poor for both ycT and ycN. Thus, ycStage based on ordinal TNM did not have the perspective of survival outcome prediction. Proposal ycStage constructed by tumor diameter and CEA may be recommended.

Contact E-Mail Address: cavestro.giuliamartina@hsr.it
Introduction: Early-onset gastric cancer (eoGC), defined as GC before 50, accounts for about 5% of GC and 3% are part of a hereditary syndrome. Its incidence is rising. eoGC was reported to present at an advanced stage at diagnosis, with a poor differentiation and a worse prognosis than in the elderly (late-onset GC, loGC), even though eoGC risk factors and characteristics remain unclear.
Aims & Methods: Therefore, we compared eoGCs with loGCs in terms of clinicopathological characteristics and risk factors. We conducted a retrospective case-case study of patients with eoGC and loGC diagnosed from 2015 to December 2022 at IRCCS San Raffaele Scientific Institute (Milan, Italy). We collected clinical data, tumor characteristics (including Helicobacter Pylori status, HP), family history of GC, smoking habit, alcohol intake, and BMI. We performed multi-gene panel testing on all eoGC.
Results: 58 eoGC (51.7%M, 48.3%F; median age at diagnosis [IQR] 44.5y [39.00, 47.75]) and 290 loGCs (63.8%M, 36.2%F; median age at diagnosis [IQR] 70.33y [63.90, 75.00]) were enrolled. 19.2% eoGCs carried a germline pathogenic variant (4 CDH1; 2 TP53; 1 MMR; 1 ATM; 1 PTEN; 1 heterozygous MUTYH). Having a second-degree relative (SDR) with GC was significantly associated with eoGC (15.8% eoGCs vs. 4.6% loGCs, $p = 0.015$). eoGCs reported lower BMI (median 22 eoGC vs 24 loGC, p=0.016). We also found a statistically significant difference between groups in alcohol consumption (P = 0.042) and smoking status (P = 0.023). While eoGCs were mainly at

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the cardia (29.3% eoGCs vs. 1.7 % loGCs; p<0.001), loGCs were mostly at the antrum (19% eoGC vs. 36.9% oGCs; *p*=0.009). eoGCs reported more dysphagia (30.9% eoGCs, compared to 4.9% loGCs, $p < 0.001$), while most patients in the loGC cohort had anemia (25.3% loGCs vs 7.3% eoGCs, $p = 0.002$) and asthenia (9.1% loGCs vs 0% eoGCs, $p = 0.012$). 48.3% eoGCs were diffuse-type adenocarcinoma (p=0.014), while 51% loGCs were intestinal-type (*p*<0.001). No significant differences were observed in terms of T and N status, while more eoGC were M1 (26.3% eoGCs vs. 9.7% loGCs, *p*=0.001) and presented at stage III-IV (56.9% eoGCs vs. 41.7% loGCs, *p*=0.042) at diagnosis.

Conclusion: 19.2% patients with eoGC carry a germline pathogenic variant, suggesting that patients with eoGC should be evaluated for germline testing at diagnosis. eoGC more often is localized at the cardia with dysphagia and presents as diffuse-type adenocarcinoma at an advanced stage (III-IV) ad diagnosis. However, 35.6% patients with eoGC presents with early gastric cancer T1 (vs 24.1% loGCs), possibly implying that younger age does not entail worse outcomes.

MICROBIOME COMPOSITION IN PATIENTS WITH UPPER GASTROINTESTINAL CANCER AND SMALL INTESTINAL BACTERIAL OVERGROWTH (SIBO).

R. Rosania[1], N. Hipler[1], K. Lehr[1], V. Keitel-Anselmino[1], A. Link[1], M. Venerito[1]

[1]Otto-von Guericke University Hospital, Gastroenterology, Hepatology, and Infectious Disease, Magdeburg, Germany

Contact E-Mail Address: rosa.rosania@med.ovgu.de

Introduction: Small intestinal bacterial overgrowth (SIBO) is frequent in patients with past or active upper GI cancer. SIBO is associated with clinical symptoms including, bloating and diarrhea that may impact negatively on quality of life. Current treatment of SIBO is empirical and relies on the cyclical use of antibiotics.

Aims & Methods: The aim of the present study was to characterize the microbiome composition of patient with upper GI cancer with or with no SIBO.

From April 2021 to May 2022, consecutive patients with past or active GI cancer attending our oncology outpatient department were enrolled in a prospective case control study. Treatment naïve patients with a first diagnosis of upper GI cancer but no SIBO-related symptoms served as controls. All included patients completed a standardised questionnaire about SIBO-related symptoms (bloating, diarrhoea), concomitant medications, and quality of life. They were offered upper endoscopy with duodenal aspirate, provided a 30-day period with no antibiotic intake. SIBO was defined as a bacterial count greater than 10^3 colony forming units per millilitre in the duodenal aspirate. Using optimized protocol, the DNA from duodenal aspirate was extracted and the V1-V2 region of the 16S rRNA gene was amplified by PCR and sequencing using the Illumina platform. Dedicated bioinformatical approach was used for the multifactorial sample analysis.

Results: The microbiome composition was analyzed in 7 controls, 17 patients with SIBO and 12 with no SIBO.

We detected 513 phylotypes from 71 genera belonging to 11 phyla in the duodenal aspirate. The most abundant genera were *Streptococcus*, *Veillonella* and *Prevotella*. All three groups differed significantly in terms of their microbiome at *phylum* level (PERMANOVA $p < 0.05$). Based on the analysis of the individual *phyla*, we were able to show that the abundance of *Proteobacteria* was significantly higher in the SIBO group (Kruskal-Wallis test $p < 0.05$). Correlation analyses revealed an association between bacterial abundance and clinical phenotype. For instance, *Proteobacteria*, correlated positively with diarrhea intensity (Spearman r=0.35, p= 0.0362), and that *Bacteroidetes* correlated negatively with the reduction in quality of life (Spearman r=-0.4525, p=0.0056). Within the overall cohort, we were able to identify two clusters characterized by different microbial composition, underlying malignant diseases and clinical symptoms.

Conclusion: Among patients with upper GI cancer, the microbiome composition of the duodenal aspirate of patients with SIBO was different compared to patients with no SIBO and controls. Microbiome composition profiling may offer the opportunity for a personalized treatment in patients with SIBO.

BIOLOGICAL CHARACTERISTICS OF OAS FAMILY AND REGULATION OF APOPTOSIS, NECROPTOSIS AND PYROPTOSIS IN GASTRIC CANCER

M. Zhang[1], T. Cai[1], J. Xie[1], X. Liu[1], F. Wang[1]

[1]The Third Xiangya Hospital, Central South University, Department of Gastroenterology, Changsha, China

Contact E-Mail Address: minglinzhang1993@163.com

Introduction: Gastric cancer (GC) is a common cancer and a leading cause of cancer-related death, with increasing morbidity and mortality in recent years. OAS gene family plays an important role in antiviral process, but its mechanism in gastric cancer is still unclear.

Aims & Methods: The biological function and prognosis of OAS gene family in human GC were analyzed by bioinformatics analysis and cell level verification. To explore the relationship of OAS3 and OASL with apoptosis, necroptosis and pyroptosis.

Results: We found through bioinformatics analysis, the expression of OAS family was up-regulated in GC, which was related to the prognosis of patients. OAS family is closely related to the immune infiltration and tumor burden mutation of GC. OAS family gene is positively correlated with the expression of apoptosis, necroptosis and pyroptosis molecules. OAS family genes were found to be up-regulated in GC by detection of clinical samples. *In vitro*, knockdown of OAS3 and OASL inhibited the proliferation and migration of GC cells, overexpression of OASL promoted the proliferation and migration of GC cells. In vitro , knockdown of OAS3 and OASL in AGS, up-regulated apoptotic molecules (cleaved Caspase 3, cleaved Caspase 9 and cleaved Caspase 8), necroptosis molecules (p-MLKL and p-RIPK3), pyroptotic molecules (cleaved Caspase 1, cleaved Caspase 4, GSDMD and PYCARD), and inflammatory factor IL-1β. In addition, knockdown of OAS3 and OASL in MKN45, up-regulated the expression of apoptosis, necroptosis and pyroptosis mentioned above, as well as the expression of inflammatory factors. overexpression of OASL in HGC27 cells decreased the expression of apoptosis molecules cleaved Caspase 3, cleaved Caspase 9 and cleaved Caspase 8, and necroptosis molecules p-MLKL and p-RIPK3, the pyroptosis molecules cleaved Caspase 1, cleaved Caspase 4, GSDMD and PYCARD were down-regulated, the expression of inflammatory factor IL-1β was down-regulated.

Conclusion: The high expression of OAS family genes is closely related to the prognosis of GC. OAS family is closely related to the immune infiltration and tumor burden mutation of GC. OAS3 and OASL may promote the progression of GC by inhibiting pan-apoptosis(apoptosis, necroptosis and pyroptosis). In summary, OAS3 and OASL may become biomarkers and therapeutic targets in GC.

Disclosure: The authors declare that they have no conflict of interest.

Introduction: Lymphoplasmacytic-rich and neutrophilic-rich tumour immune microenvironment (TIM) have been described in Epstein-Barr-virus-associated (EBV+) and microsatellite-unstable (MSI-high) gastric cancer (GC), respectively. Aim: to explore associations between EBV+/MSI-high status, TIM, peripheral blood cell ratios, tumour serum biomarkers and prognostic outcomes in GC.

Aims & Methods: Lymphoplasmacytic-rich and neutrophilic-rich tumour immune microenvironment (TIM) have been described in Epstein-Barr-virus-associated (EBV+) and microsatellite-unstable (MSI-high) gastric cancer (GC), respectively. Aim: to explore associations between EBV+/MSI-high status, TIM, peripheral blood cell ratios, tumour serum biomarkers and prognostic outcomes in GC.

Results: The series encompassed 7/140 EBV+ (5.0%) and 38/140 MSI-high (27.1%) GCs, characterised by lymphoplasmacytic-rich (EBV+:71.4% vs EBV-:5.3%, p<0.001) and neutrophilic-rich (MSI-high:28.9% vs MSS:2.0%, p<0.001) TMI, respectively. Prior to surgery, patients who underwent NAC harboured lower NLR compared to those submitted to surgery alone (3.05 vs 2.53, p=0.021). Pre-operative NLR and post-operative CRP levels were lower in neutrophilic-rich TMI GC (p=0.015 and p=0.006, respectively). Serum tumour biomarkers (CA125, CA19.9, CEA) were not related to morphological features or molecular subgroups. Overall, GC patients with lower CRP after surgery (<1.1mg/dl) showed better overall survival (p=0.032), even when stratified by type of therapy (NAC versus surgery alone), MSI status and presence of neutrophilic-rich TMI.

Conclusion: This study contributes to the growing body of evidence of blood-based biomarkers as predictive markers of GC prognosis. A reduction of systemic pro-inflammatory status after surgery (*e.g.* CRP<1.1md/dl) might contribute to better overall prognostic outcomes of GC patients. Moreover, we observed that GC patients with neutrophilic-rich TMI, a morphologic feature associated with MSI-high status, had lower levels of neutrophils in peripheral blood (low pre-operative NLR). Possible explanations include neutrophil sequestration within the tumour microenvironment and/or consumption by the tumour.

Contact E-Mail Address: luca.pignata@hotmail.it

Introduction: Nowadays there is no screening test approved on large scale for gastric cancer even if this neoplasia represents one of the leading causes of cancer-related deaths globally[1-2]. In Italy still remains one of the most frequent tumors, with incidence rates differing across geographical areas[3].

Aims & Methods: This project aims to create an easily administrable tool to detect anamnestic gastric cancer risk factors together with alarm symptoms in an age-defined target population to identify patients in need of an esophagogastroduodenoscopy (EGD).

This paper describes the first study phase: the administration of the questionnaire to a first sample of 5000 people aged from 40 to 80 years and the preliminary results. GASTROFORM is an online questionnaire (https://it.research.net/r/GASTROFORM) collecting data about demographic and anthropometric features, physiological anamnesis, familial history, non-specific upper gastrointestinal symptomatology, alarm symptoms and recent EGD performance.

Results: 4426 valid questionnaires were submitted through the online form in November 2022, 612 of them (13,82%) reported at least one alarm symptom identifying patients in need to undergo an EGD as soon as possible. From an epidemiological point of view we expect to increase the rate of diagnosis in Barret esophagus (from 1,8% to 5-8%), atrophic gastritis (from 9% to 20-30%) and early gastric cancer (from 0,019% to 1-2 %).

Conclusion: The GASTROFORM questionnaire could provide useful informations to identify a population most likely to have significant endoscopic findings in early diagnosis during a screening EGD.

GLOBAL HEALTH INEQUALITY AND YOUNG-ONSET GASTRIC CANCER MORTALITY (1990 TO 2019): A SYSTEMATIC ANALYSIS OF GLOBAL BURDEN OF DISEASE

Y. Li[1], W.K. Leung[2]
[1]*Department of Medicine, LI Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,* [2]*University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong*

Contact E-Mail Address: waikleung@hku.hk

Introduction: The temporal trend of mortality rates among young individuals with gastric cancer has sparked a contentious debate over the past few decades. Additionally, there remains an ambiguous distribution alteration of disease burden among different countries.

Aims & Methods: This population-based systematic analysis was conducted to investigate changes in health inequality related to mortality caused by young gastric cancer from 1990 to 2019. We performed a secondary analysis of the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2019 by extracting cross-sectional data on young gastric cancer (<40 years). The age-specific mortality rate was used to determine deaths attributed to young gastric cancer. A prediction of young gastric cancer mortality rate and case number up to 2030 was performed using the Nordpred APC model. The slope index of inequality (SII) and the health concentration index were used to quantitatively measure absolute and relative changes in health inequalities, taking into account the socio-demographic indexes (SDI) level. The data was further analysed across different GBD regions and sexes.

Results: The global mortality rate of young gastric cancer declined from 1.61 (95% Uncertainty interval [UI]: 1.49 to 1.72) per 100,000 in 1990 to 0.94 (95% UI: 0.87 to 1.02) per 100,000 in 2019, with an annual rate of change -0.42% (95% Confidence interval (CI): -0.47 to -0.35). The projected data suggests that the number of global mortality case and rate of young gastric cancer would decrease to 24,450 and 0.761 per 100,000 by 2030. Countries belong to the lower 50% of SDI accounted for 49.9% and 52.3% of the global young gastric cancer deaths in 1990 and 2019, respectively. Although the absolute cross-national inequality (SII) of mortality rate fell from 0.133 (95%CI: -0.533 to 0.416) in 1990 to -0.239 (95%CI: -0.432 to -0.046) in 2019, the relative inequality (concentration index) for global young gastric cancer mortality increased from 1990 (−0.058, 95%CI: −0.532 to 0.416) to 2019 (−0.104, 95%CI: −0.526 to 0.317). The observed rise in absolute health inequality was evident in both sexes, but relative health inequality increased in females only. The regions of Sub-Saharan Africa (including Western and Southern), Central Asia, and Central Europe exhibited an increase in both absolute and relative health disparities in young gastric cancer mortality.

Conclusion: Although there has been a decline in the global young gastric cancer mortality rate, health inequality has increased over the past three decades, especially in females and some low SDI countries. It is imperative to prioritize efforts in addressing inequality to further reduce the global burden of young gastric cancer mortality.

COMPARATIVE STUDY OF STANDARDIZED (HIGH DEFINITION WHITE LIGHT ENDOSCOPY WITH IMAGE-ENHANCEMENT) VERSUS NON-STANDARDIZED (ROUTINE WHITE LIGHT ENDOSCOPY) FOR DETECTION OF UPPER GASTROINTESTINAL MUCOSAL LESIONS: A PROSPECTIVE ANALYSIS FROM NORTH INDIA

N.S. Malhi[1], R. Grover[1], J.S. Dhingra[1]
[1]*Advanced Gastroenterology Institute (A.G.I.), The GASTROCITI, Ludhiana, India*

Contact E-Mail Address: doctorjasmeet@gmail.com

Introduction: This study aims to compare the diagnostic efficacy and variables of standardized high definition white light endoscopy with image-enhancement versus non-standardized routine white light endoscopy) in detecting upper gastrointestinal mucosal lesions.

Aims & Methods: A prospective analysis was conducted on 270 patients undergoing Upper Gastrointestinal Endoscopy at Advanced Gastroenterology Institute: AGI the GASTROCITI, Ludhiana located in Punjab region of North India between December 2023 and March 2024. Patients were randomly assigned (135 each) to undergo assessment using standardized versus non standardized format. Endoscopic findings were recorded and later analyzed by experienced gastroenterologists blinded to the endoscopic modality used.

Results: In the standardized group, the mean age was 47 years, with 63 % males and 37 % females. In the nonstandardized group, the mean age was 45 years, with 58 % males and 42 % females. The most common indications for endoscopy in both groups were dyspepsia and heartburn. Due to use of premedication preparation (Surfactant Simethicone + Mucolytic N acetyl-cysteine solution), the mucosal visibility score in the standardized group was significantly better at 76% versus 32% in the nonstandardized group. Also, the time taken to examine the complete mucosa (8 minutes versus 5 minutes) and corresponding Propofol anesthetic requirement dose (140 mg versus 120 mg) along with the lesion detection rate (68% versus 53%) was higher in the standardized group. Among the 135 patients, 43 were normal in the standardized group versus 64 in the nonstandardized group. The diagnostic yield of standardized high-definition white light endoscopy with image enhancement was 68.1% versus 52.5 % in nonstandardized WLE. Specific lesions with higher rates of detection were Grade A Esophagitis, early short segment Barrett's Esophagus, gastric atrophy, and intestinal metaplasia. The relative risk and odds ratio to find an abnormality while doing a standardized procedure was 1.3 and 1.93 respectively which showed very high statistical significance (p Value 0.009).

Conclusion: Standardized (High Definition White Light Endoscopy with Image-Enhancement) demonstrates superior diagnostic efficacy compared to non standardized routine white light endoscopy in detecting upper gastrointestinal mucosal lesions. Further large-scale studies are warranted to validate these findings and determine the optimal use of standardized (High Definition White Light Endoscopy with Image-Enhancement) in clinical practice.

PP0143

EFFICACY AND SAFETY PROFILES OF GASTRIC ENDOSCOPIC RESECTION FOR TREATING EARLY GASTRIC NEOPLASMS IN EXTREMELY OLD ADULTS (>80 YEARS): DATA FROM SINGLE-CENTER 10-YEAR OF EXPERIENCE

Y.I Choi[1], C.K. Lee[1], J.W. Choi[1], S.Y. Won[1], Y.S. Cho[1], B.K. Park[1]
[1]National Health Insurance Service Ilsan Hospital, Department of Gastroenterology and Hepatology, Goyang, South Korea

Contact E-Mail Address: cys7like@hanmail.net

Introduction: Even gastric endoscopic resection (ER) including endoscopic mucosal, and submucosal resection, has been an effective treatment method for treating gastric neoplasm in an early phase, there is limited data on the efficacy, and safety profiles of ER especially among extremely old age (>80year) patients.

Aims & Methods: To investigate the efficacy, and safety profiles of gastric ER among extremely old age patients, and to triage the high-risk groups for gastric ER related complication. We designed a retrospective study using data from electronic medical records in National Health Insurance Service Ilsan Hospital which performs ESD in recent 3 from January 2016 to June 2023. Among a total of 1663 gastric ESD cases, 173 cases were performed in patients aged over 76 years, and 45 cases in patients aged over 80 years. These patients were evaluated retrospectively shorterm outcomes, and survival. The shorterm efficacy profiles includes curative resection rate, and safety profiles includes perforation or bleeding risk after ESD, or ER visit or readmission rate in month after discharge.

Results: Average risk of perforation after ESD was 2.7%, and emergency room (ER) visit after dischange rate was 0.4% in this period. risk FOBT positive result patients (> 75year) at the time of health check-up, according to whether or not performed CFS within 2 years of positive results of stool occult blood, case (n=), and control(n=) groups were divided. The end point was defined as CRC diagnosis or mortality. After adjusting for confounding variables, multivariable analysis was performed to analyze the effect of colonoscopy on the risk of incidental CRC, and all-causes mortality.

Conclusion: For extremely old age patients (>80year), the efficacy, and safety profiles of gastric ER were generally acceptable for treating early gastric neoplasm. Even though still endoscopists careful to patient's medical history, life expectancy, and comparing risk/benefit from ER, clinicians might not be hesitate treating early neoplastic lesions in stomach just beacause of patients extremely old age

FORCEPS BIOPSY FOR MICRO-PHARNGEAL NEOPLASMS: A SINGLE-CENTER PROSPECTIVE STUDY

Y. Shimodate[1], M. Mizuno[1], R. Takezawa[1], T. Gotoda[1], N. Nishimura[1], K. Matsueda[1], H. Mouri[1]
[1]Kurashiki Central Hospital, Gastroenterology and Hepatology, Kurashiki, Japan

Contact E-Mail Address: kazukun26@hotmail.com

Introduction: We previously reported short-term outcomes at 3 months after cold forceps biopsy (CFB) using jumbo biopsy forceps (Boston Scientific or Olympus Medical Systems) for micro-pharyngeal neoplasms[1].

Aims & Methods: We extended the follow-up and present here outcomes at 12 months after the CFB (UMIN registry number: 000037980). One hundred twenty-five lesions in 101 patients endoscopically diagnosed with narrow-band imaging of dilated intrapapillary capillary loops with clear demarcation as micro-pharyngeal tumors of 3 mm or less and excised with CFB were prospectively registered. After excluding 28 lesions with benign pathology, 97 lesions (13 lesions of squamous cell carcinoma, 4 of high-grade dysplasia, and 80 of low-grade dysplasia) were endoscopically followed up 3 and 12 months after the first CFB. Additional CFB was performed if lesions with endoscopically determined local remnant/recurrence (ER, narrow-band imaging of dilated intrapapillary capillary loops with clear demarcation) were found. The primary outcome was ER rate. The secondary outcome was composite remnant/recurrence (CR) (ER with pathological recurrence, ER without pathological assessment, and non-ER scars but with pathological recurrence) rate.

Results: Endoscopy at 3 months after CFB was performed in 56 lesions in 47 patients, and CFB scars were identified in 25 lesions (44.6%). Additional CFB was performed in all scars judged as ER, and regular biopsy was obtained in some scars without ER. ER rate at 3 months was 23.2% (13/56, 95% confidence interval 13 - 36.4%), and CR rate was also 23.2% (13/56, 13 -36.4%) (one ER scar with negative pathology, and one non-ER scar with positive pathology). Endoscopy at 12 months was performed in 84 lesions in 71 patients. CFB scars were identified in 20 lesions (23.8%); ER rate at 12 months was 11.9% (10/84, 5.9 -20.8%), and CR rate was 8.3% (7/84, 3.4-16.4%) (3 ER scars with negative pathology, no non-ER scar with positive pathology). Regarding safety of the procedure, no intraoperative or postoperative adverse event was observed in all the 125 lesions including 24 lesions excised under continued antithrombotic therapy.

Conclusion: About 10% remnant or recurrence rates at 12 months after the procedure suggest that CFB may be minimally invasive therapeutic option for micro-pharyngeal neoplasms of 3 mm or smaller. Further follow-up study is continuing.

PP0145

UPPER-GASTROINTESTINAL ENDOSCOPY, OR OESOPHAGOGASTRODUODENOSCOPY (OGD), IS A PROCEDURE ROUTINELY PERFORMED IN SECONDARY CARE SETTINGS THROUGHOUT THE UK. LOCAL ANAESTHESIA, IN THE FORM OF THROAT SPRAY, AND INTRAVENOUS SEDATION ARE OFTEN USED TO MAKE THIS CLINICAL PROCEDURE MORE COMFORTABLE FOR THE PATIENT

E. Killan[1]
[1]*Northumbria Healthcare NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom*

Contact E-Mail Address: esther.killan@northumbria-healthcare.nhs.uk

Introduction: Upper-gastrointestinal endoscopy, or oesophagogastroduodenoscopy (OGD), is a procedure routinely performed in secondary care settings throughout the UK. Local anaesthesia, in the form of throat spray, and intravenous sedation are often used to make this clinical procedure more comfortable for the patient.

Aims & Methods: This study focused primarily on the difference in administration of the local anaesthetic throat spray. The commonly used method was to spray the back of the patient's pharynx while their mouth was open: "mouth-open" technique. This study proposed a modified technique which involved spraying the pharynx with the mouth closed around the spray nozzle: "JASMEG" technique. This was a quality improvement study of 474 patients (male: female = 1.13) who were undergoing an OGD as part of routine care in a district general hospital in the United Kingdom. It was carried out to investigate whether this new method of spray administration would increase patient comfort and reduce patient anxiety, pulse rate and incidence of cough. Comfort and anxiety scores were scored on a 5-point Liker scale (1 = most comfortable/ least anxious, 5 = least comfortable/ most anxious). Outcomes were compared between the two groups using linear regression models controlling for sex. Incidence of cough was compared between groups using Fisher's exact test.

Results: A breakdown of the sample by treatment group and sex is shown in Table 1. As compared to the "mouth-open" group, the "JASMEG" group showed a smaller increase in pulse rates (group difference = -3.97, $p < 0.001$), lower anxiety scores (group difference = -1.31, $p < 0.001$), higher comfort scores (group difference = 1.07, $p < 0.001$) and lower incidence of cough (13 out of 252 vs 190 out of 222; $p<0.001$). There were no significant differences in the results by sex.

Conclusion: The new "JASMEG" technique of local anaesthetic spray for patients undergoing OGD is superior in terms of patient comfort, anxiety levels, pulse rates and presence of cough. This is a
low-cost alternative to reduce transmission of aerosol-transmitted infections, while also making it a more favourable procedure for patients.

A PILOT STUDY ON THE UTILIZATION OF ENDOSCOPIC TWO-TOOTHED CLIPS FOR THE MANAGEMENT OF GASTROINTESTINAL DISEASES

Y. Liu[1], J. Chu[1], S. Hu[1], M. Min[1]
[1]*The fifth medical center of Chinese PLA General Hospital, Gastroenterology, Beijing, China*

Contact E-Mail Address: 13911798288@163.com

Introduction: With the progress made in the field of digestive endoscopy, a growing array of digestive disorders can now be effectively managed through endoscopic interventions. Notably, the utilization of clips for closure purposes has been documented in relation to several endoscopic procedures, including endoscopic submucosal dissection (ESD), endoscopic mucosal resection (EMR), and endoscopic full-thickness resection (EFTR). However, current clipping systems have demonstrated limitations in terms of dimensions, spacing between open arms, force exerted during closure, and adequate tissue compression. Emerging endoscopic suturing techniques are currently in the initial stage, with limited clinical investigation and insufficient reliable evidence. However, their reliance on an independent endoscopic apparatus results in elevated expenses related to equipment and treatment, and also calls for specialized clinical training.In order to tackle this concern, we have devised the two-toothed clip (TTC). Through a pilot study encompassing a cohort of 10 participants, our objective is to assess the safety, feasibility, and efficacy of the two-toothed clip.

Aims & Methods: The study employed a nitinol alloy-based two-toothed clip, where the teeth were affixed to the inner side of standard clip arms (ROCC-D-26-195-C, Micro-Tech, Nanjing, China) using plastic tubes and sutures. These teeth demonstrated enhanced length and sharpness compared to the standard clip arms. The technique used to advance the two-toothed clips towards the target lesions was the same as that employed for standard clips. Caution must be exercised while opening the arms to avoid unintentional harm to the normal mucosa due to the sharp teeth. With the aid of electrocautery snare, the TTCs were easy to be detached. Ten patients between the ages of 50 and 80 were included in this study. The treatment indications encompassed non-variceal bleeding, post-endoscopic submucosal dissection (ESD) lesions in the duodenum or colorectum, tracheoesophageal fistulas, duodenal or colorectal diverticulitis, as well as anchoring of self-expanding metal stents. Ethical approval was granted by the Institutional Review Board of our hospital, and written informed consent was obtained from all participants. The baseline characteristics of the patients were collected.The achievement of technical success was determined by the effective placement of the two-toothed clips at the designated location. Clinical success was defined as the successful resolution of the gastrointestinal issue for which the two-toothed clips were utilized. The patients were subjected to clinical and endoscopic follow-up for a duration ranging from 14 to 30 days.

Results: Ten patients meeting the eligibility criteria, with an age range of 41-80 years and consisting of 8 men and 2 women, received the TTC application. The treatment indications encompassed the closure of submucosal defects (n=2), diverticula (n=2), and non-variceal upper gastrointestinal bleeding (n=1). Additionally, the procedure involved anchoring fully covered self-expanding metal stents (n=4) and utilizing the clip-with-line traction method in endoscopic submucosal dissection (ESD) (n=1). The technical success rate and clinical success rate both reached 100%, and no adverse events related to the procedure were observed.

Conclusion: The utilization of endoscopic hemoclips for tissue compression using TTC technique has been shown to be both safe and effective. This study brings new treatment strategies for future clinical practice.

Disclosure: There are no conflicts to declare.

PP0147

OUTCOMES OF DELAYED ENDOSCOPIC MANAGEMENT FOR ESOPHAGEAL SOFT FOOD BOLUS IMPACTION: A MULTI-CENTRE RETROSPECTIVE STUDY

T. Hoang[1], A. Fetz[1], R.A. Singh[2]
[1]University of British Columbia, Vancouver, Canada, [2]University of British Columbia, Victoria, Canada

Contact E-Mail Address: thomash1@student.ubc.ca

Introduction: Esophageal food bolus impactions are a common reason for emergency room visits. Current guidelines recommend urgent endoscopy within 24 hours for incomplete obstructions, and emergent endoscopy within 6 hours for complete obstructions. While emergency endoscopy is required for sharp objects or disk batteries, data regarding soft food bolus impactions is more sparse. Recent retrospective evidence suggests that delaying endoscopy after twelve hours is not associated with an increase in morbidity or mortality.

Aims & Methods: This study expands on the existing literature to evaluate clinical outcomes associated with emergent (< 6 hours), urgent (6-12 hours), and delayed (>12 hours) endoscopy for patients presenting to emergency rooms with soft food bolus impaction.

This is a multicentre retrospective study involving two tertiary and one secondary care centre in British Columbia, Canada. All patients who presented with food bolus impaction between January 1, 2019 and Dec 31, 2022 were reviewed. The primary outcome was thirty-day mortality and repeat hospital presentation. Secondary outcomes included procedural morbidity (complications, procedural time, removal success) and length of stay. Endoscopic removal technique, optical diagnoses, and eosinophilic esophagitis incidence were also noted. Patients < 18 years old or those who had a non-food bolus impaction were excluded. Statistical analysis was performed using χ^2/Fisher Exact test wherever applicable for categorical variables and Kruskall-Wallis one-way ANOVA for continuous variables.

Results: Of 416 patients identified with complete esophageal impaction, 77 met inclusion criteria and were stratified into three cohorts: emergent (<6 hours, n=47), urgent (6-12 hours n=17), and delayed (>12 hours, n=13) intervention. All groups displayed similar baseline demographics (Table 1). Primary outcomes are outlined in Table 2. We did not observe mortality by thirty days in any group. Two patients who underwent emergent endoscopy re-presented to ED with dysphagia-related complications (4.2%) within thirty days compared to one patient (7.7%) in the delayed intervention group (OR: 1.88, CI:0.17-22.7, p=0.53). Similar to the emergent group where two (4.3%) patients required hospitalization for at least one day, one patient respectively in the urgent (5.9%, OR: 0.71, CI:0.05-8.39, p=1.0) and delayed (7.7%, OR: 1.9, CI:0.16-22.5, p=0.53) groups required hospitalization for at least one day. There was no statistically significant difference in procedural time (p=0.62), and only one complication (mucosal tear) was noted in the urgent intervention group. Only one patient had unsuccessful removal on index endoscopy, again in the urgent intervention group. There was no statistically significant difference in removal techniques, optical diagnoses, and eosinophilic esophagitis incidence. There was no statistically significant difference in the rate of mucosal injury secondary to prolonged food bolus impaction in the urgent (p=0.17) and delayed (p=0.12) groups.

Conclusion: There is no significant difference in negative clinical outcomes, including thirty-day mortality, hospital readmission, and procedural morbidity, in patients who receive emergent, urgent, or delayed endoscopy for management of a soft food bolus esophageal impaction.

These data add to the existing literature to assist endoscopists with risk stratification and timing of safe intervention for removal of food bolus causing complete esophageal obstruction.

PREVENTION OF DELAYED BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION THROUGH CLIP CLOSURE WITH NOVEL ANCHOR-PRONGED CLIP

K. Okimoto[1], T. Matsumura[1], S. Mukai[1], A. Kurosugi[1], M. Sonoda[1], T. Ishikawa[1], T. Kaneko[1], Y. Ohta[1], T. Taida[1], J. Kato[1], N. Kato[1]

Contact E-Mail Address: kenrunaway@yahoo.co.jp

Introduction: Delayed bleeding (DB) after gastric endoscopic submucosal dissection (ESD) is major complication [1] that sometimes lead to shock vitals and the effect of mucosal defect closure for preventing DB was reported [2]. However, the thickness of the gastric mucosa and proper muscle layer makes suturing difficult [3].

Aims & Methods: The aim of this study was to investigate whether clip closure using novel anchor-pronged clip (MANTIS Clip; Boston Scientific) is effective in preventing DB after gastric ESD. Out of 70 cases (78 lesions) that underwent gastric ESD at our institution from August 2023 to February 2024, a retrospective analysis was conducted on 60 consecutive cases (65 lesions) where ≥ 50% of the wound could be closed. If the wound was small, the closure method involved initially placing at least one MANTIS Clip to achieve mucosa-to-mucosa closure. If the wound was large, it was closed according to the method we previously reported [4]. In concrete terms, one side of the mucosa was grasped with MANTIS Clip, then move the clip to the opposite muscle layer, open the clip once, and after sufficient air aspiration, grasp the muscle layer. After shrinking mucosal defect enough, complete closure was achieved by adding mucosa-mucosa and mucosa-muscle closure similar to previous report of colonic closure [5] with normal clips (Sure Clip 16mm (Micro-Tech Co., Ltd, Nanjing, China) or EZ Clip (Olympus Medical Systems, Tokyo, Japan)). The primary outcome was the actual DB rate compared with the expected DB rate calculated from the BEST-J score [1]. Secondary outcomes included the technical success rate, complete closure rate (proportion of wounds with ≥ 90% closure), and closure time.

Results: M/F=42/18. DB risk based on BEST-J score (low/intermediate/high/very high) = 46/7/6/1. The median tumor size (mm) was 10 (5-40). Adenoma/cancer = 10/55. The actual rate of DB was 0%, indicating lower tendency to the expected rate of 4.5% (p=0.244). The technical success rate was 85.7% (60/70), with a complete closure rate of 90.8% (59/65). The median closure time (min) was 9 (2-24), with a median of 1 MANTIS Clip used per lesion (range: 1-4).

Conclusion: Although further accumulation of cases is necessary, clip closure using the MANTIS Clip achieved low DB with rapid and high complete closure after gastric ESD.

Introduction: Lugol chromoendoscopy (LCE) has been established as a tool to increase the sensitivity for the detection of esophageal squamous cell carcinoma (ESCC). However, LCE has some disadvantages such as the time consumed for the technique, patients' discomfort, risk of aspiration and allergic reactions when compared to white light imaging (WLE) and image enhanced endoscopy (IEE).

Aims & Methods: We attempted to develop virtual lugol chromoendoscopy (V-LCE) images for ESCC using cycle-consistent generative adversarial network (CycleGAN) and to compare their diagnostic performance with that of WLE and real lugol chromoendoscopy (R-LCE). To obtain V-LCE images, we used 3425 images (1601 WLE and 1834 LCE) of superficial ESCC from 195 cases to train CycleGAN. For the test set to evaluate the usefulness of V-LCE images, other 25 WLE images from 25 patients with superficial ESCC were translated to 25 V-LCE images using trained CycleGAN. Six endoscopists (three experts and three non-experts) evaluated images obtained under WLE, V-LCE and R-LCE with respect to the detection and the margin of ESCC, using a five-point scale from 1 (poor) to 5 (excellent). We also calculated and compared the color difference (ΔE) between cancerous and non-cancerous areas each in WLE, V-LCE and R-LCE image.

Results: Comparison of WLE and V-LCE images showed a trend towards higher scores for V-LCE images (detection 3.3 vs 3.8, p=0.089, margin 2.7 vs 3.0, p=0.13). A comparison between V-LCE and R-LCE images revealed the scores in R-LCE were significantly higher than those in V-LCE (detection; 4.7 vs 3.8, p<0.001, margin; 4.3 vs 3.0, p<0.001). Among the experts, the score for margin in V-LCE tended to be higher than that in WLE (3.0 vs 2.7, p=0.051). Among the non-experts, the score for detection in V-LCE tended to be higher than that in WLE (4.0 vs. 3.3, p=0.064). ΔE in V-LCE was significantly higher than that in WLE (29.6 vs. 18.3, p<0.001), while it was significantly lower than in R-LCE (29.6 vs. 39.3, p<0.001).

Conclusion: Images in V-LCE have the potential for high sensitivity for the diagnosis of superficial ESCC, while the imaging quality need to be improved.

MORPHOLOGY OF ULTRA-SHORT BARRETT'S ESOPHAGUS MAY BE INFLUENCED BY *HELICOBACTER PYLORI* INFECTION AND GASTRIC ATROPHY

S. Nakagome[1], O. Goto[1], M. Niikawa[1], K. Yoshikata[1], T. Habu[1], Y. Ishikawa[1], K. Kirita[1], E. Koizumi[1], H. Noda[1], K. Higuchi[1], T. Onda[1], J. Omori[1], N. Akimoto[1], K. Iwakiri[1]

[1]Nippon Medical School, Department of Gastroenterology, Tokyo, Japan

Introduction: Barrett's esophagus (BE) is known to be a precursor of esophageal and gastroesophageal junctional adenocarcinoma[1]. Adenocarcinoma of the esophagus based on BE is still relatively rare in Japan, but the Westernization of dietary habits, the increase in obese patients, and the eradication of *Helicobacter pylori* (HP) infection may increase the number of cases in the future. In Japan, the prevalence of long-segmented BE (LSBE), which is common in the Western world, is relatively low, whereas SSBE is frequently observed[2]. Atrophic gastritis (AG) caused by HP infection is also frequently observed in Japan, and the diagnosis of Japanese SSBE may be modulated by HPinfection/AG. In this study, we retrospectively investigated whether the morphology of SSBE could be influenced by HP status.

Aims & Methods: In our institution, 60 patients who had endoscopic ultra-short segmented Barrett's esophagus (USBE; length of <1cm) were retrospectively collected and divided into two groups: 30 cases with AG caused by current HP infection (AG group) or without AG (non-AG group). As patient characteristics, we investigated age, sex, presence of reflux esophagitis (RE), presence of hiatus hernia, and use of proton pump inhibitor (PPI) therapy from the medical records. To objectively evaluate the roughness of the SCJ, we compared the morphology of USBE by measuring the respective perimeters of EGJ and SCJ, followed by the calculation of the SCJ/EGJ ratio. As a sub-analysis in the AG group, the SCJ/EGJ ratio was similarly compared in terms of the degree of AG (closed-type, n = 3; open-type, n = 27) according to the Kimura-Takemoto classification.

Results: In terms of patient characteristics, the median age was higher in the AG group than in the non-AG group (72 years old vs. 49 years old, p <0.001), and RE was less common in the AG group than in the non-AG group (3% vs. 36%, p = 0.004). There were no statistical differences between the two groups in sex, presence of hiatus hernia, and use of PPI. The mean SCJ/EGJ ratio was significantly higher in the AG group than in the non-AG group (2.26 vs. 1.43, p <0.001). In the sub-analysis, the mean SCJ/EGJ ratio was likely to be higher in open-type atrophy than in closed-type atrophy (2.33 vs. 1.58, p = 0.092).

Conclusion: In endoscopically diagnosed USBE, the circumference of SCJ appeared rough in the AG group, which suggested that the morphology of BE is influenced by HP infection and subsequent AG development. Particularly in Japan, simple rough margins of SCJ influenced by HP/AG may be estimated as USBE. In diagnosing BE, the morphological characteristics of SCJ and the HP/AG status should be taken into consideration.

INTRAOPERATIVE END-TIDAL CARBON DIOXIDE CONCENTRATION IS A POTENTIAL OBJECTIVE INDICATOR OF THE PNEUMOPERITONEUM MANAGEMENT DURING PERORAL ENDOSCOPIC MYOTOMY

T. Habu[1], O. Goto[1,2], S. Nakagome[1], M. Nikawa[1], K. Yoshikata[1], Y. Ishikawa[1], E. Koizumi[1], K. Kirita[1], K. Higuchi[1], H. Noda[1], T. Onda[1], J. Omori[1], N. Akimoto[1], K. Iwakiri[1]

Contact E-Mail Address: thrush10ll@gmail.com

Introduction: Peroral endoscopic myotomy (POEM) is a less invasive endoscopic treatment for stenotic diseases caused by oesophageal motility dysfunction. During this procedure, the insufflation gas supplied from the endoscope migrates to the abdominal cavity, resulting in pneumoperitoneum. For excessive pneumoperitoneum, transabdominal puncture should be performed to rapidly decrease the intraabdominal pressure. However, the timing of puncture depends subjectively on the operator's decision.

Aims & Methods: In this study, we retrospectively analysed the factors leading to pneumoperitoneum and clarified the objective indicators to determine the timing of abdominocentesis. A total of 100 consecutive patients who underwent POEM at our hospital from October 2018 to December 2023 were included. In univariate analyses, patient-related (age, sex, body surface area [BSA], body mass index), disease-related (diagnosis, preoperative Eckardt score), and treatment-related factors (operator's POEM experience, myotomy length, peak end-tidal carbon dioxide concentration [$ETCO_2$]) were compared between Puncture and Nonpuncture groups. In these parameters, sex and BSA, which correlated with the intraabdominal space, and factors that were supposed to influence the severity of pneumoperitoneum and the need for subsequent abdominocentesis by showing p-values of less than 0.1 were enrolled for subsequent multivariate analyses.

Results: The mean age was 58 (standard deviation [SD], 19) and 51% of them were male. The mean Eckardt score was 6 (SD, 3). Most patients (n = 92, 92%) were diagnosed with oesophageal achalasia. The mean procedure time was 88 min (SD, 35 min). Abdominocentesis was performed in 65 patients (68%), who were allocated into the Puncture group. In the univariate analyses, the peak $ETCO_2$ was significantly higher in the Puncture group than in the Nonpuncture group ($p < 0.01$). In the multivariate analyses using sex, BSA, and the peak $ETCO_2$, high peak $ETCO_2$ was a single independent factor associated with abdominocentesis (odds ratio = 1.25, 95% confidence interval: 1.11–1.41, $p < 0.01$). The receiver operating characteristic curve indicated that the two groups were divided with a maximal area under the curve (0.76) when a cut-off value of the peak $ETCO_2$ was set at 44.5 mmHg (sensitivity, 0.79; specificity, 0.65).

Conclusion: This study demonstrated that the intraoperative $ETCO_2$ level was a significant independent factor related to severe pneumoperitoneum in POEM, and 45 mmHg of peak $ETCO_2$ was an optimal cut-off value to differentiate the Puncture group from the Nonpuncture group. This result should be clinically useful as an objective reference to determine abdominocentesis in patient with pneumoperitoneum due to CO_2 leakage to the abdominal space.

Disclosure: Nothing to disclose.

Introduction: Due to the widely use of potassium competitive acid blocker (P-CAB) and proton pump inhibitor (PPI) for acid-related diseases, the incidence of PPI/P-CAB-related gastropathy become more common in Japan. In the revised 3rd. edition of the Kyoto Classification [(1)], web-like mucus (WLM) has been newly described as an endoscopic finding seen in PPI/P-CAB-related gastropathy. The mechanism of its formation has been speculated to be linked to the strong and sustained inhabitation of acid secretion [(2)], however, the details of WLM are still unknown. We investigated the characteristics of WLM based on the database of upper gastrointestinal endoscopy performed at our department.

Aims & Methods: The aim of this study is to reveal the characteristics of subjects with WLM. This study is a retrospective cross-sectional study conducted in a single hospital. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2020 and December 2023. We examined subjects in which endoscopists recognized the presence of WLM. Statistical analyses were performed by Fisher's exact test.

Results: Out of a total of 3,564 subjects, WLM was observed in 14 cases (5 males and 9 females, mean age 72.4±16.3 years). All 14 patients were taking P-CAB. The duration of P-CAB administration varied from 8 days to 2 years. Interestingly, in some cases WLM was observed just a few days after starting oral administration of P-CAB. Regarding *Helicobacter pylori* infection, 10 cases were uninfected and 4 cases were past infected.

Conclusion: All subjects with WLM were taking P-CAB. All subjects with WLM were taking P-CAB. We found that WLM can be observed even just a few days after starting oral administration.

Contact E-Mail Address: hideomi.tomida.epch@hotmail.com

Introduction: Per-oral endoscopic myotomy (POEM) is a leading therapeutic procedure for third space endoscopy (TSE) and has been the first choice for treatment of esophageal achalasia. TSE requires treatment in a narrow space. The recently launched thin therapeutic endoscope (EG-840TP, Fujifilm Medical) is expected to be useful for TSE including POEM.

Aims & Methods: To clarify the effectiveness of thin therapeutic endoscopy in POEM, we conducted a retrospective observational study of 66 patients who underwent POEM in our hospital between November 2019 and March 2024. Patient characteristics and outcomes were compared between 52 patients treated with a normal-diameter therapeutic endoscope (T group) and 14 patients treated with a thin therapeutic endoscope (TP group).

Results: The patients in T group were 26 males and 26 females, median age 61 years (18-88), 44 cases of esophageal achalasia (Type I/II/III: 28/15/1), 6 cases of EGJOO, and 2 cases of DES. The TP group included 7 men and 7 women, median age 60 years (13-81), 11 cases of esophageal achalasia type I, 2 cases of EGJOO, and 1 case of DES. Sigmoid type was 58% (n = 30) and 29% (n = 4) in the T/TP group, respectively, and was significantly more common in the T group. Treatment before POEM was balloon dilation 11/1, POEM1/1, and Heller-Dor5/0 in the T/TP group, all of which were not significantly different. There was no difference in the length of myotomy between the two groups in either the esophagus or stomach. The median treatment time in each group was 92 minutes in the T group and 107 minutes in the TP group, and there was no significant difference in the submucosal tunnel creation time. However, the myotomy time per cm was 2.5 min in the T group and 3.8 min in the TP group, which was significantly longer in the TP group ($p<0.01$). Clips required for entry closure were significantly less in the TP group (8 clips in the T group and 5 clips in the TP group) ($p<0.01$). Eckardt scores after POEM improved equally in the two groups, and the rates of adverse events and GERD after POEM did not differ between the two groups.

Conclusion: POEM using a thin therapeutic endoscope resulted in similar treatment outcome as conventional endoscopes. Although there was no difference in the treatment time, TP group required fewer clips to close the entry. The prolonged myotomy time in the TP group was considered to reflect the fact that the thin therapeutic endoscope made it easier to approach the muscle layer and more careful myotomy was performed. Although further investigation is needed, a thin therapeutic endoscope may be useful for TSE.

A SINGLE-CENTRE RETROSPECTIVE STUDY OF ENDOSCOPY REFERRALS FOR ANAEMIA: INSIGHTS INTO CANCER AND NON-CANCER PATHOLOGIES

R. Al Saidi[1], C. Aydemir[1], L. Alhalabi[1], W. Taj-Aldeen[2]

[1]University of Buckingham, Buckingham, United Kingdom, [2]Milton Keynes University Hospital, Milton Keynes, United Kingdom

Contact E-Mail Address: raniahsarmad@gmail.com

Introduction: Anaemia is common and in some cases an indication for an urgent endoscopy via two week wait (2WW) pathway. This pathway allows patients with alarming symptoms to see a specialist within two weeks to exclude cancer. In this retrospective study, we assessed the clinical outcomes of such referrals, describing the types of cancer identified after full investigations in our centre.

Aims & Methods: Data was collected between December 2021 and December 2022 using Endoscopy UNISOFT system for all endoscopy procedures prompted by anaemia at Milton Keynes University Hospital, United Kingdom. Basic demographics, faecal immunochemical test (FIT) and 2WW referrals from both upper gastrointestinal (UGI) or colorectal pathway were recorded. Radiological images and multi-disciplinary team outcomes were reviewed.

Results: Total number of patients referred to our endoscopy unit was 389, 70% were referred via colorectal team while 30% were referred via UGI pathway. Age of patients was distributed between 19 to 98 years old with majority aged between 60 to 88 years old. 227 patients had both gastroscopy (OGD) + colonoscopy (COL), 76 had OGD+CT scan, 9 patients had OGD+COL+CT and 5 patients had COL+CT. The other patients had CT only, OGD only, or COL only, depending on fitness.

Data revealed that 33 (8.5%) patients referred with anaemia had cancer. 21 patients had colorectal cancer while 8 patients had upper GI cancer. Non-GI cancers were found in four patients, 2 of them lung cancer, 1 renal cancer and 1 tonsillar cancer. There were 187 patients (48%) that had UGI non-cancer pathology e.g. gastritis, duodenitis, peptic ulcer disease, oesophageal varices and coeliac disease. The remaining causes of anaemia are found in Table 1.

Total cause of Anaemia	Number of Patients
Cancer (Colon, UGI, Other)	33
Other UGI pathologies	187
Unknown	92
Other colorectal pathologies	55
Angiodysplasia (UGI + colon)	18
Anaemia of Chronic Disease	2
Gynaecological	2
Total	389

Table 1: Causes of Anaemia.

Positive FIT and colorectal cancer:

Out of the 389 patients, 100 patients (25%) had stool FIT. 37 patients had a positive FIT, and only 5 patients (14%) were diagnosed with colorectal cancer. In the remaining 16 patients with colorectal cancer, FIT was not performed.

Conclusion: The percentage of cancer in our population with anaemia was 8.5%. The main gastrointestinal cancer was colon cancer (5.4%), followed by upper gastrointestinal cancer (2.05%) and non-GI cancer was (1.02%) only. According to previous data, 8%-10% of cases with anaemia were found to have cancer which is not very different from our audit (1,2). The most common cause of anaemia was UGI non-cancer pathology, however, there was no clear aetiology identified in 23% of our population. Four non-GI cancer were discovered by radiological images/CT scans. Those patients with non-GI cancer were above the age of 60. Although the

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

number is small, radiological imaging remains an important tool to investigate anaemia in elderly people when both OGD and colonoscopy are unremarkable. FIT test revealed a high false positive rate with only 14% with positive FIT test had colorectal cancer.

BIOPSY PRACTICE DURING DIAGNOSTIC UPPER GASTROINTESTINAL ENDOSCOPY IN THE UK: ANALYSIS OF 638 000 ENDOSCOPIES IN THE NATIONAL ENDOSCOPY DATABASE

A. Srinivasa[1], N. Trudgill[1]

[1]Sandwell and West Birmingham NHS Trust, Gatroenterology, West Bromwich, United Kingdom

Contact E-Mail Address: amarsrinivasa@nhs.net

Introduction: Appropriate tissue sampling is vital for lesion diagnosis during endoscopy. We have previously found an association between higher biopsy rates and reduced compliance with national biopsy recommendations (e.g. from ulcers) with higher rates of post endoscopy upper gastrointestinal cancers (PEUGIC).

Aims & Methods: The aim of this study was to examine biopsy practice in the UK, along with comparing results to the recommendations set out by the European Society of Gastrointestinal Endoscopy.

Upper gastrointestinal (UGI) endoscopies between 01/01/2019 and 29/02/2020 were analysed from the National Endoscopy Database (NED). Surveillance endoscopies were excluded. Logistic regression analysis examined associations with biopsy rate, biopsies from gastritis or duodenitis and biopsies from ulcers.

Results: 638,280 UGI endoscopies were analysed. 289,156 (45.3%) involved biopsies: esophagus 17.1%, stomach 18.0%, duodenal bulb (D1) 3.9%, second part of the duodenum (D2) 19.4%.

Biopsy rate was associated with: clinical endoscopists OR 1.31 (95% CI 1.29-1.33) and surgeons OR 0.84 (95% CI 0.90-0.95), compared to gastroenterologists; patient age 70-79 OR 1.12 (95% CI 1.05-1.19); male patients OR 1.07 (CI 95% 1.06-1.08); urgent endoscopy OR 1.38 (CI 95% 1.35-1.39); emergency endoscopy OR 0.37 (95% CI 0.36-0.39); and therapy during endoscopy OR 0.25 (95% CI 0.24-0.27) .

During endoscopy for dysphagia with a normal appearance, only 5232 (36.3%) had biopsies to exclude eosinophilic esophagitis, with usually too few biopsies taken (mean 4.5 (SD±2.0)). When the endoscopic diagnosis was reportedly normal (excluding dysphagic indications), 35% involved potentially unnecessary biopsies (263557 biopsies). Biopsies were commonly taken from uncomplicated inflammatory conditions: 31% of endoscopic gastritis (58765 biopsies) and 31% of endoscopic duodenitis (15580 biopsies). Biopsies for gastritis/duodenitis were associated with surgeons OR 1.36 (95% CI 1.26-1.46) and clinical endoscopists OR 1.38 (95% CI 1.31-1.45), compared to gastroenterologists.

Mean number of biopsies from esophageal ulcers was 3.7 (SD±2.1) and from gastric ulcers 3.8 (SD±2.4).Biopsies of gastric or esophageal ulcers were associated with clinical endoscopists OR 1.51 (95% CI 1.37-1.65) and surgeons OR 0.53 (95% CI 0.50-0.56), compared with gastroenterologists; outpatient procedures OR 1.40 (95% CI 1.27-1.53); and emergency procedures OR 0.66 (95% CI 0.55-0.79).

Conclusion: Analysis of NED reveals a large number of apparently unnecessary biopsies for gastritis or duodenitis or during normal endoscopy. In contrast, in only 36% of normal endoscopies for dysphagia were biopsies taken to rule out eosinophilic esophagitis. Quality improvement efforts are needed to reduce unnecessary biopsies, increase appropriate biopsies, reduce costs and environmental impact.

SEDATION PRACTICE IN THE UK: AN ANALYSIS OF 617,000 DIAGNOSTIC UPPER GI ENDOSCOPIES IN THE NATIONAL ENDOSCOPY DATABASE

A. Srinivasa[1], N. Trudgill[1]

[1]Sandwell and West Birmingham NHS Trust, Gatroenterology, West Bromwich, United Kingdom

Contact E-Mail Address: amarsrinivasa@nhs.net

Introduction: Sedation is commonly used during upper gastrointestinal (UGI) endoscopy to improve tolerability. We have previously reported an association between increased sedation use and lower rates of post endoscopy upper GI cancer. We have analysed sedation practices for diagnostic upper GI endoscopy in the National Endoscopy Database (NED).

Aims & Methods: The aim of this study was to examine endoscopy practice in the UK and quantify variation in sedation use during diagnostic endoscopy. Diagnostic endoscopies performed between 01/01/2019 and 29/02/2020 were analysed from NED data. Logistic regression analysis examined associations with sedation use and procedures abandoned due to tolerability.

Results: 314,725 (51%) UGI endoscopies involved sedation: midazolam alone 36%; combined midazolam + fentanyl 14%; midazolam + pethidine 0.9%. In patients over the age of 70, during 11 887 of 206 386 endoscopies (5.8%), more than the recommended 2.5mg of midazolam was given (mean 3.4mg (SD±0.76)), including 3320 in which fentanyl was co-prescribed (mean 67.0mcg (SD±29.1)).

Sedation use was associated with: compared to gastroenterologists, clinical endoscopists OR 0.57 (95% CI 0.56-0.58), surgeons OR 0.65 (95% CI 0.64-0.66), SAS doctors 0.65 (95% CI 0.64-0.66); younger patients; males OR 0.60 (95% CI 0.59-0.61); afternoon lists OR 0.98 (95% CI 0.97-0.99) and weekends (OR 0.88 (95% CI 0.87-0.90); compared with routine endoscopy, urgent 1.22 (95% CI 1.21-1.23) and surveillance OR 0.91 (95% CI 0.88-0.94). Sedation + opioid was most frequently used by gastroenterologists, but less by others: clinical endoscopists OR 0.26 (95% CI 0.25-0.27); surgeons OR 0.26, (95% CI 0.25-0.27); and SAS doctors 0.33 (95% CI 0.32-0.34).

3499 endoscopies were abandoned due to poor tolerance: age mean 59.1 (SD±17.1), female 59%, no sedation 57%, midazolam only 32% and midazolam + opioid 10%. This was associated with: surgeons OR 1.29 (95% CI 1.07-1.53) and clinical endoscopists OR 1.39 (95% CI 1.19-1.62), compared to gastroenterologists; addition of opioids OR 0.66 (95% CI 0.59-0.73); and no sedation OR 1.32 (CI 95% 1.23-1.40).

Conclusion: There is lower use of sedation overall, and combined midazolam and opioid particularly, among endoscopists other than consultant gastroenterologists, despite improved tolerability and reduced aban-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. REMIMAZOLAM VS. MIDAZOLAM SEDATION IN UPPER GASTROINTESTINAL ENDOSCOPY IN ADULTS > 65 YEARS: RANDOMIZED CONTROLLED TRIAL

G.H. Lee[1], J.S. Park[1], J.H. Park[1], C.-K. Noh[1], S.G. Lim[1], S.J. Shin[1], K.M. Lee[1]

Introduction: Safe and effective sedation are important factors when performing gastrointestinal endoscopy. However, clinicians should be cautious when using sedatives in older patients because of their decreased physiological reserves. Remimazolam is an ultrashort active benzodiazepine that has attracted attention because of its efficacy. This study aimed to determine the safety and efficacy of remimazolam compared with midazolam as a sedative for diagnostic upper gastrointestinal endoscopy in older patients aged ≥65 years.
Aims & Methods: We randomly assigned patients aged ≥65 years who were scheduled for diagnostic upper gastrointestinal endoscopy. The average induction time, average recovery time, and side effect profile of patients who received remimazolam as a sedative were compared with those of patients who received midazolam.
Results: Patients who received remimazolam had shorter average induction (102.0 sec vs. 327.5 sec, p<0.001) and recovery times (5.8 min vs. 13.4 min, p<0.001) than those who received midazolam. No significant difference in side effect profiles was observed between the groups.
Conclusion: In performing upper gastrointestinal endoscopy in older patients, remimazolam can be a good alternative sedative to midazolam, whether used as monotherapy or in combination therapy.

LCI (LINKED COLOR IMAGING) AND HISTOPATHOLOGICAL FINDINGS FOR MAP-LIKE REDNESS AFTER *HELICOBACTER PYLORI* ERADICATION THERAPY

E. Umegaki[1], T. Ninomiya[1], S. Monden[1], M. Sasahira[1], S. Yoi[1], M. Osawa[1], O. Handa[1], H. Matsumoto[1], A. Shiotani[1]
[1]Kawasaki Medical School, Gastroenterology & Hepatology, Kurashiki, Okayama, Japan

Contact E-Mail Address: eumegaki@med.kawasaki-m.ac.jp
Introduction: Mucosal redness (so called Map-like redness) after *Helicobacter pylori* (*H. pylori*) eradication therapy reflects intestinal metaplasia clarified by changes of intra-gastric condition and repairs for gastric mucosa. It is difficult to distinguish Map-like redness and gastric cancer. Map-like redness is a high risk condition for post *H. pylori* eradicated gastric cancer. Consideration about histopathological findings of mucosal redness after *H. pylori* eradication therapy are not enough.
Aims & Methods: Image-enhanced endoscopy plays an important role in the detection and further examination of gastritis and early gastric cancer (EGC). LCI is also useful for detecting and evaluating gastritis, gastric intestinal metaplasia as a pre-cancerous lesion, and EGC. To investigate correlation between the color difference and immuno-histochemical findings for mucosal redness (map-like redness; intestinal metaplasia) detected by white light and LCI in patients with successful *H. pylori* eradication history. We get the endoscopic images by conventional white light image (WLI) and LCI with LASEREO system (FujiFilm, Tokyo, Japan), and evaluate color values (CIE L*a*b* color space and color analysis by Adobe Photoshop C54). Furthermore, we evaluate intestinal metaplasia histopathologically with the immuno-staining by MUC2/MUC5AC/HID-AB; phenotype (Gastro-intestinal Mixed type or Intestinal type, Incomplete type or Complete type) and relationship between color differences and phenotype of intestinal metaplasia.
Results: (1) Objects are 36 patients (24 males, range 56-87yo, median 71yo) and 43 lesions after successful *H.pylori* eradication therapy; cancer group 15 patients (20 lesions), non-cancer group 21 patients (23 lesions)
(2) Type of intestinal metaplasia in the cancer group and the non-cancer group: GI Mixed type 14/7(cancer group/non-cancer group), p<0.01, Incomplete type 14/6(cancer group/non-cancer group), p<0.01.
(3) In the cancer group, color differences Δa (Green to Red) with LCI between the lesion and the surrounding mucosa is significantly high compared with the non-cancer group (16.0±6.6 vs 11.8±7.0;p<0.05).
(4) Compared severe intestinal metaplasia with none/mild/moderate intestinal metaplasia, color value b (Blue to Yellow) with LCI is significantly low (20.4±9.5 vs 25.9±8.0; p<0.05)
(5) Compared GI mixed type with intestinal type of intestinal metaplasia, color values b (Blue to Yellow) with LCI is significantly low (19.2±8.6 vs 26.4±8.5; p=0.008).
Conclusion: In this study, we observed differences in LCI color values of map-like redness appearing after *H. pylori* eradication depending on the type of intestinal metaplasia. In particular, the gastric cancer group has a high rate of Gastro-intestinal Mixed Type with a high risk of carcinogenesis. This suggests the usefulness of image enhancement by LCI as a marker for the high-risk group of gastric cancer.

Introduction: Advances in surgical treatments have improved mortality of postoperative patients with gastric cancer and esophageal cancer. Then, the number of residual and gastric-tube cancers is increasing. Re-surgical treatment for postoperative gastric cancers (Po-GCs) has a high incidence and mortality rate, so the contribution of endoscopic therapy might be large.
However, endoscopic submucosal dissection (ESD) for Po-GCs is considered technically difficult. Especially during mucosal incision, we sometimes encounter unexpectable bleedings.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: We investigated the re-construction of blood vessels in the submucosal layer on ESD specimens of Po-GCs.8 cases of Po-GCs (4 cases of residual gastric cancer, 4 cases of gastric-tube cancer) underwent ESD in our hospital from 2016 to 2023 were included. Eligible specimens of cases include the lesion center. Vascular distribution in the shallow submucosal layer (a depth of 500μm from the muscularis mucosae) was well observed and the number of dilatated arteries and veins with a diameter>100μm are counted and compensated by a specimen diameter. These number of vessels were compared with 16 cases of controls (1:2) extracted from general gastric ESD underwent in the same location and period.

Results: There were 0.4±0.5/cm arteries and 1.1±1.1/cm veins/mm in control. There were 2.3±1.4/cm arteries and 5.5±2.0/cm veins in the cases of residual gastric cancers. And there were 4.1±1.1/cm arteries and 2.7±0.4/cm veins in the cases of gastric-tube cancers. Both cases of residual and gastric-tube cancers involved many dilatated arteries and veins (P<0.05) in superficial submucosal layer compared with control. On the other hands, the cases of residual gastric cancers have lots of veins compared with arteries (P <0.05), and the cases of gastric-tube cancers have lots of arteries compared with veins (P <0.05).

Conclusion: Residual stomach is small and arterial blood flow is maintained, but veins are resected on a process of surgery. These would be the reason for venous congestion is noticeably high in the residual stomach. On the other hand, the gastric-tube mucosa tends to be more abundant of blood flow due to the reconstruction method. As a result, branches of arteries remaining in submucosal layer would be developed. From the above, on the process of ESD, the probability of encountering veinous oozing increases on residual gastric cancer, and arterial bleeding increases on gastric-tube cancer. It's suggested that paying more attention to these vascular distributions of the submucosal layer is needed while postoperative gastric ESD is performed.

FEASIBILITY AND SAFETY OF COLLABORATIVE SURGERY FOR GASTROINTESTINAL TUMOURS BY ENDOSCOPISTS AND SURGEONS: A SINGLE-CENTER RETROSPECTIVE ANALYSIS OF 131 PATIENTS

Y. Ishikawa[1], O. Goto[1,2], K. Higuchi[1], S. Nakagome[1], M. Niikawa[1], K. Yoshikata[1], T. Habu[1], E. Koizumi[1], K. Kirita[1], H. Noda[1], T. Onda[1], J. Omori[1], N. Akimoto[1], K. Iwakiri[1]

[1]Nippon Medical School, Department of Gastroenterology, Tokyo, Japan, [2]Nippon Medical School, Endoscopy Center, Tokyo, Japan

Contact E-Mail Address: i-yumiko0@nms.ac.jp

Introduction: Endoscopic treatment using peroral/anal flexible endoscopy and dedicated through-the-scope electrocautery devices has been developed as a less-invasive intraluminal surgery. However, pure endoscopic treatment has limitations for lesions at the deeper layer or excessively close to the mouth/anus. Conversely, surgical approach sometimes leads to wider resection and subsequent decreases in the patient's quality of life. Collaborative surgery by both endoscopists and surgeons is considered effective for providing less-invasive local resection of gastrointestinal tumours to offset limitations either in pure endoscopic treatments or surgical intervention.

Aims & Methods: To investigate the feasibility and safety of this approach, we here retrospectively evaluated the clinical outcomes of collaborative surgery with endoscopists and surgeons. We consecutively collected data of patients who underwent collaborative surgery for lesions located from the laryngopharynx to the anus between October 2017 and December 2023. Collaborative surgery was indicated after the agreement on both flexible endoscopists and surgeons, considering possible benefits of the cooperation in terms of invasiveness, technical difficulty, and safety. Laryngopharyngeal lesions and cervical oesophageal cancer were removed using the ESD technique under laryngeal expansion using a curved laryngoscope by the otolaryngologist's manipulation. With gastrointestinal surgeons, subepithelial tumours in the gastrointestinal tract and deeply invasive gastric cancers were removed in a full-layered fashion, followed by surgical suturing. Large duodenal cancers were principally treated by ESD followed by sero-muscular suturing for the reinforcement of the mucosal defects.

In large anal canal cancer with pagetoid spread, a dermatologist externally dissected the perianally expanded area following ESD from the rectal side. Collaboration completeness, technical success, procedure time, postoperative hospitalization period, and occurrence of adverse events were analyzed.

Results: Collaboration surgery was performed for 134 lesions (33 laryngopharyngeal, 2 oesophageal, 89 gastric, 8 duodenal, and 2 recto-anal lesions, respectively) in 131 patients. Collaboration completeness was achieved in 129 lesions (96%). The en-bloc resection and pathological R0 resection of lesions were obtained in 127 (95%) and 124 (93%) lesions, respectively. The mean procedure time was 188 min. Patients were discharged on the mean postoperative day of 11. Five patients (4%) developed relevant postoperative adverse events.

Conclusion: The results indicated that collaborative surgery by endoscopists and surgeons was feasible and safe, and should contribute to providing less-invasive treatment than conventional approaches. The frequency of adverse events was considered acceptable. Collaborative surgery is worth considering as a flexible and reliable surgical option when cooperation should outperform a single treatment by either of endoscopists or surgeons. To establish this concept, further accumulation of cases and pieces of evidence by well-designed studies is desired.

Disclosure: Nothing to disclose.

PP0161

FULL-THICKNESS RESECTION DEVICE (FTRD) FOR THE TREATMENT OF GASTROINTESTINAL TRACT (GIT) LESIONS : TREATMENT OUTCOMES AND PREDICTORS OF SUCCES IN AN ASIAN COHORT

M. Chu[1,2], K.W. Lim[2], R. Ravi[2], C.P. Francisco[3], R. Asokkumar[4]

[1]Singapore General Hospital, Singapore, Singapore, [2]Singapore General Hospital, Gastroenterology and Hepatology, Singapore, Singapore, [3]St. Luke's Medical Center - Global City, Institute of Digestive and Liver Diseases, Taguig City, Philippines, [4]Singapore General Hospital, Gastroenterology, Singapore, Singapore

Contact E-Mail Address: michaelchu0712@gmail.com

Introduction: FTRD represents a novel treatment option for managing GIT lesions that are complex and not easily removed by conventional endoscopic resection techniques. However, there is limited data outside expert centers describing its efficacy and safety.

Aims & Methods: This study aims to evaluate the utility and safety of the FTRD to remove upper and lower GIT lesions and identify predictors for successful resection.

We included 34 patients (mean age 62.8 ±12.9 years; male-64.7%) who underwent FTRD at the Singapore General Hospital since 2021. We followed the recommended FTRD technique. The primary objective was to evaluate the technical success, defined as the correct

application of the FTRD clip and immediate complete en-bloc resection of the lesion. The secondary objective was to assess the safety using the Clavien-Dindo classification and identify predictive factors for successful FTRD resection. Chi-squared test, Fisher's exact test, and logistic regression were used to analyze categorical data.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: FTRD was performed for both upper (35.3%) and lower GIT (64.7%) lesions (Table-1). The common lesions were neuroendocrine tumors (NET; 52.9%), mesenchymal neoplasms (23.5 %), and residual polyps/advanced adenomas (23.5 %). Most upper GIT lesions were in the stomach (58.3%), followed by duodenum (41.7%). Likewise, the lower GIT lesions were in the rectum (73%), left (3.5%) and right colon (13.5%). The average lesion size was 12.6 ± 6 mm. FTRD deployment was technically successful in 27 patients (79.4 %)(Table-2). We found the technical success was significantly higher for lower than upper GIT lesions (91% vs. 50%, p=0.004). Similarly, lesions in the rectum (100%) had substantially higher technical success than lesions in other locations (p=0.01). Technical success was significantly higher for NET than mesenchymal lesions or residual polyps (100% vs. 37.5% vs. 75%, p=0.001). Overall, the R0 resection rate with negative histological margin was noted in 25 (73.5%) patients and was significantly higher for NET (100%) than other lesions (p=0.001). The mean procedure time was 57.5 ±25 min. Immediate complications occurred in 8 cases (23.5%) and delayed bleeding occurred in 1 patient (2.9%). Most of them were minor and treated conservatively, except one requiring endoscopic repositioning of duodenal FTRD clip causing gastric outlet obstruction. Follow-up endoscopy was performed in 11 patients at an average of 12-months. A retained clip with hyperplastic granulation change was seen in one patient. Multivariate analysis showed lesion size, location (rectum), and type of GIT lesion (NET) predicted significantly higher technical success (p=0.02).

Conclusion: Our results show that FTRD offers an acceptable technical success and R0 resection rate with a low risk of complications. Lower GIT location and non-mesenchymal lesion demonstrated better outcomes with FTRD.

Disclosure: None.

PP0162

VACUUM-STENT TREATMENT FOR TRANSMURAL DEFECTS IN THE UPPER GASTRO-INTESTINAL TRACT: CASE SERIES AND NEW INSIGHTS IN A TERTIARY REFERRAL CENTER

L. Pattynama[1,2], W.J. Eshuis[2], J.J. Bergman[1], M.I. van Berge Henegouwen[2], R.E. Pouw[1]
[1]Amsterdam UMC, Dept. of Gastroenterology and Hepatology, Amsterdam, Netherlands, [2]Amsterdam UMC, Dept. of Surgery, Amsterdam, Netherlands

Contact E-Mail Address: l.m.pattynama@amsterdamumc.nl

Introduction: Transmural defects in the upper gastro-intestinal (GI) tract are associated with severe morbidity and mortality. Endoscopic vacuum therapy (EVT) has recently been established as promising endoscopic treatment option for such defects and is most often applied using endoscopically placed vacuum-sponges. The vacuum-stent is a novel device to apply EVT, combining the advantages of negative pressure wound therapy and an intraluminal stent, allowing for oral intake.

Aims & Methods: The aim of this prospective cohort study is to describe the experiences of, and lessons learned by a tertiary referral center with EVT experience since 2018, regarding the vacuum-stent for transmural defects in the upper GI tract. All patients treated with a vacuum-stent between November 2022 and October 2023 were included. Outcome measures included successful defect closure, reasons of treatment failure, adverse events and strictures.

Results: 31 patients were included. Baseline characteristics and outcomes are displayed in Table 1. Success rates of combined vacuum-stent and –sponge treatment and vacuum-stent treatment alone were respectively 83% and 78%. In this cohort, some notable reasons of failure were observed: a defect too close to the upper esophageal sphincter (UES), inadequate vacuum on the esophago-jejunal anastomosis, a carcinoma at a persisting perforated ulcer, and two adverse events (6%). The adverse events included two patients who developed a secondary defect at the site of the proximal vacuum-stent flange, of whom one had a cervical anastomosis with a narrow proximal esophagus and one Boerhaave syndrome. Three out of four patients with a severe structure had underwent a McKeown esophagectomy (cervical anastomosis).

Etiology of defect, n (%)	31
Anastomotic leakage	18 (58%)
Boerhaave syndrome	5 (16%)
Iatrogenic	5 (16%)
Other	3 (10%)
Initial procedure in case of anastomotic leakage, n (%)	18
Ivor Lewis esophagectomy	9 (50%)
McKeown esophagectomy	6 (33%)
Gastrectomy	3 (17%)
Success rate, n (%)	31
Combined vacuum-stent and –sponge treatment	26 (83%)
Only vacuum-stent treatment	24 (78%)
Adverse events, n (%)	2 (6%)
Severe stricture requiring > 3 dilations, incision therapy or self dilation, n (%)	4 (13%)

Table 1. Baseline characteristics and outcomes.

Conclusion: The vacuum-stent is a valuable treatment option for AL after Ivor Lewis esophagectomy, Boerhaave syndrome and iatrogenic defects with success rates of 80-89%. Treating cervical anastomotic leaks is not recommended by us, due to the narrow lumen of the proximal esophagus, the proximity of the UES and high risk of severe strictures. Furthermore, caution is recommended in case of a narrow esophagus and the value of the vacuum-stent is yet to be determined in case of an esophago-jejunal anastomosis. In our experience, vacuum-stent and –sponge treatment complement each other and might be indicated in different situations. Sharing experiences on the topic is important to assess the best techniques and indications, to be able to reach the full potential of the vacuum-stent and further increase the success rate.

PP0163

OUTCOME OF OESOPHAGEAL STENTING FOR MALIGNANT DYSPHAGIA: A 10-YEAR RETROSPECTIVE SURVIVAL ANALYSIS

D. Kapila[1], R. Rameshshanker[1]
[1]Hillingdon Hospital, London, United Kingdom

Contact E-Mail Address: r.rameshshanker@nhs.net

Introduction: Advanced oesophageal cancers (OC) exhibit poor median survival rates, and often self-expandable metal stents (SEMS) are used to address malignant dysphagia. Previous studies purport to a high prevalence of adverse events post stent insertion, without an impact on mortality. We aimed to review mortality outcomes of oesophageal stenting in both squamous cell carcinoma (SCC) and adenocarcinomas (AC).

Aims & Methods: One hundred and eighty-six patients who were diagnosed with OC between September 2010 - February 2021 were included. We retrospectively analysed the data for patient demographics, histology, oncological management, oesophageal stenting, and mortality, notably overall survival (OS). Survival probability was calculated using Kaplan-Meier survival curves and compared using Log-rank testing with statistical significance determined by p value <0.05.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: From the 186 OC diagnoses made. Male: Female 136 (73%) and 50 (27%). Mean age at diagnosis was 73 years (range 32-98). Histological findings showed 132 patients had AC (71%), and 54 patients had SCC (29%). Mean OS from date of diagnosis for AC and SCC were 21.6 and 10.6 months respectively.

SEMS were inserted for 98 patients (53%); 37 (38%) for SCC and 61 (62%) for AC. Mean OS for patients with stenting vs not stenting was 11.1 and 26.4 months respectively. Median OS for stenting was 8 months (95% CI, 6.0 - 10.0) vs 10 months for not stenting (95% CI, 7.0 -16.0) with a p<0.0005) (See Figure 1). 30-day mortality post stent insertion was 23%.

For patients who underwent oesophageal stent insertion, mean OS for AC and SCC 11.9 months (95% CI, 8.989 to 14.913) and 10.1 months (95% CI, 6.709 to 13.561) respectively. Median OS for stent population for SCC and AC were 6 months (95% CI, 5.0 -8.0) and 9 months (95% CI, 6.0 -12.0) respectively (p = 0.3765).

Conclusion: Patients with OC who underwent stent insertion had overall poor survival outcome. This could reflect advanced stage of OS. Stenting is often useful for malignant dysphagia in patients who harbor inoperable disease. Analysis of stent adverse events would be useful.

Disclosure: Nothing to disclose.

Introduction: Early detection of gastric cancer may result from adequate diagnosis and surveillance of individuals with gastric intestinal metaplasia (GIM). Computer-assisted diagnosis systems based on artificial intelligence, or more specifically Deep Neural Networks (DNN) applied to esophagogastroduodenoscopy may be crucial in optimizing and standardizing patients' final diagnosis. Literature has shown promising DNN results for single datasets, some of which reaching the 90% accuracy suggested by the European Society of Gastrointestinal Endoscopy for these algorithms [1].

Moreover, traditionally Wight-Light Endoscopy is referred as suboptimal to determine the presence of GIM. We aimed to determine the accuracy of current state-of-the-art AI algorithms for WLE from 2 different scopes' providers for GIM detection.

Aims & Methods: Two datasets were used in these experiments:

• Dataset A (Fujifilm) was used for training and testing, consisting of a private benchmark dataset [1] of which we have used 4876 endoscopic White Light (WL) images (2438 normal, 2438 GIM).

• Dataset B (Olympus) was used for external validation and was collected from a lower quality clinical routine dataset, including 373 WL images (170 normal, 203 GIM). All images were annotated by clinical experts and the primary outcome was GIM classification accuracy.

We conducted experiments comparing the performance of DNNs (ResNet50) in GIM detection by training the models with and without the integration of synthetic/artificially generated endoscopy images. This involved employing four different methods: using the default dataset, augmenting the dataset with classic data augmentation transformations, incorporating images generated by Deep Convolutional Generative Adversarial Networks (DCGAN), and integrating images generated by Wasserstein GAN (WGAN). A part of dataset A (15%) was saved for testing in the different experiments and the remaining data (85%) was used to train the model, using a 5-fold cross-validation. In the end, dataset B was used as an external test set to evaluate the generalization capabilities of the different DNNs.

Results: The ResNet50 (dataset A – test set) achieved an accuracy of 92% for the default dataset, 93% for the data augmentation transformations, 93% for the DCGAN and 94% for the WGAN. The respective sensitivity values were 92%, 91%, 92% and 92%. Then, these models were evaluated in the dataset B, to infer its generalization capabilities. The ResNet50 achieved an accuracy of 63% for the default dataset, 68% for the data augmentation transformations, 65% for the DCGAN and 65% for the WGAN. The respective sensitivity values were 66%, 80%, 73% and 73%.

	Single Dataset (A->A) [Fujifilm WLE]				Generalization (A->B) [Olympus WLE]			
ResNet50	Default	Augm.	DCGAN	WGAN	Default	Augm.	DCGAN	WGAN
Accuracy	0.92	0.93	0.93	0.94	0.63	0.68	0.65	0.65
Sensitivity	0.92	0.91	0.92	0.92	0.66	0.80	0.73	0.70

Conclusion: Even for WLE, current DNN architectures seem to obtain very good results for GIM detection. However, generalization is still insufficient, since validation in different datasets (different clinical settings, different endoscopic technologies) obtains average detection accuracy and sensitivity, illustrating the excessive specialization caused by maximizing accuracy results in single datasets.

Introduction: The outcome of ESD in early gastrointestinal neoplasia in Japan is well established. However, in the west, ESD practice is variable given different disease prevalence in UGI tract and also the volume and experience of each centre.

Aims & Methods: We aim to evaluate ESD practice and outcomes in the UK and hence, multi centre registry was set up. This is a prospective observational study for patients undergoing ESD for early GI neoplasia. All technical and outcomes data was prospectively collected onto REDCap.

Results: There were 451 UGI ESD cases recruited between August 2016 to August 2023 from 6 large tertiary referral centres in the UK. Mean age of the patients was 70.8 years (range: 24-94 years) with male preponderance (318 males vs. 133 females). Majority were in oesophagus: 282 (62.53%), stomach: 159 (35.25%) and duodenum: 10 (2.22%).

Of 282 oesophageal ESDs, 277 (98.23%) were technically successful with en-bloc resection rate of 96%. There were 3 intraprocedural complications (2 oesophageal perforations and 1 oral laceration from overtube). All of them were managed endoscopically. There were 29 (10.28%) post ESD strictures requiring endoscopic dilatations. 3 (1.06%) delayed bleeding were noted and 3 were readmitted for decompensation of underlying co-morbidities.

There were 204/282 (72.34%) Barrett's cases with average length of C3 M5 and mean size 34.5mm. 34 cases (16.67%) had previous ESD or ablation at the same site. Post ESD resection showed deep submucosal (SM) invasion in 21 patients (deep R0 achieved in 42.9% and lateral R0 in 76.2%), 23 pT1bSM1 (deep R0 in 87.0% and lateral R0 in 87%), 107 pT1a (deep R0 in 89.7% and lateral R0 in 85.1%), 31 high grade dysplasia (HGD) (R0 in 97%) and 9 low grade dysplasia (LGD) (R0 in 78%) as shown in Table 1.

There were 44 squamous cell carcinoma (SCC), 26 gastro-oesophageal junctional neoplasia and 8 others (submucosal lesion and granular cell tumours). Of 44 SCC, there were 8 pT1b (5 achieved deep R0, 7 achieved lateral R0), 10 pT1a (all achieved both deep and lateral R0), 22 HGD (81.8% achieved R0), 3 LGD (all achieved R0) as shown in Table 1.

There were 160 gastric ESDs with completion rate of 96.25% and en-bloc rate of 95.5%. There were 8 (5%) intra-procedural perforation which required endoscopic clippings. There were 7 (4.36%) delayed bleeds which were managed endoscopically. Of 160 cases, 138 were epithelial neoplasia, 11 were submucosal lesions while 4 were large hyperplastic polyps. As shown in Table 1, of 138 epithelial neoplasia, 10 had deep SM invasion (7 achieved deep R0, 8 lateral R0), 14 pT1bSM1 (7 achieved deep R0, 10 lateral R0), 50 pT1a (90% achieved deep R0, 80% lateral R0), 35 HGD (94.3% R0) and 27 LGD (77.8% R0).

	Deep SM invasion (n)	Deep R0 (%)	Lateral R0 (%)	pT1b SM1 (n)	Deep R0 (%)	Lateral R0 (%)	IMC (n)	Deep R0 (%)	Lateral R0 (%)	HGD (n)	R0 (%)	LGD (n)	R0 (%)
Barrett's neoplasia	21	42.9	76.2	23	87.0	87.0	107	89.7	85.1	31	97.0	9	78.0
Oesophageal SCC	3	66.7	100.0	5	60.0	80.0	10	100.0	100.0	22	81.8	3	100.0
Gastric neoplasia	10	70.0	80.0	14	50.0	71.4	50	90.0	80.0	35	94.3	27	77.9

Table 1. Post ESD histology outcome in UGI tract.

Conclusion: Unlike in the East, most ESDs in our study were performed in Barrett's oesophagus rather than the stomach. Our data demonstrates the feasibility and safety of UGI ESD in Western setting with high en-bloc rate and low complication rates. We found that within indication of ESD, complete resection (R0) rate is high but lesions with deep submucosal invasion have poor R0 rate.

Introduction: EsoFLIP is a novel dilation balloon that utilizes high-resolution impedance planimetry to provide real-time, objective visualization and monitoring of dilation.

Aims & Methods: The aim of our prospective study is to evaluate clinical and technical success and safety of endoscopic dilation with EsoFLIP in patients affected by benign esophageal strictures (NCT05725473). Patients with symptomatic esophageal strictures, with exception of patients affected by motor disorders, were selected and endoscopic dilatations were performed with EsoFLIP (8-20 mm dilation range). Clinical condition was evaluated before and after procedure (one week and one month) using a specific questionnaire about severity and frequency of dysphagia (Brief Esophageal Dysphagia Questionnaire-BEDQ 10 items from 0 to 6). We also quantified rate of technical success, adverse events, total procedure time and fluoroscopy exposure time. We utilized EndoFLIP (impedance planimetry system) to evaluate stricture diameter (mm), cross-sectional area (CSA mm2), distensibility index (DI mm2/mmHg) before and after dilatation with EsoFLIP.

Results: We enrolled 15 patients affected by esophageal strictures due to lymphocytic (2) and eosinophilic esophagitis (2), caustic ingestion (2), Schatzki rings secondary to GERD (3), esophageal-gastric anastomosis (6). Strictures involved proximal-medial esophagus (18-30 cm from incisors) in 7 patients out of 15 and in 8 out of 15 patients medial-distal esophagus (30-42 cm). All dilation procedures were technically successful, and no adverse events occurred. The median procedure time was 52.67 min (±12.87) and fluoroscopy exposure time was 5.14 min (±1.23; 9.76% of procedure). After 1 week and 1 month from the dilatation there was a significant decrease of dysphagia severity and frequency shown by BEDQ total score (pre-BEDQ 6.87±5.82 vs 1 week-post-BEDQ 3.20±3.69, p-value 0,0486; pre-BEDQ 6.87±5.82 vs 1 month-post-BEDQ 2.33±2.81, p-value 0.0206). After procedure, there was a significant increase of stricture diameter (pre-di-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ameter 8.55±2.80 vs post-diameter 12.44±2.20 mm, p value=0.0002), distensibility index (pre-DI 1.72±1.63 vs post-DI 3.45±1.99 mm2/mmHg, p value= 0.0151) and cross-sectional area (pre-CSA 70.93 ± 45.69 vs post-CSA 114.93± 33.79 mm2, p value=0.0075).

	Pre Eso-FLIP dilatation	Post Eso-FLIP dilatation	1 week post Eso-FLIP dilatation	1 month post Eso-FLIP dilatation
BEDQ total score	6.87±5.82		3.20±3.69 (p= 0.0486)	2.33±2.81 (p=0.0206)
Stricture diameter (mm)	8.55±2.80	12.44±2.20 (p=0.0002)		
Distensibility index (mm^2/mmHg)	1.72±1.63	3.45±1.99 (p= 0.0151)		
Stricture cross-sectional area (mm^2)	70.93 ± 45.69	114.93± 33.79 (p=0.0075)		

Conclusion: Our data showed that endoscopic dilatation of benign esophageal strictures with EsoFLIP is clinically effective and safe. EsoFLIP is a promising dilation technology that may yield a larger diameter change and may potentially reduce fluoroscopy time exposure when compared to traditional endoscopic dilation.

Introduction: The development of artificial intelligence (AI) for endoscopy has significantly increased, yet the aspect of endoscopist-AI interaction remains insufficiently explored. This interaction is crucial as it could substantially influence the AI system's performance in routine clinical practice.

Aims & Methods: This study aimed to evaluate two different graphical user interfaces (GUIs) for a computer aided detection (CADe) system for recognition of early Barrett's neoplasia. We performed a comparative analysis of two GUI designs—the frequently used bounding box GUI and a novel heatmap GUI—using an extensively evaluated CADe system[1]. Thirty-seven endoscopists from six countries participated. Each endoscopist assessed 70 Barrett's esophagus. Every video was analyzed by the CADe system and contained, at some point, a detection which was visualized by the GUI. The study was conducted in two phases, with each video initially shown using one of the GUIs, followed by a two-week washout period after which the same videos were displayed with the alternative GUI. Endoscopists were tasked with identifying potential neoplastic lesions, selecting biopsy sites, and stating their GUI preference.

Results: No significant differences were found for classification performance between the two GUIs (sensitivity 83% vs. 83%, p = 0.29; specificity 86% vs. 86%, p = 0.09). Both interfaces achieved similar scores in localization accuracy, with a median of 97%. Among the participants, 23 expressed a preference for the heatmap GUI, while 14 favored the bounding box.

Conclusion: Despite a general preference for the heatmap GUI among endoscopists, there were no statistically significant differences in performance outcomes between the two interfaces.

Introduction: Currently, the Japanese guidelines for GISTs suggest endoscopic ultrasound-guided fine-needle aspiration for sampling the tissue of subepithelial tumors (SETs) and as a first-line technique. Mucosal incision-assisted biopsy (MIAB) is another tissue sampling technique; in this technique, the mucous membrane covering the SET is cut to expose and sample the tissue directly under direct visualization. However, the Japanese guidelines do not clearly state how to handle this technique, and the MIAB procedure has not been standardized, especially in technical aspects, the need for local injection to the submucosa before mucosal incision to prevent perforation, and the need for acid secretion inhibitors to prevent postoperative bleeding.

Aims & Methods: This systematic review and meta-analysis aimed to evaluate diagnostic ability and examine the efficacy of countermeasures to adverse events of MIAB for gastric SETs. We performed a literature search and identified 533 relevant articles. Eleven articles, including 339 lesions, were ultimately used in the meta-analysis. The primary endpoint was the pathological diagnostic rate of MIAB for gastric SETs, and the secondary endpoint was the incidence of adverse events. The efficacy of acid secretion inhibitors in preventing postoperative bleeding and that of local injection before incision to prevent perforation were also examined.

Results: Nine studies were performed in Japan and two in South Korea, of which only two were prospective studies. The mean age of the patients was 60.7 years, and 48.4% were male. In all studies, endoscopic ultrasound was performed to assess tumors before incision-assisted biopsy. The mucosal incision procedure was the same in all studies: The mucosal incision on the tumor was made, and tissue was sampled directly from the tumor using biopsy forceps; however, in all cases in eight articles and six cases in one article, a local injection of saline or glycerol into the submucosa before the mucosal incision was performed. Nine articles reported the closure of the incision using clips. The mean tumor diameter was 20.6 mm, and the pathological results included 150 GISTs, 70 leiomyomas, 11 schwannomas, 37 ectopic pancreas, three lipomas, three cases of inflammatory fibrotic polyp, two malignant lymphoma lesions, two glo-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

mus tumors, one neuroendocrine tumor, one adenocarcinoma, one old hematoma, and one renal cell carcinoma. In all cases in six articles and some in two, an intravenous or oral gastric acid suppressant such as esomeprazole or vonoprazan was administered after treatment. The pooled pathological diagnostic rate of MIAB for gastric SETs was 86.0% (95% confidence interval [CI]: 78.6–93.4; I^2 = 96%). The adverse event rate of the pooled population was 0.3% (95% CI: −1.15 – 1.76; I^2 = 0%). The acid secretion inhibitors significantly reduced postoperative bleeding (odds ratio: 0.06, 95% CI: 0.01– 0.66, P = 0.02). Perforation occurred in 0% and 2.6% of the local injection and non-local injection cohorts, respectively, and the pathological diagnostic rates were 50% and 66.7%, respectively.

Conclusion: MIAB is a reliable technique with a favorable diagnostic rate and few adverse events. Acid secretion inhibitors effectively prevent postoperative bleeding, but the effectiveness of local injection remains unclear. This technique is considered a robust tissue sampling method for gastric SETs.

PP0169

DIAGNOSIS AND SURVEILLANCE OF PREMALIGNANT GASTRIC LESIONS IN AN INTERMEDIATE-RISK POPULATION: WHERE ARE WE?

R. Reivytyte[1], I. Stundiene[2,1], E. Dieninyte - Misiune[1,2]
[1]Vilnius University, Faculty of Medicine, Vilnius, Lithuania, [2]Vilnius University Santaros Klinikos, Center of Hepatology, Gastroenterology and Dietetics, Vilnius, Lithuania

Contact E-Mail Address: rositareivytyte@gmail.com

Introduction: Gastric cancer is associated with a poor prognosis due to the late stage of the disease at the time of diagnosis. Consequently, the detection and surveillance of the established premalignant gastric lesions becomes imperative. Despite Eastern Europe being a region of high – intermediate gastric cancer incidence, the guidelines (MAPS-II) (1) are mainly based on the data from Western countries due to a lack of research in this area in Eastern countries.

Aims & Methods: This study aimed to assess a) the incidence of gastric cancer in patients with proven histologically proven premalignant gastric lesions b) the efficacy of endoscopic diagnosis of premalignant gastric lesions and c) trends of subsequent management of patients at an intermediate risk for the development of gastric cancer in an academic center in Lithuania.

We conducted a retrospective cohort study of patients who underwent esophagogastroduodenoscopy with histological sampling between 2012 and 2020 in a single academic centre. The pathology database was filtered for keywords “atrophy” and/or “intestinal metaplasia” in pathological conclusions or descriptions to identify patients with possible premalignant gastric lesions. Demographic (age and gender), pathology report (histological findings, presence of *H.pylori*), endoscopic evaluation (diagnosis, location of biopsies, endoscopic recognition of premalignant or cancerous lesions), patient history (family history of gastric cancer) and subsequent management (recommended *H.pylori*eradication and follow-up) data were collected.

Results: This retrospective cohort study conducted in a single academic centre identified 1842 patients who underwent diagnostic esophagogastroduodenoscopy with histological sampling between 2012 and 2020. Out of 1842 patients screened in the pathology database, 1762 had histologically proven premalignant gastric lesions (extensive gastric mucosal atrophy, intestinal metaplasia or both).

The study cohort consisted of 51% males with an average age of 64.42 (SD ±1.573). A positive family history of gastric cancer was reported in 0.7% of the patients.

Histological evaluation identified gastric atrophy in 9.9% (n = 183) of samples, distal atrophy in 6.1% (n = 113) of cases, and panatrophy in 3.8% (n = 70) of samples. Distal intestinal metaplasia was observed in 47.9% (n = 883) of cases, while extensive intestinal metaplasia was found in 47% (n = 866) of samples. Dysplasia was detected in 1.03% (n = 19) of the samples.

Endoscopically precancerous lesions were identified in only 14.4% (n = 254) of cases, with follow-up recommendations provided for 3.4% (n = 60) of the patients.

Helicobacter pylori presence on biopsy samples was detected in 37.6% (n = 662) of cases, with eradication recommended only for 36.7% (n = 243) of these cases.

Subsequently, during follow-up 0.8% (n = 14) of patients with premalignant gastric lesions were diagnosed with gastric cancer.

Conclusion: This study reveals poor efficacy of endoscopic evaluation for precancerous gastric lesions and suboptimal adherence to current guidelines for their management. These findings underpin the importance of high-quality endoscopy, dissemination and adherence to the guidelines in the hopes of reducing the morbidity and mortality of gastric cancer.

THE ROBOT-ASSISTED SYSTEM YUNSROBOT FOR REMOTE ENDOSCOPY: AN EXPLORATORY STUDY

Y. Yang[1], B. Yan[1], H. Liu[2], Y. Yang[2], L. Peng[1]
[1]The First Medical Center, Chinese PLA General Hospital, Beijing, China, [2]Shenyang Institute of Automation, Shenyang, China

Contact E-Mail Address: sunny301ddc@126.com

Introduction: The introduction of robotic and communication technology into soft endoscopy allows remote endoscopy become a reality. The ability to perform upper gastrointestinal endoscopy from remote location will eliminate geographical constraints and make endoscopic expertise available throughout the world, improving patient treatment and healthcare management, especially when faced with a pandemic. Therefore, it is of great practical significance to develop a robot system that can be used for remote endoscopy.

Aims & Methods: This study aimed to evaluate the safety and effictiveness of the robot-assisted system YunSRobot for remote human upper gastrointestinal endoscopy and investigate the optimal network for remote endoscopy.

The robot-assisted system YunSRobot was developed by the Yunsheng Y group from the PLA General Hospital and Hao L group from the State Key Laboratory of Robotics, Shenyang Institute of Automation. The master manipulator is located in the Hainan Hospital of PLA general hospital (Sanya, Hainan Province, China), while the slave robot and the patient are located in the First Medical Center, PLA general hospital (Beijing, China)——a total distance of about 2,900 km. The two sites were connected through 5G network and remote upper gastrointestinal endoscopy were performed. The average network delay, operation time, standardized images collection and the adverse events were recorded.

Results: Three remote upper gastrointestinal endoscopy operations were safely performed through a 5G network, with an average time delay of 100~150 ms. The total operation time was 1370±126.75 s, while average en-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

try time for pharynx, esophagus, stomach and pylorus was 207.67±175.05 s, 78.00±29.68 s, 104.00±10.03 s, 30.67±30.40 s, respectively. The average operation time of duodenum was 141.67±40.88 s. Forty standardized images were collected from each patient. All patients successfully completed the biopsy (gastric body, gastric angle and gastric antrum) and no adverse events occurred during the procedures.

Conclusion: The robot-assisted system YunSRobot can realize remote human upper gastrointestinal endoscopy, which has high effictiveness and safety. The 5G network facilitate smooth operation and acceptable latency. Our exploratory study can provide insights for promoting the future development of remote endoscopic surgery.

Introduction: ESD has become the standard treatment for early gastric cancer. Recently, the number of patients taking antithrombotic agents (ATAs) has increased, and the prevention of post-ESD bleeding is a main concern. EHS after gastric ESD has been developed to solve these problems, but the effectiveness and procedural success rate of EHS is not known. Here we investigate the successful introduction of EHS and evaluate the safety and effectiveness of the EHS.

Aims & Methods: 11 patients who underwent EHS after gastric ESD from December 2022 to April 2024 were included in this study. Patient and lesion background, endoscopic findings, and treatment outcomes were reviewed retrospectively. A V-loc 180 available barbed suture (VLOCL0604; Covidien, Mansfield, Mass, USA) and through-the scope flexible needle holder (SutuArt, Olympus, Tokyo, Japan) were used for EHS. The same endoscopist and the assistant performed Ex vivo training model prior to clinical introduction.

Results: Mean age was 74.8±7.3 years, 9 males and 2 females, and 4 with and 7 without ATAs. The lesion locations were as follows: upper/middle/lower = 4/0/7. Mean tumor size was 15.4±5.3 mm, mean defect size was 30.3±5.4 mm, and mean resection time was 46.6±26.4 minutes. The mean time needed for suturing was 30.6±9.6 minutes, and a mean of 4.7±0.4 stitches were placed. Suturing speed （resection area/suturing time) was 20.9±7.5 mm^2/min. Complete suture was achieved in all patients, and they began clear fluid on POD1. There were no adverse events during EHS such as bleeding or perforation.

Conclusion: In EHS, complete suture was achieved in all cases, with no post-ESD bleeding or delayed perforation. Further data is needed to confirm its effectiveness.

THE FEASIBILITY AND SAFETY OF GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION IN PATIENTS TAKING GLUCOCORTICOIDS OR IMMUNOMODULATORS

H. Fukuya[1,2], Y. Iboshi[1,2], E. Ihara[3], R. Okitsu[1,2], A. Ohkubo[1,2], T. Sasaki[1,2], S. Hamada[1,2], D. Yoshimura[1,2], N. Harada[1,2]

Introduction: Glucocorticoids (GC) and immunomodulators (IM) are frequently used to maintain clinical remission in various diseases, yet GC is implicated in delaying gastric ulcer healing [1], and IM is associated with post-endoscopic submucosal dissection (ESD) fever and post-coagulation syndrome on colon ESD [2]. The safety of gastric ESD in patients receiving oral GC or IM remains unknown.

Aims & Methods: This study evaluates the impact of oral GC or IM on gastric ESD outcomes, focusing on procedural safety and postoperative recovery. In a single-center, retrospective study, we analyzed clinical outcomes for 411 patients who underwent gastric ESD between April 2017 and April 2022 at our institute in Fukuoka, Japan. We compared data between patients using a GC or IM (32 patients) group and a standard group (379 patients), considering clinicodemographic characteristics and procedural details. Patients were further divided into three subgroups (SG) based on lesion size and procedure duration to consider treatment intensities: SG1 for lesions >20 mm and procedure times >60 minutes; SG2 for either lesions >20 mm or procedure times >60 minutes; and SG3 for lesions <20 mm and procedure times <60 minutes.

	GC Group (n=32)			Standard Group (n=379)			p-value*
Subgroup (n)	SG1 (9)	SG2 (10)	SG3 (13)	SG1 (125)	SG2 (164)	SG3 (90)	-
hospital stay(days)		10.8±7.1			8.6±3.7		0.0026
	14.1±2.3	9.3±2.2	9.8±1.9	9.4±4.8	8.3±3.3	8.1±2.0	-
□log WBC		0.12±0.12			0.20±0.15		0.005
	0.14±0.1	0.12±0.095	0.10±0.16	0.22±0.12	0.18±0.1	0.21±0.24	-
abdominal pain (%)		37.5%			16.9%		0.0066
	55.6%	40.0%	23.1%	20.0%	14.0%	15.6%	-
post-ESD fever (%)		12.5%			3.4%		0.035
	22.2%	0.0%	15.4%	6.4%	1.8%	2.2%	-

Table.
GC, glucocorticosteroid; SG, subgroup; log,logarithmetic; WBC, white blood cell
**Analyzed by the Fisher exact test and the Student t-test. Values are shown as averages±standard deviation unless otherwise stated.*

Results: The GC group (n=32, 93.8% on GC, median GC dose 5mg/day, 37.5% on IM) showed a higher prevalence of females (53.1%), were older (average age 77.5 vs. 73 years), and had poorer performance status than the standard group (n=379). Despite similar tumor characteristics, the GC group experienced more frequent abdominal pain (37.5% vs. 16.9%) and post-ESD fever (12.5% vs. 3.4%), resulting in longer hospital stays (average 10.8 days vs. 8.6 days) (Table). Meanwhile, the GC group's blood tests showed less elevation in white blood cell (WBC) and C-reactive protein

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. (CRP) levels compared to the standard group. Intraoperative perforation occurred in 6.2% of the GC group but was managed conservatively without any cases of delayed perforation. Subgroup analysis revealed that SG1 experienced the most significant increases in abdominal pain, post-ESD fever, and WBC/CRP levels (Table).

Conclusion: Gastric ESD in patients on GC or IM were feasible but poses higher procedural risks and more frequent postoperative complications, particularly at higher treatment intensities. These findings highlight the need for customized procedural strategies and increased postoperative care to enhance outcomes for this vulnerable patient population.

Introduction: Thanks to instrumental advances and accumulation of understandings of endoscopic features of early oropharyngeal neoplasia, we often encounter diminutive pharyngeal lesions. However, whether follow-up is permissible or therapeutic intervention is preferable for these lesions is uncertain. Accurate endoscopic diagnosis is pivotal for the decision-making process. This study aimed to assess the accuracy of endoscopic diagnosis for pharyngeal microlesions.

Aims & Methods: We evaluated pre-treatment endoscopic images of 121 lesions 3 mm or less in that pharyngeal neoplasia was endoscopically diagnosed with magnifying narrow-band imaging observation and resected by cold forceps biopsy. Two endoscopists, one with over 15 years of experience and another with 5 to 10 years (study A), made endoscopic diagnosis of each image and categorized the images into non-dysplasia, low-grade dysplasia, or squamous cell carcinoma (SCC)/high-grade dysplasia, and the accuracy of the endoscopic diagnosis was evaluated with the pathological findings of resected tissues. To assess interrater agreement, another physician joined to each experience group (study B), and the kappa coefficient was calculated.

Results: In study A, the overall accuracy rate of the endoscopic diagnosis was 60.7%. However, for SCC/high-grade dysplasia, the sensitivity was 12.5% (95% confidence interval [CI]: 3.5-29.0), specificity was 94.3% (95% CI: 90.2-97.0), positive predictive value was 25.0% (95% CI: 7.3-52.4), and negative predictive value was 87.6% (95% CI: 82.6-91.6). Nearly 90% of malignant or high-grade dysplastic lesion were not correctly diagnosed by endoscopic observation even with magnifying narrow-band imaging. Although the concordance rate between study A and B was low (κ coefficient 0.07, 95% CI: -0.15-0.30), study B also exhibited low sensitivity (31.2%, 95% CI: 16.1-50.0), specificity (83.3%, 95% CI: 77.6-88.1), positive predictive value (22.2%, 95% CI: 11.2-37.1), and negative predictive value (88.8%, 95% CI: 83.6-92.9) for SCC/high-grade dysplasia.

	sensitivity	specificity	positive predictive value	negative predictive value
Study A				
Expart, (%)	25.0	93.3	36.4	89.1
Senior, (%)	0.0	95.2	0.0	86.2
Average, (%)	12.5	94.3	25.0	87.6
Study B				
Expart, (%)	37.5	76.2	19.4	88.9
Senior, (%)	25.0	90.5	28.6	88.8
Average, (%)	31.2	83.3	22.2	88.8

Conclusion: The accuracy of endoscopic diagnosis of diminutive malignant pharyngeal lesions was very low regardless of proficiency of endoscopist. Thus, given that such diminutive lesions can be resected with minimally invasive cold forceps biopsy, proactive excision for diagnostic treatment is recommended.

THE NONINVASIVE ROLE OF SPLENO-PORTAL INDEX & PLATELET COUNT/SPLEEN RATIO IN THE DIAGNOSIS OF ESOPHAGEAL VARICES IN PATIENTS WITH COMPENSATED CIRRHOSIS

M. Abdel-Samiee[1], A.G. Badran[2]

[1]National Liver Institute-Menoufia University, Hepatology and Gastroenterology, Shebin El-Kom, Egypt, [2]Mansora, GIT and hepatology, Mansoura, Egypt

Contact E-Mail Address: drmohammed100@yahoo.com

Introduction: Varices are present in 30-40 % of patients with compensated cirrhosis (Child-Pugh class A). Although screening endoscopy for esophageal varices(O.V.) is recommended to all patients with cirrhosis, this recommendation is not a result of evidence-based data. We studied the association of (platelet count/spleen diameter ratio, insulin resistance and splenoportal index) and the presence of O.V. in patients with compensated cirrhosis.

Aims & Methods: 124 patients with compensated liver cirrhosis due to chronic hepatitis C virus were studied. After clinical, laboratory ultrasound examinations, all patients underwent screening endoscopy and O.V were reported as present or absent. According to presence or absence of varices; two groups were described: group I without varicesand group II with varices.

Results: Among 124 patients with mean age of (51.81±12.94), 2 groups were described: group I (30 patients) and group II (94 patients) with a male majority (20 patients in group I and 66 patients in group II). In group I and group II: the mean platelet count/spleen diameter ratio was (1022.6±73.36, 608.76±58.44) respectively, the mean insulin resistance value was (2.426±0.618, 3.081±0.474) respectively. The mean splenoportalindex (SPI) value was (2.878±0.870, 6.349±0.514) respectively.For platelet

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

count/spleen diameter ratio and SPI, the sensitivity was (95.7%), specificity (83.3%) and accuracy (92.7%). For platelet count/spleen diameter ratio andinsulin resistance(IR), the sensitivity was (70.2%), specificity (86.7%) and accuracy (74.1%). For IR and SPI, the sensitivity was (70.2%), specificity (76.7%) and accuracy (71.7%).For the three predictors combined, the sensitivity was (78.7%), specificity (82.2%) and accuracy (79.5%).

	Platelet count /spleen diameter ratio & Splenoportal index	Platelet count / spleen diameter ratio & IR	IR& Splenoportal index	Platelet count / spleen diameter ratio & IR& Splenoportal index
Sensitivity (%)	95.7	70.2	70.2	78.7
Specificity (%)	83.3	86.7	76.7	82.2
Positive Predictive Value (%)	94.7	94.3	90.4	93.2
Negative Predictive Value (%)	86.2	48.1	45.1	55.2
Accuracy (%)	92.7	74.1	71.7	79.5

Table 1. Sensitivity, specificity, positive predictive value, negative predictive value and accuracy when we combine (Platelet count / spleen diameter ratio & Splenoportal index), (Platelet count / spleen diameter ratio & IR) and (IR & Splenoportal index).

Conclusion: Low platelet count/spleen ratio and high SPI are very useful non invasive predictors for the presence of O.V. that could be used either separately or combined to decrease the number of upper GIT endoscopies needed in cirrhotic patients management, However, IR as a non invasive predictor is still in need for further evaluation.

COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARIS PROPRIA

C.B. Ryu[1], M.S. Lee[1], J.Y. Bae[2]
[1]Soon Chun Hyang University School of Medicine, Department of Internal Medicine, Bucheon, South Korea, [2]Seoul Medical Center, Department of Internal Medicine, Seoul, South Korea

Contact E-Mail Address: ryuchb@gmail.com

Introduction: Endoscopic resection for gastric subepithelialtumors(SETs) originated from the muscularispropria (GSET-PM) has offered less invasive alternatives to surgical resection.

Aims & Methods: The aims of this study were to compare endoscopic subtumoraldissection(ESD) with surgical resection for the removal of GSET-PM. This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5cm and showed an endoluminal growth pattern according to endoscopic ultrasound(EUS) finding.

Results: ESD group were more likely to have upper portion(10/17, 58.8%) and surgery group were more likely to have mid portion(41/76, 53.8%) (p=0.039). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, p=0.037) and higher endoluminal ratio (58.5±9.1 % vs 45.8±15.4 %, p=0.002). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%)(p< 0.001). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, p< 0.001). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group (p=0.006), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two group.

Conclusion: ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

Disclosure: Nothing to disclose.

PP0178

PROSPECTIVE EVALUATION OF AN EXPLAINABLE DEEP LEARNING MODEL FOR GASTROESOPHAGEAL VALVE ASSESSMENT VIA THE HILL CLASSIFICATION

I. Kafetzis[1], P. Sodmann[1], B.-E. Herghelegiu[1], K.H. Fuchs[1], F. Seyfried[2], M. Brand[3], A. Meining[1], A. Hann[1]
[1]University Hospital Würzburg, Interventional and Experimental Endoscopy (InExEn), Internal Medicine II, Würzburg, Germany, [2]University Hospital Würzburg, Department of Experimental Surgery, Würzburg, Germany, [3]University Hospital Würzburg, Internal Medicine II, Würzburg, Germany

Contact E-Mail Address: Hann_A@ukw.de

Introduction: Standardized classification of the gastroesophageal valve, achievable using the Hill classification, is a common step during gastroscopy. Given the visual nature of endoscopic examinations, artificial intelligence (AI) can support this task. We conducted a single-center prospective study to compare the performance of a self-developed AI model in determining the Hill classification with that of examiners.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: From October 2023 to January 2024 consecutive patients with unaltered anatomy of the gastroesophageal junction were enrolled in the study. The AI model ran in the background during routine gastroscopy, providing real-time predictions, while physicians assessed the Hill grade without knowledge of the model's output. The Gold standard was established through a majority vote of a three-member expert committee in the cases where a clear image of the hiatus was available. The primary outcome was accuracy in Hill grade assessment, with secondary outcomes including precision and sensitivity for each grade.

Results: Out of 150 patients that participated, 131 were eligible for analysis. Our AI model exhibited an accuracy of 84.7%, surpassing the physicians' accuracy with 61.8% (p<0.01). Regarding rating the different Hill grades the AI's lowest accuracy, precision and sensitivity were 88%, 53% and 60% respectively, while physicians achieved lowest scores of 66%, 20%, and 30%. Post hoc analysis of the videos using the systems capability for real-time explainability via heatmaps highlighting image regions influencing the classification, revealed that the model used the correct anatomical region for classification.

Conclusion: Our AI system demonstrates superior accuracy compared to physicians in Hill grade assessment. Future research should explore the impact of physician-AI interactions during examinations through a randomized controlled trial. (ClinicalTrials.gov, Trial register number: NCT06040723)

PREVALENCE, RISK FACTORS AND MANAGEMENT OF ENDOSCOPIC RESECTION RELATED DUODENAL STRICTURES

J. Gauci[1], R. Medas[2], F.V. Mandarino[1], C. Kerrison[1], A. Whitfield[1], H. Wang[1], M. Sidhu[1], L. Bracken[1], V. Perananthan[1], S. Gupta[1], O. Cronin[1], T. O'Sullivan[1], E. Lee[1], M.J. Bourke[1], N. Burgess[1]

[1]Westmead Hospital Sydney, Gastroenterology and Hepatology, Westmead, NSW, Australia, [2]Centro Hospitalar São João, Gastroenterology, Pedroso - Vila Nova de Gaia, Portugal

Contact E-Mail Address: julia.gauci@yahoo.co.uk

Introduction: Endoscopic resection (ER) of large (>/-15mm) duodenal laterally spreading lesions (D-LSLs) is now standard of care. Data on prevalence, risk factors and outcomes of post-duodenal ER strictures are absent; we sought to evaluate this is in a Western cohort.

Aims & Methods: We report a retrospective analysis of a prospectively collected cohort of D-LSLs following ER in an expert tissue resection centre. Strictures were considered "severe" if patients experienced obstructive symptoms, "moderate" if an adult gastroscope could not pass the stenosis, or "mild" if there was resistance on successful passage. If dilatation was performed, 2-4 weekly dilatation sessions were conducted until scope passage without resistance was achieved as well as symptom resolution where applicable. Primary outcomes included stricture prevalence, risk factors and management.

Results: Over 193 months until February 2023, 246 lesions in 239 patients were included (51.2% male, median age 70 years [IQR 14], median size 35mm [IQR 25]). 30 (12.2%) resections resulted in stenosis; 14 mild (46.7%), 4 moderate (13.3%) and 12 severe (40%). 18 (7.3%) required balloon dilation (median number of sessions, 2 [IQR 6]). Stricture resolution following index-ER was achieved with balloon dilatation alone in 15/18 patients (83.3%). Two patients had an excellent response to lumen apposing metal stent insertion following ER of fully circumferential D-LSL. A patient with an incompletely resected fully circumferential D-LSL, in which adenocarcinoma was confirmed post-ER, required palliative stent placement after 3 sessions of balloon dilatation, due to gastric outlet obstruction caused by residual tumour. Post ER-defect circumference ≥80% proved the strongest independent predictor for stricture formation (OR 62.9 (CI 17.9-276.7, p<0.001; Table 1). The incidence of stricture formation with an ER-defect ≥80%, 60-79% and <60% was 72.2% (n=26/36), 12.5% (n=4/32) and 0% (n=0/178) respectively. All severe strictures (12/12, 100%) occurred in ER-defects ≥80%.

Parameter		No stenosis n (%)	Stenosis n (%)	OR univariable (95% confidence interval, p value)	OR multivariable (95% confidence interval, p value)
Location involving a flexure	No (D1, D2 or D3)	210 (89.4)	25 (10.6)	-	-
	Yes (D1/D2 junction)	6 (54.4)	5 (45.5)	7.00 (1.9-24.9, p=0.0002)	4.05 (0.33-45.30, p=0.28)
Lesion length (mm)	<50	196 (95.1)	10 (4.9)	-	-
	≥50	13 (39.4)	20 (60.6)	30.2 (12.1-80.9, p <0.001)	5.25 (1.28-21.8, p=0.02)
Defect Circumference (%)	<80	206 (98.1)	4 (1.9)	-	-
	≥80	10 (27.8)	26 (72.2)	133.9 (43.2-526.7, p <0.001)	62.9 (17.9-276.7, p<0.001)
Histology	LGD/other*	188 (90.8)	19 (9.2)	-	-
	HGD/SMIC	28 (71.8)	11 (28.2)	3.89 (1.64-8.95, p=0.002)	2.23 (0.42-11.6, p=0.33)

Table 1: Logistic regression to determine lesion characteristics, endoscopic resection (ER) technique and post-ER outcomes which are risk factors for stricture development

**Other histology refers to non-adenomatous histology including Brunner's hyperplasia (n=2), gastric heterotopia (n=2) and duodenal lymphoma (n=1)*

Conclusion: ER-defect circumference strongly predicts stricture formation following ER of D-LSL. These findings can be used to guide patient counselling and post-procedural care. Based on our findings, we recommend a management algorithm determined by the extent of the ER-defect. When the ER-defect extends ≥80% of the luminal circumference, endoscopic assessment for stricture formation should be scheduled routinely at 3 weeks. When the ER-defect involves 60-79%, clinical consultation at 2-3 weeks should be conducted to screen for obstructive symptoms, and gastroscopy organised if the patient is symptomatic. ER-defects <60% can safely return to routine surveillance.

Disclosure: Nothing to disclose.

PP0180

COMPARISON OF SEDATION STRATEGIES IN DIAGNOSTIC UPPER GASTROINTESTINAL ENDOSCOPIES: A PROSPECTIVE STUDY

A. Samad[1]

[1]Hamdard University Hospital, Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: samaddhedhi@gmail.com

Introduction: Sedation during upper gastrointestinal endoscopies (UGIEs) is a common practice aimed at improving patient comfort and procedural tolerance. However, the necessity of sedation remains a subject of debate, particularly regarding its impact on patient safety and experience. This prospective study aimed to compare the outcomes of sedated and non-sedated UGIEs, focusing on patient safety, procedural experience, and post-procedural comfort.

Aims & Methods: From January 1st, 2023, to December 31st, 2023, 150 patients undergoing diagnostic UGIEs were prospectively enrolled. Indications for endoscopy included dyspepsia, dysphagia, unexplained iron deficiency anemia, weight loss, and diarrhea. Patients were randomly assigned to one of three groups: Group 1 received local pharyngeal spray (lidocaine), Group 2 received pharyngeal spray with midazolam, and Group

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

3 received pharyngeal spray with nalbuphine. Parameters assessed included patient safety, procedural experience, technical safety, pharyngeal sensitivity, and post-procedural comfort.

Results: Out of 150 patients, 90 were male and 60 were female. In Group 1 (pharyngeal spray only), 12 out of 50 patients reported mild throat irritation. In Group 2 (pharyngeal spray with midazolam), 9 out of 50 patients experienced increased sleepiness during the procedure, with reduced discomfort. In Group 3 (pharyngeal spray with nalbuphine), 6 out of 50 patients reported post-procedural anxiety. The mean ages in Groups 1, 2, and 3 were 38.5 ± 2.25, 41.25 ± 3.45, and 45.5 ± 2.14 years, respectively.

Conclusion: This study sheds light on the feasibility and outcomes of non-sedated UGIEs using pharyngeal spray alone. While sedation can enhance procedural tolerance, it may also introduce risks and post-procedural effects. The findings suggest that UGIEs with pharyngeal spray alone may be well-tolerated, particularly for select patient populations. Further research on a larger scale is warranted to validate these findings and refine guidelines for sedation strategies in UGIEs.

Disclosure: Nothing to disclose.

PP0181

EFFICACY AND SAFETY OF SNARE TRACTION ASSISTED ENDOSCOPIC SUBMUCOSAL DISSECTION FOR CIRCUMFERENTIAL SUPERFICIAL ESOPHAGEAL CANCER

S. Ullah[1], N. Dai[1], X. Cao[1]
[1]The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China

Introduction: Endoscopic submucosal dissection (ESD) has become a common treatment method for superficial esophageal cancer, allowing complete resection and accurate postoperative pathological evaluation, especially for relatively larger lesions[1, 2]. However, resection of larger lesions, especially circumferential lesions, can be time-consuming and challenging. The resected tissue can obstruct the esophageal lumen, leading to limited working space and poor visibility, thereby increasing the risk of adverse events such as perforation and muscular injury[3]. In recent years, several auxiliary traction techniques have been emerged, including positional adjustment traction, hemostatic clip elastic band traction, snare traction, line traction, and magnet anchor traction, which significantly improve the visibility of the submucosal layer during dissection and enhance the efficiency of the procedure [4-5]. Among these techniques, snare traction allows bidirectional traction through "push and pull" maneuvers, offering flexibility and practicality in clinical practice. However, due to the difficulty and limited cases of circumferential esophageal ESD, there is currently no published literature demonstrating the advantages of snare traction-assisted ESD over traditional ESD techniques.

Aims & Methods: This study aims to investigate the efficacy and safety of snare traction assisted ESD for the management of circumferential superficial esophageal cancer. A total of 68 patients who underwent ESD for circumferential superficial esophageal cancer were included in this study. All the patients were divided into two groups based on whether the snare traction was used or not; the snare traction group (S-ESD, group n=35) and the control group (C-ESD, group n=33).

Results: There was no significant difference in the size of the resected area between the groups [21.98 (18.30, 27.00) cm^2 vs 24.00 (15.28, 30.72) cm^2, P=0.976]. The snare traction group had a shorter dissection time [92.00 (74.00, 121.00) min vs 110.00 (92.50, 137.00) min, P=0.017] and a faster resection speed [0.28±0.13 cm^2/min vs 0.22±0.11cm^2/min, P=0.040] compared to the control group. There were no statistically significant differences between the two groups in terms of hospital stay, cost, en bloc resection rate, R0 resection rate, curative resection rate, bleeding rate, perforation rate, stricture rate, and recurrence rate (P>0.05).

Conclusion: Snare traction-assisted ESD is a safe and efficient approach for the treatment of circumferential superficial esophageal cancer. Its advantages includes shorter procedure so the anesthesia requirement, clear operative filed view, improved mucosal dissection efficiency, simple, and easily accessible equipment.

Introduction: Obesity has reached pandemic proportions. According to the World Health Organization, 16% of the global adult population, or about 890 million people, have obesity(1). Intragastric balloon (IGB) is an alternative method to induce weight loss in subjects with obesity. However, not all subjects tolerate an IGB, and up to 15% of the cases, the IGB may be removed early due to intolerability(2). The factors that predict IGB tolerability remain poorly studied. In this study, we investigated whether there is an association between the baseline gastric emptying rate and IGB tolerability.

Aims & Methods: Twenty-eight subjects with a Body Mass Index (BMI) over 27.5 kg/m^2 were included. Orbera 365® IGBs were endoscopically inserted and filled with 550 ml saline solution and scheduled for removal after 12-months. Before insertion, the subjects underwent a standardized, FDA-approved 13C-Spirulina breath test to measure their gastric emptying half-time (T1/2). Gastrointestinal symptoms were assessed using the Gastrointestinal Symptom Rating Scale (GSRS) at baseline and at 4, 8, 16, and 24 weeks post-insertion, even after eventual early IGB removal.

Results: Six subjects had their IGBs removed earlier than planned due to tolerance issues, which we define as early removal. Early removal in our study refers to any removal that occurred before the planned 12-months. The specific timepoints of removal varied: one at four weeks, two at six months, one at eight months, and two at eleven months.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In the group that had their IGB removed earlier, the median baseline GSRS score was 28 (range 23-41), with a median T1/2 of 81.4 min (range 38.4-140.1). The median GSRS score at 4 weeks was 55.5 (range: 42-72), at 8 weeks 45 (range: 19-82), at 16 weeks 45.5 (range: 19-31), and at 24 weeks 37 (range 22-61).

In the group that tolerated the IGB, the median baseline GSRS score was 28 (range 19-77), with a median T1/2 of 61 min (range 34.5-108.4). The median GSRS score at 4 weeks was 53 (range: 24-133); at 8 weeks 37.5 (range: 19-79); at 16 weeks 37 (range: 21-85), and at 24 weeks 37 (range 19-104), respectively.

No statistically significant differences were observed in half-times (T1/2) and GSRS scores between the two groups at the examined time points. The p-value for T1/2 was 0.09. For GSRS, p-values were as follows: 0.89 at baseline, 0.63 at 4 weeks, 0.87 at 8 weeks, 0.45 at 16 weeks, and 0.73 at 24 weeks. Additionally, correlation analysis between GSRS scores and T1/2 values showed no significant relationships at baseline (p = 0.50), 4 weeks (p = 0.89), 8 weeks (p = 0.93), 16 weeks (p = 0.983), and 24 weeks (p = 0.86). These results suggest a consistent lack of significant association across all time points.

Conclusion: Early IGB removal cannot be predicted by the baseline gastric emptying rate or baseline GSRS in our study. The GSRS scores for subjects that tolerated the IGB, regardless of the time point, do not correlate with their baseline gastric emptying rate.

Contact E-Mail Address: mandarino.francesco@hsr.it

Introduction: Although Gastric Peroral Endoscopic Myotomy (G-POEM) has shown substantial efficacy in patients with medically refractory gastroparesis (GP), comprehensive long-term data on its effectiveness are lacking.

Aims & Methods: We conducted a systematic review and meta-analysis including observational studies assessing long-term outcomes after G-POEM in patients with refractory GP. Our primary outcome was the pooled rate of clinical success1-year after G-POEM. Secondary outcomes included clinical success rates beyond 1 year, and the rate of adverse events (AEs).

Results: Fifteen studies, comprising 986 patients with refractory GP undergoing G-POEM, were eligible. The pooled 1 year-success rate was 0.722 (95% CI: 0.56, 0.86, I^2=94.92%). In the subgroup analysis, which included only studies enrolling patients with 4-hour Postprandial Gastric Residual (PGR) ≥ 10%, the clinical success rate was 0.610 (95% CI: 0.526, 0.709, I^2=46.66%). The pooled success rates at 2 and 3 years calculated on followed-up patients were 0.861 (95% CI: 0.72, 0.96, I^2=85.11%) and 0.838 (95% CI: 0.56, 0.99, I^2=91.90%), respectively. In the subgroup analysis including studies that did not exclude non-responding patients from follow-up, the 2-year pooled success rate was 0.838 (95% CI: 0.60, 0.98, I^2=89.49%). The pooled rate of AEs was 0.092 (95% CI: 0.06, 0.13, I^2=81.35%), specifically 0.078 mild and 0.014 moderate AEs, according to the American Society for Gastrointestinal Endoscopy classification.

Conclusion: G-POEM is a safe procedure with 1-year success in more than 2/3 of treated cases and substantial benefit also at 2 and 3-years follow-ups. Future studies with strict patient selection and uniform outcome definitions are warranted.

Contact E-Mail Address: julia.gauci@yahoo.co.uk

Introduction: Complete excision of upper gastrointestinal sub-epithelial lesions (SELs) eliminates diagnostic uncertainty, obviates the need for surveillance and may be necessary for definitive diagnosis and management. Current guidelines lack precision and cohesion, and surgery is associated with significant morbidity. Herein, we describe and report on the outcomes of our SEL algorithm for endoscopic (SAFE) resection.

Aims & Methods: SELs were enrolled prospectively over 115 months until March 2023. All underwent axial (CT) imaging and endoscopic-ultrasonography (EUS) to exclude a large exophytic component or invasion into local structures, and assess for muscularis propria involvement.

Results: 106 SELs were resected (mean age 60.6±13.4, 51.9% male; 41 oesophageal, 65 gastric). Oesophageal SELs underwent ESD (n=22) or STER if MP involvement was suspected (n=19). Gastric SELs underwent STER (n=6 at cardia), ESD (n=47) or exposing-EFTR (n=12). Technical success was 97.6% and 92.3% respectively. Five (7.7%) were completed laparoscopically due to deep and broad full-thickness involvement. Five (7.7%) required laparoscopic gastrotomy and surgical retrieval after successful resection and closure due to a large lesion size (mean 47 mm). There was no delayed bleeding, perforation or recurrence at a median of 13 months.

Conclusion: Upper GI SELs are effectively and safely treated by endoscopic resection. The SAFE approach provides a framework that facilitates structured decision-making. Oesophageal SELs suspected to involve the MP should undergo STER. Gastric SELs can be best managed by ESD with a view to proceed to exposing-EFTR. A laparoscopic UGI surgeon should be available in case surgical retrieval of the specimen or laparoscopic completion is required.

Introduction: Gastric adenoma is recognized as a premalignant lesion.[1]Much of the literature lumps all adenomas together with different classifications. These are few western reports regarding the prevalence, associated risk factors and outcomes of endoscopic management of different subtypes of gastric adenoma.

Aims & Methods: Aims: The aim of this study is to determine the prevalence, potential predictors, and outcomes of endoscopic management of the different subtypes of gastric adenoma.

Methods: Of 162 consecutive patients who underwent endoscopic resection for gastric lesions between 2017 and 2022 at our center, 79 patients were enrolled. All the hyperplastic polyps (n=37) and subepithelial lesions (n=46) were excluded. The patient clinical characteristics, endoscopic and histopathological features of gastric lesions were retrospectively collected. Patients were divided according to the histological types of gastric adenoma into 4 groups: intestinal group (n= 49), foveolar group (n= 23),pyloric group (n= 6) and oxyntic group (n=1). We statistically compared the clinical and endoscopic features of the three groups. In addition to the analysis of the outcomes of endoscopic resection of gastric adenomas.

Results: Of the 79 patients with a mean follow-up of 26 22 months, 51 patients were males (65 %) and 28 patients were females (35%). Forty-nine patients (49/79,62%) had intestinal adenoma, 23 patients (29%) showed foveolar adenoma, 6 patients (8%) developed pyloric adenoma and only 1 patient (1%) had oxyntic adenoma. The mean age was significantly older in the intestinal group (71 ± 13 years vs. 64 ± 16 years vs. 58 ± 18 years, $p = 0.03$). Intestinal adenomas were significantly associated with family history of gastric adenocarcinoma (14% vs. 4% vs. 0%, p = 0.01) and history of statin intake (39% vs. 26% vs. 0%, p = 0.04).Foveolar adenomas were significantly associated with multiple lesions (≥3 lesions) (p < 0.001) and 0-IIa+IIc Paris classification (6/23, 26%). the size of largest polyp was significantly higher among pyloric group (28 ±15, p= 0.00). Among intestinal group, 33/49 patients (67%) had atrophic gastritis. 82% of the adenomas were resected by ESD with histologically complete resection (R0) in 72/79 patients (91%). Although the difference was not statistically significant (p = 0.4), adenocarcinoma was most frequently encountered among the intestinal adenoma group (17/49, 35%). The post endoscopic resection outcome was comparable among 3 groups with overall recurrence rate (group1:8% vs. group 2:17% vs group 3:17%, P = 0.07) with a comparable mean time to recurrence among three groups (21 ± 17 months vs. 20±17months vs. 14 months, p=*0.8*). Family history of gastric adenocarcinoma (HR=1.33, p< 0.001) and active helicobacter pylori infection (HR=1.14, p < 0.001) were identified as independent predictors of recurrence after endoscopic resection of different gastric adenoma. Among baseline endoscopic characteristics, polyp size ³ 30mm(HR= 2.04, p< 0.001), more than 3 polyps (HR=1.51, p<0.001), lesser curvature as lesion location (HR=1.72, p< 0.001) and morphology as Paris classification IIc are potential predictors of post resection recurrence. In addition to specimen size ³ 15mm (HR=2.19, p< 0.001) and T1b as lesion histology (HR=2.07, p< 0.001), in the histopathological examination.

Conclusion: The present study clarifies the endoscopic and histopathological characteristics of different gastric adenomas, in addition to the potential predictive factors for each subtype. Potential predictors of recurrence after endoscopic resection emphazie the importance of endoscopic follow up.

PP0186

ENDOSCOPIC VACUUM THERAPY FOR THE MANAGEMENT OF GASTRO-ESOPHAGEAL PERFORATIONS

R. Valente[1], T. Irino[1], U. Arnelo[1]

[1]Umeå University, Department of Diagnostics and Intervention, Umeå, Sweden

Contact E-Mail Address: roberto.valente@umu.se

Introduction: Esophageal or gastric perforation is associated with systemic inflammatory response syndrome (SIRS), which can lead to multi-organ dysfunction and mortality in up to 50% of cases. Endoscopic vacuum therapy involves the use of a catheter with a sponge attached to its distal end, connected to a machine that applies negative pressure, allowing for continuous drainage of the perforation site and potentially promoting healing of the transmural defect. Previous series have reported promising results, indicating the potential effectiveness of this therapy in managing esophageal perforations. To evaluate the efficacy of endoscopic vacuum treatment in patients with primary or secondary gastroesophageal perforations.

Aims & Methods: Single-center retrospective cohort study on patients treated for gastroesophageal perforation between March 2019 and September 2022. The inclusion criteria for the study were patients with gastroesophageal perforation resulting from spontaneous rupture or iatrogenic damage (post-surgical or post-endoscopic treatment). The primary outcomes of the study were the success rate of endoscopic therapy, the length of hospital stay, and the specific survival at 30 and 90 days. The success rate of endoscopic therapy was assessed by considering the treatment successful if it led to the resolution of the fistula following vacuum endoscopic therapy. Secondary endpoints included the need for intensive care unit (ICU) stay between the start of vacuum endoscopic therapy and the patient's discharge.

Results: 27 patients, with a mean age of 69.8 years (95% CI 65.4-74.3), including 9 (33.3%) women, underwent endoscopic treatment with vacuum therapy for esophageal perforation. The causes of perforation were as follows: 6 (22.2%) cases were primary (Boerhaave syndrome), 15 (55.5%) cases were post-surgical (post-surgical anastomosis), and 6 (22.2%) cases were post-endoscopic treatment (endoscopic dilatation). Among the patients, 13 (48.1%) had previously undergone surgery for cancer, with 69.2% of them receiving intrathoracic stomach interposition reconstruction and the remaining patients undergoing reconstruction according to Roux-en-Y procedure. The treatment was successful in 21 (77.7%) patients, with a 14 days (9.0-24.4, 95% CI) median duration of treatment, and 4 (3-7, 95% CI) median number of endoscopic devices used per patient. One patient (3.7%) died within 30 days, and another one (3.7%) within 90 days. A total of 10 (38.4%) patients required an ICU stay, and there were no readmissions within 30 days. No procedure-related complication was reported.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In the current pilot study, the findings support the feasibility and safety of endoscopic vacuum therapy as a treatment modality for both primary and secondary gastro-esophageal perforations.

Contact E-Mail Address: yoenyoungchuah@gmail.com

Introduction: The cervical inlet patch (CIP) is an islet of heterotopic gastric mucosa that is observed in the upper esophagus during conventional diagnostic esophagogastroduodenoscopy. Commonly encountered laryngopharyngeal symptoms, including globus sensation, hoarseness, odynophagia, and dysphagia, have been linked to CIP. In most cases, medical intervention for symptomatic CIP commences with the administration of potent acid suppressive agents, such as proton-pump inhibitors (PPI); however, the efficacy of these agents is limited. A few Western studies have demonstrated that endoscopic therapy with argon plasma coagulation (APC) is increasingly effective in relieving laryngopharyngeal symptoms in patients with CIP.[1,2] Additionally, long-term effects lasting up to 27 months of follow-up have been documented.[3] Regarding the use of APC in patients with CIP, however, no pertinent research has been conducted in Asia-Pacific countries. Therefore, we retrospectively reviewed a cohort with six symptomatic CIP patients recruited for the APC ablation therapy. This case shed light on the possible use of APC for symptomatic CIP patients in Asia-Pacific countries.

Aims & Methods: We recruited a total of six symptomatic patients, proven to be CIP endoscopically and pathologically, from May 22, 2022, to April 20, 2024. We excluded patients who were less than 20 years old and who refused the option of argon plasma coagulation ablation. To ablate the CIP, all recruited patients underwent endoscopic ablation at 60 W and 2 L/min in one session. Questionnaires consisting of visual analog scores (from 0 to 10. The higher the score, the more severe the symptoms) for symptoms of dry throat, burning throat, globus sensation, hoarseness and clearing throat were distributed to patients at the time points of before the use of proton pump inhibitors, after the use of proton pump inhibitors and one month after the endoscopic ablation with APC to assess the efficacy endoscopic procedure. We defined symptomatic CIP with at least one any of the aforementioned symptoms with more than 5 out of 10 of pain score.

Results: The current study recruited a total of six patients. Two-thirds of patients were female (4/6) in gender and had an average age of 41 years. The CIP was located in the upper esophagus at 16.7cm from the incisors (15–18 cm), and two-thirds of the patients had more than one CIP. The average size of CIP was about 0.6 cm (ranging from 0.3cm to 0.8cm). The APC ablation significantly improved the five parameters (dry throat, burning sensation, foreign body sensation, and hoarseness) from more than 4/10 to less than 2/10. Foreign body sensation showed the most prominent improvement, decreasing from 7/10 to 1/10. (Figure1) There were no complications, such as perforation, infection, ulcers, or stricture, after the procedure. One month after the APC procedure, the follow-up EGD of all patients showed no residual CIP.

Conclusion: APC ablation shows a promising results for symptomatic CIP patients with laryngopharyngeal symptoms in Asia-Pacific population. However, further prospective randomized studies with a larger sample size are needed to validate the effectiveness and safety of APC ablation in symptomatic CIP patients in the region.

DEPTH ESTIMATION ALGORITHM-BASED LESION SIZE MEASUREMENT IN GASTROSCOPY: A COMPARATIVE STUDY WITH ENDOSCOPISTS

B. Kim[1], H. Chung[2], J.K. Ryu[2]

[1]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, South Korea, [2]Seoul National University Hospital, Seoul, South Korea

Contact E-Mail Address: bkkim1119@gmail.com

Introduction: Precise measurement of lesion sizes during endoscopic procedures is crucial but often compromised by the reliance on visual estimations.

Aims & Methods: This study evaluates the precision of a novel depth estimation algorithm-based lesion size measurement function embedded in an electrically controlled endoscopy system, comparing its accuracy to visual and forceps-assisted estimations. A synthetic 3D-printed stomach model featuring 15 artificial lesions (6 ulcers and 9 polyps, size range: 6-39 mm) was used. Nineteen endoscopists (6 experts, 13 novices) measured the lesions using three methods: 1) visual estimation (VE) with a conventional endoscope, 2) forceps-assisted estimation (FE) with a conventional endoscope, and 3) depth estimation algorithm (DEA) with an electrically

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

controlled endoscope. Measurements were then compared to the actual lesion sizes according to endoscopic proficiency and lesion size (<1 cm, 1-2 cm, >2 cm).

Results: VE had the highest mean percentage error (MPE) at 39.97% (95% CI 36.66%-43.28%), followed by FE (MPE 31.39%, 95% CI 28.81%-33.98%). DEA was most accurate with an MPE of 13.59% (95% CI 11.46%-15.73%), significantly outperforming both VE and FE (all $P < 0.01$). For VE and FE, experts showed greater precision over novices (all $P < 0.01$). With DAE, the accuracy was consistent across experience levels ($P = 0.60$). Novices using DEA showed greater precision compared to both VE and FE (Table 1). Novices using VE had the least accuracy with an MPE of 43.93% (95% CI 39.67% - 48.19%). For experts, DEA was accurate than VE but was comparable to FE except in lesions over 2cm.

		VE (MPE ± 95% CI)	FE (MPE ± 95% CI)	DEA (MPE ± 95% CI)	VE vs FE (P value)	VE vs DEA (P value)	FE vs DEA (P value)
Total		39.97% (36.66% - 43.28%)	31.39% (28.81% - 33.98%)	13.59% (11.46% - 15.73%)	<0.01	<0.01	<0.01
Novice (N=13)	All size	43.93% (39.67% - 48.19%)	37.67% (34.51% - 40.82%)	13.56% (10.77% - 16.35%)	0.01	<0.01	<0.01
	<1 cm	43.49% (34.90% - 52.09%)	35.09% (28.96% - 41.22%)	19.58% (14.27% - 24.90%)	0.08	<0.01	<0.01
	1-2 cm	44.24% (38.50% - 49.99%)	37.82% (33.77% - 41.86%)	12.79% (8.88% - 16.70%)	0.04	<0.01	<0.01
	>2 cm	43.37% (33.94% - 52.79%)	42.16% (32.42% - 51.89%)	4.95% (3.49% - 6.42%)	0.7	<0.01	<0.01
Expert (N=6)	All size	31.40% (26.77% - 36.02%)	17.80% (14.80% - 20.79%)	13.67% (10.57% - 16.78%)	<0.01	<0.01	0.09
	<1 cm	33.15% (23.59% - 42.71%)	18.66% (13.89% - 23.43%)	20.80% (14.75% - 26.84%)	0.01	0.04	0.61
	1-2 cm	31.21% (25.05% - 37.37%)	17.13% (12.77% - 21.49%)	11.64% (7.41% - 15.87%)	<0.01	<0.01	0.11
	>2 cm	28.74% (15.89% - 41.60%)	19.07% (11.13% - 27.01%)	8.58% (5.22% - 11.95%)	0.02	0.01	0.03

Conclusion: The novel lesion size measurement function using a depth estimation algorithm outperforms traditional visual and forceps-assisted method, especially in novice. Its adoption in endoscopic practice and training could improve lesion sizing accuracy, enhancing clinical outcomes and decision-making.

ENDOSCOPY IN THE SETTING OF INCIDENTAL HYPERMETABOLIC LESION ON PET SCAN

B. Soukaina[1], A. Moualif[1], F. Haddad[1], F.Z. Elrhaoussi[1], M. Tahiri Joutei Hassani[1], W. Hliwa[1], B. Ahmed[1], W. Badre[1]
[1]Hospital University Center IBN ROCHD, Gastroenterology, Casablanca, Morocco

Contact E-Mail Address: bannanisoukaina@gmail.com

Introduction: Positron emission tomography (PET) scan involves injecting a radioactive isotope (18-fluoro-2-deoxyglucose) to locate areas where the radiotracer accumulates. The established indications of PET scanning mainly concern oncology, where it is used for staging, treatment monitoring, and long-term surveillance. It is also useful in cases of secondary lesions for identifying the primary lesion. Outside of oncology, PET scan has other clinical applications such as diagnosing and monitoring inflammatory diseases, and searching for infectious foci. The incidental discovery of metabolic hyperfixation in the digestive system on PET scan is becoming increasingly common, raising questions about the clinical significance of this hypermetabolism and the need for endoscopic exploration. The aim of our study is to report the endoscopic findings from examinations performed in our department where the indication was the incidental discovery of digestive hypermetabolism on PET scan.

Aims & Methods: This is a descriptive and analytical retrospective monocentric study including all patients referred for endoscopy due to the incidental discovery of digestive metabolic hyperfixation on PET scan, not corresponding to a previously known lesion, between January 2017 and September 2023. Only hypermetabolic fixations located in the stomach, colon, and rectum were included.

Results: 28 hypermetabolic fixations were included in the study, of which 46.4% were located in the colon, 42.9% in the rectum, and 10.7% in the stomach. The mean age was 54.9 years with a standard deviation [32,78]. The male-to-female sex ratio was 0.6. PET scan indications were mainly dominated by surveillance of treated cancers or during treatment (57.1%). In 21.4% of cases, PET scan was requested for staging a newly diagnosed tumor, and in 17.9% of patients, it was used to search for a primary tumor with hepatic, pulmonary, or bone metastases. Other indications were rarer, representing 3.6% of cases. Hypermetabolism on PET scan corresponded to a neoplastic lesion in 17.9% of cases, an adenoma in 14.3% of cases, and a benign lesion (non-specific ulceration, inflammatory lesion, or stenosis) in 32.2% of cases. In 35.7% of patients, endoscopic examination did not reveal detectable abnormalities. Hypermetabolism was most often focal (67.9%). According to this study, the presence of focal metabolic hyperfixation was significantly associated with the presence of a neoplastic lesion on digestive endoscopy (P <0.01).

Conclusion: All metabolic hyperfixations on PET scan referred to our endoscopy center underwent endoscopic exploration to rule out a neoplastic lesion. However, additional studies, ideally prospective and multicentric with a larger sample size, are essential to establish the criteria for endoscopic exploration in the case of incidental discovery of digestive hypermetabolism on PET Scan

ENDOSCOPIC MANAGEMENT OF UPPER DYSPHAGIA OF UNKNOWN ETIOLOGY – A SINGLE CENTER PILOT EXPERIENCE

D. Simkova[1], J. Mareš[2], M. Vašátko[1], K. Hugova[1], J. Martinek[1]
[1]Institute for Clinical and Experimental Medicine (IKEM), Department of Hepatogastroenterology, Prague, Czech Republic, [2]Institute for Clinical and Experimental Medicine (IKEM), Department of Statistical Analyses, Prague, Czech Republic

Contact E-Mail Address: drazilovad@gmail.com

Introduction: Upper dysphagia is a swallowing disorder associated with underlying pathology in the mouth, throat, or esophagus. Cricopharyngeal achalasia (CA) may cause upper dysphagia and its diagnosis is not well established. In case of CA, endoscopic myotomy of upper esophageal sphincter (C-POEM) may be offered to relieve symptoms.

Aims & Methods: We present our experience in diagnosing and managing upper dysphagia with suspicion on CA in patients referred to our center between May 2022 and April 2024. The patients with Zenker diverticulum or organic stricture were not enrolled. All patients underwent X-ray examination, high-resolution manometry and endoscopy. In patients with suspected CA, botulinum toxin injection (100 IU) was administered into the upper esophageal sphincter.

After botulinum toxin injection, the follow up visits were scheduled 1, 5 and 12 months after the procedure. In case of a positive effect of the injection, C-POEM (endoscopic myotomy of cricopharyngeal muscle) was considered after the effect of botulinum toxin had vaned. FOSS Function Outcome Swallowing Score and Dakkak and Bennett score of dysphagia were used to assess the severity of the symptoms. The score systems are listed in the table.

Dakkak and Bennett score of dysphagia		FOSS Function Outcome Swallowing Score	
Grade	Characteristic	Grade	Characteristic
Grade 0	No dysphagia	Grade 0	Asymptomatic
Grade 1	Solids	Grade 1	Episodic or daily symptoms of dysphagia with normal meal time
Grade 2	Semi-solids	Grade 2	Dysphagia requiring significant dietary modifications or prolonged meal time
Grade 3	Liquids	Grade 3	Dysphagia with weight loss ≤10% of body weight with daily symptoms
Grade 4	Aphagia	Grade 4	Dysphagia with weight loss >10% of body weight or severe aspiration or requiring intermittent non-oral feeding for nutrition
		Grade 5	Non-oral feeding for all nutrition

Results: Ten patients (4 males, 6 female) were referred to our center with long term upper esophageal dysphagia and considered eligible for botulinum toxin injection. The mean age was 69.7 years (ranges 30, 85), mean duration of symptoms was 8.6 years (SD ± 11) Three patients were unable to swallow safely and PEG tube had to be placed for nutritional support. Aetiologies of dysphagia were cervical injury (n=2), radiotherapy (n=2) and previous neurosurgery (n=1) or idiopathic dysphagia.

All patients underwent botulinum toxin injection. One patient developed vocal cord paresis one week after the injection and her condition improved after corticoid administration. No other adverse events of botulinum toxin were observed.

Improvement of dysphagia occurred in 7 patients after botulinum toxin injection while no change in symptoms was present in 3 patients. One month after the procedure mean

FOSS Function Outcome Swallowing Score improved from 3.3 to 1.56 (p = 0.015) and Dakkak and Bennett score of dysphagia from 2.7 to 1.33 (p=0.012). Two patients received successful C-POEM, the remaining patients will be offered C-POEM once a recurrence of symptoms will occur.

Three patients without effect of botulinum toxin injection were considered endoscopically incurable and referred back to neurology or otorhinolaryngology departments.

Conclusion: Botulinum toxin injection may be effective in treating upper dysphagia caused by a spasm of cricopharyngeal muscle and may serve as a useful selection tool for endoscopic myotomy.

Disclosure: Nothing to disclose.

Introduction: Early gastric cancer (GC) detection allows for early intervention and better patient outcomes. Yet, current diagnostic methods for early GC still need to be improved. Raman microscopy offers a noninvasive, label-free approach for a wide range of ex vivo (e.g. intraoperative tumour margin detection) and in vivo (e.g. early GC diagnosis) clinical applications. However, the specificity of Raman microscopy is limited by the high signal-to-noise ratio due to light scattering and the inherent molecular complexity of human tissues.

Aims & Methods: Aim: This study aims to identify lipidomic and proteomic tissue signatures that correlate with Raman microscopy, thereby shortlisting a more specific Raman spectrum to better differentiate GC from normal gastric tissue.

Methods: Real-time Raman spectrometry-based AI was applied to 19 consecutive patients (aged 51 - 85 years old, 14 male) with high risk for gastric dysplasia or cancer. Patients underwent high-definition white light upper endoscopy. Upon localisation of the lesion/s, the endoscopist used the SPECTRA IMDx™ probe to capture the Raman spectra (1251 features) from the dysplastic lesion and its adjacent normal mucosa. Biopsies paired to the sites of Raman readings were obtained for histopathologic examination, and lipidomic and proteomic profiling. 254 lipids (from 15 subclasses) and 4168 proteins were obtained through mass-spectrometry-based techniques. Differential abundance analysis of the lipid, protein and Raman spectra was undertaken using DESeq2 [1], which uses shrinkage estimation for dispersions and fold change to improve the stability and interpretability of estimates.

Results: Using 25 tissue samples (12 control, 13 with gastric dysplasia or cancer), we identified specific lipid species and protein markers as potential biomarkers (FDR <0.05) for GC; 45 lipid species (13 cholesterol esters, nine phosphatidylethanolamines, five diacylglycerols, five lysophosphatidylethanolamines, four hex ceramides, four phosphatidylcholines, two lysophosphatidylcholines and one sphingomyelin, one ganglioside) as well as ten proteins (PLOD2, GGPS1, C8G, COX7C, DCK, ACTBL2, EMC10, H2AC21, HDHD2). Integrating the putative lipid and protein features and the Raman spectra, only a shortlist of 56 Raman features were significantly correlated with only ten lipids (3 HexCeramides, three cholesterol esters, two diacylglycerols, one phosphatidylethanolamine and one lysophosphatidylethanolamine) and two protein features (C8G, ACTBL2).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our findings demonstrate the potential of integrating Raman microscopy with lipidomics and proteomics. The potential lipid and protein signatures provide insight into the biochemical alterations associated with dysplastic transformation identified by Raman microscopy. This approach brings promise for improving the accuracy of Raman-based non-invasive GC early detection strategies.

Introduction: Data evaluating the utility of Blue light Imaging (BLI) and Linked Color Imaging (LCI) in the diagnosis of gastric intestinal metaplasia (IM) and atrophic gastritis (AG) is limited.

Aims & Methods: We aimed to evaluate and compare the diagnostic accuracy of BLI and LCI without magnification for the detection of IM and AG. Single centre prospective study involving consecutive patients aged ≥18 years undergoing diagnostic upper gastrointestinal endoscopy (UGIE), endoscopic follow-up of intestinal metaplasia or gastric cancer screening. Exclusion criteria: previous gastrectomy, contraindication to UGIE due to comorbidities, no gastric mucosal biopsies, refusal of consent. Endoscopy was initially performed with white light image (WLI), followed by BLI and LCI. Standardized photodocumentation of stomach was performed with WLI, BLI and LCI. Imaging features suggestive of IM: lavender color sign and whitish flat elevation with LCI, and light blue crest and white opaque substance with BLI. EGGIM and Kimura-Takamoto Classification (KTC) were applied when IM and AG were suspected. Systematic random biopsies of the antrum, incisura angularis and corpus along with targeted biopsies of suspicious gastric mucosal lesions were obtained. Histology was considered gold standard. Performance of endoscopic imaging in the detection of IM, AG and EGC was evaluated.

Initially, 134 patients were evaluated and 64 were excluded: previous gastrectomy-22, pending histology-20, non-BLI imaging-15, intolerance to UGIE-3, refusal of consent-1, esophageal stenosis-1 and contra-indication to biopsies-2. Final sample included 70 patients.

Qualitative data expressed as percentage were compared with Chi-square test. A p value of <0.05 was considered significant.

Results: Median age was 56 (19-86), with 49 (63%) female. There was family history of gastric cancer in 12(15%) and history of smoking in 35 (44%). Histological AG was found in 15 (19%) and IM in 20 (26%) patients. WLI was suggestive of IM in 14(20%), confirmed histologically in 9 (64%). IM was suspected by LCI and BLI in 24 (34%) and 23 (32%) cases, confirmed by histology in 16 (67%) and 17 (74%), respectively.

WLI classified 56 (71%) as EGGIM 0 and after LCI and BLI, 10 (18%) and 8 (15%) of these cases had EGGIM 1 or 2. In 10 patients, EGGIM 1-2 with WLI, only 1 was upgraded to EGGIM 3-4 with LCI and BLI. In 3 (4%) EGGIM 3-4 with WLI, after LCI and BLI,1 had extensive IM (EGGIM 6). Among 19(24%) patients EGGIM 1-2 with LCI, 3(16%) had EGGIM 0 with BLI.

Atrophy was suspected by WLI and LCI in 9(12%) and 15(21%) patients, confirmed by histology in 6(67%) and 8(53%) cases, respectively. According to KTC, 5 (6%) were classified as C1, 2 (3%) as C2 and 4 (5%) as O3 with WLI. With LCI images, 8 (10%) were classified as C1, 3(4%) as C2 and 4(5%) as O3. The sensitivity (Sens), specificity (Spec), accuracy, positive predictive value (PPV), negative predictive value (NPV) of WLI, BLI and LCI in detecting AG and IM are shown in table 1.

	Sens (%)	Spec (%)	Accuracy (%)	PPV (%)	NPV (%)
Intestinal metaplasia					
WLI	47	90	79	61	83
LCI	80	84	83	62	92
BLI	85	88	97	70	94
Atrophic gastritis					
WLI	40	94	80	71	83
LCI	53	87	78	58	85

Table 1. Sens, Spec, accuracy, PPV and NPV in detecting AG and IM with WLI, LCI and BLI.

Conclusion: Both BLI and LCI are promising advanced endoscopic imaging techniques with BLI having higher accuracy than LCI in detection of IM.

SAFETY AND FEASIBILITY OF GASTROINTESTINAL ENDOSCOPY IN NEONATES AND INFANTS UNDER 3 MONTH OF AGE

H. Yang[1], S. Liu[1], Y. Fang[1]
[1]*Xi 'an Children's Hospital, Department of Gastroenterology, Xi'an, China*

Contact E-Mail Address: liushan92263@163.com

Introduction: With the development of minimally invasive endoscopic diagnosis and treatment technology in children, the application age of pediatric digestive endoscopy is gradually expanded to infants and even neonates. Compared with older children, the gastrointestinal lumen of this population is more distorted and narrow, the wall is thinner, and the operation is more difficult and risky. This study aims to investigate the safety and feasibility of gastrointestinal endoscopy in neonates and infants under 3 months of age.

Aims & Methods: A retrospective analysis was performed on the clinical data of 145 neonates and infants under 3 months of age who underwent gastrointestinal endoscopy in Xi 'an Children's Hospital from June 2018 to May 2023. The general condition, clinical manifestations, main diagnosis, endoscopic treatment and adverse events of all children were statistically analyzed.

Results: A total of 145 patients were enrolled in this study, including 30 neonates (20.7%). There were 96 males (66.2%) and 49 females (33.8%). The age ranged from 1 day (9 hours after birth) to February 29 days, with a mean age of January 17 days. The main symptoms of children undergoing gastrointestinal endoscopy were vomiting (79 cases, 54.5%), followed by hematochezia (25 cases), diarrhea (19 cases), bucking (10 cases), abdominal distension (6 cases), hematemesis (5 cases) and foreign body in digestive tract (1 case). All children underwent general anesthesia under tracheal intubation. Gastroscopy was performed with XP290 electronic nasal gastroscope (external diameter of 5.8mm), gastroscopy was performed with H290 electronic gastroscope (external diameter of 8.9mm), and colonoscopy was performed with Q260 electronic colonoscopy (external diameter of 9.2mm). 114 cases (78.6%) underwent gastroscopy and 31 cases (21.4%) underwent colonoscopy. The most common diagnosis was congenital hypertrophic pyloric stenosis (55 cases, 37.9%), followed by allergic colitis (15 cases), esophageal stenosis (13 cases), erosive gastritis (11 cases), multiple colonic ulcers (7 cases), duodenal stenosis (5 cases), colonic stenosis (4 cases) and reflux esophagitis (3 cases). In addition, 25 cases (17.2%) showed no abnormalities after the examination, and gastrointestinal diseases were excluded. In addition to routine examination, a total of 63 children received endoscopic treatment. The most common endoscopic treatment was peroral endoscopic pyloromyotomy (G-POEM), 37 cases, accounting for 58.7% of all children who received endoscopic treatment. The others included 15 cases of endoscopic nutrition tube placement, 8 cases of endoscopic balloon dilatation, 1 case of endoscopic foreign body removal, 1 case of endoscopic magnetic ring placement and 1 case of endoscopic hemostasis. All children underwent gastrointestinal endoscopy successfully, with a success rate of 100%. No adverse events related to anesthesia and surgery occurred in all children.

Conclusion: The application of gastrointestinal endoscopy in neonates and infants under 3 months of age may be feasible and safe. Endoscopic diagnosis and treatment is minimally invasive, safe and fast recovery, which has a wide application prospect in young children.

Disclosure: Nothing to disclose.

GASTRIC ENDOSCOPICAL SUBMUCOSAL DISSECTION: ARE WE EXCEEDING EXPECTED PROCEDURE TIMES?

M.I. Viegas[1], M. Areia[1], L. Elvas[1], S. Alves[1], D. Brito[1], S. Saraiva[1], A.T. Cadime[1]
[1]*Portuguese Oncology Institute of Coimbra, Department of Gastroenterology, Coimbra, Portugal*

Contact E-Mail Address: mariainesviegas96@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) stands as the gold standard treatment of gastric superficial lesions. Due to its technical complexity, ESD procedures often require extended durations, and longer procedural times are related to a higher level of adverse events. We intend to analyze our procedural time according to the predictive formula developed by Goto et al.

Aims & Methods: Prospective cohort study, single center, of patients who underwent gastric ESD between 2017 and 2023. The characteristics of the lesion were evaluated, and logistic regression of risk factors associated with longer procedural time (≥ 60 minutes) was performed. The predictive formula of procedural time was calculated for each patient and comparison between predictive and actual procedural time was performed using Pearson correlation coefficient.

Results: Included 101 gastric ESDs, 63.4% female, with a mean age of 69.7 ± 8 years. Among the analyzed lesions: 43.6% measured between 0-20mm, 56.4% ≥ 20mm; 13.9% were sessile, 60.4% flat, 14.9% depressed and 10.9% subepithelial; 22.8% were located in the upper-third of the stomach, 17.8% in the middle-third and 59.4% in the lower-third. Ulcerative findings were identified in 10% of the lesions. The most frequent histological results were: 38.6% low grade dysplasia, 26.7% high grade dysplasia and 19.8% intramucosal adenocarcinoma. The mean procedure duration was 87±43 minutes. Intra-procedure adverse events registered in 2% (perforation).

Evaluating the risk factors for longer procedures (≥ 60 minutes), the following revealed statistical significance: lesion size ≥ 20mm (89.5% vs. 65.9%; p=0.004), histology indicative of intramucosal adenocarcinoma (95.7% vs. 74.4%; p=0.027) and location in the upper or middle-third of the stomach (95.1% vs. 68.3%; p=0.001), but not the Paris classification (78.6% vs. 75.4% vs. 93.3%; p=0.4), ulcerative findings (63.6% vs. 67.1%; p=0.8) and the use of anticoagulant therapy (64.3% vs. 81.6%; p=0.138). Logistic regression analysis revealed that lesion size ≥ 20mm (OR 5.7; IC95%: 1.7-18.7) and location in the upper or middle-third of the stomach (OR 13.6; IC95%: 2.3-80.7) were significantly associated with longer procedural time.

When comparing predicted and actual procedural time, the overall Pearson correlation coefficient (r) was 0.58 (p<0.01), with the following values per consecutive 25 cases: 0.70, 0.67, 0.54 and 0.46.

Conclusion: Previous identification of risk factors for prolonged ESD procedures, such as lesion size ≥ 20mm and proximal lesion location, can be useful in optimizing workflow scheduling. Our correlation between predicted and actual time demonstrated a decreasing value, probably due to a higher complexity of the lesions, giving room for improvement.

Disclosure: Nothing to disclose.

Contact E-Mail Address: mariainesviegas96@gmail.com

Introduction: Delayed bleeding after gastric endoscopic submucosal dissection (ESD) is one of the most frequent complications (up to 7%). The BEST-J score is a risk predictive model for delayed bleeding following gastric ESD.

We aim to assess potential risk factors associated with bleeding and validate the BEST-J score in a population of patients undergoing ESD.

Aims & Methods: Prospective cohort study, single centre, of patients who underwent gastric ESD between 2017 and 2023. The characteristics of the lesion were evaluated, and logistic regression of risk factors associated with bleeding after ESD was performed. The BEST-J score was calculated for each patient and the discriminative ability was evaluated through the area under the receiver operating characteristic curve (AUC-ROC).

Results: Included 101 gastric ESDs (63.4% female), with a mean age of 69.7 ± 8 years. 17.8% of patients were on antiplatelet therapy and 13.9% were on anticoagulant therapy. Among the analyzed lesions: 43.6% measured between 0-20mm, 56.4% were ≥ 20mm; 13.9% were sessile, 60.4% flat, 14.9% depressed and 10.9% subepithelial; 22.8% were located in the cardia, fundus, or body, 17.8% in the incisura *angularis* and 59.4% in the antrum. The most frequent histological results were: 38.6% low-grade dysplasia, 26.7% high-grade dysplasia and 19.8% intramucosal adenocarcinoma. The mean procedure duration was 87±43 minutes. Delayed bleeding after ESD occurred in 5.9% (n=6) of cases. In the univariate analysis of risk factors, the lesion size ≥ 20mm showed statistical significance (10.5% vs. 0%; p=0.034), but not the location in the antrum (6.7% vs. 4.9%; p=0.5), lesion nature (7.1% vs. 8.2% vs. 0% vs. 0%; p=0.5) or procedure duration ≥60 minutes (5% vs. 9.5%; p=0.3). The BEST-J score predicted the risk of delayed bleeding after gastric ESD with an AUC of 0.70 (95% CI: 0.53-0.87; p=0.1).

Conclusion: The use of bleeding predictive scores may be useful in identifying high-risk patients; in our series, the BEST-J score was not very effective, with only lesion size ≥ 20mm being a relevant factor for bleeding after ESD.

RISK FACTORS ASSOCIATED WITH METACHRONOUS LESIONS FOLLOWING GASTRIC SUBMUCOSAL DISSECTION (ESD): A SINGLE CENTRE EXPERIENCE

M.I. Viegas[1], L. Elvas[1], M. Areia[1], S. Alves[1], D. Brito[1], S. Saraiva[1], A.T. Cadime[1]

Introduction: Endoscopic submucosal dissection (ESD) is the first-line treatment for superficial gastric lesions with a negligible or very low risk of lymph node metastasis. However, a permanent risk of developing metachronous lesions persists. We intend to analyze the risk factors associated with the development of metachronous lesions in a population of patients undergoing ESD.

Aims & Methods: Prospective cohort study conducted at a single centre, involving patients who underwent gastric ESD for lesions between 2017 and 2023, with a follow-up period of ≥ 6 months. Lesion characteristics were analyzed, including the rate of metachronous lesions, and logistic regression was performed to identify risk factors associated with the development of metachronous lesions.

Results: Included 78 ESDs performed on gastric epithelial lesions (59% female), with a mean age of 70.3±7.9 years. Regarding family history of gastric adenocarcinoma, 17.9% of patients had a first-degree relative. Among the analyzed lesions: 42.3% measured between 0-20mm, 57.7% ≥ 20mm; 12.8% were sessile, 71.8% flat and 15.4% depressed; 19.2% were located in the cardia, fundus or body, 21.8% in the incisura *angularis* and 59% in the antrum.

Regarding histological findings: 42.3% low-grade dysplasia, 30.8% high-grade dysplasia, 23.1% intramucosal adenocarcinoma and 3.8% adenocarcinoma with submucosal invasion. Nine metachronous lesions (11.5%) were detected, with a median time of occurrence of 24 [13-32] months. In the analysis of risk factors, statistical significance was found for location outside the antrum (21.6% vs. 1.9%; p=0.002) and the presence of adenocarcinoma (23.8% vs. 7%; p=0.039), but not for size ≥20mm (13.7% vs. 5.1%; p=0.178) or ulceration of the lesion (9.1% vs. 10.1%; p=0.915). Logistic regression analysis revealed that only location outside the antrum had a significant risk for the development of metachronous lesions (OR 13.4; 95% CI: 1.4-127.1).

Conclusion: Given the permanent risk of developing metachronous lesions, the identification of associated risk factors is important as it may eventually allow for the adaptation of surveillance programs.

Disclosure: Nothing to disclose.

Introduction: Although an effective and relatively safe procedure, bleeding complications often occur after gastric endoscopic submucosal dissection (ESD). We aimed to comprehensively evaluate the risk factors of post-procedural bleeding following gastric ESD.

Aims & Methods: This study was designed as a nationwide, population-based, retrospective study utilizing the Korean National Health Insurance Service database, comprising patients who underwent gastric ESD for gastric cancer or adenoma from November 2011 to December 2022. Operational definitions were created to identify the target population and post-procedural bleeding using the diagnosis and procedure code, which underwent validation.

We established operational definitions to identify the target population and post-procedural bleeding by utilizing diagnosis and procedure codes, which underwent validation. The risk factors analyzed included age, sex, hospital volume, socioeconomic status (SES), histology, lesion numbers, comorbidities, and medication usage.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: During the study period, there were 191,932 procedures conducted on 175,779 patients, resulting in 9921 cases of bleeding events. Several factors were associated with increased post-ESD bleeding risk. Following multiple logistic regression, relevant factors with adjusted odds ratios (aORs) were identified. These factors included young age (aOR: 0.990, 95% CI 0.987-0.992), male sex (aOR: 1.377, 95% CI 1.311-1.448), low-volume center compared to high-volume center (aOR: 1.289, 95% CI 1.022-1.621), medical aid compared to the top 25% SES (aOR: 1.307, 95% CI 1.188-1.440), higher Charlson comorbidity index (aOR: 1.040, 95% CI 1.026-1.054), gastric cancer (aOR: 1.369, 95% CI 1.307-1.434), and multiple lesions (aOR: 1.144, 95% CI 1.032-1.267). Furthermore, bleeding risk was significantly higher in groups with several comorbidities and antithrombotic agent users, particularly showing Notably high aORs in groups with renal failure (aOR: 2.086, 95% CI 1.909-2.278), warfarin (aOR: 2.641, 95% CI 2.219-3.143), direct oral anticoagulants (aOR: 2.519, 95% CI 2.220-2.859), and antiplatelet combinations (aOR: 2.073, 95% CI 1.783-2.410).
Conclusion: This study revealed various factors associated with increased bleeding risk after gastric ESD using a large cohort, which could be an important issue in terms of risk stratification and personalized treatment.

Introduction: Mediastinal lesions develop from structures located in the mediastinal compartments and the paravertebral areas. The diagnosis of these lesions is primarily based on imaging studies such as computed tomography and magnetic resonance imaging, which confirm the presence of the lesions and suspected metastatic disease
Aims & Methods: This study aims to assess the factors that determine the diagnostic accuracy and yield of endoscopic ultrasound (EUS) in diagnosing mediastinal lesions. This multicenter study involved a list of centres providing EUS services across ten countries all over the globe. The appropriate information was collected regarding EUS-FNA and EUS-FNB

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

procedures, including nature of the lesion, needle types, needle passes, and complications of the techniques. The frequency/percentage conveyed data on the qualitative variables. The p-values were obtained using the Chi-square two-tailed exact test. The significance of the analysis was defined as p<0.05. All the syntheses were performed using the Statistical Package for the Social Sciences (SPSS version 27; SPSS Inc., Chicago, IL).

Results: A total of 439 participants were involved in this study, 255 (58.1%) males and 184 (41.9%) females, with a mean age of 55.7314.93 years. The average accuracy from the valid matched cases between EUS, cytopathy, and final diagnosis (300 out of 331) was 90.63%. EUS-FNA and EUS-FNB diagnostic yield was influenced by needle types, needle size, number of needle passes, and lesion size. Needles with smaller diameters (22G) offered greater diagnostic yield than needles with larger diameters (19G). However, the diagnostic matching accuracy of EUS in relation to needle sizes was statistically insignificant (p= 0.774). A minimal number of needle passes (between 2 and 4) showed a higher diagnostic yield than a higher number of needle passes (>5) with more diagnostic matching accuracy (p = 0.009). EUS-FNB accounted for a 0.5% complication incidence rate each for fever, pain, thoracic pain, and hemorrhage. Patients undergoing EUS-FNA, EUS-FNB, or both procedural examinations had no significant complications (p = 0.085) Table 1.

EUS diagnosis			Complications					P value
			Fever and Pain	Hemorrhage	None	Pain	Thoracic pain	
EUS FNA or FNB	EUS-FNA	Count	0	0	75	0	0	0.085
		% within FNA	0.0%	0.0%	67.0%	0.0%	0.0%	
	EUS-FNB	Count	1	1	178	1	1	
		% within FNB	0.5%	0.5%	82.8%	0.5%	0.5%	
	FNA and FNB	Count	0	0	4	0	0	
		% FNB and FNA combined	0.0%	0.0%	1.6%	0.0%	0.0%	

Table 1: Incidence rate of complications associated with EUS examination techniques.

Conclusion: The diagnostic yield of EUS procedures is affected by needle types, number of needle passes, lesion size, and needle size. Besides, EUS-FNA and EUS-FNB are infrequently associated with serious complications, these techniques are safe and offer higher diagnostic yield when utilised responsibly by endosonographers.

USING NEEDLE BIOPSY UNDER ECHO-ENDOSCOPY (EEH-FNB) TO DIAGNOSE STOMACH LINITIS: A MOROCCAN UNIVERSITY CENTER'S EXPERIENCE

O. Nacir[1], F. Lairani[1], A. Ait errami[2], S. Oubaha[1,3], Z. Samlani[1], K. Krati[1]

[1]Department of GastroEnterology and Hepatology, Mohammed VI University Hospital Centrer, Faculty of Medicine and Pharmacy of Marrakech, Cadi Ayyad University, Marrakech, Morocco, [2]UHC Mohammed VI, Hepatogastroenterology, Marrakech, Morocco, [3]Department of Physiology, Faculty of Medicine and Pharmacy of Marrakech, Cadi Ayyad University, Marrakech, Morocco

Contact E-Mail Address: o.nacir@uca.ac.ma

Introduction: Gastric linitis is a kind of adenocarcinoma that invades the stomach and is composed of separate cells. The predicted survival rate for this condition over a five-year period ranges from 3 to 10%. The excessive cell growth that characterizes gastric linitis also results in the formation of fibrous tissue, which makes the stomach wall thicker and less flexible. Consequently, mucous biopsies frequently do not provide useful information.

Aims & Methods: The aim of this study is to evaluate the diagnostic performance of echo-endoscopic biopsy puncture (EUS-FNB) in the diagnosis of gastric linitis.This study is an observational retrospective monocentric analysis conducted over a period of 4 years from January 2018 to December 2022. It includes all patients who underwent a parietal gastric and/or ganglionary puncture under echo endoscopic guidance using a 20G or 22G Procore® or Acquire® type 22G FNB needle. The purpose of the procedure was to investigate suspected cases of gastric linitis. The study is conducted at the University Hospital Centre in Marrakech, which serves as a tertiary care department and is a point of reference for all regional and provincial hospitals. The appearance of parietal gastric thickness, abdominal DMT, an infiltrated aspect of the stomach, folds, or gastric stenosis in high digestive endoscopy led to the suspicion of gastric linitis. The data was obtained from various sources, including hospital registers, patient medical records, the computerized system "Hosix" for morphological and anatomopathological data, and the collaboration of the medical and paramedical staff from the departments of gastroenterology, visceral surgery, and anatomopathology. The statistical analysis was conducted using SPSS version 22.0. Socio-demographic, clinical and para-clinical data were collected taking into account the global ethical rules relating to confidentiality and protection of patient-specific data.

Results: Out of 42 patients who performed biopsy puncture under high echo-endoscopy on suspicion of diagnosis, ten patients had gastric linitis. The diagnosis of gastric linitis was obtained by puncture in 90% of cases (9/10). Eight patients (80%) had previously undergone at least one oeso-gastro-duodenal fibroscopy with returning negative mucous biopsies. Six patients were diagnosed as early as 1st EEH while 3 others required a second series of biopsies. While the mucous biopsies were also unsuccessful, echo-guided biopsy allowed the diagnosis of other more serious diseases in 43% of cases (n = 18/42) including gastric metastases of a breast cancer (n=2), other gastric adenocarcinomas of the intestinal type (N=8), and cases of T-type gastric lymphoma in one case and MALT type in 2 cases.

Conclusion: In case of suspicion of gastric linitis, guided biopsy puncture under echo-endoscopy is a cost-effective approach in 90% of cases, without noticeable side effects. It should be considered the procedure of choice for early diagnosis of gastric linitis when mucous biopsies return negative.

Disclosure: Nothing to disclose.

PP0203

PLATINUM FIDUCIAL SEEDS MADE IN HOUSE FOR EUS GUIDED IMPLANTATION

S. Abbott-Tate[1], A. Chatterjee[1]
[1]Ottawa Hospital Research Institute, Gastroenterology, Ottawa, Canada

Contact E-Mail Address: samabbott@ohri.ca

Introduction: Stereotactic Body Radiation Therapy (SBRT) has proven to be a safe and effective therapy for patients with deep abdominal malignancies who are ineligible/suboptimal candidates for surgery[1,2].

SBRT's effectiveness is dependent on precise targeting, achieved through both bone imaging and implantation of small markers (fiducials) that are visible during imaging which delineate margins of the target lesion[3].

Fusion of computed tomography (CT) and magnetic resonance imaging (MRI) can provide enhanced soft tissue contrast and improved delineation of the tumor[4], and is the preferred choice at our institution.

Fiducials have traditionally been made of gold due to its bioinertness and visibility on CT imaging, however gold is not accurately detected on MRI[5]. Platinum fiducials have recently emerged as an attractive alternative[5], considering their improved detectability on MRI imaging.

Endoscopic ultrasound (EUS)-guided implantation techniques have largely supplanted percutaneous methods for deep abdominal targeting, due to improved access and visualization[6].

Aims & Methods: The objective of this case series was to describe our novel platinum seed (PS) fiducials developed in house for EUS-guided fiducial SBRT application. We reviewed the adequacy of fiducial placement, quality of pre-treatment imaging, and migration rates of our fiducials.This single-center case series included patients diagnosed with cancers of the abdomen, including pancreas, adrenal, and liver, who were scheduled to undergo SBRT requiring EUS-guided fiducial implantation between January 2011-February 2024.

The cohort was derived from a prospectively collected EUS database at The Ottawa Hospital in Ottawa, Canada. Patient demographics (sex and age), procedure details (tumor site, number of fiducials implanted, complications), and radiologist's interpretation of MRI/CT imaging were assessed using hospital records. Approximately 70% of patients received antibiotics ((either IV x 1 does or oral antibiotics for 5 days post-procedure (eg. Ciprofloxacin, 500mg)). Our PS fiducials are made from 0.75mm wire cut into 3mm seeds which are then autoclaved in-house. Fiducials were implanted using a 19g FNA needle and advanced using an ERCP guidewire using EUS and fluoroscopic guidance.

Results: 55 patients underwent EUS implantation for a total of 176 fiducials. Preplanning CT/MRI imaging identified 166/176 (94.3%) fiducial signal voids. When evaluating fiducial placement adequacy, 52 of 55 (94.5%) patients had adequate placement for SBRT. Two patients required a repeat procedure with additional fiducial implantation. One case was due to suspected migration, and the second case was due to fiducials being placed too closely preventing adequate delineation. In a third case, no signal voids were visualized for an unknown reason, however, no repeat procedure was required as spine tracking was used. None of the patients developed post-procedure infection or other adverse events (AEs) in this case series (follow up at 1 month). Cost analysis revealed the fiducials made in-house were ~20-fold less expensive compared to commercially available solid gold, gold coil, or solid platinum fiducials.

Conclusion: Our platinum seed fiducials made in-house appear to have similar adequacy and no increased risk of AEs for EUS-implantation when compared to commercially available fiducials[7,8]. For centres using fused CT-MRI imaging for SBRT planning, PS fiducials are recommended. Moreover, significant cost-saving can be achieved through in-house production.

DIAGNOSIS OF GASTROINTESTINAL SUBEPITHELIAL LESIONS USING A NOVEL ENDOSCOPIC ULTRASONOGRAPHY IMAGING TECHNIQUE

C. Robles-Medranda[1], R. del Valle[1], M. Egas Izquierdo[1], M. Puga-Tejada[1], J. Baquerizo-Burgos[1], D. Cunto[1], M. Arevalo-Mora[2], J. Alcivar-Vasquez[1], H. Pitanga-Lukashok[1]
[1]Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Guayaquil, Ecuador, [2]Larkin Community Hospital, South Miami, United States of America

Contact E-Mail Address: miguel.puga01@hotmail.com

Introduction: Gastrointestinal stromal tumors (GIST) are the most common malignant subepithelial lesions (SELs) found in the gastrointestinal tract. Due to GIST's notable features including vascularity and deep location, endoscopic ultrasound (EUS) is the first-line diagnostic approach. Three models, color-doppler EUS, power-doppler EUS, and e-FLOW EUS, are useful for real-time vascularity detection; however, they are not effective for fine and slow flow vessel detection. Therefore, contrast enhanced EUS (CE-EUS) is proposed as a first-line approach. Nevertheless, the use of contrast may be detrimental, thus limited to some patients. To avoid contrast-related adverse events, a novel diagnostic method known as detective flow imaging endoscopic ultrasonography (DFI-EUS) has emerged.

Aims & Methods: To evaluate the utility of DFI-EUS in the diagnosis and differentiation of gastrointestinal SELs (GIST and leiomyomas) in comparison to CE-EUS.

A single-center, prospective, diagnostic study was conducted between December/2022 and October/2023 at IECED, Ecuador. The study protocol was approved by the Institutional Review Board and was conducted in accordance with the Declaration of Helsinki. Patients ≥18 years old with a suspected diagnosis of gastrointestinal SELs were enrolled for EUS vascularity assessment. Patients with contraindication for contrast agent administration, any clinical condition rendering EUS-DFI or CE-EUS unfeasible, pregnant and nursing were excluded. First, SELs' assessment was

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

performed by two expert endosonographers (blinded to patient's clinical information) using DFI-EUS, followed by a CE-EUS examination (using Sulphur hexafluoride contrast agent) for diagnostic confirmation. The identification rate along with diagnostic accuracy of DFI-EUS and CE-EUS based on histopathological confirmation was the primary endpoint. The type of vascularization (microvascular/microvascular) along with endosonographic appearance (hyper/hypovascular) were also recorded.

Results: A total of 24 patients were included, comprising 54.2% females. The examined lesions consisted of 70.8% GIST and 29.1% leiomyoma. Predominantly, lesions were found in the stomach (91.7%) and within the muscularis propria layer (91.7%). All GIST were hypoechoic and mainly heterogeneous, larger than leiomyoma in size (>2 cm; $p < 0.001$). Tortuous vessels were significantly identified in GIST (p 0.045). Both CE-EUS (94.1%; p 0.003) and DFI-EUS (94.1%; p< 0.001) successfully detected GIST *(Table 1)*.

The overall sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of DFI-EUS was comparable with CE-EUS with rates of 94.12% vs 94.12, 100% vs 99.64%, 100% vs 99.85% and 87.5% vs 99.64%, respectively *(Table 2)*.

A strong inter-rater agreement between CE-EUS vs DFI-EUS was detected with a kappa of 0.903 (p<.001).

Conclusion: DFI-EUS proves to be a reliable diagnostic tool, exhibiting high diagnostic accuracy, comparable to that of CE-EUS in the differentiation of GIST and SELs in the gastrointestinal tract. Larger multicenter studies are necessary to position this alternative for SELs' differentiation in clinical practice.

THE ROLE OF EUS IN THE ASSESSMENT OF SUBEPITHELIAL LESIONS OF THE UPPER GASTROINTESTINAL TRACT: A SINGLE CENTER EXPERIENCE

G. Georgiadou[1], E. Athanasiadou[1], G. Lazaraki[1], K. Soufleris[1], S. Mamalis[1], B. Molayusufoglou[1], M. Stafylidou[1], D. Tzilves[1]

Contact E-Mail Address: eftychiaath1@gmail.com

Introduction: The increasing number of performed gastroscopies worldwide has lead to higher detection rates of the subepithelial lesions (SELs) of the upper gastrointestinal tract. This study aims to describe the role of endoscopic ultrasonography (EUS) in the diagnosis and management of SELs at a tertiary public reference hospital in Northern Greece.

Aims & Methods: Records of patients who were referred to the Endoscopy Unit of Theageneio Hospital between 2018 and 2023 for upper EUS evaluation were retrospectively reviewed. We conducted data concerning patient characteristics, SELs features, details of the procedure and the final management of each case. All the examinations were performed by a single operator (DT).

Results: A total of 310 patients, male:130 and female:180, with a median age of 59 (range:17-86) were referred to EUS examination. EUS showed extraluminal compression in 16 cases (5.2%), gastric folds in 8 cases (2.6%), vascular structure in 8 cases (2.6%), and in 26 patients (8.4%) no lesion could be identified. A total of 252 (81.3%) patients had confirmed SELs. The lesion's location was: gastric body/corpus in 40.0% (101/252), antrum 34.5% (87/252), duodenum 15.1% (38/252), esophagus 10.3% (26/252). Regarding the size of the lesion in 31.7% of the cases (80/252) was <10mm, 41.3% (104/252) 10-19mm and in 27% (68/252) was >20mm. The most common EUS features were the following: regular borders 98.8% (249/252), hypoechoic lesions 67.5% (170/252), homogenous 77.8% (196/252), without vascularity 90.5% (228/252), and 69.5% (155/252) were originating from the third layer. Sixty-nine SELs (69/252, 27.4%) were malignant or had malignant potential as defined by the EUS findings. More specifically, forty-three patients (43/69, 62.3%) were referred for surgical resection. Twenty-three patients (23/69, 33.3%) were referred for further radiological evaluation and one patient (1/69, 1.4%) was referred for endoscopic resection. Endoscopic reassessment was recommended in 155 patients (155/252, 61.5%). Only one patient had persistent regurgitation, as an examination-related complication, probably due to the periprocedural

anesthesia that led to discontinuation of the examination.

Conclusion: EUS is a practical and safe tool for characterizing and assessing the features and malignant potential of SELs. In our center we could identify the malignant or potential malignant lesions and refer them to surgery.

EUS-GUIDED GASTROENTEROSTOMY TO TREAT REFRACTORY GASTROPARESIS: PRELIMINARY RESULTS OF THE FIRST GERMAN EXPERIENCE

M. Heilmaier[1], J. Wiessner[1], J. Ulrich[1], D. Schulz[2], M. Elnegouly[1], R.M. Schmid[1], M. Abdelhafez[1]
[1]Klinikum rechts der Isar der Technischen Universität München, Gastroenterologie, München, Germany, [2]Universitätsklinikum Augsburg, Gastroenterologie, Augsburg, Germany

Contact E-Mail Address: markus.heilmaier@gmail.com

Introduction: Gastroparesis is a motility disorder of the stomach characterized by a delayed emptying of food into the small bowel in the absence of mechanical obstruction. Medical treatment is difficult and symptoms such as epigastric pain, nausea and vomiting can lead to a significantly reduced quality of life. As endosonographic-guided gastroenterostomy facilitates gastric emptying and has been used successfully in patients with gastric outlet obstruction over years, it might be a viable option to treat refractory gastroparesis. The aim of the study was to report the first experience with that approach and to evaluate its feasibility and efficacy.

Aims & Methods: The data of 7 patients with refractory gastroparesis undergoing EUS-GE between march 2021 and August 2023 were retrospectively collected and analyzed. Primary endpoint was to assess the clinical and technical success of the intervention. Secondary endpoints were to assess the stent patency, adverse events and the rate of reinterventions.

Results: Technical and clinical success rate was 100% with a mean reduction in gastroparesis cardinal symptom index of 71%. During the ongoing surveillance, 2 stents had to be replaced after 12 months due to ingrowth, the other 5 stents remained patent after up to 36 months. We observed 2 stent obstructions in one patient due to food which had to be removed gastroscopically.

Conclusion: EUS-GE can effectively reduce the symptom burden in patients with gastroparesis refractory to medical treatment.

Disclosure: Nothing to disclose.

PEDIATRIC DEVICE-ASSISTED ENTEROSCOPY – INSIGHTS FROM A TERTIARY CENTER

F. Mendes[1], M. Martins[1], J. Afonso[1], T. Ribeiro[1], M. Marques[1], A.P. Andrade[1], E. Trindade[2], H. Cardoso[1], G. Macedo[1]
[1]Centro Hospitalar Universitário São João, Department of Gastroenterology, Porto, Portugal, [2]Centro Hospitalar Universitário São João, Paediatrics Department, Porto, Portugal

Contact E-Mail Address: francisco.cnm@gmail.com

Introduction: Device-assisted enteroscopy (DAE) is the only exam capable of a panendoscopic diagnostic and therapeutic intervention in gastrointestinal tract. Despite the limited data, DAE appears to be a safe procedure in pediatric population. In fact, a few studies demonstrate the feasibility and safetiness of DAE in several clinical contexts, namely small bowel bleeding, polyposis syndromes or inflammatory bowel disease.

Aims & Methods: With this study, the authors aim to describe DAE experience, specifically balloon assisted enteroscopy, in a pediatric population of a tertiary center.

A unicentric retrospective study was performed in patients up to 18 years old undergoing DAE (either by anterograde or retrograde pathway), between January 2011 and February 2024.

Results: A total of 23 DAE exams from 16 patients were included in the study, 56% from the male gender. The study population had a medium age of 13 years (ranging from 4 to 18 years old). DAE was performed due to polyposis syndromes in 8 cases (6 cases of Peutz-Jeghers syndrome and 2 cases of juvenile polyposis) and in suspicious cases of middle gastrointestinal bleeding in 8 patients (5 with melena and 3 with ferropenic anemia). There was a total of 17 anterograde DAE, 5 retrograde DAE and 1 intraoperatory enteroscopy. 35% of the procedures were performed in an inpatient setting.

DAE had a diagnostic yield of 95%, identifying polyps in the small bowel or other locations, ulcers, small bowel stenosis and foreign body. A therapeutic procedure was performed in 56% of the cases, namely polypectomy, argon plasma coagulation and foreign body removal. A self-limited bleeding was observed in the first 24 hours after an anterograde DAE, solved without the need of an additional endoscopic or surgical procedure. DAE led to a modification in the clinical outcome in over 90% of the patients.

Conclusion: The present study confirms the safety profile of DAE in the pediatric population. In a cohort from a tertiary referral center, DAE led to therapeutic procedure in the majority of patients, without significant procedure related complications.

EVEROLIMUS-COATED LASER-CUT SELF-EXPANDABLE METALLIC STENT SUPPRESSES STENT-INDUCED TISSUE HYPERPLASIA IN THE RAT GASTRIC OUTLET

C.E. Yun[1,2], Y. Park[1,2], S.H. Kim[1,3], D.H. Kim[3], J.-H. Park[1,2]

Contact E-Mail Address: ybeen9733@amc.seoul.kr

Introduction: Self-expandable metallic stents (SEMS) are commonly used to relive malignant gastric outlet obstruction (GOO). However, SEMS with high radial force can occurs tissue proliferation caused by mechanical injury. To overcome these problems, drug-eluting stents using antiproliferative drugs have been developed. Specially, everolimus have demonstrated efficacy in reducing restenosis rates in arteries, but their potential application in the gastrointestinal tract remains unexplored. Additionally, recent studies have reported that stents with thinner struts have a reduced risk of clinical restenosis compared to stents with thicker struts. However, the application of everolimus-coated laser-cut stents, which offer robust antiproliferative properties, has not yet been investigated or established in the gastrointestinal tract.

Aims & Methods: This study aims to investigate the efficacy and safety of everolimus-coated laser-cut SEMS in suppressing stent-induced tissue hyperplasia in a rat gastric outlet model.

Everolimus-coated laser-cut SEMS were prepared using ultrasonic spray technology, and the characteristics of the SEMS before and after coating process were evaluated. Twelve male rats were randomly divided into two groups: control (laser-cut SEMS, n = 6) and everolimus (everolimus-coated laser-cut SEMS, n = 6). The effectiveness of everolimus-coated laser-cut SEMS were assessed by comparing results of fluoroscopy, endoscopy, and histopathological analyses.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Everolimus were uniformly coated onto the surface of the laser-cut SEMS and approximately 80% of everolimus was slowly released for a week. Stent placement was successful in all rats. Stent-induced tissue hyperplasia variables were significantly lower in the everolimus group compared to the control group (all $p < 0.05$). The luminal diameter was significantly larger in the everolimus group than in the control group ($p < 0.05$). The degrees of α-SMA-, Ki-67-, and BrdU-positive deposition were significantly lower in the everolimus group ($p < 0.001$), while the degree of TUNEL-positive deposition was significantly higher than in the control group ($p < 0.001$).

Conclusion: Everolimus-coated laser-cut SEMS effectively suppressed stent-induced tissue hyperplasia in a rat gastric outlet model. Local treatment with everolimu via laser-cut SEMS was safe and effective to maintain the stent patency and has therapeutic potential in the prevention of restenosis after stent placement in the gastrointestinal tract.

OCCURRENCE AND RISK FACTORS OF MISSED CARCINOMA IN THE UPPER GASTROINTESTINAL TRACT (PEUGIC) 2013-2023 – RETROSPECTIVE OBSERVATIONAL STUDY

J. Langner[1], I. Mikoviny Kajzrlikova[1], P. Vitek[1,2], B. Horavova[3], M. Chrostek[4]

[1]Beskydy Gastrocentre, Department of internal medicine, Frydek-Mistek Hospital, Frydek-Mistek, Czech Republic, [2]University of Ostrava, Faculty of Medicine, Ostrava, Czech Republic, [3]Frydek-Mistek Hospital, Department of Pathology, Frydek-Mistek, Czech Republic, [4]Frydek-Mistek Hospital, Department of Surgery, Frydek-Mistek, Czech Republic

Contact E-Mail Address: langnerjakub@gmail.com

Introduction: PEUGIC (Post-Endoscopy Upper Gastrointestinal Cancer) is defined as carcinoma in the upper gastrointestinal (GI) tract which was preceded by negative upper endoscopy in the last 3 years. According to current knowledge, the rate of PEUGIC is an important parameter of quality and should not exceed 10 %. The aim of this study was to evaluate the occurrence and risk factors of PEUGIC at non-university hospital in Frydek-Mistek (Czech Republic) between 2013 and 2023.

Aims & Methods: This is a retrospective analysis of the patients diagnosed with upper GI cancer from January 2013 to December 2023. The data analyzed included family history of upper GI cancer, indications of the examination, therapy, tumor location and histological type. Risk factors for PEUGIC were calculated using the Chi-squared test and Fisher's exact test, with p <0,05 considered significant.

Results: During the study period, a total of 22727 gastroscopies were performed in total, and 122 patients were diagnosed with upper GI cancer (88 men and 34 women), including 35 esophageal tumors, 80 gastric tumors, and 7 duodenal tumors. Family history of upper GI tumor was reported in 10 patients. PEUGIC was identified in 12 patients (9,84%, 9 men and 3 women, mean age 69,25 years), including 6 in the esophagus, 5 in the stomach, and 1 in the duodenum. Two patients had early detection as part of adequate surveillance (Barrett's esophagus, post-polypectomy). Thus, we can evaluate 10 patients as true PEUGIC (8,20%). The rate of PEUGIC was 17,14 % (6/35) in the esophagus, 6,25 % (5/80) in the stomach, and 14,3 % (1/7) in the duodenum. Tumor location (for esophagus p=0,086, for stomach p=0,065, for duodenum p=0,525), histology (for adenocarcinoma p=0,332, for spinocelular cancer p=0,402, for neuroendocrine tumor p=0,25), male gender (p=0,815), or family history of upper GI tumor (p=0,335) were not statistically significant risk factors for detecting PEUGIC.

Conclusion: The overall rate of PEUGIC at our institution over the 11-year study period was 9,86 %, without early detected lesions as part of adequate surveillance, it was 8,20 %. Early detection of PEUGIC, which indicate poorer endoscopy quality, need to be distinguished from early detection of carcinoma within adequate surveillance.

Disclosure: Nothing to disclose.

Introduction: Treatment of gastrojejunal anastomotic ulcers, also known as marginal ulcers, is challenging, especially when established techniques such as proton pump inhibitor have failed.

Pura Stat, is a biocompatible transparent synthetic peptide hemostatic gel that is indicated for hemostatis of bleeding in small blood vessels or capillaries of the GI tract and vascular anastomoses. Our aim was to evaluate the feasibility of PuraStat in the setting of non-healing marginal ulcers when used in addition to proton pump inhibitor (PPI) therapy after failed standard therapies

Aims & Methods: We conducted a multi-center prospective case study of adult patients that underwent PuraStat application (3 ml) for marginal ulcers after failing multiple initial therapies with proton pump inhibitors for at least 8 weeks

Results: A total of 10 patients were included in the study. Patients who had an initial presentation of pain, nausea, anemia, with confirmed anastomotic ulceration seen on endoscopy were included. A total of 3mL of Purastat was applied on each of these patients' ulcers, and a repeat endoscopy was performed to evaluate ulcers at ~3months. 9 out of 10 patients showed healing of marginal ulcer on repeat endoscopy in 3 months, while one patient did not present for repeat endoscopy. 9 out of 10 patients showed clinical improvement in their symptoms (90%), and one patient did not show improvement in their symptoms.

Surveillance EGD 3 months post PuraStat	No. (%)
Healing of Marginal Ulcer	
Yes	9 (90)
No	0 (00)
No follow-up EGD	1 (10)
Improvement in Clinical Symptoms (Abdominal pain, nausea, GI Bleed)	
Yes	9 (90)
No	1 (10)

Table 1. Post-PuraStat application results.

Conclusion: PuraStat is an important useful addition to the therapeutic toolbox for the treatment of anastomotic ulcers. Our small prospective case series shows effectiveness in symptom relief as well as clinical healing of anastomotic ulcers. Larger randomized clinical trials are needed.

COLONOSCOPY INDICATIONS ACCORDING TO EPAGE II CRITERIA

B. Soukaina[1], F. Amkhaou[1], F. Haddad[1], F.Z. Elrhaoussi[1], M. Tahiri Joutei Hassani[1], W. Hliwa[1], B. Ahmed[1], W. Badre[1]
[1]Hospital University Center IBN ROCHD, Gastroenterology, Casablanca, Morocco

Contact E-Mail Address: bannanisoukaina@gmail.com
Introduction: The prescription of colonoscopies is constantly increasing for the screening and diagnosis of colorectal cancer, precancerous lesions, polyps, and adenomas. Sometimes, indications become excessive due to the availability of this examination on one hand and the fear of missing a neoplastic lesion on the other. The EPAGE II criteria (European Panel on the Appropriateness of Gastrointestinal Endoscopy) was developped to assess the relevance of colonoscopy indications and to rationalize its prescription.
The aim of our study was to evaluate the relevance of colonoscopy indications performed in our department according to EPAGE II criteria and to investigate a possible correlation between the appropriateness of the examination and the endoscopic result.
Aims & Methods: A retrospective study was conducted at a hepatogastroenterology department including all colonoscopies performed during the period from January 2022 to June 2023. The relevance of colonoscopy indications according to EPAGE II criteria was classified as appropriate, uncertain, or inappropriate.
Results: The relevance of the indication was evaluated in 406 colonoscopies. The sex ratio (Male / Female) was 1.15. The median age was 51 with an IQ [15.93]. Rectal bleeding represented the most frequently found indications (30%), followed by Crohn's disease (12.8%), then chronic diarrhea (11.1%). 49% of colonoscopies had satisfactory preparation (Boston ≥7). Colonoscopy was complete in 86% of patients, with catheterization of the terminal ileum in 36.2% of cases.
A significant endoscopic lesion was found in 63% of colonoscopies, represented mainly by inflammatory lesions of inflammatory bowel disease (20.7%) followed by neoplastic lesions (15.3%) of colorectal cancer, then polyps (10%), benign strictures (6.4%), and diverticulosis (5.7%).
Overall, colonoscopy indication was appropriate in 83.5% of cases, uncertain in 10.8%, and inappropriate in 5.7%. A significant endoscopic lesion was found in 63% of patients with an appropriate indication.
Conclusion: The indication for colonoscopies performed in our department was considered appropriate in more than 80% of cases, with rectal bleeding being the main indication.
Significant endoscopic lesions were mostly found in cases of appropriate indication, leading us to encourage the use of this software to regulate colonoscopy indications

GASTRIC ULCER FOLLOW UP - IS ONE LOOK ENOUGH?

M. Clarke[1], T. Sheehan[1], R. Connaughton[1], H. Kerr[1], A. Omar[1], C. Smyth[1], R.J Farrell[1], C. Egan[1], B. Hall[1], M.M. Elsiddig[1], O. Kelly[1]
[1]Connolly Hospital, Blanchardstown, Gastroenterology Department, Dublin, Ireland

Contact E-Mail Address: maeve.j.clarke@gmail.com
Introduction: Current guidelines recommend 12 week follow up for gastric ulcer surveillance. This represents a significant proportion of follow up oesophago-gastro-duodenoscopies (OGDs). Debate is ongoing regarding the need for universal endoscopic follow-up to ensure gastric ulcer healing.
Aims & Methods: Aims: We aimed to assess the value of follow-up OGD for gastric ulcer healing in Connolly Hospital Endoscopy Unit with regards to cancer diagnosis and the yield of index biopsies.
Methods: Patient endoscopy data for gastric ulcers diagnosed 2021-2023 via Endoraad were examined. All gastric biopsies including index biopsy of ulcers were reviewed. Time to repeat procedure was recorded.
Results: 147 documented diagnoses of gastric ulcers were identified for the study period (51% female, mean age 60.2). 56% (n=83) of ulcers were biopsied at index OGD. 6 (4% of total) malignancies were diagnosed at index biopsy with no malignancies diagnosed on repeat, chi sq., p =0.02. 76% (n=111) had a repeat procedure, with 43% (n=63) meeting the target of 12 weeks. 16% (n=24) index biopsies taken were HLO positive. Following review of the images by three gastroenterology consultants; 26.% (n=38) were deemed erosions rather than ulcers. Of those deemed ulcers their Forrest classification are as follows; 34% (n=50) Forrest 3, 8% (n=13) Forrest 2c, 2% (n=3) Forrest 2b, 2% (n=3) Forrest 2a and 6% (n=10) Forrest 1b. The remaining 20% of images (n=30) deemed not a gastric ulcer included: malignancy, healed ulcers and severe gastritis. Regarding findings at second scope, 20 patients (18.3%) had persistent ulceration, with no new malignancies identified. Of note, of those not followed, 95% were biopsied at index procedure and had benign features. The average time to repeat procedure was 9.7 weeks.
Conclusion: The Covid pandemic and HSE ransomware attack may have significantly contributed to delay in repeat procedures. However, the majority of patients had either index ulcer biopsies or repeat endoscopy performed. The cancer yield of FU-OGD after benign biopsies remains low. Strategies to reduce the burden of FU-OGD such as risk stratification approach using high quality index examination, ulcer features and index biopsies may aid selective patient follow-up, improve yield of repeat procedures and reduce burden on the patient and health service.
Disclosure: Nothing to disclose.

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are both standard endoscopic treatments for early-stage gastrointestinal tumors. Submucosal fluid injection is an important part of endoscopic procedure, increasing the space between the lesion and the muscle layer and enabling easy and safe resection. Recently, PuraLift™ (3-D Matrix Ltd, Tokyo, Japan), a novel submucosal injection solution made from self-assembling peptide hydrogel (SAP) was developed in Japan. SAP is fully synthetic and consists only of amino acids present in the human body, giving it the advantages of biodegradability and biocompatibility over conventional solutions.

In addition, the 3D structure of the hydrogel supports cell proliferation in vitro, and self-assembling peptide hydrogel (SAPH) may promote wound healing. However, there are no reports on the effect of SAPH on ulcer healing after endoscopic resection.

Aims & Methods: The aim of this study was to assess the effect of SAPH on wound healing after endoscopic resection. EMR procedures were performed in the stomach of 4 living pigs with 3 patters of submucosal injection solution; normal saline injection group (NS); sodium alginate injection group (SA); PuraLift™ injection group (SAPH). Each pig received 3 separate submucosal injections with 3 mL of the different solutions and then EMR was performed using a 15mm diameter snare. Immediately after EMR (W0) and on week 1(W1) and week 2(W2), we measured the ulcer diameter endoscopically using a measuring device. On week 3(W3) after EMR, all pigs were sacrificed and necropsied by en-bloc gastrectomy, followed by macroscopic measurement of ulcer diameter. All wound sites of the resected specimens were examined histopathologically by haematoxylin and eosin (HE) and Masson's trichrome (MT) and immunohistochemistry staining (αSMA, CD3, CD 31, CD107a). The ulcer reduction rate was calculated as follows : [(ulcer diameter at W0) -(ulcer diameter at week X)] / (ulcer diameter at W0) x 100(%). Ulcer epithelialisation and submucosal foreign bodies were assessed by HE staining, tissue damage in the muscle layer and the thickness of the fibrotic layer by MT staining. Five random fields at each wound site were photographed, and the average rate of positive areas by immunostaining in each injection solution group was calculated.

Results: Ulcer reduction rate at W1 was higher in SAPH group and SA group than NS group (24.1±13.5%; 24.6±17.9%; -6.9±7.6%; p<0.05), b but there were no significant differences at W2 and W3 among three groups. Complete epithelialisation of the ulcer occurred in all except one case of NS group. In SA group, all four cases showed residual injection solution in the submucosal layer with foreign body giant cell reaction and fibrous tissue growth. In contrast, in SAPH group, only one case showed a focal foreign body giant cell reaction without residual injection solution. The thickness of the fibrotic layer is greater in SA group than SAPH and NS groups (SA: 4.2±0.8mm, SAPH: 1.6±0.4mm, NS: 2.0±1.2mm, p<0.05). Tissue damage was not observed in either group. There were no differences in the rates or positive area of αSMA, CD3 and CD31 staining between groups. In contrast, the rates of positive area of CD107a staining were significantly higher in SA group than SAPH and NS group(SA: 13.9±1.0%, SAPH: 5.7±2.2%, NS:1.2±2.1%, p<0.001), indicating a high degree of macrophage accumulation.

Conclusion: SAPH induced good healing after EMR and was more biodegradable and biocompatible than sodium alginate.

SAFETY, EFFICACY AND CARBON FOOTPRINT OF A CAPSULE SPONGE PATHWAY IN PATIENTS WITH REFLUX - A 3YR FOLLOW-UP

D. Angel[1], K. Shaw[1], F. Cole[1], K. Mohanathass[1], D. Corrigall[1], D. Morris[1]

[1]East and North Hertfordshire NHS Trust, Gastroenterology and Hepatology, Stevenage, United Kingdom

Contact E-Mail Address: dylan.angel@nhs.net

Introduction: With the need to reduce the burden of endoscopy, capsule sponge enables cost effective and efficient triage for patients with reflux as shown in the National Health Service England (NHSE) pilot study whilst achieving a smaller carbon footprint in comparison to gastroscopy. Negative sponge follow up has yet to be reported. Using the largest single UK site database, we describe 1, 2 and 3 year follow up and quantify the effect of gastroscopy avoidance on the endoscopic carbon footprint.

Aims & Methods: Patients routinely referred between November 2020 and November 2023 to gastroscopy or gastroenterology clinic with reflux were selected as part of the DELTA or NHSE pilot studies and triaged to a new nurse led early diagnosis teleclinic where they were first offered a capsule sponge. Patients with positive tests, (Trefoil factor 3 TFF3 and/or atypia/p53 positivity indicating possible Barrett's/gastric intestinal metaplasia or dysplasia respectively) all underwent mandatory gastroscopy and were excluded from this analysis. In the event of a negative test, nurse led teleclinic follow up occurred by 3 months and gastroscopy was only requested for ongoing/concerning symptoms. The endoscopy database for patients with a negative capsule sponge was reviewed at 1, 2 and 3 year intervals to review if gastroscopy had occurred and what findings were identified.

Results: At the 1, 2 and 3 year follow up intervals, 429 and 204 and 41 patients were identified respectively. 86% of the 1 year follow ups (n=371) had not represented for a gastroscopy. The most frequent findings in the 14% (n=57) who did undergo gastroscopy were gastritis (n=14), hiatus hernia (n=9) and normal (n=16).

The most significant finding in this cohort was one case of gastric cancer, identified two weeks post capsule due to new concerning symptoms. In total 371 gastroscopies were avoided in year 1, equating to 42294L of water and 1846 kgeCO2. Of the 204 2 year follow up group, 92% (n=187) had not had a gastroscopy.

There was no significant pathology (including Barrett's) identified in any of the remaining 8% (n=17) and the most common endoscopic conclusion in this cohort was normal. Only 2/17 patients underwent their gastroscopy in the second year of follow up.

Finally, of the 41 patients with a negative capsule sponge available to review at 3 year follow up, 21% (n=9) had undergone a gastroscopy however only 3 of these had been performed in year 3 and they were all normal. Importantly, no patient who represented for OGD at any of the intervals after a negative capsule sponge were found to have Barretts.

Conclusion: Over 1, 2 and 3 year follow up periods, our study provides reassuring data from the largest UK capsule sponge site. Our data shows

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

that capsule sponge safely excluded significant upper GI pathology in a less invasive manner, enabling symptomatic management without necessitating gastroscopy in the majority of patients. Nurse led teleclinic safety netting proved effective in identifying patients needing additional investigations whilst reducing the number of gastroscopies performed. This has helped improve endoscopy access overall, whilst also tackling the growing concern surrounding the endoscopic carbon footprint. Our study supports a new paradigm for the investigation of reflux symptoms which can be incorporated in both community and secondary care pathways.

Contact E-Mail Address: tombor@tlvmc.gov.il

Introduction: A patency capsule (PC) test is advised before video capsule endoscopy (VCE) to prevent capsule retention in high-risk patients. Although up to 30% of patients cannot expel the PC within 30 hours and are ineligible for VCE, those without strictures, but with slow transit time, can safely undergo VCE. Currently there are no recommendations regarding PC protocol.

Aims & Methods: In this prospective cohort study, we aimed to evaluate the success rate of a 2nd PC attempt with augmented pro-motility preparation protocol, in patients who previously failed to pass PC and to ascertain the risk factors for failure in PC test.

During 2019-2023, Patients who failed their initial PC test in our referral center were offered to undergo a 2nd augmented pro-motility bowel preparation protocol (Table 1). Exclusion criteria: age<18 years, total colectomy or ileostomy and inability to sign informed consent. Patients were followed during the 2nd PC test and the subsequent VCE for success rates and safety outcomes, i.e. VCE retention. Demographic and clinical characteristics were collected for assessing potential risk factors for 1st PC failure and successful 2nd PC by multivariate regression analysis.

		Pro-motility protocol 1st PC	Augmented pro-motility protocol 2nd PC
-2 day	All day	Low residue diet	
-1 day	12:00-20:00	Clear liquid diet	
	14:00	-	Bisacodyl 10mg
	19:00-21:00	-	PEG 3350 1.5L
	20:00-till PC ingestion	Fasting	
PC day	Morning	PC ingestion + Bisacodyl 10mg	
	2hours post-ingestion	Drink clear liquids	
	4 hours post ingestion	A light meal	
+1 day	30 hours post ingestion	X-ray or confirmed expulsion	

Table 1: Patency Capsule Preparation Protocols

PC, patency capsule; PEG3350, Poly-ethylene Glycol

Results: A total of 396 patients performed a PC test and were included in the study (age 45.4±18.6 years, male gender 47.7%). The indications for VCE were suspected/established Crohn's disease (86.1%); anemia/bleeding (8.3%) and radiologic findings (5.6%).

Successful PC expulsion was documented in 323 (81.6%) patients, while 73 (18.4%) failed. A 2nd attempt with augmented pro-motility protocol was accepted by 35/73 patients (48%) and rejected by 38/73 patients (52%). no clinico-demographic differences between the groups.

Successful 2nd PC attempt was documented in 20/35 patients (57%), with all of them completing VCE without adverse events. Failed 2nd PC was documented in 15/35 patients (43%) without adverse events, while 3/15 performed tandem abdominal CT confirming PC in colon (i.e false failure) followed by uneventful VCE.

Performance of a 2nd PC attempt reduced the failed PC rate by 57% (Absolute risk reduction) and the number needed to treat (NNT) is 1.8 for a successful 2nd attempt. Multivariate regression for success with 2nd PC vs. 1st PC was limited by small numbers.

However, diabetes mellitus showed a trend as a risk factor (9.6% in 1st PC test success vs. 20% in 2nd PC test success, OR 3.7, p=0.057, adjusted for age, gender, BMI and stools/day).

Conclusion: In this prospective cohort study, a novel augmented pro-motility PC test preparation protocol improved the success rate in patients who previously failed an initial PC test, without any adverse events. Subsequent abdominal CT should be considered in selected cases to further reduce false positive results. Patients with diabetes mellitus might benefit from performing the augmented protocol upfront, but further large-scale studies are required to establish that.

Disclosure: Nothing to disclose.

INCRETIN EFFECT *DURING A LOW-CALORIE MIXED BREAKFAST SMARTPILL® INVESTIGATION:* TIMING OF POST-PRANDIAL METABOLIC HORMONE AND GLUCOSE CHANGES IN HEALTHY VOLUNTEERS

M.A. Halim[1], D. Javidi[1], P. Kalamees[1], M.u. Din[1], H.O. Diaz Tartera[1], P.M. Hellström[1], D.-L. Webb[1]

[1]Uppsala University, Gastroenterology & Hepatology, Medical Sciences, Uppsala, Sweden

Contact E-Mail Address: dominic-luc.webb@medsci.uu.se

Introduction: The "incretin effect", the concept that gut hormones amplify insulin secretion, has been around for decades. In the 1960's, it was discovered that oral glucose leads to greater circulating insulin response than IV glucose (1). This was later attributed to gut hormones, such as GLP-1 and GIP. Activation of their receptors on pancreatic β-cells raises cAMP, accounting for amplified insulin secretion. This study aimed to determine if incretin and related metabolic analytes consistent with the incretin effect are detectable during SmartPill® wireless motility capsule (WMC) investigations. These increasingly common investigations represent a convenient resource to study metabolism and relate this to gut physiology.

Aims & Methods: Healthy volunteers (n=41) arrived following overnight fasting. They consumed a standardized 270 kcal mixed meal breakfast. Details of methods including validation of motility data have been published (2). Blood was tapped -10, 0, 10, 20, 30, 40, 50, 60, 90, 120, 180 and 240 min into the meal. Protease inhibitors, including DPP4 inhibitor KR-62436, were added and plasma was prepared. Glucose was measured by the clinical chemistry unit. Active GLP-1, total GIP, acyl-ghrelin and insulin were measured by multiplex ELISA (MesoScale Discovery, USA). Glucagon was measured by ELISA (Mercodia, Sweden). Statistics for comparing pairs of peak or trough timing was done by rank-sum test. Data is presented as median ±SD.

Results: Following meal ingestion, the GLP-1 peak (30 ± 11 min) preceded those of glucose (40 ± 16 min), insulin (40 ± 12 min) and GIP (50 ± 26 min) (p<0.01, all comparisons). Glucose peaked about same time as insulin and before GIP (p<0.01).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

However, the rising phase of insulin and GIP overlapped somewhat, with no statistical difference in time to peak. GLP-1 peaked before insulin in 68% (28/41) of subjects, at the same time in 29% (12/41) of subjects, and after insulin in only 2% (1/41) cases in which insulin appeared to peak at 10 min and GLP-1 at 30 min. GIP peaked before insulin in 20% of subjects (8/41), at the same time as insulin in 49% of subjects (20/41), and after insulin in 32% of cases (13/41). Ghrelin and glucagon deflected downward at 30 min. Ghrelin reached trough at 60 ± 31 min, which was later than peaks of GLP-1 (p<0.01), glucose (p<0.01), insulin (p<0.01) and GIP (p<0.05). Glucagon reached trough at 55 ± 44 min, which was also later than peaks of GLP-1 (p<0.01), glucose (p<0.01), insulin (p<0.01) and GIP (p<0.05). GLP-1 peaked before glucagon reached trough in 95% of cases (38/40)(p<0.01) and at the same time or after glucagon in only 5% (2/40) of cases. GIP peaked before glucagon reached trough in 75% (30/40) of cases (p<0.01). Expulsion of the WMC from the stomach (gastric emptying time 185 ± 72 min) occurred after all peaks and troughs were reached in 95% (39/41) of subjects (p<0.001).

Conclusion: GLP-1 rise to peak is detectable as an early event during SmartPill® WMC investigation, usually preceding peaks or troughs of any of the other analytes. This is consistent with GLP-1 raising intracellular cAMP in pancreatic β-cells to prime them for insulin secretion. GIP rise to peak trails GLP-1, implying a later, prolonged action that parallels insulin. Ghrelin and glucagon start to decline when GLP-1 peaks, tending to reach trough after other hormones peak. Studies of these events require blood taps at a number of time points during a meal.

Introduction: Motility disorders, such as gastroparesis and slow transit constipation (STC), are common gastrointestinal (GI) conditions affecting up to 5% of individuals worldwide. The symptoms of motility disorders can be debilitating, affecting quality of life and driving utilisation of healthcare systems. Diagnosis relies on evaluation of regional transit times, with delayed gastric and colonic transit indicated for gastroparesis and STC, respectively. The SmartPill GI Monitoring System (SmartPill), an FDA-cleared wireless motility capsule (WMC), has been used in the assessment of gastroparesis and STC since 2008 but has recently been discontinued, leaving a need for a like replacement.

This study aimed to assess a new WMC, the Atmo Gas Capsule System (Atmo Capsule), against SmartPill for the assessment of regional transit times in these conditions.

Aims & Methods: Individuals with upper, lower, or overlapping GI symptoms were recruited in a prospective multi-centre study. Participants concomitantly ingested the Atmo Capsule and SmartPill in a randomized order. Regional transit times including Gastric Emptying Time (GET) and Colonic Transit Time (CTT) were measured and compared between the devices, where paired data were available. GET >5 hours and CTT >59 hours were defined as delayed.

Results: 213 participants (median age 41 [range 20-77], 188 female) were recruited across 12 sites: 177 yielded paired GET results, and 147 for CTT. Pearson correlation coefficients for GET and CTT comparisons between Atmo Capsule and SmartPill were 0.86 (0.81-0.89) and 0.74 (0.66 – 0.81) respectively. GET demonstrated a positive predicted value (PPV) of 78.00% (SE: 5.86%), negative predictive value (NPV) of 85.83% (SE: 3.09%), and overall agreement (OA) of 83.62% (SE: 2.78%). For CTT, PPV was 67.35% (SE: 6.70%), NPV was 92.89% (SE: 2.60%), and OA was 84.35% (SE: 3.00%). No serious adverse device events were reported. 32.2% of the total GET evaluable cohort had delayed GET, 27.2% of the CTT evaluable cohort had delayed CTT. For the cohort that had measurements for all transit regions (n=142), 20% had delayed CTT only, 11% had delayed GET only and 18% had a delay in multiple GI regions as measured by the Atmo capsule.

		Atmo Result Mean (SD) hours	SmartPill Result Mean (SD) hours	Pearson Correlation P-value
Regional Transit Times	GET (n=177)	3.84 (1.57)	4.05 (1.45)	<0.0001
	SBTT (n=183)	5.13 (2.56)	5.18 (2.23)	<0.0001
	CTT (n=147)	47.01 (29.67)	41.79 (27.73)	<0.0001
Multi-regional transit delays as determined by Atmo Capsule	Overall (n=142)	No regional delay	62 (43.7%)	
		Single region delay	55 (38.7%)	
		Multi-region delay	25 (17.6%)	
	Single region delay only (n=55)	GET	16 (11.3%)	
		SBTT	10 (7.0%)	
		CTT	29 (20.4%)	
	Multi-region delay (n=25)	GET & SBTT	6 (4.2%)	
		GET & CTT	9 (6.3%)	
		SBTT & CTT	6 (4.2%)	
		All regions	4 (2.8%)	
Safety	Adverse events related to study devices	17 (8.1%): Abdominal Pain: 1 (0.47%), Capsule Retention: 15 (7.1%), Headache: 1 (0.47%)		
	Serious adverse device effects	0 (0%)		

Conclusion: The Atmo Capsule exhibited substantial agreement with SmartPill in measuring both GET and CTT, highlighting its utility as a potential replacement for the discontinued SmartPill for assessment of motility disorders. Nearly 1 in 5 patients studied had delayed upper and lower transit times highlighting the benefit of evaluating multiple regions of the GI tract with a single test.

Contact E-Mail Address: Hann_A@ukw.de

Introduction: In accordance to current European guidelines, an emergency endoscopy in hemodynamically stable patients with suspected nonvariceal, upper gastrointestinal bleeding (nvoGI bleeding) should be performed within the first 24 hours. This practice consumes scarce human resources, especially at weekends. A recently available photometric capsule enables a prompt, non-invasive assessment of blood or haematin in the gastrointestinal tract.[1]

Aims & Methods: We investigated whether this capsule is a proficient tool to identify patients for whom an emergency endoscopy (within 24h) can be avoided.

A total of 73 patients with suspected hemodynamically stable nvoGI bleeding were included at four different sites using the photometric capsule. Capsule data were assessed after 120 minutes. All patients with a positive capsule result (bleeding index, HI>=1) underwent an upper gastrointestinal endoscopy within 12 hours (Group A). Patients with a negative result (HI<1.0) received a proton pump inhibitor at a standard dose twice daily and underwent endoscopy within 48 to 96 hours (Group B).

If clinical or laboratory signs of acute bleeding became apparent in the meantime, an early endoscopy (within 12h) was performed.

Results: Mean modified Glasgow-Blatchford score (mGBS) was 8.9 for all 73 patients. Among the 41 patients of Group B, two patients (4.8%) received early endoscopy due to persistent hypotension (<90mmHg syst.) (1x cardiac tumor, 1x Forrest III ulcer, both without active bleeding). Two patients received no endoscopy (1 patient refused, 1 patient suffered from a stroke).

Active bleeding was excluded in the remaining 37 patients (sensitivity regarding active bleeding = 100%, negative predictive value = 100%). In Group A, (n=32), emergency endoscopy was performed on average within 2.7 h and detected active bleeding sources in nine patients (28.1%). There were no technical, capsule-associated or bleeding-associated complications as assessed within 30 days of follow-up.

Group	B (capsule negative)	A (capsule positive)	p-value
number	41	32	
mGBS	8.45 ± 2.9	9.3 ± 3.1	n.s.
anticoagulation	25 (61.0%)	19 (59.4%)	n.s.
mean time to endoscopy (EGD)	65.0h (21-97)	2.7h (0.25 – 18)	<0.05
active bleeding in EGD	0 (0%)	9 (28.1%)	<0.05

Conclusion: Due to the very high negative predictive value in detecting active upper GI-bleeding, the applied novel photometric capsule can reliably identify patients in whom emergent endoscopy is not necessary.

PASSING YOUR PATENCY TEST: DO PRUCALOPRIDE AND FASTING MAKE A DIFFERENCE?

D. Alsharqi[1], P. Maligaya[1], S. Ismail[1], E. Gibbons[2], L. Keating[2], B. Hall[2], E. Coughlin[3], M. Ferry[3], V. Parihar[3]

[1]Beaumont Hospital, Dublin, Ireland, [2]Connolly Hospital Blanchardstown, Dublin, Ireland, [3]Letterkenny University Hospital, Gastroenterology, Letterkenny, Ireland

Contact E-Mail Address: Dana_alsharqi@hotmail.com

Introduction: Capsule endoscopy (VCE) is generally safe, however a subset of patients require confirmation of bowel patency before undergoing the procedure, using a self-dissolvable patency capsule of similar calibre to the video capsule, with interval imaging to confirm excretion. Patency capsule absence on imaging confirms bowel patency. Prucalopride, a 5-HT4 agonist that enhances bowel motility, has been used in VCE to improve completion rates[1], but its use in the context of patency testing remains unknown. Similarly, the role of fasting in improving pass rate is unclear.

Aims & Methods: This study aims to determine whether Prucalopride and fasting enhance the pass rate of patency tests. Data from procedures performed in 3 centers in the Republic of Ireland was reviewed retrospectively. We compared the pass rate in the context of Prucalopride (Group A), fasting (B), and non-fasting (C) states. All patients had an abdominal x-ray between 24-30 hours post-patency capsule ingestion to confirm passage. ANOVA test was used to compare means between all groups, and student t-test between individual groups.

Results: A total of 127 patients were included. Group A (Pruculopride): 59 patients, Group B (fasting, no Prucalopride): 22 patients, Group C (non-fasting, no Prucalopride): 46 patients.

Demographics:

Group A: 47.5% males and 52.5% females, Group B: 45.5% males and 54.5% females, Group C: 32.6% males and 67.4% females

Mean age – Group A: 50.3 years (range 18-82), Group B: 48.4 years (24-82), Group C: 47.9 (17-79).

Indication based on European Society of Gastrointestinal Endoscopy guidelines

Appropriate: 80 (63%)

Inappropriate: 35 (27.6%)

Undocumented: 12 (9.4%)

Pass Rate:

Group A: 36/59 (61%), Group B: 17/22 (77%), Group C: 19/46 (67%).

ANOVA test f-ratio 4.55, p= 0.012.

T-test: Group A vs B (61% vs 77%, p=0.087). A vs C (61%vs 67%, p=0.023), B vs C (77% vs 67%, p=0.002).

Group	Description / Intervention	Male	Female	Mean Age (Range)	Pass Rate
A	Prucalopride	47.5%	52.5%	50.3 years (18-82)	36/59 (61%)
B	No Prucalopride, fasting	45.5%	54.5%	48.4 years (24-82)	17/22 (77%)
C	No Prucalopride, non-fasting	32.6%	67.4%	47.9 years (17-79)	19/46 (67%)

Conclusion: This study shows that fasting improves patency tests pass rates, but Prucalopride does not. Fasting and subsequent patency capsule ingestion promoting the gastro-ileal reflex is a possible explanation. It is

unclear in this study why Prucalopride, a prokinetic and laxative, failed to show an improvement in pass rates despite being shown to improve VCE completion rates in other studies. Longer duration of Prucalopride at split intervals is a potential area for further studies.

EVALUATION OF "PATENCY AT HOME" PILOT PROGRAM; SUCCESS, SATISFACTION AND SAVING

G. Madders[1], R. Grainger[1], C. Costigan[1], D. McNamara[1]
[1]Tallaght University Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: gillianmadders@gmail.com

Introduction: Capsule retention is the major risk associated with Video Capsule Endoscopy (VCE) with a frequency reported between 2-8% depending on indication. To mitigate this risk, a Patency Capsule (PC) is used to confirm functional patency of the GI tract. Ingestion of a dissolvable capsule followed by plain film radiography 28 hours post ingestion confirms patency. We established a pilot "Patency at Home" programme with the goal of providing a more efficient service for both patients and the hospital.

Aims & Methods: The aim of this study was to evaluate the pass rate of the service as well as patient satisfaction and cost saving. Patients referred for VCE between October 2023 and March 2024 were randomly selected to undergo a home patency test. Pre-assessment for VCE by phone call was carried out prior to postage of the home patency test kit. Written instructions were provided in the kit and an X-ray for a designated day was booked. Questionnaires to evaluate patient experience were included in the testing kit and returned on the day of X-ray. Follow-up phone calls were also offered to those who did not submit questionnaires.

Results: A total of 53 home patency tests were carried out. 68% of referrals were female (n=36). Suspected Crohn's Disease was the most frequent indication for VCE (36%, n=19). NSAID exposure was the most common reason for PC (30%, n=16). The pass rate in this study was 45%, similar to our institution's reported pass rate for hospital patency testing. 96% of patients felt home testing was logistically easier and 94% would choose home patency testing if offered a choice. A cost of €129 per patient visit was offset by this program, totalling a saving of €6,837.

Conclusion: *"Patency at Home"* is an effective and agreeable method for confirming functional patency of the GI tract prior to VCE. Pass rates in home patency testing proved to be similar to those achieved for hospital patency testing. The programme was cost effective with a saving of €129 per patient visit.

SAFETY AND FEASIBILITY OF MAGNETICALLY CONTROLLED CAPSULE ENDOSCOPY IN CHILDREN

H. Yang[1], S. Liu[2], F. Wang[2], Y. Fang[2]
[1]Xi 'an Children's Hospital, Department of Gastroenterology, Xi 'an, China, [2]Xi 'an Children's Hospital, Department of Gastroenterology, Xi'an, China

Contact E-Mail Address: liushan92263@163.com

Introduction: In recent years, Magnetically controlled capsule endoscopy (MCE) has become increasingly popular in the diagnosis of gastrointestinal diseases in children. This study aims to investigate the safety and feasibility of MCE in the diagnosis of gastric and small intestinal diseases in children by retrospective investigation of the application of MCE in Xi 'an Children's Hospital in a single center.

Aims & Methods: The data of 109 patients who underwent MCE in Xi 'an Children's Hospital from September 2022 to May 2023 were retrospectively analyzed. The general condition, clinical manifestations, completion of gastric and small intestinal examinations, detection of lesions and adverse events of all patients were statistically analyzed.

Results: A total of 109 patients were enrolled in this study, including 56 males (56/109, 51.4%) and 53 females (53/109, 48.6%). The age ranged from 6 to 18 years (mean, 9.9 years). There were 94 outpatients (94/109, 86.2%) and 15 inpatients (15/109, 13.8%). The main indications for MCE examination were abdominal pain (102/109, 93.6%), nausea, vomiting and acid reflux (46/109, 42.2%), abdominal distension (31/109, 28.4%) and anorexia (3/109, 2.7%). Among them, 59 patients (59/109, 54.1%) underwent gastric examination, and 50 patients (50/109, 45.9%) underwent gastric and small intestine combined examination. The completion rate of both examinations was 100% (the capsule reaching the ileocecal junction during the battery life was defined as completion). A total of 91 cases (91/109) of gastric lesions were detected, and the detection rate of lesions was as high as 83.5%. The main manifestations were gastritis, erosion, bile reflux and reflux esophagitis. Nine cases (9/50) of small intestinal lesions were detected, and the detection rate of lesions was 18.0%. The main manifestations were mucosal erosion, ulcer, lymphangiectasis and villous atrophy. The capsule excretion time of all patients was within 1-10 days, and no adverse events such as abdominal pain, hematochezia and capsule retention occurred during the period.

Conclusion: MCE is feasible and safe in the diagnosis of gastric and small intestinal lesions in children. The main indication of MCE in children is abdominal pain. However, most of the abdominal pain in children is caused by functional factors. MCE has great advantages in the exclusion diagnosis of organic diseases in these children because of its safety, non-invasive examination, no need for anesthesia and outpatient examination.

Contact E-Mail Address: bures.jan@uvn.cz

Introduction: The functional lumen imaging probe (FLIP) relies on the principle of impedance planimetry that enables direct measurement of intraluminal cross-sectional areas, allowing the assessment of intraluminal diameters, lumen geometric profiles, and wall biomechanical properties. Electrical impedance refers to the opposition to alternating current presented by the combined effect of resistance and reactance in a closed circuit.

Planimetrics is the study of plane measurements, including distances and areas. Since the early 2000s, impedance planimetry has been introduced into clinical practice, allowing principally assessment of any sphincter function / dysfunction.

In humans, the functional lumen imaging probe is applied mostly to diseases of the oesophagus (achalasia, dysphagia, gastro-oesophageal junction outflow obstruction, eosinophilic oesophagitis, gastro-oesophageal reflux disease), pyloric distensibility (gastroparesis), and ano-rectal disorders (faecal incontinence).

The physiology of the gastrointestinal tract of pigs is similar to that of humans, and therefore porcine experimental models are suitable for various endoscopic and preclinical studies.

Aims & Methods: Aims: The aim of our pilot project was to introduce this method to assess function of the lower oesophageal sphincter and pyloric muscle in experimental pigs.

Methods: All measurements were accomplished in one session under general anaesthesia in six adult female pigs (mean weight 34.2 ± 3.6 kg). EndoFLIP 1.0 System with EndoFLIP catheters (length of measuring zone 80 mm; 16 paired impedance planimetry sensors; filling volumes: 20, 30 and 40 mL). Five major parameters were evaluated for each filling volume: balloon pressure (mm Hg), estimated diameter (mm), cross-sectional area (mm^2), distensibility defined as cross-sectional area divided by balloon distending pressure (mm^2/mm Hg), and zone compliance defined as the change in volume over a 2-cm long segment spanning five electrodes, centred around the gastro-oesophageal junction or pylorus (mm^3/mm Hg).

Results: In total, 180 particular readings were successfully accomplished, see Table 1.

Most of the measured values were nearing lower average figures for the lower oesophageal sphincter and upper average figures for the pylorus in healthy humans. The porcine pyloric sphincter is composed of the *torus pyloricus*. It serves as a sturdy "gatekeeper" between the stomach and D1 duodenum, thus explaining higher pyloric readings.

There was a clear trend for increasing values of CSA, diameter, and balloon pressure with increased filling balloon volumes. However, the sphincter distensibility did not change with increasing filling volumes either for the lower oesophageal sphincter or pylorus.

Conclusion: Endoscopic functional luminal planimetry in experimental pigs is feasible, both for the lower oesophageal sphincter and the pylorus. This is an important starting point for future experimental endoscopic trials and pharmacology studies.

Disclosure: Nothing to disclose.

SAFETY OF OESOPHAGEAL SELF-EXPANDABLE METALLIC STENT PLACEMENT IN PATIENTS WITH MALIGNANT DYSPHAGIA UNDERGOING ONCOLOGIC THERAPY

B. Abreu[1], L.M. Roque Ramos[1], C. Gouveia[1], B. Morão[1], R. Loureiro[1]
[1]Unidade de Saúde Local de Loures-Odivelas, Hospital de Loures, EPE, Gastroenterology, Loures, Portugal

Contact E-Mail Address: barbara.abreu.45@gmail.com

Introduction: Oesophageal self-expandable metallic stent (SEMS) placement is useful in malignant dysphagia palliation. However, its safety in patients undergoing chemoradiotherapy (CRT) remains unclear.

Aims & Methods: Our aim was to evaluate the safety of SEMS placement in these patients.

Retrospective study of consecutive patients between July 2012 and August 2023, with malignant dysphagia and inoperable tumors, who underwent SEMS placement alone or with oncologic treatment (CRT or chemotherapy (CT)) in a tertiary center. Demographic, tumor and stent characteristics, complications and follow-up data were collected.

Results: 44 patients were included; 86.4% male; median age 68.3 IQR 39-97 years; 70.5% (n=31) with esophageal squamous cell carcinoma and 29.5% (n=13) with esophagogastric junction adenocarcinoma. Patients were in stage IV (72.7%, n=32) and stage III (27.3%, n=12).

A partially covered SEMS was placed in most cases (90.9%, n= 40), and a fully covered SEMS in the remainder 4 patients. Median follow-up was 76 days (IQR 2-417 days). One third of patients (n=15) underwent CRT: nine priors, four after and two before and after SEMS placement. Seven patients only had CT: five after and two before and after stent placement. The remaining 50% did not undergo CRT nor CT. The overall median sur-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. vival was 81.5 days (IQR 42.8-115). Survival was similar between patients with and without oncologic treatment 81.5 versus 77.5 days. Major complications occurred in 15.9%: six perforations and one hemorrhage. Severe complications were similar between patients with or without oncologic treatment peri stent placement. Similarly, there was no difference in complications between partially and fully covered SEMS (15% vs 25%, *p*=0.602).

Conclusion: In our cohort, CRT or CT did not increase the rate of major complications of SEMS placement for malignant dysphagia palliation.

SELF-DILATATION FOR THE MANAGEMENT OF REFRACTORY BENIGN OESOPHAGEAL STRICTURES: OUTCOMES FROM THE LARGEST EUROPEAN TERTIARY CENTRE EXPERIENCE TO DATE

G. Ioannidis[1], P. Pilavaki[1], R. Basra[1], J. Gertner[1], N. Aslam[1], M. Duku[1], S. Thorpe[1], R.J. Haidry[1], O.F. Ahmad[1,2,3], R. Sweis[1], D.G. Graham[1], M. Banks[1], L.B. Lovat[1,2,3], V. Sehgal[1]

Contact E-Mail Address: giannis.ioannidis@nhs.net

Introduction: Benign oesophageal strictures are commonly encountered in endoscopy and often effectively managed with endoscopic dilatation. However, up to 40% of patients may develop refractory benign oesophageal strictures (RBES), necessitating frequent endoscopic intervention that is challenging, poses a greater risk of complication and negatively impacts patients' quality of life.

Oesophageal self-dilatation (SD) offers an alternative treatment that potentially reduces the need for repeat hospital visits while allowing greater autonomy in managing their condition.

Aims & Methods: We describe the efficacy and safety of oesophageal SD at a tertiary referral centre. We retrospectively reviewed electronic records of patients with RBES who started SD between 2013 and 2024. Data were collected on stricture characteristics, endoscopies, dysphagia scores, and adverse events. The primary outcomes were the endoscopic dilatation-free interval (longest period of time patients did not require endoscopic dilatation) and the number of endoscopic procedures performed within 12 months of starting SD. Secondary outcomes included improvement in dysphagia score, technical success rate, and complications.

Results: We identified 43 patients who initiated SD during the study period. The technical success rate was 95.3%, with 41 out of 43 patients learning to perform SD successfully.

Among the remaining patients, the median age was 57 years (range 27-84 years), and 28/41 patients (68.3%) were female. Patients initiated SD for refractory peptic (32%), post-radiation (19.5%), post-surgical (12.2%), post-endoscopic resection (11.6%), caustic (7.3%), and other aetiology-related strictures. Stricture location varied, with 10/41 patients (24.4%) having proximal, 12/41 (29.3%) having middle, and 14/41 (34.1%) having lower oesophageal strictures, while the remainder had strictures involving multiple segments. Before initiating SD, patients had a median of 9 endoscopic interventions (IQR 7-17). The median follow-up post-SD was 23.2 months (IQR 6.8–49.4). The median dilatation-free interval significantly increased from 68.5 days (IQR 41-106 days) to 161 days (IQR 121-279 days) within 12 months before and after SD, respectively (P < 0.001). The median all-time intervention-free interval after SD was 405 days (IQR 130-705 days). Additionally, there was a significant reduction in the number of endoscopic interventions from a median of 7 (IQR 4.7-10) to 1 (IQR 0.75-3) within 12 months before and after SD, respectively (P < 0.001). Dysphagia scores improved, with a median Dakkak and Bennett Dysphagia Score of 2 (IQR 2-2) at baseline and 0 (IQR 0-1) after SD (p<0.001). Two adverse events were reported: one patient experienced clinically significant haematemesis while another patient suffered presumed iatrogenic oesophageal perforation secondary to SD. Both patients were managed endoscopically but discontinued SD.

Conclusion: To our knowledge, we have described the largest European case series of oesophageal SD that has been published to date. Oesophageal SD appears to be an effective, well-tolerated, and safe approach in managing often complex patients with RBES providing a viable alternative to conventional endoscopic interventions. However, the occurrence of adverse events highlights the importance of careful patient selection and ongoing monitoring. Further research is warranted to validate these findings and identify predictive factors for treatment success.

Disclosure: Nothing to disclose.

ESOPHAGEAL ATRESIA WITH TRACHEOESOPHAGEAL FISTULA IS ASSOCIATED WITH CONSANGUINITY

O.E. Hougui[1], M. Zerem[1], M. Omary[1], Z. Assi[2], G. Ling[1], B. Yerushalmi[1], R. Nassar[1]

[1]Soroka University Medical Center, Pediatric Gastroenterology Unit, Beer Sheva, Israel, [2]Soroka University Medical Center, Pediatric Surgery Department, Beer Sehva, Israel

Contact E-Mail Address: OEH8811@yahoo.com

Introduction: Esophageal atresia with tracheoesophageal fistula (EA-TEF) is a rare congenital malformation. The incidence of TEF is 1.3-4.6 cases per 10,000 live births. The specific etiology of EA-TEF is unknown. Environmental risk factors such as maternal use of medications and alcohol consumption during pregnancy are suggested. Genetic factors have also been described, especially among the syndromic types such as VACTERL, CHARGE, and Down syndrome, but less among non-syndromic types.

Aims & Methods: Aim: To examine the association between non-syndromic EA-TEF and consanguinity.

Methods: A retrospective study comparing the incidence of EA-TEF between low-consanguineous Jewish population and high-consanguineous Bedouin population. All patients were treated at Soroka University Medical Center, the only tertiary medical center in southern Israel.

Results: During the years 2000-2022, 579,130 children were born in southern Israel, 386,915 (67%) were Jewish and 192,215 were Bedouin Muslims. A total of 96 patients were diagnosed with EA-TEF, 83 of them were non-syndromic EA-TEF. The incidence of non-syndromic EA-TEF was 1.43 cases per 10,000 live-births and was statistically higher among the Bedouin population (2.65 *vs.* 0.83 cases per 10,000 live-births, P<0.001). The consanguinity rate among the Bedouin group was higher comparing with the Jewish (71% *vs* 0% P<0.001). There were no differences in other risk factors.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The incidence of EA-TEF is exceptionally higher among the Bedouin population that live in the same geographic region and the same medical access as the Jewish population, proposing consanguinity as an important/essential risk factor of EA-TEF.

PROPHYLACTIC ENDOLUMINAL VACUUM THERAPY – TOWARDS AN ERA OF REDUCING LEAK RELATED MORBIDITY AFTER ELECTIVE OESOPHAGO-GASTRIC RESECTION

I.-u.-d. Saqib[1], Z. Al-Ani[2], S. Gourgiotis[1], R. Hardwick[1], P. Safranek[1], V. Sujendran[1], A. Hindmarsh[1], A. Noorani[3,1]

[1]Cambridge Oesophago-Gastric Unit, Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Auckland City Hospital, Auckland, New Zealand, [3]Wellcome Sanger Institute, Hinxton, United Kingdom

Contact E-Mail Address: imaduddinsaqib@gmail.com

Introduction: Uncontrolled sepsis following leak from major oesophago-gastric surgery is a devastating condition with increased morbidity and mortality and intensive care stay. We hypothesised that endoluminal vacuum therapy (EVT) could be used in the prophylactic setting to provide source-control, prevent mediastinitis and minimise sepsis related morbidity from leaks.

Aims & Methods: An ad-hoc EVT device was created using VAC granufoam (KCI) and a nasogastric-tube (16/18Fr), and placed intraluminally across the high risk anastomosis/area of repair. Continuous negative pressure (75–125mmHg) was applied. Assessment of the repair site/anastomosis was performed by radiology, endoscopy, clinical assessment or a combination following cessation of EVT and removal of the prophylactic EVT device.

Results: Twenty-seven patients had prophylactic EVT; M:F ratio was 3:1 and the median age was 68 years (range: 41-82 years). Twenty-six patients had cancer resections while 1 had benign surgery. The rationale for prophylactic EVT included preoperative factors (10), intra-operative factors (16) or both (1). The median duration of prophylactic EVT was 7 days (range: 4-14 days). The median length of stay was 19.7 days (range: 6-96 days), the two longest admissions were unrelated to the anastomosis (prolonged chyle leak, and long-term-sequelae of life-threatening bleed). One patient developed full-thickness microleak at endoscopic evaluation, remained clinically well with no systemic signs of sepsis, and was successfully managed with luminal EVT for a further 6 days in a ward-based environment. Though prophylactic EVT did not prevent the leak, it significantly minimised the systemic hit that traditionally results from leak and associated mediastinal sepsis.

Conclusion: Prophylactic EVT is a useful adjunct for management of patients with a high-risk for leak and can serve as a risk reducing strategy in select cases. There are no short-term complications, yet the additional morbidity, mortality, and length of stay associated with a fully-fledged leak is avoided. Our results lay the foundation for the use of prophylactic EVT in randomised controlled trials to further standardise selection criteria, assess longer term potential patient benefit and impact on survivorship.

Introduction: Esophageal perforation is a rare condition with a high mortality rate. Often it has an iatrogenic origin, being caused by transesophageal echocardiography, different endoscopic and surgical procedures. Furthermore, there are other causes such as foreign body ingestion, tumor associated perforation and Boerhaave's syndrome. Esophageal perforation can be difficult to diagnose since the clinical presentation is often unspecific. This can lead to a delay in appropriate treatment. Optimal management of this condition challenges clinicians in daily practice. Therefore, we present a monocentric retrospective study, evaluating our experience in treating esophageal perforations over more than a decade as a tertiary referral University Medical Center in Germany.

Aims & Methods: This study comprises the retrospective analysis of data from all patients treated for esophageal perforation in our clinic in the departments of general and visceral surgery and gastroenterology between

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2012 and 2024. Only patients with confirmed esophageal perforation were included. Data was collected by means of a retrospective analysis of digital and analogous data archives as well as information from the physicians providing further treatment.

Results: A total of 78 cases (47 male, 31 female) of esophageal perforation were included. The leading cause was iatrogenic (n=45), consisting of endoscopic procedures (n=22), operative complications (n=11), TEE (n=6), diagnostic EGD (n=5) and one case of endotracheal intubation. The second most common cause of perforation was Boerhaave's syndrome (n=23), followed by perforations associated with foreign body ingestion (n=5) or tumors of the esophagus (n=4). Traumatic perforations were rare (n=1). Most perforations occurred in the lower third of the esophagus (58 cases), 11 perforations were located in the mid esophagus and 9 in the upper third. Primary treatment consisted of direct surgical management in 26 cases (suture of the esophagus, gastrectomy, esophagectomy, definitive cervical esophagostomy, thoracic drainage, lavage), endoscopic therapy in 38 cases (Endo-VAC, stenting and application of OTSC or TTSC clips) and a conservative approach in 14 cases. Eventually a total of 48 patients underwent surgical treatment. Survival was poorest in spontaneous and tumor associated perforations (mean survival 22 and 23 months). Iatrogenic perforations showed an intermediate outcome.

The best outcome was observed in perforations associated with foreign body ingestion (mean survival 50 months). In correlation with perforation location, the survival was best for perforations in the upper esophagus, followed by those in the lower esophagus, while lesions in the mid esophagus showed the worst outcome. Perforation associated death was recorded in 17 cases.

Conclusion: Esophageal perforations are a life-threatening event that require immediate and adequate treatment. Our analysis identified risk groups resulting in poorer survival: perforations in the mid esophagus, primary surgical treatment, advanced age. Within the last years, endoscopic techniques have reduced the need for surgical interventions. Nevertheless, surgical treatment remains the therapy of choice for patients not eligible for endoscopic treatment or after failure of endoscopic therapy. Our analysis emphasizes the importance of multidisciplinarity, close monitoring and continuous reassement of treatment strategy. Further investigation will help to improve the outcome via prospective studies or the establishment of a local or interregional database seem promising to underline suggestions derived from our analysis.

ENDOSCOPIC TRANS-ORAL OUTLET REDUCTION IS SAFE AND EFFECTIVE FOR WEIGHT REGAIN AFTER ONE-ANASTOMOSIS GASTRIC BYPASS

S. Fishman[1], M. Shnell[1], F. Kinaany[1], R. Reicher[1], W. Mathur[2], M. Galvao Neto[3], M. Bhandari[3]

[1]Tel Aviv Sourasky Medical Center affiliated to Tel Aviv University, Dept. of Gastroenterology, Tel Aviv, Israel, [2]Sri Aurobindo Medical College and PG Institute, Department of Surgery, Indore, India, [3]Mohak Bariatric and Robotic Center, Bariatric Endoscopy department, Indore, India

Contact E-Mail Address: rellyr@tlvmc.gov.il

Introduction: Obesity is a global health concern with increasing prevalence, and bariatric surgery remains a prominent treatment option. One-anastomosis gastric bypass (OAGB) has gained popularity for its advantages, including significant weight loss and fewer early complications. However, concerns arise regarding nutritional deficiencies, weight regain, and other complications. This study aims to assess the effectiveness and safety of endoscopic transoral outlet reduction (TORe) as a treatment for weight regain after OAGB.

Aims & Methods: Consecutive Patients with weight regain following OAGB were evaluated. Weight regain was defined as a 10% increase in total body weight from the post-surgery weight nadir. Diagnostic gastroscopy determined anastomosis diameter, pouch dimensions and ruled out contraindications for TORe. The procedure involved circumferential argon plasma coagulation and full thickness endoscopic suturing to narrow the anastomosis. Patient data was collected, and outcomes assessed in accordance with ethical standards

Results: sixty four patients were treated during a 4 years duration and followed up for 1 a minimum of 1 year. Fourty seven percents were females, mean pre-treament BMI 35.5. Average weight loss was 7% of total body weight after 6 months and 8% after 12 months (p=0.03). A reduction of at least 5% and 10% was seen in 65% and 31%, respectively. Additional treatment was needed in 17% of patients. Major complication that required surgical intervention occurred in only one patient

Conclusion: Endoscopic transoral outlet reduction appears safe and effective fot the treatment of weight regain s/p OAGB. Sustained weight loss was seen during a 1 year follow up. Further investigation is needed to assess the long term durably of the effect.

Disclosure: Nothing to disclose.

ENDOSCOPIC TREATMENT OF REFRACTORY MARGINAL ULCERS - A CASE SERIES

T. Bar-on[1], S. Fishman[2], M. Shnell[3], R. Reicher[3]

[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]TASMC Dept. of Gastroenterology, Dept. of Gastroenterology, Tel Aviv, Israel, [3]Tel-Aviv Medical Center Dept. of Gastroenterology, Tel Aviv, Israel

Introduction: Ulceration at the gastrojejunostomy is a late complication following gastric bypass surgery, usually responsive to high dose PPI. However, in refractory cases, patients may require surgical treatment. Recently, a new technique of endoscopic jejunal flap over-suturing has been reported with exceptional success rates. We aimed to evaluate the implementation of this approach in our practice.

Aims & Methods: Consecutive patients with symptomatic marginal ulcers, who failed to response to a two-month course of high dose PPI were included. Patients were treated with endoscopic suturing of a jejunal flap

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

over the ulcer. In case of a narrow anastomosis, a self-expandable metallic stent (SEMS) was used alone or in combination with suturing. The stent was removed after 2 months. Endoscopy was repeated 8 weeks after the procedure. Technical success was defined as a fully covered marginal ulcer. Clinical success was defined as an ulcer heal on repeat endoscopy, while persistent ulcer, perforation or need for surgical repair was considered as failure.

Results: Ten patients were included, seven after Roux-en-Y gastric bypass and after 3 single anastomosis gastric bypass. All patients were negative for Helicobacter Pylori, deny alcohol abuse or NSAIDS use, 2 patients were active smokers at the time of diagnosis. All patients were on chronic PPI at the time of diagnosis, and the average therapy duration was 27 months. Jejunal over-suturing was performed in 9 patients of them 3 in combination with a SEMS, and 1 patient was treated only with a SEMS. Overall technical success rate was 100%, and a clinical success rate was 50% with 4 patients going through surgery thereafter. No adverse events occurred during the procedure or follow up period.

Conclusion: To date, marginal ulcers remain a dreaded late adverse event necessitating prolonged PPI use, repeat endoscopies and even revisional surgery. Endoscopic treatment to promote healing of refractory marginal ulcers appears safe. Technical success was achieved in all patients while clinical success only in half. However, since the only alternative treatment is surgery the endoscopic approach should still be considered. The lower than expected clinical success might be related to a more PPI resistant population compared with previous published series. Further research is needed to determine the appropriate therapeutic algorithm.

INFLUENCE OF RECURRENT LARYNGEAL NERVE PALSY AFTER ESOPHAGECTOMY AND FUTURE PLAN OF TREATMENT USING AMNION MEMBRANE SHEET

Y. Taniyama[1], Y. Watanabe[1], K. Tokokdai[1], H. Okamoto[1], C. Sato[1], Y. Ozawa[1], H. Ishida[1], R. Ando[1], M. Unno[1], T. Kamei[1]

Introduction: The therapeutic effect of recurrent laryngeal nerve (RLN) dissection in the treatment of esophageal cancer, particularly squamous cell carcinoma, is well-established. However, due to the risk of RLN palsy as a consequence, this procedure is often avoided. Nonetheless, the prevalence of this adverse event and its impact on prognosis remain unclear.

Aims & Methods: In this study, we aimed to evaluate the influence of recurrent laryngeal nerve palsy and long-term effects on prognosis. Moreover, we introduce some basic science of treating injured nerve using amnion membrane sheet.

We analyzed 726 cases of esophageal cancer who underwent bilateral recurrent laryngeal nerve lymphadenectomy during esophagectomy between 2000 and 2021. Cases with combined nerve resection and R2 resection were excluded. Recurrent laryngeal nerve palsy was confirmed by bronchoscopy on the first postoperative day, if even a slight difference in the movement of the vocal cords between the left and right sides was detected.

Results: RLN palsy was observed in 40.7% of cases (left: 234 cases, right: 31 cases, bilateral: 30 cases), with 12 cases experiencing paralysis lasting over a year. Analysis revealed significantly higher rates of complications such as aspiration ($p < 0.0001$), postoperative pneumonia ($p = 0.0004$), and prolonged hospital stay ($p < 0.0001$) in RLN palsy cases. Furthermore, there were associations between postoperative pneumonia and patient factors including age ($p = 0.0364$), sex ($p = 0.0066$), RLN palsy ($p = 0.0005$), and reconstruction route ($p = 0.0098$), each identified as independent risk factors in multivariate analysis. However, only age and sex showed associations with pneumonia-related mortality. Long-term prognosis analysis using propensity score matching revealed slightly poorer outcomes in the RLN palsy group, although no statistically significant difference was observed.

Additionally, we are conducting research on a treatment method using amniotic membrane sheets in a sciatic nerve injured rat model. Electromyography studies showed a trend toward improved motor function in the amniotic membrane sheet treatment group compared to the control group at 8 weeks post-injury ($p = 0.0887$). Further investigation with increased sample size is planned to refine this approach for future clinical application.

Conclusion: Although RLN palsy after esophageal cancer surgery did not affect patient prognosis in the long term, we discovered it as a cause of aspiration and postoperative pneumonia in the short term. With the growing understanding of respiratory complications as important prognostic factors in various cancers, including esophageal cancer, strategies to prevent RLN palsy are crucial. Amniotic membrane sheets represent a potential intervention for the early recovery of RLN palsy.

ASSESSING THE EFFICACY OF SELF-EXPANDING METAL STENTS FOR POSTOPERATIVE UPPER DIGESTIVE LEAKS AND FISTULAE: A DECADE OF EXPERIENCE AT A TERTIARY CENTER

D. Feijó[1], A.E.P. Silva[1], M. Costa[1], M. Gravito-Soares[1], E. Gravito-Soares[1], P. Amaro[1], C. Agostinho[1], M. Ferreira[1], P. Narra Figueiredo[1]

Introduction: Postoperative anastomotic leaks and fistulae in the upper digestive tract are severe complications that can lead to significant morbidity and mortality. Traditionally, surgical intervention has been the primary approach to address these complications. However, self-expanding metal stents (SEMS) have emerged as a less invasive alternative, offering a potential pathway to achieve closure of these leaks and fistulae. Despite their growing use, the efficacy and safety profile of SEMS in this context is not fully understood.

Aims & Methods: This study aims to evaluate the success rates, safety, and predictive factors of therapeutic success for SEMS in managing postoperative upper digestive tract leaks and fistulae, drawing on a 10-year experience at a tertiary center.

We conducted a retrospective review of patients with postoperative anastomotic leak or fistula who underwent endoscopic SEMS placement at our tertiary center between 2014 and 2022, and prospectively from 2022 onwards. Therapeutic success was defined as complete closure of the leak/fistula, while failure indicated non-closure.

Results: We included a total of 43 patients (69.8% male) with a median age of 61 years (IQR 17). There were no statistically significant differences regarding distribution by gender, age, Charlson comorbidity index, benign vs malignant disease, time from surgery to endoscopic treatment and leak size between the different types of stents ($p>0.05$). The technical efficacy was 100%, with a therapeutic success rate of 55.8%. Bariatric stents ex-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

hibited the highest success rate (85.7%), followed by fully covered SEMS (60.0%) and partially covered SEMS (46.2%) (p = 0.166). Success was significantly higher in patients with a smaller leak size (10 mm vs. 12 mm, p<0.05).

Therapeutic failure was associated with greatest need for endoscopic adjuvants (57.9% vs. 37.5%, p=0.183). The overall mortality rate was 34.9%.

Conclusion: This study indicates that self-expanding metal stents (SEMS) offer a viable and safe treatment option for postoperative upper digestive tract leaks and fistulae. With a technical efficacy of 100% and a therapeutic success rate of 55.8%, SEMS demonstrated promising results. The success rate was influenced by stent type, with bariatric stents showing the highest rate, followed by fully covered SEMS and partially covered SEMS. Smaller leak size emerged as a significant predictor of therapeutic success, emphasizing the importance of early detection and timely intervention. Although the overall mortality rate was 34.9%, this study's outcomes suggest that SEMS can play a crucial role in managing these complications, with early diagnosis and prompt stent placement being pivotal for success. Further research is needed to better understand the factors contributing to therapeutic success and to optimize endoscopic strategies for patients with upper digestive tract leaks and fistulae.

Disclosure: Nothing to disclose.

CGAS-STING PATHWAY ACTIVATION ENHANCES ANTI-TUMOR EFFECT OF TALAPORFIN PHOTODYNAMIC THERAPY THROUGH REACTIVE OXYGEN SPECIES PRODUCTION AND DNA DAMAGE

M. Sasaki[1], M. Tanaka[1], Y. Kojima[1], Y. Sasaki[1], T. Suzuki[1], H. Nishie[1], H. Kataoka[1]

[1]Nagoya City University Graduate School of Medical Science, Department of Gastroenterology and Metabolism, Nagoya, Japan

Contact E-Mail Address: sasakimakiko@gmail.com

Introduction: Photodynamic therapy (PDT) is a relatively non-invasive anti-cancer therapy that employs a photosensitizer and a specific wavelength of light irradiation. PDT induces tumor shrinkage in various malignancies due to three main mechanisms, direct effects of reactive oxygen species (ROS), vascular shutdown leading to tumor infarction, and acute inflammation with immune response. Among them, ROS is important factor of DNA damage. It was reported that cGAS (cyclic GMP-AMP synthase)-STING (stimulator of interferon genes) pathway regulates a transcriptional program that controls the generation of ROS and that STING loss alters ROS homeostasis. STING loss reduces ROS induction and that causes therapeutic resistance.

Thus, we predicted that pharmacological activation of cGAS-STING pathway would be an actionable target for reducing therapeutic resistance and enhance DNA damage caused by PDT. Our study investigated the efficacy of STING agonist (2'-3'-cyclic GMP-AMP sodium or AUS-100) combined with talaporfin sodium PDT.

Aims & Methods: 1. We established STING knockout cells in a colon cancer cell line (HCT116) using CRISPER-Cas9.

2. We compared the induction of cell death after in vitro talaporfin PDT in parental and knockout cells. We analyzed IC50 by MMT assay.

3. We measured ROS generation, using DCFDA assay after in vitro talaporfin PDT in parental and knockout cells.

4. We analyzed the induction of cell death treated with ROS scavenger (N-acetyl cysteine; NAC) after in vitro talaporfin PDT in parental and knockout cells.

5. We measured DNA damage by immunofluorescence microscopy with an anti–g-H_2AX antibody after in vitro talaporfin PDT in parental and knockout cells.

6. We investigated PDT-induced STING pathway activation of STING-regulated genes by western blot analyses after in vitro PDT in parental and knockout cells.

7. We compared the *in vivo* efficacy of talaporfin PDT between the parental and knockout cells.

8. We assessed the *in vivo* efficacy of talaporfin PDT, STING agonist (2'-3'-cyclic GMP-AMP sodium or AUS-100), and their combination in a xenograft tumor model bearing HCT116.

Results: 1. We established STING knockout cell. STONG knockout was confirmed by western blot analyses.

2. STING KO suppressed cell death induction of TS-PDT (IC_{50} 12.5 (±1.35) vs 14.5 (±1.18)μmol/L).

3. STING KO suppressed TS-PDT induced ROS generation (M.F.I. 4491 vs 1706).

4. STING KO suppressed cell death induction of TS-PDT with NAC.

5. Treating parental cell lines with talaporfin PDT led to significantly more γ-H_2AX foci formation than in STING knockout cells.

6. At the protein level, TS-PDT enhanced TBK-1 phosphorylation in parental cell. STING dependent signaling was enhanced by TS-PDT, and the effects were eliminated by STING loss.

7. The *in vivo* efficacy against towards parental cells was significantly greater than that towards STING knockout cells.

8. The combination exhibited significantly greater tumor growth inhibition than by single agents alone in a xenograft tumor model.

Conclusion: We have established STING knockout cell using CRISPER-Cas9 and identified novel regulators of DNA damage in Photodynamic therapy. Our results point to a role for STING in DNA damage sensing and cyclic dinucleotide detection that goes beyond its conventional function. According to these results, talaporfin PDT is more effective when a STING agonist is used to control the degree of DNA damage. Combining talaporfin PDT with a STING agonist would offer a potentially strong combination for next-generation anticancer treatments.

Disclosure: Nothing to disclose.

PP0238

OLGA AND OLGIM STAGING ARE POOR PREDICTORS OF GASTRIC CANCER RISK

P. Nalivaiko[1], I. Bogdanova[1,2], I. Liepniece-Karele[2], I. Polaka[1,3], E. Syundyukov[4], I. Tolmanis[5], Y. Tarasenko[6], L. Morozova[7], S. Abdelmassi[8], M. Leja[1,5]

Contact E-Mail Address: paula.nalivaiko@gmail.com

Introduction: Gastric cancer continues to be one of the main challenges worldwide, with a predictable increase in the number of new cases in the coming decades. Staging systems for gastric precancerous lesions: Operative Link on Gastritis Assessment (OLGA) and Operative Link on Gastric Intestinal Metaplasia (OLGIM) are considered to be the best predictors for gastric cancer development. Only OLGA/OLGIM stages III-IV are considered high-risk lesions with a significant potential of progressing towards gastric cancer.

Aims & Methods: The purpose of this study was to evaluate the predictive role of OLGA and OLGIM staging in gastric cancer development.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

We conducted a retrospective cohort study by matching gastric adenocarcinoma cases registered in the Latvian Cancer Registry between 2005 and 2022 to the pathology reports in the database of Academic Histology Laboratory from upper endoscopies performed in the Digestive Diseases Centre GASTRO, Jurmala hospital and Riga 1st hospital. Only cases with antral and corpus biopsies (as the minimum) available from the index endoscopy allowing OLGA / OLGIM staging were included in the study. If data from several endoscopies were available for the same patient, the case with the highest OLGA/OLGIM stage was used as the index endoscopy; if OLGA/OLGIM staging was identical across several endoscopies, the first endoscopy was used as the index case. The presence of dysplasia in any of the previous pathology reports was also considered. Patients with suspected cancer at the enrolment or having been recorded in the cancer registry less than 6 months after the index endoscopy were excluded from the study.

Results: Altogether 54 patients were available for the analysis; 38.9% were male. The mean age at the time gastric cancer detection 69.2 years, range 40-90. The median time between the index endoscopy and gastric cancer diagnosis was 1403.5 days (IQR: 826.5-2793.3). Forty-one patients (75.9%) had one endoscopy, eleven (20.4%) had two, one (1.9%) had four and one (1.85%) – 8 endoscopies. Biopsies from incisura angularis of the stomach were available for 43 patients (79.6%).

Altogether 16 patients (29.6%) had dysplasia reported at one of the preceding endoscopies, of those 14 were low grade, 2 – high grade. Patient distribution per OLGA and OLGIM stages at the index endoscopy is shown in Table 1. Among patients ultimately diagnosed with gastric cancer, only 11 (20.4%) had OLGA III-IV stages and 10 (18.6%) had OLGIM III-IV stages at the time of the index endoscopy. Excluding cases with dysplasia reported during any of the preceding endoscopies did not make a substantial change in the OLGA and OLGIM stage distribution at the index endoscopy.

	Stage 0	Stage I	Stage II	Stage III	Stage IV
OLGA (all cases)	7 (13.0%)	17 (31.5%)	19 (35.2%)	6 (11.1%)	5 (9.3%)
OLGIM (all cases)	12 (22.2%)	15 (27.8%)	17 (31.5%)	5 (9.3%)	5 (9.3%)
OLGA (excluding cases with previously reported dysplasia)	7 (18.4%)	15 (39.5%)	10 (26.3%)	4 (10.5%)	2 (5.3%)
OLGIM (excluding cases with previously reported dysplasia)	12 (31.6%)	12 (31.6%)	9 (23.7%)	3 (7.9%)	2 (5.3%)

Table 1. OLGA and OLGIM stages at the time of the index upper endoscopy in patients having developed gastric cancer thereafter.

Conclusion: The majority of patients having undergone upper endoscopy before the diagnosis of gastric cancer were in low-risk OLGA and OLGIM stages. Continued research is warranted to identify the best approach for risk stratification of gastric precancerous lesions. Yet, the current study demonstrates that the assessment should not be solely based on OLGA or OLGIM staging.

Introduction: The increasing availability of gastrointestinal (GI) interventions has raised the need to treat luminal defects. Endoscopic suturing (ES) is a minimally invasive technique, used for a wide range of indications.

Aims & Methods: This retrospective cohort study aimed evaluate the performance of ES in treating upper GI defects.Data from a tertiary centre were collected for patients undergoing ES to treat upper GI defects. The primary outcome was technical success, defined as the successful sutures' deployment. Secondary outcomes included immediate clinical success (confirmation of closure at the time of the procedure), recurrence, long-term outcomes and complications. Descriptive statistics and x^2 test were used to calculate the rates of the outcomes and assess any link between independent variables and results.

Results: Forty-two procedures were performed on 25 patients between 2018 and 2023. The mean age was 55 (±16.2) years and 56% were female. The technical success rate was 88.1% (37/42) and immediate clinical success 91.9% (34/37), with only two (4.8%) adverse events. The overall recurrence rate was 61.8% (21/34), with a long-term clinical success rate of 69.6% (16/23). Technical success was higher in oesophagus (92.3%), and stomach (100%) (p=0.002), and immediate clinical success was more likely in patients with leak (88.9%) or fistula (95.2%) compared to perforation (50%; p=0.005).

Conclusion: ES demonstrated high rates of technical and immediate clinical success for defect closure in the upper GI tract, with low rates of complications. The benefit is most prominently seen among patients with leaks and fistulas in the stomach and oesophagus.

Disclosure: Nothing to disclose.

LONG TRANSPARENT CAP SUTURING TECHNIQUE FOR THE CLOSURE OF ENDOSCOPIC FULL-THICKNESS RESECTION DEFECTS: A NOVEL ALTERNATIVE

N. Dai[1], S. Ullah[1], X. Cao[1]
[1]The First Affiliated Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China

Contact E-Mail Address: xinguangcao@126.com

Introduction: Gastric submucosal tumors (SMTs) are elevated lesions originating from below the gastric mucosal layer. Pathological types of SMTs include stromal tumors, leiomyomas, lipomas, etc., with stromal tumors being the most common[1]. Endoscopic full-thickness resection (EFTR) has gradually become the main treatment modality for SMTs [2]. However, in order to completely remove lesions involving the submucosal and deeper layers, EFTR often involves intentional perforation during the procedure. Therefore, successful closure of the full-thickness defect after the procedure is crucial to prevent serious complications such as pneumothorax and pneumoperitoneum[3]. Currently, availabloe techniques for the full-thickness GI wall defects closure includes metal clip closure, ny-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

lon suture purse-string closure, Over-The-Scope-Clip system (OTSC), and the OverStitch suture system [4-5]. However, due to variations in endoscopic center equipment, individual physician skills, and patient economic conditions, most of the suture devices are not widely available including in China. Using metal clips alone may sometimes be insufficient for closing the large GI defects, while the purse-string suture technique can be relatively cumbersome.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of the long transparent cap suturing technique for the closure of large endoscopic full-thickness resection (EFTR) defects. A total of 62 patients who underwent EFTR for their large gastric submucosal tumors at the First Affiliated Hospital of Zhengzhou University between January 2017 and March 2023 were included in this study. The novel long transparent cap suturing technique was used for EFTR defect closure in all the patients.

Results: The procedure technical success rate was 100%. The median tumor size was 1.5 cm (range: 0.6-6.5 cm), and the median number of metal clips used was 7 (range: 4-14). The median EFTR procedure time was 53.5 minutes (range: 22-136 minutes), and the median suturing time was 14 minutes (range: 3-45 minutes). The median length of postoperative hospital stay was 4.5 days (range: 3-7 days). Postoperative complications including bleeding occured in 1 case, fever in 3 cases, and abdominal pain in 2 cases. During the median 29 months (range: 7-79 months) of follow up, no residual lesions, tumor recurrence, or metastasis were detected, and no formation of digestive tract fistulas or sinuses was observed.

Conclusion: The long transparent cap suturing technique is a simple, safe, and effective method for wound closure after EFTR. It is beneficial for clinical application and widespread use.

Introduction: Achalasia is a primary motility disorder, which presented by dysphagia. The most effective treatment of the disease is surgical (peroral myotomy or laparoscopic myotomy). However, there are few studies which assess the changes in esophageal motility after surgery.

Aims & Methods: The aim of our study was evaluating the changes in esophageal manometry in patients with achalasia after peroral endoscopic myotomy (POEM).

Subjects and methods: 43 patients with achalasia were consequently observed before and 1 year after POEM. Females predominated (28 subjects). All patients examined endoscopically, then high resolution manometry (HRM) was performed by Solar™ GI (MMS/Laborie, Netherland). Achalasia was defined as described in Chicago Classification 4.0. Eight patients had I type of achalasia, 24 – II type and 11 – III type.

Results: The median Eckardt score was 7 on the start and 2 – after POEM in 35 patients (group A). However, 8 patients were dissatisfied with the surgery (4 pts with II type achalasia and 4 – III type). They continued to suffer from dysphagia and/or noncardiac chest pain (group B).

According to HRM the mean resting pressure of LES in group A reduced 2 folds from 39,1±2,7 mmHg to 18,9±1,4 mmHg. Also we revealed the dramatic decrease in integrated residual pressure (IRP) from 22,8±0,7 mmHg to 9,8±0,6 mmHg and DCI: from 1865,5±286,9 to 128,2±53,8. In a group B the mean resting pressure of LES reduced from 48,8±2,4 mmHg to 33,6±2,4 mmHg. The integrated residual pressure (IRP) decreased from 22,8±0,7 mmHg to 15,01±0,6 mmHg and DCI: from 2999,6±417,6 to 1038,1±107,7.

Even though, we didn't observed the peristaltic waves in two groups before and after POEM as a normal manometric criteria: the consistent contraction of upper part of esophagus and then lower part of esophagus. Besides, HRM evaluated persisting spastic contraction in the middle and lower part of esophagus in patients with type III achalasia from group B. Two patients from group B with type II had good results in esophageal manometry.

Conclusion: The reduction of resting pressure, integrated resting pressure and distal contractile interval in several times can be accepted as criteria of POEM effectiveness. Besides, in patients with III type of achalasia we must assess the absence of spastic contraction as additional criteria of POEM satisfaction.

LUMEN-APPOSING METAL STENTS: A MINIMALLY INVASIVE TREATMENT OPTION FOR GASTROINTESTINAL OUTFLOW OBSTRUCTION

E. Gökce[1], P. Hindryckx[1]
[1]*Ghent University Hospital, Dept. of Gastroenterology, Ghent, Belgium*

Contact E-Mail Address: Emine.gokce@ugent.be

Introduction: The introduction of lumen-apposing metal stents (LAMSs) has revolutionized the field of therapeutic endoscopic ultrasound (EUS). LAMSs were initially developed for drainage of pancreatic fluid collections, but in the last decade its use for off-label indications has increased significantly. One of the most common off-label indications is treatment of gastrointestinal outflow obstruction.

Aims & Methods: This study aims to evaluate the effectiveness and safety of LAMS in creating EUS-guided gastro-enterostomy (EUS-GE) and entero-enterostomy (EUS-EE) anastomoses for the treatment of gastrointestinal (GI) outflow obstruction.

We collected data on all LAMS procedures conducted in patients with gastrointestinal (GI) outflow obstructions, including malignant gastric outlet obstruction (mGOO), benign gastric outlet obstruction (bGOO), candy cane syndrome, and afferent loop syndrome, between October 2019 and November 2023 at the University Hospital of Ghent. We used our prospective LAMS database and retrieved missing data from retrospective analysis of the medical patient records. The main outcome data of interest were technical success, clinical success, and adverse events. Technical success was defined as a successful placement of LAMS in the desired position. Clinical success was defined as either successful re-initiation of oral food intake in patients with mGOO and bGOO, or achievement of the intended therapeutic goal for the remaining conditions. Adverse events were classified according to the AGREE criteria.

Results: A total of 72 LAMS procedures were performed for GI outflow obstructions. The indications included 50 (69.4%)cases of mGOO, 19 (26.4%) cases of bGOO, 2 (2.8%) cases of afferent loop syndrome, and 1 (1.4%) case of candy cane syndrome. The overall technical and clinical success rates were very high (97.2% and 94.4%, respectively). Adverse events were observed in 9/72 (12.5%) cases, including 4 (5.6%) minor events (AGREE < 3) and 5 (6.9%) major events (AGREE ≥ 3). Major events included persisting fistula (N=1), and bleeding (N=4). All could be successfully managed, and there were no procedure-related deaths. Loss of LAMS patency occurred in 3/72 (4.2 %) cases and could be endoscopically managed in all cases.

Conclusion: In conclusion, our study shows that EUS-GE and EUS-EE offer an effective and safe approach when performed by experts. With high technical (97.2%) and clinical (94.4%) success rates, LAMS proves beneficial for treating GI outflow obstruction. Adverse events (12.5%) were manageable, with no procedure-related mortality. The extended patency duration and low re-intervention rate highlight LAMS as a minimally invasive and durable therapeutic option. Further prospective studies are needed.

Disclosure: Nothing to disclose.

ENDOSCOPIC TREATMENT FOR SHORT-SEPTUM ZENKER'S DIVERTICULUM: A COMPARISON OF TRADITIONAL FLEXIBLE ENDOSCOPY SEPTOTOMY AND PERORAL ENDOSCOPIC SEPTOTOMY

R. de Sire[1], G. Franchellucci[1], A. Capogreco[1], D. Massimi[1], E. Mastrorocco[1], L. Alfarone[1], M. Spadaccini[1], G. Marcozzi[1], A. Facciorusso[2], C. Hassan[1], A. Repici[1], R. Maselli[1]
[1]*Humanitas Research Hospital, IRCCS, Gastroenterology, Endoscopy Unit, Rozzano, Italy,* [2]*University of Foggia, Gastroenterology, Foggia, Italy*

Contact E-Mail Address: roberto.desire@libero.it

Introduction: Short-septum Zenker's diverticulum (ZD) is considered difficult-to-treat because the limited anatomical space which restricts the operating area. Recently, peroral endoscopic septotomy (POES) emerged as a novel third-space technique for addressing this condition.

Aims & Methods: This study aims to compare the effectiveness and safety of POES with traditional flexible endoscopic septotomy (FES) for the treatment of symptomatic patients with short-septum ZD (<25 mm). In this single-center, prospective study we included all consecutive patients referred to Humanitas Research Hospital with symptomatic short-septum ZD who were scheduled to undergo either FES or POES. The primary outcome was the rate of technical success and adverse events (AEs). The secondary outcome was the rate of clinical success at 12 months and recurrence requiring a retreatment. A sensitivity analysis was conducted using propensity score matching. Hazard Ratio (HR) and its associated 95%CI were used for a time-dependent analysis of recurrence.

Results: A total of 94 patients (63.8% male; mean age 72.7 ± 10.7 years) underwent endoscopic treatment for a short-septum ZD (mean size 17.0 ± 4.3 mm) were included. Among them, 41.5% (n=39) were treated with FES and 58.5% (n=55) with POES (p=n.s.). Overall, the mean procedural duration was 25.3 ± 15.7 min, while the mean hospital stay was 0.3 days. Septotomies were performed under deep sedation in 91.5% of patients (n=86), while in 8.5% of them (n=8) the procedure was performed under general anesthesia. Technical success was achieved in 98.9% of patients (n=93), while AEs occurring in 5.3% of cases (n=5), with no statistical difference between groups (p=n.s.). Clinical success was observed in 91.5% of patients (n=86), while recurrence necessitating retreatment in 14.9% of cases (n=14) with no statistical difference between groups (p=n.s.).

Conclusion: Our findings suggest that POES is an effective and safe technique for the treatment of short-septum ZD, showing comparable outcomes to traditional FES.

BESPOKE, IN-HOUSE MADE ENDOSCOPIC VACUUM THERAPY DEVICES FOR THE TREATMENT OF UPPER GASTRO-INTESTINAL ANASTOMOTIC LEAKS: A SINGLE, TERTIARY CENTER EXPERIENCE

T. Alexopoulos[1], V. Lekakis[1], M. Tampaki[1], S. Papadakos[1], G. Mpouga[1], P. Fytili[1], A. Koutsoumpas[1]
[1]*Laiko Hospital, Academic Department of Gastroenterology, Athens, Greece*

Contact E-Mail Address: thodorisalexo1990@gmail.com

Introduction: Anastomotic leaks (AL) are a challenging complication after upper gastro-intestinal (UGI) surgery, with significant mortality and morbidity. Endoscopic vacuum therapy (EVT) has recently emerged as the

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

mainstream tool for the management of UGI AL, both with commercially available devices and with in-house devices. Our group has recently (since July 2022) started to use bespoke, in-house made devices for EVT.

Aims & Methods: The aim of this study is to describe our experience with EVT for UGI AL in oncological patients undergoing surgery. We retrospectively collected and analysed data from all our patients who underwent EVT for AL after UGI oncological surgery, between July 2022 and December 2023 (18 months period). EVT was offered with bespoke, in house, handmade negative pressure endoscopic devices connected to commercial, medical vacuum pumps. EVT was performed twice per week and initial response was assessed during the 5th EVT (after the completion of two weeks of endoscopic therapy) at latest; if AL had not improved endoscopically and radiologically by that point, no further EVT was offered and alternative therapies were considered.

Results: In total, 8 patients (5 male; mean age 61) underwent EVT over the above-mentioned period. Six of them underwent Ivor-Lewis esophagectomy with esophago-gastric anastomosis and 2 underwent total gastrectomy with esophago-jejunal anastomosis. Five of them had received neo-adjuvant chemotherapy prior to surgery. EVT was placed intracavitary initially if technically possible (5 patients) and then intraluminally as the leak site decreased in size, or directly intraluminally (3 patients) if the anastomotic leak was <5mm and could not accommodate our smallest in-house device.

EVT was successful in 7 out of 8 patients (success rate 87,5%). Only one patient had no response on day 15, and after discussion at our MDT he was offered a redo surgery (this was a patient with esophago-jejunostomy) with good final result. The mean time between AL diagnosis and first EVT was 9 days. A median of 6 endoscopic EVT procedures was needed (range 2- 15) for total AL closure. There were no technical issues related to the device itself, all patients tolerated EVT well and no adverse event directly related to EVT was recorded (the one patient who underwent reconstructive surgery experienced worsening of extraluminal cavity/collection but this was deemed secondary to the leak itself rather than EVT).

Conclusion: EVT is an effective therapy for UGI post-surgical anastomotic leaks, with a success rate of 87,5% in our experience. It is demanding in terms of resources (high number of repeat endoscopies needed), but it is well tolerated and safe.

PP0246

COMPARING TRANSNASAL PEG TUBE PLACEMENT WITH AND WITHOUT SEDATION IN PATIENTS WHERE TRANSORAL PEG TUBE PLACEMENT NOT POSSIBLE

N. Ahmed[1]

[1]*Sindh institute of advanced endoscopy and gastroenterology karachi, Gadtroenterology, Karachi, Pakistan*

Contact E-Mail Address: nasierahmedkhan@gmail.com

Introduction: In patients with indications for transnasal PEG tube placement, such as oral cavity, head and neck tumors where the conventional upper gastrointestinal endoscopic procedure to place a PEG tube through the oral cavity can be difficult due to complete or partial occlusion of mouth and/or pharynx.In such cases transnasal placement of a PEG tube is proven to be useful.

Aims & Methods: The aim of this study was to compare the efficacy, safety, procedure time, patient tolerance ,recovery time, immediate and late complication of transnasal PEG tube (T-PEG) placement with and without conscious sedation.A total of 150 patients had a successful PEG tube placement. Out of which 49 patients required transnasal PEG tube placement through ultra-thin video gastroscope with an external diameter of 5.9 mm. patients were selected randomly for sedation and without sedation. After all asceptic measures,transillumination18-Fr PEG tube was placed transnasally by the Gauderer-Ponsky pull technique. 25 of the patients underwent T-PEG without any sedation and the remaining 24 patients were placed under conscious sedation with 2 mg midazolam.

All patients were followed immediately and after 1 month of the procedure.

Results: T-PEG tube was placed successfully in all 49 patients.very surprisingly all patients for transnasal were male.all had history of tobacco chewing in the form of ghutka/mawa. mean age was 38 years. 24 patients had a transnasal-PEG tube placed under conscious sedation of 2 mg midazolam.2 patients in the sedated group had drop in oxygen saturation which was managed during procedure.one patient in sedated and one in unsedated group had minor nasal trauma during peg tube placement. procedure time, procedure tolerance in both groups were almost similar.while post procedure recovery,observation,monitoring and discharge time by the staff was shorter for unsadated group 10mins +-5 min as compared to the sadated group 60mins +-10mins.two patients in sedated group While only one patient in the unsedated group had stoma site infection which were treated according to c/s report. The overall tolerance and success rate was similar in both groups.

Conclusion: In patients with oral cavity obstructing mass or trismus where oral route of PEG tube placement cannot be done, a transnasal route can be considered for placement of PEG tube safely with no requirement of sedation.it decreases the patient hospital stay,staff nurse monitoring,risk of resuscitation tracheostomy.This method is especially useful if the procedure is done in remote settings where anesthesiologists are not available.

Introduction: The spread of Endoscopic Sleeve Gastroplasty (ESG) as an effective bariatric endoscopic technique has been notable, particularly for treating patients with class I and II obesity with related comorbidities. Our study aimed to assess the efficacy of ESG in class III obese patients [Body Mass index (BMI) >40 kg/m^2] focusing on weight loss and comorbidities improvement.

Aims & Methods: This retrospective analysis on a prospective dataset, focused on subjects with a baseline BMI >40 kg/m^2 who underwent ESG from June 2017 to November 2023. Weight loss outcomes [BMI, Excess Weight Loss (%EWL), Total Body Weight Loss (%TBWL), BMI loss (BMIL) and Absolute Weight Loss (AWL)] were assessed at 3, 6, 12 and 24 months. Additionally, the impact of ESG on Type 2 Diabetes (T2D), Hyperinsulinemia (H-INS), Arterial Hypertension (AH), and Obstructive Sleep Apnea Syndrome (OSAS) was analyzed.

Results: A total of 129 patients were included (74 female, mean age 47 ± 12.7, mean BMI: 44.4 ± 4.1 kg/m^2). We observed a significant regression to grade II obesity starting within the first three months postoperatively, with a BMI reduction of 7.1 ± 4.8 at 24-months follow-up (Table 1).

At 12-month follow-up, our data showed improvement or complete remission of T2D, H-INS, AH and OSAS, in 50% (7/14), 36.3% (12/33), 41% (20/49) and 31% (9/29) of patients, respectively.

Follow-up	n	Weight (kg)	p	AWL (kg)	EWL (%)	TBWL (%)	BMI (kg/m2)	p	BMIL (kg/m2)
3m	99	106.1 (15.7)	**<0.01**	19.3 (8.0)	25.3 (11.1)	15.3 (5.0)	37.7 (3.8)	**<0.01**	6.8 (2.6)
6m	90	103.8 (17.1)	**<0.01**	21.6 (9.5)	39.9 (16.0)	17.2 (6.9)	36.6 (4.7)	**<0.01**	7.7 (3.3)
12m	83	105.4 (21.5)	**<0.01**	19.9 (13.1)	37.2 (23.2)	16.0 (10.0)	37.5 (5.9)	**<0.01**	7.2 (4.6)
24m	44	106.1 (17.4)	**<0.01**	19.8 (13.4)	34.7 (22.2)	15.4 (10.0)	37.7 (4.3)	**<0.01**	7.1 (4.8)

Weight loss outcomes of primary ESG in subjects with BMI >40 kg/m².
Data are reported as mean value (standard deviation).
A two sample T-Test was used to compare baseline weight and weight loss outcomes.

Conclusion: Based on our observations, while Endoscopic Sleeve Gastroplasty (ESG) demonstrated effectiveness in inducing weight loss and ameliorating comorbidities in class III obese patients, it did not fully resolve obesity, potentially due to the high baseline BMI. Consequently, surgical intervention should continue to be the primary treatment modality for class III obesity. However, when surgery is contraindicated or refused by the patient, ESG represents a less invasive option and could be considered as an effective first-stage or multi-step treatment.

Disclosure: Nothing to disclose.

Contact E-Mail Address: masato@murakami-kinen.or.jp

Introduction: Percutaneous transesophageal gastrotubing (PTEG) was established as an alternative route to access the gastrointestinal tract for the patients that Percutaneous Endoscopic Gastrostomy was contraindicated. More than two hundred cases without indication of PEG were rescued by this ideal method.

Aims & Methods: The aim of this study is to evaluate the clinical usefulness of PTEG. A rupture-free balloon (RFB) catheter is inserted into the upper esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. Double Balloons equipped Over tube type RFB were used instead of primary RFB in fifty-seven cases that the puncture needle is punctured into the over tube trough the balloon. We perform PTEG in a total of 204 patients (124 men and 80 women, mean age 71.5 years) PTEG was performed for nutrition in 116 patients and for decompression in 88.Eighty-five patients had peritoneal carcinoma , 62 patients had prior gastrectomy , 30 patients had gastric herniation into the thoracic cavity.

Results: Satisfactory results were achieved in all 204 patients. Median follow-up was 65.0 days in patients who received decompression because of the obstruction due to mainly malignancies and 359.0 days in those who received nutrition. Nine patients who were started in the fluoroscopically assisted according to the original method needed endoscopic assistance to complete the procedure in first 30 cases.

Another 174 patients were performed in endoscopic assistance instead of fluoroscopy.

About the complications, there was 2 patient with severe bleeding requiring blood transfusion, Two patient had tracheal penetration, which was managed conservatively. Other complications were minor oozing bleeding in thirteen patients that did not require blood transfusion, subcutaneous emphysema in two patients, which were managed conservatively. Complication rate was 9.8%. No patient required surgical treatment or died after PTEG.

Conclusion: PTEG is feasible, safe, and useful for long-term nutrition and/or decompression for the patient who is contraindicated to PEG. PTEG may become the only procedure of the liberation from nasogastric tube for the patient who is contraindicated to PEG. PTEG is the ideal solution for the patients with PEG contraindicated.

Disclosure: Nothing to disclose.

ACUTE ESOPHAGEAL NECROSIS IS ASSOCIATED WITH CELIAC TRUNK STENOSIS: A SINGLE CENTER EXPERIENCE OF 15 CASES

M. Maibier[1], D. Geisel[2], A. Arnold[3], M. Schulz[1], J. Wizenty[1], M. Sigal[1], A. Wree[1], F. Tacke[1], A. Fischer[1]

[1]Charité Universitaetsmedizin Berlin, Department of Hepatology & Gastroenterology, Berlin, Germany, [2]Charité Universitaetsmedizin Berlin, Department of Radiology, Berlin, Germany, [3]Charité Universitaetsmedizin Berlin, Department of Pathology, Berlin, Germany

Contact E-Mail Address: martin.maibier@charite.de

Introduction: Acute esophageal necrosis (AEN) is an uncommon but often fatal esophageal condition with a mortality rate of approximately 30%. AEN predominantly affects elderly, male patients with significant comorbidities and typically presents with signs of upper gastrointestinal hemorrhage. The pathophysiology of AEN is attributed to a combination of local hypoperfusion, loss of mucosal barrier function and acid reflux. However, AEN still remains poorly understood due to its low incidence. In example, it has not been investigated whether celiac trunk stenosis might contribute to AEN development.

Aims & Methods: In this case series, we aimed to review clinical, laboratory and endoscopic features of AEN patients with an additional focus on celiac trunk diameter. 15 patients diagnosed with AEN between 2014 and 2024 at a single center in Berlin, Germany, were included in this study. Clinical data were reviewed and retrospectively analyzed on a case-by-case basis. AEN diagnosis was made endoscopically applying well-described criteria including diffuse, circumferential livid or black discoloration of esophagus mucosa with sparing of the gastroesophageal junction. Celiac trunk was assessed using contrast-enhanced computed tomography imaging to measure the extent of narrowing in the celiac trunk artery. The stenosis was classified into atherosclerotic or median arcuate ligament compression and graded into < 30% (grade 0), 30 - 50% (grade 1), 50 - 80% (grade 2) and > 80% narrowing (grade 3). Laboratory tests were carried out for each patient. However, in some cases not all parameters were available in retrospect.

Results: 73% (11/15) of AEN patients were male with a median age of 63.4 years (23 – 85 years). In 47% (7/15) of cases, cardiovascular disease was present. 67% (10/15) of patients presented with gastrointestinal hemorrhage, other clinical presentations included dysphagia, abdominal pain, dyspnea, and shock. 100% (15/15) of patients showed elevated CRP (mean: 70.9 mg/dl, 13.8 - 224.5 mg/l), 92% (11/12) hypalbuminemia (mean: 22.4 g/dl, 6.0 - 36.3 g/dl), 90% (9/10) lactatemia (mean: 97.5 mg/dl, 17 - 259 mg/dl), 82% (9/11) hyperglycemia (mean blood glucose: 146 mg/dl, 73 - 200 mg/dl), 67% (10/15) leukocytosis (mean: 17.96/nl, 4.64 - 42.02/nl) and 67% (10/15) anemia (mean hemoglobin: 11.0 g/dl, 5.0 - 16.1 g/dl). Endoscopy revealed panesophageal necrosis in 71% (10/14) of cases and mid-distal disease in 21% (3/14). Duodenal involvement, mostly reflected by duodenal ulcers, was found in 79% (11/14) of cases. 87% (13/15) of AEN patients showed celiac trunk stenosis. Grade 2 or 3 stenosis was present in 47% (7/15) of cases. 85% (11/13) of celiac trunk stenoses were atherosclerotic, 15% (2/13) were caused by median arcuate ligament compression. Case fatality rate was 40% (6/15) in this series.

Conclusion: Our study confirms that AEN is a potentially life-threatening medical condition often observed in critically ill patients. For the first time, we show that celiac trunk stenosis is associated with this condition. Future research is needed to confirm this data and carve out a possible role for endovascular revascularization in the treatment of AEN patients.

Introduction: The effect of Helicobacter pylori eradication (HPE) on body weight and lipid profile is not well known.

Aims & Methods: We prospectively enrolled 102 patients who were treated for H pylori eradication from Apr 2021 to Jan 2024 at a university hospital in Goyang, South Korea (Inje University Ilsan Paik Hospital). Patients who had active peptic ulcer were excluded. Patients' body weight and lipid profile were measured before enrollment and 3 months after taking medications for HPE. The difference between before-and-after measurements were compared using the paired t-test. To test the difference in lipid profile, patients who had newly started lipid lowering drugs before the three-month follow-up visit were excluded from the analysis.

Results: Among 102 patients who were enrolled to treat H. pylori, 87 patients (46 males, 41 females) were followed up three months after taking HPE prescriptions. The median age was 59 years (range, 19-82). The baseline body mass index was 25.0 kg/m2 (range, 16.2-37.5).

There were 39 patients (44.8%) who were using lipid lowering drugs at the baseline. Five patients who had started lipid lowering drugs before the follow-up visit were excluded when analyzing the lipid profile change. Hp eradication rate was 91.9% (80/87). The HPE regimen included triple therapy (n=46 [52.9%]), quadruple therapy (n=31 [35.6%]), and concomitant therapy (n=10 [11.5%]).

	Baseline, mean (95% CI)	3 month follow-up after H. pylori eradication, mean (95% CI)	P-value (before-and-after t-test)	Difference among HPE successful (n = 80), median (interquartile range)	Difference among HPE failed (n = 7), median (interquartile range)	P-value (according to H. pylori eradication)
Body weight (kg)	67.4 (64.7-70)	66.9 (64.3-69.5)	0.079	-0.15 (-1.55,1)	-1 (-2.8, 0)	0.386
Serum glucose (mg/dL)	111.7 (106.9-120.5)	109.4 (104.1-114.5)	0.068	-1 (-11, 7)	-14.5 (-18, 23)	0.465
Total cholesterol (mg/dL)	166.5 (157.5-175.6)	162.1 (152.7-171.5)	0.172	-5 (-17, 7)	14 (-13, 43)	0.770
LDL cholesterol (mg/dL)	93.4 (84.9-101.8)	84.2 (76.4-92.1)	0.009	-7 (-21, 6)	-1.5 (-70, 19)	0.264
HDL cholesterol (mg/dL)	52.7 (49.6-55.8)	54.5 (51.2-57.9)	0.074	1 (-3, 7)	3 (-1, 22)	0.113
Triglyceride (mg/dL)	120.0 (105.3-134.7)	122.4 (103.9-140.9)	0.702	-3 (-30, 31)	-12 (-44, -1)	0.507

The body weight decreased from mean 67.4 kg (95% confidence interval [CI], 64.7-70.0) to mean 66.9 kg (95% CI, 64.3-69.5; p = 0.079). Serum glucose decreased from mean 111.7 mg/dL (95% CI, 106.9-120.5) to mean 109.4 (95% CI, 104.1-114.5; p = 0.068).

Total cholesterol decreased from mean 166.5 mg/dL (95% CI, 157.5-175.6) to mean 162.1 (95% CI, 152.7-171.5; p = 0.172). Low-density lipoprotein (LDL) cholesterol decreased from mean 93.4 mg/dL (95% CI, 84.9-101.8) to mean 84.2 (95% CI, 76.4-92.1; p = 0.009). High-density lipoprotein (HDL) cholesterol increased from mean 52.7 mg/dL (95% CI, 49.6-55.8) to mean 54.5 (95% CI, 51.2-57.9; p = 0.074). Triglyceride changed slightly from 120.0 mg/dL (95% CI, 105.3-134.7) to 122.4 mg/dL (95% CI, 103.9-140.9; p = 0.702). The number of non-Hp eradicated subjects was too small (n = 7) to compare the differences in body weight and lipid profile according to actual H. pylori eradication.

Conclusion: In a short-term prospective study among Korean patients who were treated for H. pylori, there was a decrease in body weight and a favorable effect on serum lipid levels. The number of non-Hp eradicated subjects was too small to draw conclusions about the effect of successfully eradicated Hp on body weight and lipid profile. The long-term effect of HPE on body weight and lipid profile remains to be analyzed, and a randomized study is required to achieve non-biased results.

GUINEA PIG - A CONVENIENT MODEL TO STUDY THE PATHOGENESIS OF *HELICOBACTER PYLORI* INFECTIONS

W. Gonciarz[1], P. Płoszaj[1], M. Chmiela[1]
[1]University of Lodz, Institute of Microbiology, Biotechnology and Immunology, Faculty of Biology and Environmental Protection, Department of Immunology and Infectious Biology, Łódź, Poland

Contact E-Mail Address: weronika.gonciarz@biol.uni.lodz.pl

Introduction: *Helicobacter pylori* (*Hp*) is an etiological agent of chronic gastritis, gastric and duodenal ulcers and gastric cancers. The use of an appropriate animal model for experimental studies on the pathogenesis of *H. pylori* infections is necessary due to the chronic character of such infections and difficulties in identifying their early stage in humans.

Aims & Methods: The aim of this study was to develop a guinea pig model of *H. pylori* infection and identify its microbiological, histological, molecular and serological determinants. Guinea pigs (*Cavia porcellus*) were inoculated *per os* with *H. pylori* strain: CCUG 17874 positive for-vacuolating cytotoxin A (VacA) and cytotoxin associated gene A (CagA) protein, suspended in *Brucella* broth with fetal calf serum (FCS) and Skirrow supplement (on permission of Local Ethics Committee for Anima Experiments, Medical University of Lodz Poland, Decision 58/ŁB45/2016).

To determine *H. pylori* colonization, 7 and 28 days after inoculation, a gastric tissue was used for culturing *Hp* histopathological examination of gastric tissue sections, stained by Mayer,s haematoxylin and eosin, Giemsa staining or Warthin-Starry silver staining to assess inflammatory

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

response,-or to visualize *Helicobacter*-like organisms (HLO). Furthermore an immunostaining with anti-Ki-67 antibodies was developed to assess epithelial cell proliferation. *H. pylori* infection was also confirmed by polymerase chain reaction (PCR) for detection in gastric tissue of *ureC* and *cagA* genes and by serological assessment of *Hp* antigens in feces and serum anti-*Hp* antibodies.

Results: This study showed the successful colonization of guinea pigs with *Hp* on the basis of microbiological, histological, molecular and immunological determinants In the light of obtained results *Cavia porcellus* can be a good model for studying *Hp* pathogenesis and the related immune response against this pathogen.

Conclusion: The ability to induce and confirm the *Hp* infection in guinea pig makes this animal model suitable for studying the pathogenesis of infection and the course of related immune response, which *in vivo* is modulated by the components of these bacteria.

Financing: The research was financially supported by the National Science Center by the grant SONATA 18 "Assessment of the ability of *Mycobacterium bovis* BCG-onco bacilli to control the development of *Helicobacter pylori* infection", UMO-2022/47/D/NZ7/01097.

BARRIERS TO EFFECTIVE GERD SYMPTOM CONTROL POST-H. PYLORI TREATMENT IN SOCIO-ECONOMICALLY DIVERSE POPULATIONS

R. Rammohan[1], M. Joy[1], S.G. Magam[1], D. Natt[1], W. Lau[1], A. Tadikonda[1], S.R. Magam[1], L. Pannikodu[1], J. Desai[1], P. Mustacchia[1]

[1]Nassau University Medical center, Department of Gastroenterology, East Meadow, United States of America

Contact E-Mail Address: rrammoha@numc.edu

Introduction: The interplay of race and gender significantly influences the manifestation of Gastroesophageal Reflux Disease (GERD) symptoms following Helicobacter pylori (H. pylori) treatment.

This multifaceted relationship, deeply rooted in biological, cultural, and socioeconomic factors, presents a complex medical challenge. Understanding these disparities is crucial for tailoring effective treatment strategies, ensuring equitable healthcare outcomes, and advancing personalized medicine in managing GERD symptoms in diverse populations post-H. pylori eradication

Aims & Methods: Our research, spanning 2009 to 2023, retrospectively analyzed patients treated for H. Pylori, ensuring a minimum one-year follow-up. We collected data encompassing comorbidities, insurance status, and socioeconomic factors, particularly targeting the emergence of GERD symptoms, Esophagitis, and duodenal ulcers, identified using CPT and ICD codes. Initially, we employed a Chi-square test of independence to evaluate the association between race and GERD symptoms.

We conducted a post-hoc analysis with adjusted standardized residuals to delve deeper, pinpointing specific races with notably higher or lower GERD symptom frequencies than expected. We performed pairwise race comparisons via Chi-square tests, applying a Bonferroni correction for multiple comparisons.

Results: Between 2009 and 2023, 4,205 patients received H. Pylori treatment, with 3,329 qualifying for our study after excluding those lost to follow-up. The average age was 54.5 years, with 64% female (2,134) and 48% Caucasian (1,664).

The Chi-square test revealed a significant association between Race and GERD symptoms (Chi sq stat:8.69 p-value <0.01). In-depth post-hoc pairwise comparisons showed that the Hispanic race had significantly higher rates of GERD symptoms when compared to other races Other races (p <0.01), White (p <0.01), Black (p <0.01), and Asian races (<0.01). Adjusted residual analysis further confirmed that the Hispanic race (5.54, p<0.023) showed a higher-than-expected number of GERD symptom cases.

Among the Hispanic races, Patients with low socioeconomic status showed increased GERD symptoms (Chi. Sq: 7.65, P<0.01). Gender does not significantly impact GERD symptoms (Chi. sq: 0.831, P = 0.512)

Conclusion: Our study, analyzing data from 2009 to 2023 on patients treated for H. Pylori, underscores the significant influence of race and gender on GERD symptoms post-treatment.

Notably, the Hispanic population exhibited a higher incidence of GERD symptoms compared to other races, with socioeconomic status further intensifying this trend.

These findings highlight the need for more personalized, culturally sensitive approaches in healthcare, emphasizing the importance of considering race, gender, and socioeconomic factors in the treatment and management of GERD following H. Pylori eradication.

CHANGES OVER TIME IN THE PREVALENCE OF *HELICOBACTER PYLORI* INFECTION IN THE NORTH-WESTERN REGION OF THE RUSSIAN FEDERATION FROM 2015 TO 2023

N.V. Bakulina[1], S.V. Tikhonov[1], I.V. Savilova[1], A.V. Zharkov[1,2], V.A. Ponomarenko[1], I.G. Bakulin[1]

[1]North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation, [2]Healthcare Committee of the Leningrad Region, Saint Petersburg, Russian Federation

Contact E-Mail Address: nv_bakulina@mail.ru

Introduction: Russia is among the countries with a high prevalence of *Helicobacter pylori (H. pylori*) infection. The North-Western Federal District, comprising one-tenth of Russia's population, is predominantly urban. As of 2023, its population is over 13 million people. Current information on *H. pylori* infection prevalence is necessary for the development of clinical guidelines for the prevention of *H. pylori*-associated disorders.

Aims & Methods: To evaluate the dynamics of *H. pylori* infection prevalence among patients with dyspepsia between 2015 and 2023 based on ^{13}C-urea breath test (^{13}C-UBT).

The study was conducted in the North-Western Federal District. Patients with dyspepsia (n=50,884) who underwent ^{13}C-UBT between 2015 and 2023 were included in this descriptive study. If Delta Over Baseline (DOB, $\delta^{13}CO2$) was less than 2.5‰, the result of the test was considered negative, while $\delta^{13}CO2$ value ≥2.5‰ indicated the presence of *H. pylori* infection.

The criteria for the infection grade (IG) were defined as follows: IG I (2.5–3.4‰), IG II (3.5–6.4‰), IG III (6.5–9.4‰), and IG IV (>9.5‰). The database for subsequent statistical analysis included such parameters as the patients' age, gender, history of prior eradication therapy, and the result of the ^{13}C-UBT test.

Results: Among all included individuals (mean age 43.3 years (31.0; 55.0); 57.5% of whom were female), there were 83.6% (n=42,543) of primary "naive" patients (who had had no history of prior eradication therapy) (95% confidence interval (CI) 83.3-83.9). The proportion of treated patients was 16.4% (n=8,341; 95% CI 16.1-16.7).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The prevalence of *H. pylori* infection among the primary patients was 51.4% in 2015 (874/1701 subjects; 95% CI 49.0–53.8) and gradually decreased to 32.2% (1904/5916 subjects; 95% CI 31.0–33.4) in 2022. In 2023 *H. pylori*-positive was 32.7% (1450/4433 subjects; 95% CI 31.3–34.1). Eradication failure was 39.1% in 2015 (148/379 subjects; 95% CI 34.5-44.3). Eradication rate in 2016 was 80.2% (684/853 subjects; 95% CI 77.4-82.7) and increased to 86.8% (702/809 subjects; 95% CI 84.3-88.9) in 2023.
Naive and unsuccessful treated patients demonstrated a very high IG - 73.0 and 66.5%, respectively. *H. pylori* was detected more often in young adults (18–44 years old (y.o.)). The infection was less commonly detected among children (1.6% of primary and 1.3% of treatment-failure patients).

Total, n	Naive, 15358	Treatment failure, 1284
Women, n (%) Men, n (%)	8804 (57,3) 6554 (42,7)	728 (56,7) 556 (43,3)
2–17 y.o., n (%)	247 (1,6)	17 (1,3)
18-44 y.o., n (%)	7918 (51,5)	613 (47,7)
45-59 y.o., n (%)	4401 (28,7)	403 (31,4)
Over 60 y.o., n (%)	2792 (18,2)	251 (19,6)
IG I, n (%)	736 (4,8)	119 (9,3)
IG II, n (%)	1605 (10,5)	179 (13,9)
IG III, n (%)	1802 (11,7)	132 (10,3)
IG IV, n (%)	11215 (73,0)	854 (66,5)

Table 1. Characteristics of the H. pylori-positive primary and treatment failure patients.

Conclusion: Overall, our study highlighted a significant decrease of *H. pylori*-infection from 2015 to 2023. However, the eradication rates in the North-Western district of Russia remain low and do not reach the threshold value of 95%.

Introduction: Portugal is an intermediate-high risk country for gastric cancer and *Helicobacter pylori* (Hp) infection is an important risk factor for such condition. All of infected patients should be treated; however, the increasing frequency of antibiotic resistance reduces its eradication rate.

Aims & Methods: Aims: To analyze the prevalence of Hp infection in Portugal and its antimicrobial resistance profile. To evaluate the prevalence of premalignant gastric conditions.
Methods: A multicentric cross-sectional study involving 9 endoscopy units from Portugal, distributed across the country (north, central and south regions). We included patients aged ≥40 who underwent upper endoscopy in these units between February and March 2024. Hp detection was performed using immunohistochemistry (IHC). In positive IHC samples, clarithromycin, fluoroquinolones and metronidazole resistances were assessed in biopsy samples using real-time polymerase chain reaction.
Results: Four hundred twenty-one patients were included (58% women, mean age 60), 172 of which were Hp-positive (41%). Excluding patients with prior eradication therapy, the prevalence of Hp infection was 47.4%. Infection was more prevalent in the north region of the country (north 46.8%; central 36%; south 36.5%). The antimicrobial resistance rates were: clarithromycin 26%; fluoroquinolones 16%; metronidazole 2%; clarithromycin/fluoroquinolones 4%. Intestinal metaplasia (IM) was identified in 138 patients (32.8%), 24 of which (6%) had extensive IM (both antrum and corpus) and 31 (7%) had an endoscopic grading of gastric IM (EGGIM) ≥5.
Conclusion: Hp infection in Portugal is frequent, showing a north-south gradient, albeit smaller than expected. More than half of the strains showed no antibiotic resistance and only 4% exhibited dual resistance to clarithromycin/fluoroquinolones. We demonstrate the feasibility of studying resistance profile in endoscopic biopsies, suggesting that such tests may lead to reduce antibiotic consumption and associated side effects, as well as lower therapeutic costs. The presence of IM in approximately one-third of patients, in a predominantly young population, reinforces the relevance of endoscopic screening in Portugal.

PREVALENCE OF *HELICOBACTER PYLORI* INFECTION AND VIRULENCE GENES IN PATIENTS WITH UPPER GASTROINTESTINAL DISEASES FROM SOUTHWEST OF IRAN

P. Alavinejad[1], N. Karimi[2], M. Savari[2], E. Abbasi Montazeri[2]
[1]Ahvaz Jundishapur university of medical sciences, GI department, Copenhagen, Denmark, [2]Ahvaz Jundishapur university of medical sciences, GI department, Ahvaz, Iran

Contact E-Mail Address: Pezhmanalavinejad@gmail.com

Introduction: Various virulence factors of *H. pylori* have been identified that play an important role in pathogenesis. The aim of this study was to investigate the prevalence of *H. pylori* infection by rapid urea test and histopathology examination and determining the prevalence of the cytotoxin associated gene A (*cagA*), vaculating cytotoxin A (*vacA*) and restriction endonuclease-replacing gene (*hrgA*) in *H. pylori* strains isolated from patients with upper gastrointestinal diseases from Khuzestan.

Aims & Methods: Gastric biopsy specimens were obtained from 426 patients with gastrointestinal disorders undergoing endoscopy in Imam Khomeini Hospital, Ahvaz, the capital of Khuzestan province. *H. pylori* infection was investigated in patients by rapid urea test and histopathology examination and positive specimens were reconfirmed by PCR of the *ureB* gene. The presence of *cagA*, *vacA s/m* and *hrgA* genotypes were determined by PCR from culture or gastric biopsies.

Results: *H. pylori* was detected in 33.8% (144/426) of patients by rapid urea test and in 44.13% (188/426) by histopathology. 60.2% of infected patients were female and 39.8% were male and the mean age of patients was 47.1 years (range 14 to 89 years old). Epigastric pain was the most commonly reported symptom (62.7%), followed by anorexia (24.9%), nausea (21.4%), epigastric burning (20.4%), gastrointestinal bleeding (14.9%), fullness (12.4%), vomiting (12.4%), weight loss (12.9%) and bloating (11.9%). The main endoscopic findings were non-ulcer dyspepsia 56.7%, erosive gastritis 20.9%, gastric ulcer 13.4%, duodenal ulcer 7.5% and gastric cancer 1%. The *cagA*, *vacA*s1, *vacA*s2, *vacA*m1, *vacA*m2 and *hrgA* genotypes were detected in 93.3%, 71.6%, 23.1%, 25.4%, 70.1% and 67.2% of isolates, respectively. The allelic variant *vacA*s1m2 was more prevalent (45.5%) than *vacA*s1m1 (23.9%) and *vacA*s2m2 (23.1%).

There was a statistically significant association between the presence of *vacA*s1m2 genotype and gastric ulcer (P = 0.004), while the *vacA*s2m2 significantly was observed in strains isolated from patients with non-ulcer dyspepsia (P = 0.017). Also the presence of *hrgA* gene was associated with duodenal ulcer (P = 0.043).

Conclusion: the histopathology examination is more specific than the rapid urea test especially in gastric ulcer bleeding cases and the use of both tests can help to more accurate diagnosis of *H. pylori* infection. Based on the results *vacA*s1, *vacA*s2 and *hrgA* genotypes may be the predictors of gastric ulcer, non-ulcer dyspepsia and duodenal ulcer, respectively.

Introduction: Global rise in primary *Helicobacter pylori* (*H. pylori*) antibiotic resistance has led to a decrease in the treatment efficacy. Understanding the rates of clarithromycin resistance in *H. pylori* management is essential for determining the optimal eradication therapy and achieve successful clinical outcomes.

Aims & Methods: This review aimed to evaluate the prevalence and geographical distribution of *H. pylori* primary clarithromycin resistance in Europe. Bibliographical searches were performed in PubMed up to March 2024. Selection: Included studies assessing rates of *H. pylori* primary resistance to clarithromycin with no time restriction. Publications in any language were considered. Studies that focused on children only or non-European countries were excluded.

Table 1. Clarithromycin primary resistance prevalence in Europe in the last four decades (1990-2024). Number of patients tested for Clarithromycin: n (positive resistance results)/N (total with H. pylori). NA: not available.

Results: Overall, 188 studies were included, evaluating 81,458 patients over more than 30 years (1990-2024). In this time span, the mean prevalence of primary *H. pylori* clarithromycin resistance in Europe was 17%.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. This rate increased from 7.3% in the period 1990-1999, to 13% in 2000-2009, reaching 26% in 2010-2019; and then reported a decreased rate to 22% in 2020-2024. In almost all European countries, the clarithromycin resistance rate increased over time, reporting the highest rates in Switzerland (67%), Ireland (50%), Israel (44%), Portugal (40%) and Poland (39%) (2010-2019). The prevalence remained stable in recent years in France (decreasing from 21% to 17%), in Spain (around 15%), and in Turkey (decreasing from 28% to 15%). Southern European countries reported higher rates (>15-20%) than in northern countries (<10-15%).

Conclusion: In Europe, overall *H. pylori* primary clarithromycin resistance was above 15% in the last 30 years. Variability exists between countries, with Southern European and Mediterranean countries showing higher levels of resistance.

ASSOCIATION OF AUTOIMMUNE ATROPHIC GASTRITIS WITH HELICOBACTER PYLORI INFECTION

G. Gharbi[1], A. Khsiba[1], A. Ben Mohamed[1], M. Yakoubi[1], M. Moufida[1], M. Medhioub[1], M.L. Hamzaoui[1]

[1]Faculty of medicine Tunis, Tunisia Mohamed taher Maamouri hospital Nabeul Tunisia, Gastroenterology and Hepatology departement, Nabeul, Tunisia

Contact E-Mail Address: gharbighada1801@gmail.com

Introduction: In patients with Helicobacter pylori (HP) infection, superficial gastritis proceeds to atrophic gastritis in about half of the patients. Although, it usualy involves the antrum, it can also proceed to the corpus with sometimes neuroendocrine cell hyperlasia and chromogranin A antibody positivity, like in classic autoimmune gastritis.

Aims & Methods: The aim of our study was to determine the frequence of HP infection in autoimmune atrophic gastritis and its characteristics

A retrospective study was conducted over patients with autoimmune atrophic gastritis diagnosed in the gastroenterology department in Mohamed taher maamouri hospital between January 2019 and December 2021. Clinical, biological, endoscopic and pathology features were abstracted from medical records.

Results: A total of 31 patients were included in this study. The sex ratio M/F was 0.8 and the mean age was 56 years [28- 82 years]. The average haemoglobin level was 9,9 g/dl and the average mean corpuscular volume was 95,6 fL. Serum markers were available in 13 patients. Intrinsic factor antibodies were positive in five patient and anti-parietal cell antibodies in 11 patients. Pathology findings of fundal biopsies showed mild atrophy in 16,1% patients, moderate in 48,4% and severe in 35,5% with presence of intestinal metaplasia in 90,3%. The antrum was atrophic in one patient and antral intestinal metaplasia was detected in 11 patients (35,5%). HP infection was diagnosed in 23 patients (74,2%). The presence of HP infection was correlated with the severity of anaemia (p= 0.048). No correlation was found between HP infection and the degree of atrophy or the presence of intestinal metaplasia (p= 0.35 et 0.38 respectively).

Conclusion: Our study showed the presence of HP in 74.2% of patients with autoimmune atrophic gastritis , which may support the inplication of HP infection in the development of autoimmune gastritis. The presence of HP infection was correlated with the severity of anaemia, hence the importance of HP eradication treatment.

Disclosure: Nothing to disclose.

Introduction: Inflammatory Bowel Diseases (IBD) are chronic conditions whose etiology remains elusive. Several hypotheses, including a potential association with Helicobacter pylori (HP), have been proposed, as evidenced by declining prevalence due to eradication protocols. However, literature data exhibit considerable variability. Our study aims to determine the prevalence of HP infection in a population of IBD patients based on gastric biopsy results, alongside predictive factors for HP infection in this population, integrating epidemiological, endoscopic, and histological analyses.

Aims & Methods: This retrospective descriptive study spanned four and a half years from January 2019 to July 2023, encompassing all IBD patients who underwent gastroscopy with biopsy. Patients with fewer than four gastric biopsies were excluded. Data were collected from medical records, and statistical analysis was performed using SPSS software version 21.0.

Results: 150 patients were included, with a median age of 39.9 years [range: 18-71 years; ±13.49], including 80 females (53.3%) and a sex - ratio of 0.8. All patients reported tea consumption (100%), while 25 patients (16.66%) were smokers, and 18 (12%) reported alcohol use. NSAID use was noted in 17 patients (11.3%), and proton pump inhibitor (PPI) use in 5 patients (3.3%). Additionally, 15 patients reported herbal therapy. All patients underwent gastroscopy with at least 3 antral and 2 fundic biopsies. 93.3% of patients underwent systematic gastroscopy. Among participants, 66 tested positive for HP (HP+) , including 61 asymptomatic individuals. Symptomatically, 4 patients experienced epigastric pain, and one case of gastroesophageal reflux disease (GERD) was observed. HP prevalence in our sample was 44%, with a higher prevalence among females (56% vs. 44% males). HP infection was more common among individuals

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. aged 21-45 and over 60, peaking between 30 and 40. Endoscopic findings in HP+ patients included esophagitis in 6 patients (9%), erythematous and erosive gastritis in 4 patients (6%), hiatal hernia in 3 patients (4.5%), and micronodular antritis in 1 patient (1.5%). Duodenal and bulbar aphthoid ulcers were observed in 5 patients (7.5%). Notably, gastroscopy was normal in 112 patients. Epidemiological data analysis revealed that chronic NSAID use (P=0.01), herbal therapy (P=0.05), tea consumption (P=0.03), history of digestive cancer (P=0.01), young age (<37 years; P=0.05), and patients with ulcerative colitis (P=0.001) were significant risk factors for HP infection.

Conclusion: In our study, the prevalence of Helicobacter pylori infection was 44%. Ulcerative colitis was a significant risk factor for HP infection in our sample, with a highly significant P value of 0.0001. Therefore, should all IBD patients be systematically screened for HP infection?

DIAGNOSIS OF HELICOBACTER PYLORI IN PATIENTS WITH OBESITY: COMPARISON BETWEEN ^{13}C-UBT AND PCR

L. Miranda Fernandes[1], C. Garcia Montes[2], E. Cazzo[3], G. Fernanda Soares Ruppert Reis[2], C. Rodrigues dos Santos[4], M. Viviane Sá dos Santos Rondon[4], N. Hifumi Hara[4], C. Regina Pavan[4], E. Adami Chaim[3], C. Kibune Nagasako[2]

Introduction: The prevalence of gastric infection by *Helicobacter pylori* (Hp) in individuals with obesity ranges from 8.7% (1) to 85.5% (2). In candidates for bariatric surgery, Hp infection is associated with an increased risk of perioperative complications, including marginal ulcers, ulcer perforations, anastomotic dehiscence, fistulas, and bleeding. It also exacerbates symptoms related to pre-existing gastrointestinal diseases (3,4). Preoperative eradication of Hp reduces complication rates. However, there is a lack of standardization in the diagnostic methods and eradication control of this bacterium in the population with obesity (5).

Aims & Methods: To compare the performance of the carbon-13 urea breath test (^{13}C-UBT) with molecular test based on PCR in diagnosing Hp infection in candidates for bariatric surgery. To assess the prevalence of Hp infection in these individuals and analyze the correlation with gastrointestinal symptoms and endoscopic findings.

Results: Ninety-two patients were evaluated, 83.7% female, with an average age of 41 ± 10.8 years and a mean body mass index of 41.8 ± 5.2 kg/m2. The majority of participants (71.7%) had at least one comorbidity (arterial hypertension in 42.4%). The prevalence of Hp infection was 55.4% by PCR. Among the participants, 33.4% were symptomatic, predominating gastric symptoms. Abnormal endoscopic findings were observed in 56.5%, with no significant differences between the Hp negative and positive groups (51.2% *vs*. 60.7%, p=0.47). The most common endoscopic finding was erosive gastritis (45.6%). Table 1.

The sensitivity of the ^{13}C-UBT was 86.2% (CI95%: 73.1 to 93.8), with a specificity of 100% (CI95%: 89.3 to 100) and diagnostic accuracy of 92.3% (CI95%: 84.4 to 96.6). There was good concordance between the ^{13}C-UBT and PCR (kappa value 0.84, CI95%: 0.74 to 0.95), supporting the use of ^{13}C-UBT as a noninvasive test for the diagnosis of Hp in patients with obesity. Considering that Hp eradication therapy in obese individuals can contribute to reducing postoperative complications, this method becomes an alternative to endoscopy after eradication therapy, minimizing risks and costs in the preoperative period.

Parameter	Total (n=92)	Hp negative (n=41)	Hp positive (n=51)	p value
Abnormalities in endoscopy	52 (56.5)	21 (51.2)	31 (60.7)	0.47
Erosive gastritis	42 (45.6)	18 (43.9)	24 (47)	0.92
Esophagitis	17 (18.4)	6 (14.6)	11 (21.5)	0.56
Nodular gastritis	5 (5.4)	0 (0)	5 (9.8)	0.06*

*Table 1. Comparison between endoscopic findings and Hp diagnosis, n (%). *calculation using Fisher's exact test, as the value of n for Hp-negative group was zero.*

Conclusion: The prevalence of Hp infection is 55.4% in obese individuals, with no correlation with symptoms and endoscopic findings. The ^{13}C-UBT showed high sensitivity, specificity, and good correlation with PCR in detecting Hp in candidates for bariatric surgery. This non-invasive test can be used in the eradication control of Hp in the preoperative of bariatric surgery.

Introduction: *Helicobacter pylori* (*H. pylori*) infection is a common etiological cause of gastritis, peptic ulcer, atrophic gastritis, gastric adenocarcinoma, and mucosa-associated lymphoid tissue lymphoma. Accurate diagnosis and sufficient efficacy evaluation duration are both critical for effective treatment to avoid precancerous conditions.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: This retrospective, observational, multicenter, real-world study (NCT05073367) was performed across 3 hospitals using a preexisting electronic medical record (EMR) database between January 1, 2019, and March 31, 2021, to evaluate the diagnosis and treatment pattern of *H. pylori* infection in China. The study included adult patients (aged ≥18 years) with a record of diagnostic tests or positive results of *H. pylori* infection.

Here we analyzed the current pattern of diagnosis testing, eradication efficacy testing after eradication therapy, and the duration (≤4 or >4 weeks) from the termination of eradication therapy to efficacy evaluation testing.

Results: A total of 22,971 patients with *H. pylori* infection data was extracted from EMR databases. Among them, 15,712 patients had 15713 initial diagnostic testing records before the eradication therapy (One participant had both RUT testing and UBT at the index date), and 1,626 patients received efficacy evaluation after the eradication therapy. Of 15,713 initial diagnostic testing records, non-invasive testing was the main diagnostic test used by 99.99% (n=15,712) of records, and invasive testing was used by only 0.01%（n=1.

Among non-invasive testing, ^{13}C- Urea breath testing (UBT) was used by 76.8% and ^{14}C-UBT was used by 23.19%. An increasing trend was observed in the use of ^{13}C-UBT diagnostic test with 47.54%, 73.20%, and 99.98% in 2019, 2020, and 2021, respectively. ^{14}C-UBT was 52.46% in 2019，26.80% in 2020，0% in 2021.Among 1,426 patients with eradication efficacy evaluation (duration ≥ 4 weeks), non-invasive testing- UBT was the only evaluation method used, with ^{13}C-UBT in 72.3% and ^{14}C-UBT in 27.7%. In 2019, ^{13}C-UBT was used by 53.69%, in 2020 it was 69.88%, and in 2021, ^{13}C-UBT was the only evaluation method to assess the efficacy (Table 1).

The mean (Standard Deviation) duration from the termination of eradication therapy until the eradication efficacy evaluation testing was 7.0 weeks (4.37).

Of 1626 patients with efficacy evaluation, 87.7% had > 4 weeks duration and 12.3% had ≤ 4 weeks. In 2019, 83.4% had a duration of > 4 weeks, 91.21% in 2020, and in 2021, 90.68% had a duration of > 4 weeks to receive an efficacy evaluation.

Testing condition	Total count (N)	Invasive testing, RUT, n (%)	Overall Noninvasive testing, UBT, n (%)	Noninvasive testing, ^{13}C-UBT, n (%)	Noninvasive testing, ^{14}C-UBT, n (%)
Diagnostic testing used before eradication therapy	15,713*	1 (0.01)	15,712 (99.99)	12,068 (76.80)	3644 (23.19)
Year 2019	4516	0 (0)	4516 (100)	2147 (47.54)	2369 (52.46)
Year 2020	4757	0 (0)	4757 (100)	3482 (73.20)	1275 (26.80)
Year 2021	6440	1 (0.02)	6439 (99.98)	6439 (99.98)	0 (0)
efficacy evaluation testing used after eradication therapy ≥ 4 weeks	1426	0 (0)	1426 (100)	1031 (72.30)	395 (27.70)
Year 2019	583	-	583 (100)	313 (53.69)	270 (46.31)
Year 2020	415	-	415 (100)	290 (69.88)	125 (30.12)
Year 2021	428	-	428 (100)	428 (100)	0 (00.00)

Table 1. Diagnostic Testing Used Before and After Eradication Therapy
Abbreviations: RUT, Rapid Urease Test; UBT, Urea Breath Testing
**A patient may have ≥1 diagnostic test. One participant had both RUT testing and UBT at the index date.*

Conclusion: In China, non-invasive testing was dominant for the initial diagnosis of *H. pylori* infection, and ^{13}C UBT was commonly used compared with ^{14}C-UBT. The eradication efficacy evaluation testing was the same. Even over a tenth had insufficient evaluation duration, a higher proportion of evaluation duration >4 weeks was discovered with an increasing tendency.

Contact E-Mail Address: hangdao.fsh@gmail.com

Introduction: *H.pylori* infection is common in developing countries leading to of high prevalences of peptic ulcers and gastric cancer. However, the diagnostic tests such as rapid urease test or urease breath test requires facilities and patients need to go to medical sites, which raise a more and more need for non-invasive and convenient tests appropriate to community.

Aims & Methods: A cross-sectional study was conducted at the Institute of Gastroenterology and Hepatology, Hanoi, Vietnam to compare the *H.pylori* determination results of the qualitative detection of 2 antibodies specific to FliD and CagA with the rapid urease test and urease breath test in Vietnamese patients with upper gastrointestinal symptoms. Patients over 18 years old with upper GI symptoms and no prior history of treated peptic ulcers or *H.pylori* eradication were invited to participate in the study. Patients were indicated with upper GI endoscopy and three methods to diagnose *H.pylori* infection: Rapid Urease Test (RUT), Urease Breath Test (UBT), and qualitative detection of 2 antibodies specific to FliD and CagA (Pylori Duotect). Pylori Duotect is considered positive if either antibody for FliD and CagA are positive. The parameters for evaluating the diagnostic accuracy of Pylori Duotect include sensitivity, specificity, positive predictive values (PPV), and negative predictive values (NPV). Patients are considered *H.pylori* positive if both RUT and UBT are positive.

Results: From December 1, 2023, to April 20, 2024, 189 patients were recruited for the research. The mean age were 45.8 years old (min-max: 18-76 years old), 40.7% were female. The most common symptom of patients was epigastric pain (46.6%). There were 172 patients (91%) with gastritis, 27 patients (14.3%) with gastric ulcers and 16 (8.5%) with duodenal ulcers. Using the Pylori Duotect test, 50.8% of the patients were positive, in which 39.6% were positive with FliD and 86.5% were positive with CagA. Based on RUT and UBT results, 31.2% of patients were diagnosed with *H. pylori* infection. Pylori DuoTect's sensitivity, specificity, PPV, and NPV were 81.4%, 63.8%, 50.5%, and 88.3%, respectively.

Conclusion: The Pylori DuoTect test had low sensitivity and specificity in diagnosis *H. pylori* infection in patients with upper gastrointestinal symptoms.

Disclosure: Nothing to disclose.

Introduction: Helicobacter pylori (H. *pylori*) is a bacterium which inhabits the gastric epithelium and has been associated as a causative agent for dyspepsia, chronic gastritis, peptic and duodenal ulceration and gastric cancer. Testing for this pathogen is by Urea Breath Test (UBT) or OGD, and treatment varies according to local sensitivities and guidelines. H. *pylori* rates in developed countries have been falling in recent years as have those of associated conditions including gastric cancer, however increases in antimicrobial resistance recently has slowed this trend.

The current burden of disease either in asymptomatic population or symptomatic in Ireland is unknown, as are the rates of reinfection and recrudescence. Having up-to-date data on local epidemiology could have an effect on our strategy to detect and manage this class 1 carcinogen..

Aims & Methods: All UBTs performed in a tertiary hospital since 2016 were retrospectively assessed.

Demographic data & test results were taken from the UBT computer database and electronic patient record. All patients returning positive tests were offered appropriate antimicrobial therapy based on up to date local guidelines, and follow-up post-eradication testing by repeat UBT.

Results: From 2016-2023, 6716 UBTs were performed. 32 were excluded due to incomplete data. N=6684. 2752 (41.16%) were male, mean age was 43. Overall, 1589 (23.77%) tests were positive. There was no significant difference in positivity by gender (p=0.321). However there was a slight positive correlation with increasing age (AUC=0.5178 p=0.035). The positivity rate in our cohort reduced by roughly 2% per annum from 2016-22 (30%-18.5%).

Data on UBT type (Diagnostic vs Post-Eradication) was available from 2020-2023 when 3496 tests were performed and 2570 (73.5%) were diagnostic tests: 1060 (41.2%) male, mean age 41 years, 48 (19%) were positive. Positivity between genders was similar (p=0.3771). Conversely, in the post-eradication group n=926 (412, 44.5% Male), 259 (28%) were positive, females were more likely to remain positive post-therapy (32% vs 23%, X2=8.031, p=0.0046).

Over the 8 years, 747 patients returned positive tests (306 (41%) male). All were offered follow up testing. Males were significantly less likely to attend follow-up testing (140/306, 46% vs 254/441, 58%, p=0.0017)

In all 83 (2.4%) patients were re-tested for H. pylori after returning negative UBT tests due to persistent symptoms. Mean time to re-testing was 270 days, 34 (40%) were positive, representing 0.97% of the cohort.. Both genders were equally likely to have had a false negative UBT, male 10/30 versus 24/77 women, p=0.8214)

Conclusion: The overall positivity rate for diagnostic tests over the past 8 years was (19%) and is falling year on year.

The high positivity rate for post-eradication tests (28%) reflects rising antibiotic resistance.

The overall attendance rates for post-eradication tests after positive results were disappointing

Finally, the false negative rate in patients with persistent symptoms was high, 40% retested remained positive, raising the possibility of residual infection in our asymptomatic cohort.

Introduction: The Maastricht VI consensus recognizes the ^{13}C-urease breath test (^{13}C-UBT) as the "gold standard" in the diagnosis of *H. pylori* infection, including in patients with dyspepsia, in which this infection is detected quite often [1, 2]. Atrophic gastritis of the body of the stomach can cause both false-positive (due to the increased activity of urease producers other than *H. pylori*) and false-negative ^{13}C-UBT result (due to a decrease in the microbial load of *H. pylor*i associated with severe atrophy and metaplasia of the gastric mucosa and deterioration of habitual living conditions bacteria) [3]. Serological tests for the detection of *H. pylori* IgG are the primary screening method for *H. pylori* infection, recommended by the Maastricht VI consensus [1]. However, negative ^{13}C-UBT and *H. pylori* antigen in stool with positive antibodies in patients with CAG, it often causes difficulties in assessing the *H. pylori* status, which emphasizes the relevance of searching for new diagnostic predictors.

Aims & Methods: Aim: evaluate the role of ferritin in determining the presence of *H. pylori* infection. 143 patients aged from 20 to 79 years were examined. The mean age was 59 (49–66) years. All participants underwent serum determination of pepsinogen-I (P-I), pepsinogen-II (P-II), gastrin-17 and antibodies to H. pylori; esophagogastroduodenoscopy with biopsy according to the OLGA system. Confirmation of *H. pylori* infection was performed by assessing the presence of antigen in stool using immunochromatography. To confirm autoimmune gastritis (AIG), the level of antibodies to parietal cells and intrinsic factor was determined in the blood. The indicators of clinical and biochemical blood analysis of patients (iron levels, ferritin) were assessed. When not normally distributed, quantitative data were described using the median (Me) and lower and upper quartiles (Q1–Q3). Comparison of two groups according to a quantitative indicator, the distribution of which differed from normal, was carried out using the Mann–Whitney U test. Comparisons of percentages in the analysis of multifield contingency tables were performed using the Pearson chi-square test.

Results: In 69.2% of cases, when verifying the etiology of CAG, AIH was identified, in 21.7% *H. pylori*-associated gastritis was identified, in 9.1% - CAG of mixed etiology. There was a weak positive correlation between P-I and iron levels (ρ=0.220, p=0.01), as well as between P-I and ferritin levels (ρ=0.229, p=0.007), the ratio P-I/ P-II and ferritin ρ=0.286, p<0.001), P-I/P-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

II and iron level (ρ=0.229, p=0.007). There was no relationship between P-II and iron content in the blood (ρ=0.025, p=0.775), as well as no association of P-II with ferritin levels (ρ=-0.085, p=0.323). When analyzing the concentrations of iron and ferritin, no statistically significant differences were revealed in these indicators depending on the stage of atrophy in CAG. When comparing groups of patients with IDA and iron deficiency, no statistically significant differences in the etiology of CAG could be found (p=0.167). When comparing ferritin values depending on the presence/absence of *H. pylori* antigen in stool, statistically significant differences were noted in this parameter (negative – Me = 43.0, 19.8–59.0, positive – Me = 67.0, 51, 7–80.5, p<0.001).

Conclusion: The presence of iron deficiency does not depend on the etiology of chronic atrophic gastritis. A positive correlation was revealed between P-I, P-I/P-II and iron deficiency. Ferritin levels may be a promising diagnostic predictor of *H. pylori* infection in patients with CAG.

Contact E-Mail Address: ardilagastro@gmail.com

Introduction: Helicobacter pylori infection involves a high proportion of the Colombian population (1). It has been established that Helicobacter pylori infection increases the risk of developing gastric cancer (2). Multiple treatment regimens have been proposed to eradicate Helicobacter pylori, but it is not known which one could be associated with the best eradication rate in our population (3).

Aims & Methods: The aim of this research was to determine the factors most associated with the successful eradication of Helicobacter pylori in an adult population in Colombia.

An analytical cross-sectional study was conducted to assess risk factors associated with the eradication of Helicobacter pylori in an adult population in Colombia. The cross-sectional design facilitated data collection at a specific time point, while the analytical approach aimed to uncover connections between risk factors and the success of eradication.

A sample size calculation was performed for logistic regression using the Freeman formula. Based on estimated proportions of patients experiencing treatment failure, an approximate sample size of 400 patients was determined for the evaluation of 10 variables. Participant patients were adults diagnosed with Helicobacter pylori infection who were prescribed eradication treatment and underwent verification of eradication between January 1, 2022, and December 31, 2022. Patients with incomplete information, the pediatric population, or those without eradication verification were excluded from the analysis.

A descriptive analysis was conducted to characterize the sample and risk factors. Subsequently, a bivariate analysis examined the relationship between each independent variable and Helicobacter pylori eradication. Variables with a p-value < 0.05 in the bivariate analysis were included in a multivariate logistic regression model to identify independent risk factors associated with successful eradication. The multivariate analysis was adjusted for treatment adherence and compliance.

Results:

Variable	Odds ratio	95% Confidence Interval		p value
Proper treatment adherence*	13.72	3.1840	59.0874	< .001
Regimen with esomeprazole	4.97	1.1034	22.3592	0.037
Regimen with bismuth	2.04	1.1580	3.5977	0.014
Duration of the regimen: 14 days	7.21	1.2304	42.2908	0.029
Lactobacillus reuteri	1.79	0.8633	3.7249	0.117
Eradication regimen with amoxicillin	2.58	0.1512	43.9183	0.513
Eradication regimen with clarithromycin	6.88	0.4417	107.1126	0.169
Eradication regimen with metronidazole	6.94	0.4185	115.1961	0.176
Eradication regimen with levofloxacin	11.76	0.7801	177.1968	0.075

*Table 1. Multivariable analysis, factors associated with Helicobacter pylori eradication. * Adherence assessed by the Morisky-Green Test.*

A total of 386 patients were included in the study, of whom 74% achieved successful eradication of Helicobacter pylori. The multivariate analysis identified factors associated with successful eradication of Helicobacter pylori: proper adherence to the treatment, the inclusion of esomeprazole and bismuth subsalicylate in the treatment, and a eradication regimen duration of 14 days (Table 1).

Conclusion: Our results support the promotion of treatment regimens lasting 14 days. Strategies to ensure proper adherence to treatment should be encouraged, always incorporating esomeprazole and bismuth subsalicylate in the regimen.

HELICOBACTER PYLORI SECONDARY ANTIBIOTIC RESISTANCES: A GENOTYPIC STUDY ON STOOL SAMPLES

M. Mezzapesa[1], M. Piazzolla[1], I. Ditonno[1], M. Pricci[2], B. Girardi[2], F. Celiberto[1], G. Galeano[3], G. Riezzo[3], F. Russo[3], A. Iannone[1], E.G. Ierardi[1], A. Di Leo[1], G. Losurdo[1]

Contact E-Mail Address: martino.mezzapesa@gmail.com

Introduction: Helicobacter pylori (H. pylori) antibiotic resistances are the leading cause for unsuccessful eradication therapy. After one or more failures, the chance of encountering secondary antibiotic resistances increases. The aim of this study was to characterize genotypic secondary resistances in a cohort of Southern Italy H. pylori patients with at least one previous failure.

Aims & Methods: Patients with at least one previous eradication failure collected stool samples by a dedicated kit (THD fecal testTM) and bacterial DNA was extracted and amplified by RT-PCR. Resistance to clarithromycin, amoxicillin, metronidazole, levofloxacin and tetracycline was assessed by high-resolution melting curve.

Results: We enrolled 50 patients. The 72% failed one previous antibiotic course, the 16% two, the 10% three and the 2% four. The rate of secondary antibiotic resistance was 16% for clarithromycin, 18% for metronidazole, 14% for amoxicillin, 14% for levofloxacin and 2% for tetracycline. Multi-resistance was detected in 9 patients (18%) and double resistance to clarithromycin + metronidazole was the most common one (n = 5). Among patients with a previous failure to an amoxicillin-containing regimen, amoxicillin resistance was found in 4 out of 20 (20%). Among patients with a previous failure to a clarithromycin-containing regimen, resistance to such antibiotic was detected in 6 out of 19 (31.6%). Among patients with a previous failure to a metronidazole-containing regimen (n = 21), metronidazole resistance was found in 3 cases (14.3%). A failed levofloxacin-based therapy was given in 3 patients, but in none of them resistance was found (0%). Finally, among patients with a previous failure to a tetracycline-containing therapy, resistance to such antibiotic was detected in 1 out of 12 (8.3%)

Conclusion: In conclusion, our data seem to show that, despite secondary resistances are not so high, a resistance to clarithromycin could be very likely related to previous exposure to this antibiotic.

Disclosure: Nothing to disclose.

PP0270

THE FREQUENCY OF HELICOBACTER PYLORI INFECTION AND THE EFFECT OF ERADICATION THERAPY ON SYMPTOM IMPROVEMENT IN FUNCTIONAL DYSPEPSIA SUBGROUPS ACCORDING TO ROME IV CRITERIA: A STUDY FROM TURKEY WITH A HIGH PREVALENCE OF HELICOBACTER PYLORI

S. Demirbaş Yüceldi[1], M. Sadeçolak[2], A. Bilgili[2], M. Tozlu[2], A.T. Eminler[2], M.I. Uslan[2]

Introduction: Different pathophysiological mechanisms are thought to play a role in functional dyspepsia (FD) subgroups defined by Rome IV criteria. Studies are needed to determine whether Rome IV subgroups are linked to distinct pathophysiologies and treatment responses.

This study aims to investigate the impact of Helicobacter pylori (H. pylori) infection in the pathogenesis of each FD subgroups, subdivided according to the Rome IV consensus, within a high H. pylori prevalence country, Turkey.

The investigation centered on assessing the frequency of H. pylori and examining the impact of eradication therapy on alleviating symptoms, in each Rome IV subgroup.

Aims & Methods: Eradication treatment was applied to cases who were initially diagnosed with FD using the Rome IV criteria and subsequently found to have H. pylori gastritis through endoscopic biopsy. 8-12 weeks after treatment, H. pylori state was evaluated with fecal antigen test. Symptom responses were evaluated in each subgroup at 2, 6, and 12 months post-therapy using a Likert scale and statistically with SPSS version 23.0.

Results: The H. Pylori frequency was statistically more common in individuals with symptoms consistent with epigastric pain syndrome (EPS) (73.1% in EPS, 41% in postprandial distress syndrome (PDS), and 43.9% in overlapping subgroups (p< .001)).

With eradication treatment of H. pylori-positive cases, all subgroups demonstrated a significant response and the response rates didn't exhibit significant difference between subgroups (73.7% in total cases; 70.5% in EPS; 71.4% in PDS; 82.6% in overlapping, in the 12th month (p>0.05)). Eradicated patients showed significant symptomatic improvement with 70.2% in the 12th month. None of the non-eradicated patients experienced symptomatic improvement.

Subgroups	In EPS cases Responsive(n) / Total(n) (%)	In PDS cases Responsive(n) / Total(n) (%)	In overlapping cases Responsive(n) / Total(n) (%)	In all cases Responsive(n) / Total(n) (%)
Respond rate at 2nd month (%)	23/51 (45.1%)	15/39 (38.5%)	11/26 (42.3%)	49/116 (42.2%)
Respond rate at 6th month (%)	31/46 (67.4%)	18/35 (51.4%)	18/25 (72%)	67/106 (63.2%)
Respond rate at 12th month (%)	31/44 (70.5%)	20/28 (71.4%)	19/23 (82.6%)	70/95 (73.7%)

FD, functional dyspepsia; PDS, postprandial distress syndrome; EPS, epigastric pain syndrome

Table 2. The ratios of symptomatic response after H. pylori eradication therapy among FD Rome IV subgroups that received therapy, at 2nd, 6th, 12th month visits.

Conclusion: Using Rome IV consensus confirmed the data that H. pylori plays a notable role as a pathogenic factor in FD, particularly in EPS, and it is recommended to screen all FD subgroups, particularly EPS, for H. pylori and eradicate, if detected. Additionally, this study suggests that regions with a high H. pylori prevalence tend to have a higher H. pylori-associated dyspepsia prevalence.

Introduction: After a first eradication attempt, approximately 10-20% of patients will fail to achieve *H. pylori* eradication.

Aims & Methods: To evaluate the effectiveness of second-line empirical treatment.

A systematic, prospective, registry of the clinical practice of European gastroenterologists (38 countries) on *H. pylori* management was established. All infected adult patients were systematically registered at AEG-REDCap e-CRF until December 2023. Modified intention-to-treat (mITT) and per-protocol (PP) analyses were performed.

Results: Overall, 8,984 patients received a second-line empirical therapy. Mean age was of 50 years, 66% were women, and 5% had penicillin allergy. Most frequent treatment indications were dyspepsia (70%) and gastroduodenal ulcer (15%). Overall effectiveness was 83% (both by mITT and PP). Over 96.5% of patients were compliant.

Adverse events were reported in 23% of the cases, most of them mild. Most frequent second-line prescriptions and their effectiveness by region is shown in table 1.

None of the European regions achieved an optimal effectiveness. However, in those patients receiving optimised therapy (i.e., 14-days and high dose PPIs), triple regimens containing levofloxacin and bismuth quadruple therapies either with metronidazole-tetracycline or clarithromycin-amoxicillin, as well as quadruple therapy with clarithromycin-amoxicillin-metronidazole, showed optimal effectiveness. Also, 10-day bismuth quadruple therapy as single-capsule achieved over 90% cure rates when prescribed with standard PPI doses. After failure of first-line clarithromycin-containing therapy, optimal eradication was only obtained with moxifloxacin-containing triple therapy (92%). Quadruple therapy with clarithromycin-amoxicillin-metronidazole and bismuth quadruple therapies either with clarithromycin-amoxicillin, amoxicillin-levofloxacin or the single-capsule provided encouraging results (>85%).

Treatment	N	Use (%)	mITT, N (%)	(95% CI)	PP, N (%)	(95% CI)
Triple-A+L	2,212	25.5	1,959 (81)**	(79-83)	1,936 (81)	(79-83)

Overall (optimised conditions)	2,005	23.1	1,747 (89)	(87-90)	1,709 (89)	(88-91)
East	1,425	15.9	1,159 (84)	(82-86)	1,121 (84)	(82-87)
East-Centre	1,625	18.1	1,160 (84)	(82-86)	1,147 (84)	(82-87)
South-West	4,190	46.7	3,973 (83)	(82-85)	3,895 (84)	(83-85)
West-Centre	1,103	12.3	979 (84)	(82-87)	962 (85)	(82-87)
North	631	7.0	547 (72)	(68-76)	530 (73)	(69-77)
Total	8,974	100	7,803 (83)	(82-84)	7,641 (83)	(83-84)

95% CI –confidence interval; mITT: modified intention-to-treat; PP: per-protocol, N: total number of patients analysed; C – clarithromycin; M – metronidazole; A – amoxicillin; L – levofloxacin; B – bismuth salts; Tc – tetracycline; R – rifabutin; Mx – moxifloxacin; Other – Other second-line empirical treatments with less than 150 patients treated in each category; East – Ukraine, Serbia, Bulgaria, Turkey, Russia , Romania, Albania, North Macedonia; East-Centre – Croatia, Poland, Hungary, Latvia, Lithuania, Greece, Slovenia, Czech Rep, Azerbaijan, Slovakia, Malta; South-West – Portugal, Spain; West-Centre – France, Austria, Belgium, Germany, Italy; North – United Kingdom, Finland, The Netherlands, Ireland, Israel, Norway, Switzerland, Sweden, Denmark; *three-in-one single-capsule containing metronidazole tetracycline and bismuth; **achieved over 90% effectiveness when optimised (high-dose PPIs and 14-days length in all schemes but the single-capsule optimised with standard-dose PPIs).

Table 1. Second-line empirical treatment prescriptions and effectiveness by treatment scheme and geographical region.

Conclusion: In Europe, empirical second-line treatment achieves optimal effectiveness with bismuth quadruple therapy as single-capsule when prescribed standard doses of PPIs, and when regimens including triple therapy with levofloxacin, quadruple therapy with clarithromycin-amoxicillin-metronidazole and bismuth quadruple therapies with metronidazole-tetracycline or clarithromycin-amoxicillin are prescribed for 14 days and with high-dose PPIs.

Many other second-line treatments evaluated achieved low eradication rates.

Introduction: The effectiveness of first-line treatment for *H. pylori* infection varies between countries. Local data are necessary to guide clinical practice. We aimed to assess the effectiveness of first-line eradication treatments for *H. pylori* in Israel.

Aims & Methods: International, multicenter, prospective, non-interventional registry aiming to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists (Hp-EuReg).

All infected adult patients treated with a first-line therapy at 10 centers in Israel between 2013 and 2023 were registered at e-CRF AEGRedCap and were included in the current study.

Effectiveness was assessed by modified intention-to-treat (mITT) and per-protocol (PP) analyses.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 663 cases were registered, where 320 (48%) had received a 1st line empirical therapy with an average age of 51±18 years and 183 (57%) were females. The most common indication for *H. pylori* investigation was dyspepsia (67%). Infection was diagnosed with histology (56%), ^{13}C-Urea breath test (22%), rapid urease test (17%) and monoclonal stool Ag test (5.3%). Quadruple concomitant therapy with PPI-clarithromycin-amoxicillin-tinidazole was the most frequent 1st line treatment (43%), mostly prescribed for 14 days (87% of the patients) and with high-dose PPIs (91% of the cases), followed by triple therapy with PPI-clarithromycin-amoxicillin (16%) and quadruple concomitant therapy with PPI-clarithromycin-amoxicillin-metronidazole (12%). The majority of prescriptions were of 14-day (70%) length, followed by 10-day (22%) and 7-day (7.3%) duration. High potency proton pump inhibition (PPI) was prescribed to most patients (75%).

Overall treatment success was 84% (160/191) and 86% (155/181) by mITT and PP, respectively, with the highest effectiveness provided by 10-day and high-dose PPIs of sequential therapy with clarithromycin-amoxicillin-tinidazole (89.5% by mITT), and by 14-day and high-dose PPIs of concomitant therapy with clarithromycin-amoxicillin-tinidazole (85% by mITT). Longer treatment durations and higher PPI doses provided better cure rates. Treatment effectiveness did not change significantly during the study period, and remained suboptimal (<90%) over the years. Compliance (>90% drug intake) was 97%. The incidence of at least one adverse event was reported in 10%, necessitating treatment cessation in 1.5%.

	Use, n (%)	mITT Success n/N (%)	PP Success n/N (%)
Treatment scheme			
Triple-C+A	49 (16.1)	36/44 (81.8)	36/44 (81.8)
Sequential-C+A+T	20 (6.6)	17/19 (89.5)	17/19 (89.5)
Quadruple-C+A+T	132 (43.3)	73/86 (84.9)	71/80 (88.8)
Quadruple-C+A+M	38 (12.5)	13/13 (100)	13/13 (100)
Treatment Duration			
7 days	22 (7.3)	16/20 (80)	16/20 (80)
10 days	68 (22.4)	43/50 (86)	42/49 (85.7)
14 days	213 (70.3)	92/111 (82.9)	88/102 (86.3)
Potency of acid inhibition*			
Low	63 (20.6)	48/58 (82.8)	47/57 (82.5)
Standard	12 (3.9)	6/6 (100)	6/6 (100)
High	231 (75.5)	105/125 (84)	101/116 (87.1)
Overall	320 (100)	160/191 (83.8)	155/181 (85.6)

Abbreviations: n: total number of patients analysed; mITT, modified intention to treat; PP, per-protocol; C, clarithromycin; A, amoxicillin; T, tinidazole; M, metronidazole; *Low dose PPI – 4.5 to 27 mg omeprazole equivalents. b.i.d.; standard dose PPI – 32 to 40 mg omeprazole equivalents. b.i.d.; high dose PPI – 54 to 128 mg omeprazole equivalents. b.i.d.

Table: Empirical first-line therapy effectiveness by modified intention-to-treat and per-protocol analyses, by treatment duration and acid inhibition in Israel.

Conclusion: In Israel, empirical first-line treatment for *H. pylori* eradication is still suboptimal (<90%). Treatments should consist of four drugs and should be optimised with a 14-day duration and standard/high doses of PPIs.

Disclosure: None.

Introduction: The link between the misuse in global antibiotic consumption and increased antimicrobial resistance is well documented. Clarithromycin-based anti-*H. pylori* eradication therapy as a triple regimen (encompassing a PPI plus two antibiotics) has been used empirically worldwide without antimicrobial susceptibility testing. In the last decade, a marked decreased in the effectiveness of clarithromycin-based regimens has been observed globally.

Aims & Methods: This study aimed at exploring the potential relationship between the consumption of macrolides in the overall population as a factor influencing the effectiveness of *H. pylori* clarithromycin-containing regimens.

Data from the European Registry on *Helicobacter pylori* management (Hp-EuReg) were used for this analysis. A multivariate logistic regression was built using the modified intention-to-treat (mITT) effectiveness analysis as the outcome and the following main effects: first-line treatment scheme (using the 10 most frequent antibiotic combinations), duration of treatment (as 7, 10 or 14-day lengths), proton-pump inhibitor (PPI) dose (categorised as low, standard, or high; that is, 20 mg, 40 mg or 80 mg omeprazole equivalent twice a day), compliance (that is, >90% of drug intake), and clarithromycin consumption expressed as daily doses per 1,000 inhabitants per day. Data of macrolide community consumption was taken from the European Surveillance of Antimicrobial Consumption Network (ESAC-Net). Hierarchical nested models were constructed by adding macrolide consumption, matching by year and country with the corresponding patients' therapy, and the interaction between consumption and treatment scheme (taken from the Hp-EuReg).

Results: In total, 28,590 first-line treated patients from 24 European countries participating in the Hp-EuReg, on which data of macrolides consumption in the period 2013-2022 was available, were evaluated. Three nested models were analysed: the first one with the main effects without including macrolides consumption (A), the second with the full set of main effects (including macrolides consumption) (B) (likelihood ratio test A-B p-value=$2.11.10^{-2}$), and the third one included both macrolides consumption and interactions between this main effect and treatments (C) (likelihood ratio test B-C p-value=$4.08\ 10^{-10}$). Model B (without interactions) showed a global decrease in treatment mITT effectiveness (OR: 0.95 [0.91-0.99]). Model C (with interactions) showed a significant decrease in the mITT effectiveness in three different treatments (Table): triple-clarithromycin-metronidazole (OR: 0.37 [0.25-0.53]), triple-clarithromycin-amoxicillin (OR: 0.60 [0.43-0.82]), and sequential-clarithromycin-amoxicillin-metronidazole/tinidazole (OR: 0.60 [0.43-0.84]); whereas, bismuth quadruple therapy (single capsule) remained unaffected.

Introduction: Gastric lesions associated with *Helicobacter pylori*, eradication issues and problems of its sometimes-insufficient effectiveness continue to remain one of the most pressing topics in modern healthcare.

Aims & Methods: The analysis aimed to assess the usage, efficacy, and safety of initial empirical treatment for *H. pylori* infection in Azerbaijan.

Data were collected at e-CRF AEG-REDCap from the European Registry on *Helicobacter pylori* Management (Hp-EuReg) and quality reviewed from January 2020 to May 2023. All treatment-naïve cases were assessed for effectiveness by modified intention-to-treat (mITT), per-protocol (PP) analyses, and a separate multivariate analysis was performed.

Results: The study included 3,898 patients (67% reported dyspepsia). In 1.9% of patients, at least one type of allergy was reported (1.6% to penicillin). A total of 226 patients (5.8%) received concurrent medication: PPI (5.1% on demand, 0.1% daily), aceltylsalicylic acid (1.2% on demand, 0.2% daily), NSAIDs (1.3% on demand), statins (1.2% on demand, 0.1% daily).

The most frequent indication for treatment was dyspepsia with normal endoscopy in 2,610 patients (67%). In total, 3,853 (99%) patients were diagnosed pre-treatment using the rapid urease test, which was the most frequently used. The following tests were likewise used in a lower number of cases: monoclonal stool antigen test (MSAT)(0.7%) and polyclonal stool antigen test (0.1%). In 2,661 (68%) cases a MSAT was used, being the most frequent post-treatment confirmation method. Additionally, in 55 (1.4%) cases an invasive method, that is endoscopy, was performed, to confirm the eradication. First-line empirical treatment prescriptions and mITT effectiveness by treatment schemes is presented in Table 1.

Triple regimens were the most frequently prescribed in over 3,000 (82%) patients, where the PPI-C+A treatment scheme represented 54% of the total of first-line prescriptions. Treatment length varied from 14 days in 56% of cases, 10 days in 27%, and 7 days in 17%. Following 14-day treatments prescriptions achieved optimal (>90%) mITT effectiveness: PPI-C+A (94%), PPI-C+M (97%), PPI-C+M+ B (96%) and PPI-C+A+B (98%). Following schemes also provided optimal results when combined with standard-dose (i.e., 40 mg omeprazole equivalent twice a day) PPIs: PPI-A+Tc (100%) and PPI-C+A+B (96%). Additionally, prescriptions concomitantly administered with high-dose (i.e., 80 mg omeprazole equivalent twice a day) PPIs provided also over 90% eradication rates: PPI-C+A (94%), PPI-C+M (97%), PPI-C+M+B(100%) and PPI-C+A+B (99%). Compliance with treatment was over 90% in the vast majority of cases. The incidence of at least one adverse event was reported in 12% of cases.

Treatment	Number of prescriptions	Use (%)	mITT, N (%)	PP, N (%)	mITT, N (%) Low-dose PPI	mITT, N (%) Standard-dose PPI	mITT, N (%) High-dose PPI
Triple-C+A	2,117	54.3	1,832 (91,2%)	1,819 (95.2%)	873 (91.2%)	527 (89.3%)	420 (93.8%)
Triple-C+M	760	19.5	584 (93,3%)	581 (96.5%)	326 (93.4%)	89 (86.4%)	167 (97.1%)
Quadruple-C+A+B	610	15.6	579 (98%)	574 (99.8%)	219 (98.2%)	187 (96.4%)	178 (99.4%)
Triple-A+L	159	4.1	124 (82,1%)	124 (99.2%)	52 (82.5%)	68 (81.9%)	4 (80.0%)
Triple-A+Tc	75	1.9	71 (94,7%)	71 (100.0%)	28 (93.3%)	43 (95.6%)	NA
Quadruple-C+M+B	44	1.1	40 (95,2%)	40 (100.0%)	26 (100.0%)	6 (75.0%)	8 (100.0%)
Other	44	1.1	114 (90,5%)	113 (97.4%)	55 (93.2%)	55 (90.2%)	4 (66.7%)
Total	3,809	97.6	3,344 (92.4%)	3,322 (96.6%)	68 (92.5%)	975 (89.9%)	776 (95.4%)
A-amoxicillin, C- clarithromycin, M- metronidazole, L- levofloxacin, Tc- tetracycline, B - bismuth			mITT-modified Intention-to-treat;	PP: per protocol analysis;	low-dose PPI, between 4.5 and 27 mg omeprazole equivalents given twice a day;	standard-dose PPI, between 32 and 40 mg omeprazole equivalents given twice a day;	high-dose PPI, between 54 and 128 mg omeprazole equivalents given twice a day; NA: not available data.

Table 1. Most frequent first-line empirical treatment prescriptions and modified intention-to-treat effectiveness in Azerbaijan.

Conclusion: The prescribed *H. pylori* eradication regimens during the period 2020–2023 in Azerbaijan adhered only partially to the Maastricht VI recommendations; however, most of first-line empirical therapies achieved high (≥90%) cure rates, providing a good safety profile.

Disclosure: Nothing to disclose.

Introduction: In light of the growing global problem of antibiotic resistance, eradication of clarithromycin (CLA)-resistant *Helicobacter pylori* (*H. pylori*) strains has been recognized as a top priority health problem. Poor antibiotic stewardship, and the complexity of antibiotic resistance patterns, has made *H. pylori* gastritis the most prevalent infectious disease. Pretreatment assessment of *H. pylori* antibiotic sensitivity has been suggested as a reasonable solution in overcoming antibiotic resistance and treatment failure.

Aims & Methods: The aim of the study was to assess the prevalence and pattern of *H. pylori* resistance towards most common prescribed antibiotics, through the use of molecular, PCR-based technique. A multicentric, prospective registry of the clinical practice of European gastroenterologists on the management of *H. pylori* (Hp-EuReg) collects since 2013 the real clinical practice of European gastroenterologists. Adults *H. pylori*-infected and PCR-tested patients registered at AEG REDCap e-CRF were analysed. Two types of molecular testing were performed: a non-invasive (stool sample PCR) and an invasive (gastric sample PCR) test.

Results: In total, 265 *H. pylori* patients were tested, of which 130 were treatment-naive cases and 135 had already received at least one eradication attempt. In treatment-naïve cases, CLA resistance (CLA-R) was 31%, fluoroquinolone resistance (FLQ-R) was 33% and metronidazole resistance (MET-R) was 14% (Table).

There was no statistically significant difference in the bacterial resistance rate of tested antibiotics based on the gender and age distribution. In the rescue line, CLA-R was 62%, FLQ-R was 53% while MET-R was 7% (Table). Multiple eradication attempts significantly increased CLA-R (53% vs. 79% vs. 100%, for the 2^{n}, 3rd and 4th line respectively, p=0.001).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Antibiotics	First line (n, %)	Rescue line (n, %)
Clarithromycin	40, 31%	84, 62%
Fluoroquinolones	43, 33%	72, 53%
Metronidazole	18, 14%	10, 7%

Table. PCR-detected resistance to most common prescribed antibiotics in Europe.

Conclusion: Alarmingly high *H. pylori* resistance to CLA and FLQ as well as its steep increase following multiple eradication attempts, implies an urgent need of continuous and systematic antibiotic stewardship, in order to further optimise *H. pylori* eradication strategies.

Introduction: Lithuania remains in the area with a high prevalence of *H. pylori* infection, which is estimated to be ~30-40%. Therefore, it is important to analyze the local *H. pylori* management in order to achieve better treatment results.

Aims & Methods: To evaluate the trends and effectiveness of *H. pylori* first- and second-line treatment prescriptions in Lithuania during 2013-2023.

Prospective, multicenter, international, non-interventionist registry on the management of *H. pylori* (Hp-EuReg) by European gastroenterologists. Lithuanian data from 2013 to 2023 were analysed. The effectiveness of the five most frequent first- and second-line *H. pylori* eradication prescriptions was evaluated using the modified intention-to-treat (mITT) analysis.

Results: In total 4,168 patients from Lithuania were included in the Hp-EuReg. The confirmation of *H. pylori* eradication was assessed in 37% of the first-line and 44% of the second-line cases. The overall first-line treatment effectiveness was 88%; the effectiveness of the most frequent first-line treatment prescription (standard triple therapy with amoxicillin and clarithromycin) increased from 78% in 2013 to 95% in 2023, obtaining the optimal (>90%) cure rates during the last 4 years. The overall second-line treatment effectiveness was 91%; the overall effectiveness of the most frequent second-line treatment prescription (triple therapy with amoxicillin and levofloxacin) was 92%. Since 2020 this triple therapy was taken over by bismuth quadruple therapy with amoxicillin and levofloxacin in prescription frequency – this quadruple regimen managed to maintain optimal eradication effectiveness rates during the last 6 years. The trends and effectiveness of other most frequent first- and second line prescriptions are presented in Table 1.

First-line treatment	Years period								
	2013-2016			2017-2020			2021-2023

mITT – modified Intention-to-Treat analysis; C- clarithromycin; A – amoxicillin; B – bismuth; L – levofloxacin; M – metronidazole; 95% CI – 95% confidence interval; N/A – not applicable;

Table 1. Most frequent first- and second-line prescriptions and their modified intention-to treat (mITT) effectiveness in Lithuania during 2013-2023.

Conclusion: During 2013-2023 there was a trend of increasing *H. pylori* eradication effectiveness of the main first-line prescription, managing to maintain optimal cure rates in the last 4 years. There has been an increase in first- and second-line quadruple therapies prescriptions since the year 2018.

PP0278

COMPARISON OF ERADICATION EFFICACY OF 1-WEEK METRONIDAZOLE TRIPLE REGIMEN WITH BISMUTH ADD-ON AND 2-WEEK BISMUTH QUADRUPLE REGIMEN FOR H PYLORI WITH CLARITHROMYCIN RESISTANCE-RELATED GENE MUTATION (A2143G)

K.A. Jang[1], D.Y. Cheung[1], T.H. Kim[2]

Introduction: In regions where there is a prevalence of clarithromycin resistant strains, 2-week bismuth quadruple therapy (PBMT) is recommended as the first-line treatment. In cases where CLA resistance-related genetic mutations are identified, 1-week metronidazole triple therapy is recommended. The aim of this study is to investigate whether 1-week bismuth-added metronidazole triple therapy (PBMA) therapy can achieve equivalent efficacy to 2-week PBMT therapy.

Aims & Methods: This study was a multicentred retrospective analysis using electronic medical records, employing propensity score matching to analyze the results. The study population consisted of individuals who were confirmed to have H. pylori infection with clarithromycin resistance-associated genetic mutation (A2143G) using PCR and who were administered either 2-weeks PBMT or 1 week PBMA.

Results: From October 2019 to May 2023, a total of 121 patients were confirmed for H. pylori infection and clarithromycin resistance-related genetic mutations using PCR. Among them, 6 patients with the A2142G mutation were excluded, leaving 115 patients with the A2143G mutation for analysis. Out of these 115 patients, retrospective analysis was conducted on 82 patients who underwent UBT testing at least 4 weeks after completing the antibiotic regimen and had complete medical records.

Among the 82 patients analyzed, 51 had received the conventional 2-week PBMT while 31 had received a 1-week PBMA. Propensity score matching was performed for gender, age, and body mass index, factors suspected to influence the efficacy of eradication, resulting in 25 matched cases in each group.

The baseline characteristics, including age and gender distributions, did not differ significantly between the two groups of analyzed subjects.

The efficacy of eradication therapy was confirmed through UBT conducted 4-8 weeks after treatment. In the analysis before propensity score matching (PSM), the eradication rates for the 2-week PBMT group and the 1-week PBMA group were 70.6% and 77.4% in the intention-to-treat (ITT) analysis, respectively, and 94.7% and 85.7% in the per-protocol (PP) analysis, respectively. There was no significant difference between the two groups in both analyses.

After PSM, the analysis still showed no significant difference between the 2-week PBMT group and the 1-week PBMA group. In the ITT analysis, the eradication rates were 68.0% for the OBMT2w group and 80.0% for the OAM+B1w group, while in the PP analysis, the rates were 94.4% for the OBMT2w group and 87.0% for the OAM+B1w group.

Regarding adverse events, there was no difference in the frequency of adverse events between the two groups. However, the need to discontinue medication occurred in 5.3-5.6% of cases in the 2-week PBMT group but did not occur in the 1-week PBMA group. Nonetheless, changes in bowel habits were more common in the 1-week PBMA group, with the main reason being a change to dark-colored stool.

Conclusion: For patients infected with H. pylori carrying the A2143G point mutation, there was no difference in the eradication rate between the 2-week PBMT regimen and the 1-week PBMA regimen. The 1-week PBMA regimen showed superior drug compliance and a tendency for fewer adverse effects compared to the 2-week PBMT regimen.

INITIAL RESULTS OF THE FOLLOW-UP OF A GISTAR PARTICIPANT COHORT FOR ASSESSING THE POTENTIAL NEGATIVE LONG-TERM EFFECTS OF *HELICOBACTER PYLORI* TEST AND TREAT

D. Razuka-Ebela[1], N. Sapurovs[1], I. Polaka[1], S. Parshutin[1], I. Ebela[2], Y. Tarasenko[1], D. Santare[2], M. Leja[1]

Introduction: These are the initial results based on currently ongoing follow-up of the participants in the GISTAR study in Latvia (Multicentric randomized study of *H. pylori* eradication and pepsinogen testing for prevention of gastric cancer mortality) within the EUROHELICAN project.

Aims & Methods: The aim was to investigate the potential adverse health effects of the *Helicobacter pylori* (*H. pylori*) test-and-treat strategy in the long term. Baseline data on sociodemographic and lifestyle factors, medical history, body mass index (BMI), waist to hip ratio (WHR), and blood pressure were collected 5 to 11 years ago. Blood samples were also drawn. Participants in the intervention group were tested for *H. pylori* (initially with serology, then urea breath test (UBT)). Those who tested positive were offered eradication therapy. Participants in the control group were not tested for *H. pylori* and received regular healthcare. During follow-up, data on the same characteristics were collected. UBT was performed for those who were *H. pylori* positive at baseline. The symptom-based GERDQ score was assessed at the follow-up. The change in parameters from baseline to follow-up was examined between groups using chi-square and Mann-Whitney tests in SPSS 29.0.

Results: A total of 1305 GISTAR participants were recruited at follow up within EUROHELICAN. Their median age was 60 years (IQR 11). Among them, 57 % were female, of whom 691 (53%) were in the intervention group. Baseline data on *H. pylori* status and eradication were available for 687 participants, of whom 423 (61.6%) were positive at baseline.

When comparing differences in the change of characteristics between baseline and follow-up in the treated (n = 356, 51.8%) and non-treated groups (331, 48.2%), there were no significant differences in BMI, WHR, systolic and diastolic blood pressures (Table 1).

When examining changes in characteristics of participants in the eradicated (n = 281, 84%) and non-eradicated (53, 15.9%) groups, there were no significant differences in BMI and blood pressure. There was a significant difference in the WHR change.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Characteristics	Treated (n = 356, 51.8%)	Not treated (n = 331, 48.2%)	p value	Eradicated (n = 281, 84%)	Non-eradicated (n = 53, 15.9%)	p value
	Median, interquartile range (IQR)	Median, interquartile range (IQR)		Median, interquartile range (IQR)	Median, interquartile range (IQR)	
BMI	1.01 (2.55)	0.91 (2.90)	0.38	1.06 (2.65)	1.05 (2.61)	0.75
WHR	0.00 (0.05)	0.01 (0.05)	0.06	0.0003 (0.05)	0.02, 0.07	0.03

Table 1. Comparison of the change in values from baseline to follow-up between groups.

Using GERDQ at least 8 points, 40 (11.3%) met the cut-off for GERD in the treated group versus 48 (14.9%) in the non-treated group (p = 0.16). The prevalence of GERD was 30 (10.9%) in the eradicated versus 5 (9.6%) in the non-eradicated group (p = 0.78).

Conclusion: The project will provide data missing on the potential negative effects of eradication. So far, no negative effects were confirmed. The study is ongoing, and a larger number of participants will be included. More data will be available to better assess whether there is a significant change in parameters covered in this abstract as well as additional variables pertaining to GERD, and potential metabolic and cardiovascular effects.

Introduction: According to recent studies, the prevalence rate of *H. pylori* infection in Russia is over 30%, but a decreasing trend has recently been observed. Comprehensive multicenter evaluation of effectiveness of different eradication treatments in Russia has not yet been performed. One of the most efficient tools of such analysis is the on-going European Registry on *H. pylori* Management (Hp-EuReg), an international, prospective, multicenter, observational study, which begun in 2013.

Aims & Methods: The objective of our study was to evaluate the effectiveness of first-line empirical eradication therapy in Russia between 2013-2022 according to the data of Hp-EuReg. The treatment effectiveness was analysed by per-protocol (PP), and modified intention-to-treat (mITT), also stratifying by PPI dose (low dose - 4.5 to 27 mg omeprazole equivalent, twice daily; standard dose - 32 to 40 mg omeprazole equivalent, twice daily; high dose - 54 to 128 mg omeprazole equivalent, twice daily) and duration of treatment (7, 10 or 14 days).

Results: Overall, 8,354 patients from 14 cities in Russia who had received a first-line empirical eradication therapy between 2013 and 2022, were included. Invasive (i.e. endoscopic) methods (rapid urease test, histology/cytology) for the *H. pylori* primary evaluation were mostly used in almost all cities. The highest rate of ^{13}C-urea breath test was observed in Rostov-on-Don (89% of cases), Saint-Petersburg (37%), Omsk (25%), Perm (25%), and Moscow (23%). The most frequently used first-line treatments were: triple (PPI, amoxicillin, clarithromycin) and triple plus bismuth (PPI, amoxicillin, clarithromycin, bismuth) therapies, accounting for more than 60% of prescriptions in almost all cities. Most cities prescribed 14-day length therapies; whereas standard PPI doses were most frequently used in Chelyabinsk (94%), Smolensk (84%), Saint-Petersburg (68%), Moscow (67%), Khabarovsk (66%) and Rostov-on-Don (54%), low PPI doses prevailed in Krasnoyarsk (80%), Izhevsk (70%), Novosibirsk (65%), Omsk (60%), and Kazan (52%). Quadruple therapy with PPI, amoxicillin, clarithromycin and bismuth achieved optimal (>90%) mIIT effectiveness in Saint-Petersburg, Perm, Chelyabinsk, and Khabarovsk, where it was more frequently used than in the remaining cities. Effectiveness of triple therapy (PPI, amoxicillin, clarithromycin) varied from 62% (Novosibirsk) to 99% (Omsk), achieving over 85% across all cities. However, high eradication rates with triple therapy prescriptions were observed in the cities with a small number of

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. patients or in those cases where histology were the unique tests used for eradication control, possibly giving false negative results. Classic bismuth quadruple therapy (PPI, tetracycline, metronidazole, bismuth) provided optimal (>90%) mITT effectiveness in Moscow and Saint-Petersburg, where it was predominately used as compared to other cities (table 1).

Eradication therapy	Moscow	St. Peters-burg	Kazan	Perm	Kovrov	Chelyab-insk	Khaba-rovsk	Rostov-On-Don	Smolensk	Che-boksary	Omsk	Kras-noyarsk	Novosi-birsk	Izhevsk	Overall
Triple therapy (PPI+A+C)	83.4%	87%	77.2%	89.2%	76.1%	96.3%	72.6%	88.3%	78%	94%	99.1%	81.7%	62%	100%	83.1%
Quadruple therapy (PPI+M+Tc+ bismuth)	92.1%	91.4%	100%	100%	80%	100%	100%	-	100%	100%	100%	-	-	-	92.9%
Quadruple therapy (PPI+A+C+ bismuth)	88.3%	93.1%	86.4%	95.2%	87.3%	100%	92.4%	100%	86.7%	96.2%	100%	-	71.4%	91.2%	92.7%

Table.1 Effectiveness by modified intention-to-treat of most common first-line empirical therapies in 14 cities of Russia in 2013-2022

PPI: proton pump inhibitor; A: amoxicillin; C: clarithromycin; M: metronidazole; B: bismuth salts; Tc: tetracycline

Conclusion: To date, in Russia, bismuth quadruple therapies either with classical metronidazole-tetracycline-bismuth or amoxicillin-clarithromycin-bismuth achieve optimal (> 90%) results, providing significantly better rates when prescribed for 14 days

Disclosure: Nothing to disclose.

Introduction: *Helicobacter pylori* (HP) is regarded as a class I carcinogenic factor and eradication therapy can reduce the risk of gastric cancer. Patients with HP infections are administered with bismuth quadruple therapy (BQT), triple and dual therapies based on their eradication effectiveness. BQT (bismuth + acid suppressants + 2 antibiotics) and dual therapy are both recommended in China now. Comprehensive understanding on the distribution of current eradication therapies is required to identify gaps observed in real-world practice.

Aims & Methods: This multicenter, retrospective, real-world study (NCT05073367) extracted preexisting electronic data including adult patients (aged ≥18 years) with HP infection between January 1, 2019 and March 31, 2021 from 3 hospitals to assess the diagnosis and treatment pattern of HP infection and effectiveness of eradication therapy in China. In this abstract, we reported the distribution of eradication therapies, difference in initiation year for treatment, and treatment duration.

Results: Of the 22,971 eligible patients with HP infection, 13,233 (57.61%) were prescribed eradication regimens. Mean ± SD age of patients with eradication treatment was 43.7 ± 14.0 years; 65.94% of patients had medical insurance; and 54.50% of patients were women.

In patients who received eradication therapy, the BQT therapy was predominantly prescribed (85.39%; n=11301), followed by triple therapy (7.55%; n=999) and dual therapy (7.06%; n=934). Among those receiving BQT, use of amoxicillin + clarithromycin based regimens (38.72%; n=4376) were the most prevalent, followed by amoxicillin +furazolidone (18.35%; n=2074) and amoxicillin + levofloxacin (17.76%; n=2007) based combination regimens. Proportion of patients receiving BQT decreased over years: 97.24% patients in 2019, 79.98% in 2020, and 78.71% in 2021. The proportion of patients receiving dual and triple therapy increased over the years in 2019, 2020, and 2021 were shown in Table 1. A total of 10,903 patients were analyzed according to various treatment durations with the usage of various eradication therapies. Treatment duration is defined as the number of days that prescribed drugs can cover. Out of the three types of treatments, BQT had the highest proportion of 14-day treatment duration at 90.16%, followed by triple therapy at 76.78%, while dual therapy had the least proportion at 14.42%. For treatment duration >14 days, BQT, dual and triple therapy had a proportion of 4.38%, 82.35%, and 17.27% respectively.

Treatment	Type of Eradication therapy (N=13, 234) n (%)[a]	Year of treatment initially prescribed , 2019 (N=4492) n (%)[a]	Year of treatment initially prescribed, 2020 (N=4125) n (%)[a]	Year of treatment initially prescribed, 2021 (N=4616) n (%)[a]
Total	13,234[b] (-)	4492 (-)	4125 (-)	4617 (-)
Bismuth quadruple therapy	11,301 (85.39)	4368 (97.24)	3299 (79.98)	3634 (78.71)
Amoxicillin and Clarithromycin	4376 (38.72)	1800 (41.21)	1324 (40.13)	1252 (34.45)
Amoxicillin and Furazolidone	2074 (18.35)	689 (15.77)	480 (14.55)	905 (24.90)
Amoxicillin and Levofloxacin	2007 (17.76)	1021 (23.37)	516 (15.64)	470 (12.93)
Amoxicillin and Metronidazole	76 (0.67)	27 (0.62)	10 (0.30)	39 (1.07))
Amoxicillin and Tetracycline	9 (0.08)	5 (0.11)	1 (0.03)	3 (0.08)
Furazolidone and Tetracycline	12 (0.11)	1 (0.02)	0 (0.00)	11 (0.30)
Other Bismuth quadruple	2747 (24.31)	825 (18.89)	968 (29.34)	954 (26.25)
Triple therapy[c]	999 (7.55)	105 (2.34)	551 (13.36)	343 (7.43)
Dual therapy[c]	934 (7.06)	19 (0.42)	275 (6.67)	640 (13.86)

Table 1. Distribution of eradication therapy based upon the type and year of treatment initiation

Abbreviations: N, total number; n, number in respective category.

[a]% = The total usage count of BQT or Triple or Dual eradication therapy/the total usage count of all standard eradication therapies received by eligible participants. Of BQT, the total usage count of different BQT/the total usage count of all BQT.

[b]There is a recurrent patient who changed the treatment pattern from triple therapy (ilaprazole, clarithromycin, levofloxacin) to dual therapy (ilaprazole, ornidazole) after the recurrence.

[c]Considering the table size, outcomes of different treatment regimens under dual and triple therapy were not included in the table.

Conclusion: BQT-based regimen for 14 days was the predominant eradication regimens in all therapies, amoxicillin + clarithromycin based BQT was the most prevalent. Use of dual therapy gradually increased with years for HP eradication in the Chinese real-world clinical practice.

TREATMENT EFFECTIVENESS OF DIFFERENT ERADICATION TREATMENTS IN CHINESE PATIENTS WITH HELICOBACTER PYLORI: A RETROSPECTIVE REAL-WORLD STUDY

W. Pan[1], Y. Zhao[2], P. Li[3], F. Zhou[3], L. Xie[3], H. Xu[4]
[1]Zhejiang Provincial People's Hospital (Affiliated People's Hospital), Hangzhou, China, [2]Shanghai Tenth People's Hospital, Shanghai, China, [3]Takeda (China) International Trade Co, Shanghai, China, [4]Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Contact E-Mail Address: fang.zhou1@takeda.com

Introduction: *Helicobacter pylori* (*H. pylori*) infection has a high prevalence (44.8%) in China and is an important risk factor of gastrointestinal diseases including gastric cancer. Bismuth quadruple therapy (BQT; bismuth + acid suppressant + 2 antibiotics [ABs]) is the currently recommended first-line regimen for *H. pylori* in China. Increasing AB resistance poses a vital challenge and remarkably reduces the eradication rate (ER) from 95% to 80% globally and 89% to 78% in China. Real-world ER analysis assessed only quadruple therapy in a few single centers and did not focus on different antibiotic combinations and other different regimens.

Aims & Methods: This study was designed to evaluate the diagnosis and treatment pattern of H. pylori infection and the effectiveness of eradication therapy in real-world settings in China. In this retrospective, multicenter study (NCT05073367), de-identified patient data were extracted from the electronic medical records database of 3 hospitals between January 1, 2019, and March 31, 2021. Patients aged ≥18 years with a record of *H. pylori* infection diagnosis were included. Here we presented the eradication rate of different treatment regimens and the eradication rate of different years with different treatment regimens.

Total (N=1426) → /Treatment regimens ↓	ER-success n (%)[b]	Year 2019 Success n (%)[b]	Year 2020 Success n (%) [b]	Year 2021 Success n (%)[b]
Total	1028 (72.09)	454 (77.87)	253 (60.96)	321 (75.00)
Bismuth Quadruple Therapy	879 (76.70)	443 (77.86)	186 (67.64)	250 (82.78)
Amoxicillin and Clarithromycin	391 (76.07)	169 (78.24)	106 (67.95)	116 (81.69)
Amoxicillin and Furazolidone	181 (87.44)	55 (87.30)	44 (83.02)	82 (90.11)
Amoxicillin and Levofloxacin	159 (77.94)	126 (79.25)	10 (55.56)	23 (85.19)
Amoxicillin and Metronidazole	2 (50.00)	2 (50.00)	0 (0.00)	0 (0.00)
Other Bismuth Quadruple Therapy	146 (67.28)	91 (71.65)	26 (54.17)	29 (69.05)
Triple therapy[c]	59 (48.36)	11 (78.57)	37 (46.25)	11 (39.29)
Dual therapy[c]	90 (56.96)	0 (0.00)	30 (50.00)	60 (61.22)

Table 1. Eradication rate of H. pylori positive patients based on the type of eradication therapy.

Abbreviations: N, total number; n, number in respective category.
[a]% = The total usage count of BQT/Triple therapy/Dual therapy eradication therapy/ the total usage count of all standard eradication therapies taken by eligible participants. Of BQT, the total usage count of different BQT/the total usage count of all BQT.
[b]% = The number of participants with a negative efficacy evaluation result/the number of participants receiving certain eradication therapy.
[c]Considering the table size, outcomes of different treatment regimens under dual and triple therapy were not included in the table.

Results: A total of 1426 patients received ET with efficacy evaluation duration>4 weeks after the eradication therapy and the total eradication rate was 72.09% (n=1028). Most patients (80.36%; n=1146) received standard BQT with an ER of 76.70% (n=879). 158 patients (11.08%) received dual therapy (ER=56.96%; n=90) and 122 patients (8.56%) received triple therapy (ER=48.36%; n=59). Compared with triple and dual therapies, BQT was the predominant regimen in all the years with an ER of 77.86%, 67.64%, and 82.78% in 2019, 2020, and 2021, respectively. The ER of dual therapy was 50% in 2020 and 61.22% in 2021. The triple therapy ER showed a decreasing trend with 78.57% (n=11), 46.25% (n=37), 39.29% (n=11) from 2019 to 2021. Among the BQT regimens, amoxicillin plus furazolidone based regimens showed a higher ER (87.44%; n=181), while the ER of amoxicillin plus levofloxacin, amoxicillin plus clarithromycin based BQT was 77.94% (n=159) and 76.07% (n=391), respectively. Amoxicillin plus furazolidone based BQT showed a higher ER of 87.30%, 83.02%, and 90.11% in 2019, 2020, and 2021 respectively (Table 1).

Conclusion: BQT-based regimens were predominantly prescribed for *H. pylori* management and the current *H. pylori* treatment regimens have a suboptimal eradication rate in the real-world settings.

Contact E-Mail Address: wfen-judy@csu.edu.cn

Introduction: Due to certain shortcomings of traditional triple and quadruple therapy for *Helicobacter pylori* (*H. pylori*), high-dose dual therapy (HDDT) is proposed as another option.

Aims & Methods: Our study aims to evaluate the efficacy and safety of HDDT, and provide more reference for clinical eradication of *H. pylori*. The subjects were untreated *H. pylori* patients from three medical centers in Central China. Totally, 439 subjects were randomly assigned to EA (esomeprazole-amoxicillin) or B-quadruple (esomeprazole-amoxicillin-clarithromycin-bismuth) group. A total of 367 subjects were randomly assigned to VA (vonoprazan-amoxicillin) or VAC (vonoprazan-amoxicillin-clarithromycin) group. The effect, adverse events, compliance, symptom relief and cost were recorded.

Results: EA-dual was non-inferior to B-quadruple regimen in mITT and PP analysis (P<0.025). But the eradication rate of EA was lower than that of B-quadruple group (70.59% vs. 83.49%, 92.86% vs. 98.38%, 93.94% vs. 98.38%, ITT, mITT, PP respectively, P<0.05). In ITT, mITT and PP analysis, VA-dual was non-inferior to VAC treatment (84.15% vs. 83.15%, 96.25% vs. 92.73%, 96.75% vs. 93.75%, P<0.025).

There was no significant difference in adverse events, compliance, and symptom relief between groups. Cost of VA was the lowest. Antibiotics use within 2 years, poor compliance and suburban area residence reduced the eradication efficacy (P<0.05).

Conclusion: The HDDT based on esomeprazole or vonoprazan was non-inferior to the classical B-quadruple or VAC triple regimen. So, the HDDTs should be recommended as first-line therapies of *H. pylori* eradication. Antibiotics use in 2 years, adherence and residence were crucial for eradication.

Disclosure: The authors declare that they have no conflict of interest.

Introduction: Prevalence of Helicobacter pylori (H. pylori) infection remains high. Despite the reported relatively low prevalence in Switzerland, the real burden is considered to be much higher, primarily due to the phenomenon of migration. Till now, there is scarce evidence regarding effectiveness of H. pylori eradication schemes in Switzerland.

Aims & Methods: Sub-study of the "European Registry on *H. pylori* Management" (Hp-EuReg), an international, multicenter, prospective non-interventional registry of the routine clinical practice. All infected adult patients were systematically registered at AEG-REDCap e-CRF from 2013 to December 2023. Swiss data were analysed for effectiveness on a modified intention-to-treat (mITT) basis.

Results: A total of 486 adult patients, diagnosed with *H. pylori* infection, were collected. Out of them, 428 (88.1%) were treatment-naïve patients. Two prescription regimes included more than 90% of the cases (triple with Clarithromycin and Amoxicillin in 49% and single-capsule bismuth quadruple in 42%). For the effectiveness analysis, 280 naïve patients were eligible, due to their availability of a confirmatory *H. pylori* eradication test. The overall effectiveness of 1st line empirical therapy was 92% by mITT. The lowest effectiveness was recorded with triple therapy with amoxicillin and clarithromycin (28/34 cases, 82.4 % for seven days duration, and 86.9% overall (126/145). On the other hand, the highest effectiveness was reached with the single-capsule bismuth quadruple therapy (97.1%, 100/103). In respect to potency of gastric acid inhibition by proton pump inhibitors (PPI), the group with low-dose (i.e. 20 mg omeprazole equivalent twice daily) PPI yielded an overall eradication success of 90.8%, whereas for the standard-dose (i.e. omeprazole equivalent 40mg bid) and high-dose (i.e. omeprazole equivalent 80mg bid) PPI inhibition the rates increased up to 100% and 96.3%, respectively. Regarding safety, the eradications treatments were generally well tolerated, and serious adverse events were reported in 16 cases (5.7%). Mild adverse effects were rather uncommon and included dysgeusia (n=1), diarrhoea (n=6), nausea (n=6) and dyspepsia (n=3).

Conclusion: This first interim analysis of Swiss population as sub-study of the Hp-EuReg suggests that bismuth quadruple therapy prescribed as single-capsule represents a reliable option as first-line empirical therapy.

Disclosure: Nothing to disclose.

Introduction: It is not yet clear what is the best first-line empirical therapy in patients with *Helicobacter pylori* (*H. pylori*) infection. For this reason, it is important to constantly monitor the effectiveness of the different therapies used in clinical practice.

Aims & Methods: The aim of this study was therefore to assess the effectiveness of empirical first-line treatment prescribed in Italy evaluating the European Registry on *H. pylori* Management (Hp-EuReg). The Hp-EuReg is an international multicentre prospective non-interventional registry recording information on *H. pylori* infection management since 2013. All infected adult patients enrolled were systematically registered at AEG-REDCap e-CRF. Data of all *H. pylori*-positive treatment-naïve patients enrolled from 2013 to December 2023 by Italian centres participating in the Hp-EuReg, were extracted, subject to quality control, and analysed. The effec-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tiveness of the first-line treatment empirically prescribed was evaluated according to the modified intention-to-treat (including all patients that completed follow-up, *i.e.*, a confirmatory test of success or failure available after eradication treatment), and per-protocol analysis (including all patients that completed follow-up and took at least 90% of the treatment drugs).

Results: In total, 4,144 patients were included for analysis; the mean age was 52 years (SD ± 5), and 60% of patients were women. Overall, 1.0% of the cases were allergic to penicillin. Among those non-allergic to penicillin, 10-day sequential therapy (mainly as PPI-clarithromycin-amoxicillin-tinidazole) was most commonly prescribed (54%), followed by 10-day single capsule bismuth quadruple therapy with metronidazole and tetracycline (19 %), and 10 or 14-day non-bismuth concomitant treatment (mainly as clarithromycin-amoxicillin-tinidazole) (9.3%), providing these regimens optimal cure rates (91.5%, 95.5%, 92% and 97%; respectively). Additional first-line prescriptions encompassed 7, 10 or 14-day triple therapy with PPI-clarithromycin-amoxicillin (5.5%), and 10-day triple therapy with PPI- -levofloxacin-amoxicillin (2.9%) (see Table 1).

First-line treatment	Length (days)	mITT % (95% CI)	PP % (95% CI)
Sequential (PPI + C-A-T/M)	10	91.5 (90.2 to 92.7)	90.9 (89.5 to 92.1)
PPI + Single capsule (M+Tc+B)	10	95.5 (93.7 to 96.8)	96.6 (94.9 to 97.7)
Concomitant (PPI + C-A-M/T)	10	92.2 (86.6 to 95.6)	93.5 (88.1 to 96.5)
	14	96.6 (93.6 to 98.4)	98.1 (95.6 to 99.2)
Triple PPI-C-A	7	83.6 (72.9 to 90.6)	86.2 (75.7 to 92.5)
	10	80 (71.1 to 86.7)	80.4 (71.4 to 87.1)
	14	100 (0.77 to 100)	100 (0.77 to 100)
Triple PPI-A-L	10	81.4 (72.7 to 87.7)	82.8 (74.2 to 89)

mITT: modified intention-to-treat; PP, per protocol; A, amoxicillin; B, bismuth salt; C, clarithromycin; L, levofloxacin; M, metronidazole; PPI, proton pump inhibitor; T, tinidazole; Tc, tetracycline.

Table 1; Effectiveness by modified intention-to-treat (mITT), and per-protocol (PP) analyses of first-line empirical treatment in patients not allergic to penicillin enrolled in the Italian centres participating in the European Registry on H. pylori management (Hp-EuReg).

Conclusion: Among the first-line empiric treatments prescribed by the Italian centres participating in the Hp-EuReg, only single-capsule bismuth quadruple therapy with metronidazole-tetracycline-bismuth, sequential therapy with clarithromycin-amoxicillin-tinidazole, and non-bismuth concomitant therapy with clarithromycin-amoxicillin-tinidazole, achieved over 90% effectiveness.

NON-BISMUTH QUADRUPLE CONCOMITANT TREATMENT FOR *H. PYLORI* ERADICATION: SYSTEMATIC REVIEW AND META-ANALYSIS

P. Parra[1], O. P. Nyssen*[1], J.P. Gisbert*[1], *co-last authors
[1]*Department of Gastroenterology, Hospital Universitario de La Princesa, IIS-Princesa, Universidad Autónoma de Madrid (UAM), and Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain*

Contact E-Mail Address: pablo.parra.hlp@gmail.com

Introduction: *Helicobacter pylori* eradication with standard triple therapy fails in ≥20% of the cases, mainly due to bacterial antibiotic resistances. Non-bismuth quadruple concomitant therapy is among the most widely used first-line treatments against *H. pylori* infection, even in high clarithromycin resistance areas.

Aims & Methods: To evaluate the efficacy and safety of non-bismuth quadruple concomitant therapy (proton pump inhibitor, clarithromycin, amoxicillin and nitroimidazole) in the treatment of *H. pylori* infection, and to compare it with other triple and quadruple regimens.

Bibliographical searches were performed in PubMed up to April 2024. We performed a meta-analysis of the studies evaluating the concomitant therapy as a first-line regimen, and of the randomised controlled trials comparing concomitant vs. standard triple, sequential, hybrid, and bismuth quadruple therapies.

Results: 115 studies (78 randomised trials) were included (23,454 patients); 39 studies compared concomitant vs triple (13,494 patients), 38 studies vs sequential (11,907 patients), 12 studies vs hybrid (3,719 patients) and 11 studies vs bismuth quadruple (3,258 patients). Concomitant regimen achieved an overall eradication rate of 86% (95%CI=85-86%) by intention-to-treat, and 90% (90-91%) by per-protocol. Concomitant therapy achieved high eradication rates even in single clarithromycin resistant (89%) and metronidazole resistant (95%) patients, but poor cure rates in dual (clarithromycin and metronidazole) resistance (68%). The overall efficacy by intention-to-treat with concomitant therapy was significantly higher as compared to both triple therapy (risk difference [RD]=0.11; 95%CI=0.09-0.14; 39 studies) and sequential therapy (RD=0.04; 0.02-0.06; 38 studies); however, in the latter comparison, when only 14-day prescriptions were considered, no significant differences were observed (RD=0.01; -0.05-0.06; 4 studies). Likewise, the overall efficacy of concomitant therapy was similar to hybrid (RD=0.01; -0.01-0.03; 12 studies), and to bismuth quadruple therapy (encompassing the classical form and the single-capsule (RD=0.01; -0.03, 0.06; 11 studies). The overall incidence of adverse events with concomitant therapy was 37% (36-38%) (85 studies). When comparing only the studies with the same treatment durations, the incidence of adverse events with concomitant therapy was similar to that of triple (RD=0.04; -0.01-0.09; 15 studies), sequential (RD=0.03; -0.00-0.06; 16 studies), and bismuth quadruple therapies (RD=0.02; -0.06-0.09; 7 studies), but higher than that of hybrid therapies (RD=0.10; 0.04-0.15; 7 studies).

Conclusion: Non-bismuth quadruple concomitant therapy is highly effective for *H. pylori* eradication (achieving a cure rate of approximately 90%), even in the presence of clarithromycin or metronidazole resistance, being superior to standard triple and sequential therapies, and similar to hybrid and bismuth quadruple regimens. The incidence of adverse events with concomitant treatment is relatively high (37%), similar to that of triple and bismuth quadruple regimens.

Introduction: Increasing resistance to antibiotics represents a significant challenge for the successful eradication of *Helicobacter pylori (H. pylori)*. Therefore, there is a growing need to find novel modalities to improve treatment outcomes.

Aims & Methods: This study aimed to assess the efficacy and safety of levofloxacin- or moxifloxacin-containing nitazoxanide-based regimens for eradicating *H. pylori* as first- and second-line therapies. Patients with dyspeptic symptoms and a positive *H. pylori* antigen test in the stool were eligible for inclusion in this study. Naïve patients were randomized into three groups according to treatment regimens: levofloxacin, nitazoxanide, doxycycline, and lansoprazole (LNDL); moxifloxacin, nitazoxanide, doxycycline, and lansoprazole (MNDL); or amoxicillin, clarithromycin, and lansoprazole (ACL) for 14 days. Treatment-experienced patients received the LNDL or MNDL regimen. *H. pylori* eradication was confirmed by stool antigen testing at least 4 weeks after the cessation of therapy.

Results: In naïve patients, eradication rates were significantly greater by intention to treat (ITT) analysis in patients treated with the LNDL regimen (83.3%) than in those treated with standard triple therapy (ACL) (59.2%). According to the per-protocol analysis (PP), both the LNDL and MNDL regimens had significantly greater eradication rates (87.7% and 81.6%, respectively) than did the ACL regimen (60.9%). Regarding treatment-experienced patients, eradication rates were comparable for the LNDL and MNDL regimens in both ITT (65.9% and 77.5%, respectively) and PP analyses (72.5% and 82.7%, respectively). All treatment regimens were well tolerated.

H. pylori stool antigen test result	Eradication regimen			p-value
	LNDL	MNDL	ACL	
Intention to treat	n: 90	n: 102	n: 71	
Negative (%)	75 (83.33%)	71 (69.61%)	42 (59.15%)	0,003
95% CI	75.73-91.27	60.92-78.90	47.96-71.16	
Per-protocol	n: 86	n: 87	n: 69	
Negative (%)	75 (87.21%)	71 (81.61%)	42 (60.87%)	< 0.001
95% CI	80.21-94.47	73.57-90.01	49.57-72.95	

Table 1 Eradication Rates of Helicobacter pylori infection in treatment-naïve patients

Conclusion: levofloxacin- and moxifloxacin-containing nitazoxanide-based regimens exhibit substantial efficacy for the eradication of both naïve and resistant *H. pylori* infections over a 14-day course with a considerable safety profile.

Introduction: Bismuth-based quadruple therapy (BQT) is recommended as the first-line therapy for Helicobacter pylori eradication as it is not associated with resistance. Tegoprazan, a new, fast, and strong potassium-competitive acid blocker, has been approved for the treatment of gastric acid-related diseases in México. However, real-world clinical data regarding this drug are scarce. We aimed to compare the Helicobacter pylori eradication rates of tegoprazan- and omeprazole-based quadruple therapy.

Aims & Methods: Aim: To investigate the efficacy and safety profiles of tegoprazan-based BQT (TBMT) versus omeprazole-based BQT (OBMT) for H. pylori eradication.

Methods: We included patients older than 18 with an H. pylori infection without a history of H. pylori eradication who visited two centers between January 2024 and April 2024. H. pylori infection was diagnosed using histology. Patients received tegoprazan 50 mg BID , bismuth subcitrate 300 mg QID, metronidazole 500 mg QID, and doxycycline 100 mg QID for 14 days. An historic control groups was used as comparator. Historic controls were age-sex matched subjects that received omeprazole 40 mg BID , bismuth subcitrate 300 mg QID, metronidazole 500 mg QID, and doxycycline 100 mg QID, in the previous year.

Results: Until now, 80 patients have been included (40 TBMT and 40 OBMT). Most common indication for erradication was dyspeptic symptoms (78%), followed by peptic ulcer disease (10%), folicular gastritis (9%) and familiar hystory of cance (2.5%). Eradication rates of TBMT and OBMT were 90% and 77.4% (=OR 2.61, CI 95% 0.73-9.37, p=0.12), respectively. There was no significant difference in the rate of adverse events between the TBMT and OBMT groups (42.5% vs. 55,5%, p = 0.37). Nausea was the most common adverse effect (37.5% vs 40%, p=0.92) , followed by abdominal pain (12.5% vs 17.5%, p=0.16%)Adherence to the treatments was similar between groups (> 90%, 10% vs 12%, p=0.98)

Conclusion: TBMT showed a noninferior eradication rate and similar adverse events to OBMT as a first-line eradication regimen. Our results suggest that tegoprazan might be substituted for proton pump inhibitors in H. pylori eradication regimens in Mexico. A further randomized controlled trial es required to confirm our findings.

Introduction: The emergence of antimicrobial resistant *Helicobacter pylori* (*H. pylori*) has impacted treatment success rates. Local audits of prescription patterns and eradication rates are necessary to assess treatment efficacy and compliance with clinical guidelines. The first Irish consensus guidelines on the management of *H. pylori* were published in 2017. Clarithromycin-amoxicillin triple therapy (CTT) or bismuth quadruple therapy (BQT) were the recommended first-line options. Other key recommendations included extending treatment durations to 14 days and the use of high-dose proton pump inhibitors (PPIs).

Aims & Methods: This study aimed to (i) investigate first-line *H. pylori* prescription patterns and cure rates over a 10-year period in Ireland, and (ii) evaluate the impact of the first Irish consensus guidelines on these trends. Data were collected at e-CRF AEG-REDCap from the European Registry on *Helicobacter pylori* Management (Hp-EuReg) and quality reviewed from 2013 to 2022. All treatment-naïve cases were assessed for effectiveness by modified intention-to-treat (mITT) analysis. Multivariate analysis was performed using a logistic regression model to evaluate the relationship between mITT rates and age, sex, indication, compliance, PPI dose and treatment duration.

Results: In all, data from 1,000 patients (mean age 50±15 years; 54% (n=536) female) were included in the analysis, from those 78% (n=784) were from Tallaght University Hospital, Dublin and 22% (n=216) were from Beacon Hospital, Dublin. The most common indication was dyspepsia (92%; n=920), followed by duodenal ulcer and gastric ulcer (2%; n=20 and 1%; n=10, respectively). CTT was the most common first-line treatment (88%; n=880). BQT represented 1.7% (n=17) of prescriptions. Of the reported treatment durations (n=998), 87% (n=868) were for 14 days, 4.5% (n=45) were for 10 days and 8.5% (n=85) were for 7 days. Of the reported PPI dose prescribed (n=999), 86% (n=860) were high (i.e., 80 mg omeprazole equivalent twice daily), 0.9% (n=9) were standard (i.e., 40 mg omeprazole equivalent twice daily), and 13% (n=130) were low (i.e., 20 mg omeprazole equivalent twice daily).

The eradication rate was 80.1% (95% confidence interval (CI) 77.5-82.5%) overall and 81.4% (95% CI 78.9-83.7%) for CTT. Multivariate analysis revealed that good compliance and the use of high dose PPI were significantly associated with higher overall mITT rates (odds ratio (OR) 4.5, 95% CI 1.4-14.2, p<0.05 and OR 1.9, 95% CI 1.2-2.8, p< 0.005, respectively) and CTT mITT rates (OR 4.2, 95% CI 1.2-14.2, p<0.05 and OR 1.9, 95% CI 1.1-3.2, p<0.05, respectively).

Following publication of the Irish consensus guidelines in 2017, prescriptions for 14 days therapy increased from 39% (n=82/208) pre-2017 to 99% (n=786/790; p<0.0001) and the use of high dose PPI increased from 37% (n=77/207) pre-2017 to 99% (n=783/792; p<0.0001). In line with this, overall eradication rates significantly increased from 74.5% (95% CI 68.2-80.0%) pre-2017 to 81.6% (95% CI 78.7-84.1%; p<0.05). CTT eradication rates significantly increased from 75.7% (95% CI 68.2-81.8%) pre-2017 to 82.6% (95% CI 79.6-85.1%; p<0.05).

Conclusion: CTT was the most frequently prescribed first-line therapy between 2013-2022. BQT was rarely prescribed, reflecting difficulty accessing bismuth in Ireland. While treatment success increased following publication of the Irish consensus guidelines, cure rates remain below 90%. Alternative first-line treatment strategies are required in the Irish healthcare setting.

Introduction: *Helicobacter pylori* is a microaerophilic gram-negative bacillus that colonizes the gastric mucosa and is associated with gastroduodenal diseases such as chronic gastritis and gastric adenocarcinoma. Although triple therapy is the recommended treatment for its eradication, its effectiveness has decreased due to the lack of knowledge about bacterial susceptibility patterns and the emergence of resistant strains, a phenomenon related to the bacterium's adaptation to hostile environments and antibiotic use. This infection is associated with gastroduodenal diseases such as chronic gastritis, peptic ulcer, and gastric adenocarcinoma, and although various therapeutic regimens are available, the indiscriminate use of antibiotics has led to resistance, highlighting the need to study alternatives and reevaluate the criteria that determine the selection of a specific therapeutic regimen.

Aims & Methods: We analyzed 169 *Helicobacter pylori* Whole Genome Sequences (WGS) from Colombian participants. Bioinformatics analyses were performed using the ATCC 26695 genome as a reference strain. We searched for mutations in specific genes to assess resistance rates to different antibiotics: *23S* rRNA for clarithromycin, *16S* rRNA for tetracycline, *pbp1A* for amoxicillin, *gyrA* for levofloxacin, *rdxA* for metronidazole, *rpoD* for rifampicin, and *porD* for furazolidone. The phylogenomic analysis was conducted using the core genome consisting of 1,594 genes of *Helicobacter pylori*-ATCC 26695

Results: Our findings revealed that the resistance rate of *Helicobacter pylori* to clarithromycin was 3.62%, mainly associated with the A2143G and A2142G mutations in the *23S* rRNA gene. For tetracycline, the resistance rate was 7.23%, with mutations A926G, A926T, and A928C observed in the *16S* rRNA gene. Resistance to amoxicillin was found in 25.9% of cases, with mutations observed in the *pbp1A* gene, including T556S, T593, R649K, R656P, and R656H. In the *gyrA* gene, mutations N87K, N87I, D91G, D91N, and D91Y were identified, resulting in a resistance rate of 12.04% to levofloxacin. The most common mutations in the *rdxA* gene associated with

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

metronidazole resistance were a stop codon and mutations at D59N and D59S, resulting in a resistance rate of 99.3%. No mutations were found for rifampicin in the *rpoD* gene, and a resistance rate of 0.84% was found for furazolidone due to mutations C357T in the *porD* gene.

Conclusion: The high rate of *Helicobacter pylori* resistance to metronidazole indicates that this drug should be excluded from eradication therapy. However, resistance rates for tetracycline and clarithromycin did not exceed the 10% threshold established in Colombia. The increased resistance rate of *Helicobacter pylori* to levofloxacin and amoxicillin may partially explain the therapeutic failures observed in Colombia. As rescue therapy, rifampicin and furazolidone antibiotics can be used along with bismuth in *Helicobacter pylori* treatment, following the guidelines recommended by the Maastricht VI/Florence consensus report. Phylogenomic analysis showed that the *Helicobacter pylori* isolate belongs to its own lineage (hspColombia). These findings provide valuable information to improve the characterization of treatment protocols for the specific *Helicobacter pylori* lineage (hspColombia) at the local level.

Introduction: Helicobacter pylori (Hp) infection remains a major public health problem, associated with significant morbidity and mortality, whose eradication therapy has proven to be effective in preventing these complications.[1,2] Given the high resistance to antibiotics and the scarcity of available antibiotic therapy worldwide, there is not enough data on the best eradication strategy.[3,4]

Aims & Methods: Aim: The aim of this study was to perform a comparative evaluation of the efficacy and safety of the different quadruple therapy regimens currently recommended for the Hp eradication, including Esomeprazole 40 mg bid.

Methods: A blind randomized controlled clinical trial of consecutive patients with gastric infection by Hp, diagnosed by 13C-urea breath test (UBT) or histological analysis were randomized in 5 therapy arms (A: Quadruple with metronidazole 500 mg tid, 14 days; B: Quadruple with metronidazole 500 mg bid, 14 days; C: Quadruple with bismuth, 10 days; D: Sequential, 7 days; E: Hybrid, 7 days). Hp eradication with evaluation of the efficacy and safety rates at 1-2 months after the eradication therapy was made.

Results: From a total of 200 patients currently included, 193 concluded the protocol study (164-histological analysis; 29-UBT), 102 males (52.8%), mean age of 57.2±16.3 (A: 38; B: 39; C: 38; D: 41; E: 37). Overall efficacy rate of quadruple therapy regimens was 95.9% (n=185), being 100.0% for arm A, 92.3% for arm B, 97.3% for arm C, 97.6% for arm D and 91.9% for arm E (p=0.431). Overall adverse events rate of quadruple therapy regimens was 53.9% (n=104), being diarrhea (27.5%) and nausea (26.9%) the most common. Major symptoms (need for therapy or impairment of daily living activities) occurred in 8.3%. Adverse events/Major adverse events rates for the different regimens were 50.0%/5.3% for arm A, 69.2%/15.4% for arm B, 48.6%/7.9% for arm C, 48.8%/4.9% for arm D and 54.0%/8.1% for arm E (p=0.287/p=0.451).

Conclusion: In Portugal, all the quadruple therapy regimens currently recommended for the eradication of Hp, with or without bismuth, have been effective in eradicating Hp gastric infection. However, concomitant therapy with metronidazole bid seems to have a higher rate of adverse effects, including major adverse effects.

Introduction: Prevention of gastric cancer, both primary and secondary, is an extremely important component of the management of patients infected with Helicobacter pylori. An important component of secondary prevention of gastric cancer is the use of gastroprotectors and repair stimulants, in particular the alpha-glutamil-triptophan, especially in people with a potentially precancerous condition – chronic atrophic gastritis

Aims & Methods: The aim is to estimate the effectiveness of the alpha-glutamyl-tryptophan as a local cytoprotector for gastric mucosa cells in patients with chronic atrophic gastritis (CAG).

116 patients with H. pylori-associated CAG took two treatment lines: 1. standard eradication therapy 10 days, 2. alpha-glutamyl-tryptophan(58 patients)/placebo(58 patients) 28 days. For all patients before and after treatment we performed gastroscopy with two biopsies from atrophic area, histological study of these biopsies, daily pH-metry and Gastropanel.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Alpha-glutamyl-tryptophan in comparison with placebo have statistically significant: *regenerative effect* (26.1% increase in the number of glands per 1 mm^2 of the gastric mucosa (GM) by histological study) and *anti-inflammatory effect* (decrease of GM edema and hyperemia by endoscopy data, reduction of the number of inflammatory infiltration cells per 1 mm^2 of GM: eosinophilic granulocytes – 3 times, neutrophilic leukocytes – 4 times, macrophages – 1.5 times, lymphocytes – 28.2%, plasmocytes – 29.6% by histological study). Also alpha-glutamyl-triptaphan improved the functional posibilities of stomach: a decrease in the level of gastrin-17 (p = 0.005) and an increase in the value of the PG I/PG II ratio (p=0.003), there was a shift in the acidic side of the pH values (p=0.001) when comparing indicators before and after treatment. There were no statistically significant changes in these parameters in the placebo group. According to the results of gastroscopy, a statistically significant decrease in the severity of edema of the gastric mucosa (p=0.008), the total set of signs of an acute inflammatory process (p=0.006), and a decrease in the proportion of outcomes with negative dynamics of the inflammatory process (p=0.038) were revealed in alpha-glutamyl-tryptophan group.

Conclusion: Alpha-glutamyl-tryptophan can be recommended for local cytoprotection in CAG, espessially fpr H. pylori associated gastritis for prevention the progression of atrophy and inflammation, and also lowering the risk of gastric cancer.

THE EPIDEMIOLOGICAL PROFILE OF GASTRIC CANCER PATIENTS IN GROOTE SCHUUR HOSPITAL CAPE TOWN, SOUTH AFRICA

I.E. Francis[1], G. Chinnery[2], M. Scriba[2], F. Patel[3], M. Setshedi[1]
[1]Groote Schuur Hospital, University of Cape Town, Gastroenterology Unit, department of Medicine, Cape Town, South Africa, [2]Groote Schuur Hospital, University of Cape Town, Upper Gastroenterology Surgery, Cape Town, South Africa, [3]University Of Cape Town, Microbiology department, Cape Town, South Africa

Contact E-Mail Address: francisinno@gmail.com

Introduction: Gastric cancer (GCA) is the 5th most common cancer and 3rd leading cause of cancer-related death. *Helicobacter pylori* (*H. pylori*) is the chief risk factor. The prevalence of *H. pylori* in Africa is between 60-90%, despite this GCA appears to be low, the so-called African enigma.

Aims & Methods: To document the epidemiological profile and risk factors of GCA in a South African cohort.

A retrospective folder review of patients with GCA from 2018-2022

Results: 443 patients were included; median age= 63 (range 29-86), 65% male (61% ≥ 60 years old). HPT (38.2%) and diabetes (17.6%) were the main comorbidities. 46% and 8.4% had history of smoking and alcohol use respectively. NSAID and PPI use were reported in 8.8% and 7% respectively. The commonest symptom was loss of weight (38.6%) and epigastric pain (29%). 68% had a Hb<12g/dl with a median Hb=10 (range 3.8-17). Endoscopically, gastritis or duodenitis or ulcers were recorded in 63% of cases. The commonest site of GCA was non-cardia (82.2%); antral and corpus cancers in 40.9% and 53.2% respectively. Histologically, *H. pylori* was reported in 11.5%, while chronic atrophic gastritis (CAG) in 15.6%. *H. pylori* was not associated with either antral or corpus cancer, or CAG, however PPIs were associated with a reduced odd of antral cancer, OR=0.42, CI=0.18-0.97, p=0.04. None of the other demographic or clinical factors were associated with the location of GCA.

Conclusion: GCA is higher in males and those ≥60 years. Loss of weight and anaemia are key red flags. Non-cardia gastric cancers are the commonest in this cohort. The low prevalence of *H. pylori* suggests previous eradication, although CAG was high, thus maintaining the increased risk of non-cardia CGA. Interestingly, PPI use was significantly protective against developing antral cancer. This highlights the need to treat *H. pylori* before CAG occur.

Disclosure: None.

Contact E-Mail Address: gharbighada1801@gmail.com

Introduction: Helicobacter pylori (HP) infection induces chronic gastritis and represents a major factor in gastric cancer. The histological sequence leading to gastric cancer is well known: gastritis induces atrophy and intestinal metaplasia, two precancerous lesions detectable by early endoscopy and meticulous anatomopathological examination.

Operative Link on Gastritis Assessment (OLGA) and Operative Link on Gastric Intestinal Metaplasia Assessment (OLGIM) are two systems designed to detect patients at high risk of developing gastric cancer by assessing, respectively, the degree of atrophy and intestinal metaplasia in the gastric mucosa.

Aims & Methods: The aim of our study was to evaluate the OLGA and OLGIM staging systems in HP infection.

A retrospective study was conducted over patients who had upper gastrointestinal endoscopy between January 2018 and December 2019 with the presence of HP infection on pathological examination of gastric biopsies. Patients with stage III or IV gastritis according to the OLGA or OLGIM systems were considered at high risk of progression to gastric cancer.

Results: Two hundred patients were included in this study. The mean age was 52.5 years [10-92], with a F/M sex ratio of 1.67. The main indications for upper GI endoscopy were epigastralgia (66.5%) and anemia (18.5%).

Various morphological aspects were observed. The gastric body was normal in 59.5% of cases, with gastroraphy present in 40.5%, mainly congestive (17.5%), but also mosaic (11%), nodular (6.5%), atrophic (4.5%), erosive (3%) and ulcerated (2.5%). The antrum was normal in only 23.5% of cases. Antral gastroraphy was congestive (46.5%), nodular (14.5%) or ulcerated (14%).

On anatomopathological examination of gastric biopsies, atrophy was present in 15.5% of patients and intestinal metaplasia in 45%. Only 3 patients (1.5%) were considered at high risk of developing gastric cancer according to the OLGA system, while this risk was estimated at 13.5% according to the OLGIM classification.

There was no statistically significant association between the OLGA and OLGIM staging systems in the selection of patients at high risk of developing gastric cancer (p=0.09). Nevertheless, an association was noted between OLGA classification and the presence of intestinal metaplasia (p=0.009), the presence of a high risk of developing gastric cancer according to the OLGA system and the finding of moderate to severe intestinal metaplasia on gastric biopsies (p=0. 018), and between the existence of a high risk of progression to gastric cancer according to the OLGIM system and the presence of moderate to severe atrophy (p=0.005).

Conclusion: The OLGA and OLGIM staging systems assess the risk of developing gastric cancer in HP infection. Our study didn't found a correlation between the two systems. A concomitant assessment of this risk by the two systems will enable a better selection of high-risk patients for appropriate surveillance and early management.

Introduction: The aging with weight gain induces pathological changes in the liver, exacerbating non-alcoholic fatty liver disease (NAFLD). In the reproductive age, NAFLD is more prevalent and severe in males, however, NAFLD occurs at a higher rate among postmenopausal females. The liver and small bowel are closely interrelated through enterohepatic circulation, such that damage to the small bowel can significantly impact hepatic function. In small intestine, the expression of tight junction protein (TJP) in nearly associated with the development of NAFLD.

The aim of this study was to investigate the effects of age and sex on hepatic steatosis and the small bowel under conditions of a high fructose, high-fat diet (HFHFD) in rats.

Aims & Methods: 6-week-old male and female F344 rats divided into control and HFHFD groups, along with 2-year-old F344 rats. Over an 8-week period, the high fat diet (Raonbio, 60 kcal% fat) provided twice weekly and high fructose water (20%) gave once weekly for HFHFD groups. After 8 weeks, all animals were sacrificed, and both liver and small intestinal tissue were collected.

All tissue samples were subjected to hematoxylin and eosin staining for histological analysis. RNA extraction from the jejunum mucosa was followed by qRT-PCR analysis to assess claudin-2 (cldn-2, one of TJP) gene expression.

Results: The body weight change (%) and the hepatic steatosis scores were significantly higher in the HFHFD groups compared to both male and female control groups (Table).

Histological scores of old rat HFHFD groups were significantly higher than those of 6 week HFHFD groups, regardless of sex (Table).

In terms of histological inflammation scores of old control group small bowel were higher than those of 6 week control group regardless of sex (Table).

The jejunum villus/crypt ratio of 6-week-old rats significantly decreased only among males (Table).

In contrast, in the 2-year-old groups, the villus/crypt ratio resulted in a reduction only among females and the mRNA expression of cldn-2 observed in females with significant elevation (Table).

		Weight	Steatosis score	Inflammation score			Jejunum villus/crypt length ratio	Cldn-2 mRNA expression
				Duodenum	Jejunum	Ileum		
Male	6-week Con vs. 6-week HFHFD	**increase** ($p = 0.006$)	**increase** ($p = 0.003$)	**increase** ($p = 0.072$)	**increase** ($p = 0.026$)	**increase** ($p = 0.049$)	**decrease** ($p = 0.072$)	-

	2-year Con vs. 2-year HFHFD	**increase** ($p = 0.004$)	**increase** ($p = 0.002$)	-	-	-	**decrease** ($p = 0.076$)	**increase** ($p = 0.005$)
	6-week Con vs. 2-year Con	-	-	**increase** ($p = 0.007$)	**increase** ($p = 0.002$)	**increase** ($p = 0.002$)	-	-
	6-week HFHFD vs. 2-year HFHFD	-	**increase** ($p = 0.011$)	-	-	-	-	-

Con, control; HFHFD, high fructose high fat diet; Cldn-2, Claudin-2; vs., versus.

Conclusion: Our data showed that high fructose, high-fat diet induced hepatic steatosis and inflammation of small bowel, especially in old rats. This indicates that NAFLD is related with damage of small bowel brush border membrane. The upregulated gene expression of cldn-2 ($p = 0.005$) and the decreased tendency of jejunum villus/crypt ratio ($p = 0.076$) in the aged females rats suggests a potential role of TJP in advancing NAFLD in postmenopausal females.

Contact E-Mail Address: kevin_thl@163.com

Introduction: To investigate the impact of small intestinal bacterial overgrowth (SIBO) on the efficacy of Fecal Microbiota Transplantation (FMT) in patients with chronic constipation

Aims & Methods: Inclusion of 218 chronic constipation patients treated with FMT, divided into constipation with SIBO group (SIBO) based on breath test results for SIBO, and constipation without SIBO group (Non-SIBO). The efficacy of the two groups was evaluated using constipation-related scoring scales. At the same time, feces and small intestinal fluid samples were collected from both groups before and after FMT to compare the changes in the intestinal microbiota through 16S rRNA sequencing

Results: In this study, it was found that the clinical efficacy of FMT in the SIBO group was superior to that in the Non-SIBO group. After FMT treatment, both groups showed a significant increase in bowel frequency and improvement in stool characteristics. Abdominal symptoms, rectal symptoms, and defecation symptoms were significantly alleviated (P<0.05), and patients' quality of life was significantly enhanced (P<0.05). After FMT, except for the CAS scale scores, other scale scores showed significant differences between the two groups, the SIBO group scoring significantly better than the Non-SIBO group (P<0.05).

After FMT, there were minor changes in the colonic microbiota but more substantial changes in the small intestinal microbiota. At baseline, the SIBO group had a higher abundance of *Veillonella*, and lower abundances of *Escherichia-Shigella* and *Acinetobacter* compared to the Non-SIBO group.

Characteristics	Overall (N=218)
Age (mean ± standard deviation)	55.62±16.48
Gender (Male/Female)	95/123
SIBO (Positive/Negative)	88/130
Disease Duration (year)	13.46±7.98
Complete Spontaneous Bowel Movements (CSBM) time/week	1.32±0.66
Spontaneous Bowel Movements (CSBM) time/week	1.76±0.59
Wexner Scale	16.27±1.68
Bristol Stool Form Scale (BSFS)	1.30±0.46
PAC-SYM	2.95±1.32

Table 1 General Information of the Patients

Conclusion: Chronic constipation patients with SIBO have a better response to FMT than those without SIBO.

Introduction: The incidental finding of terminal ileal inflammation during routine colonoscopy is not uncommon and is of unclear significance. It has been reported among asymptomatic persons undergoing non-diagnostic colonoscopy. There is limited data on long term follow-up and outcomes of such findings.(1)

Aims & Methods: This is a monocentric retrospective observational study spanning from 2018 to 2023, comparing two periods: the first period (P1) before the impact of the Covid-19 pandemic in 2020, and the second period (P2) starting 2020 reflecting the impact the pandemic left on colonoscopies. For each patient, variables were collected from medical records.

Results: Our initial database included 11200 colonoscopies, from which we randomly selected 2394 patients proportionally to the annual activity (mean of 1686/year before 2020 and 1189/year after 2020). Among indications of colonoscopy were screening and follow-up, change in bowel habits, anemia and bleeding. We excluded 287 patients (known history of inflammatory bowel disease and no ileum intubation). Then the sample was divided into P1 (681 patients) and P2 (1483 patients). Characteristics and findings are shown in Table 1. We noted better bowel preparation (77.1 vs 91.7%) and a higher ileum intubation in P2 (79.7 in P1 vs 93.8% in P2).

N=2164		P1 (N1=681)	P2 (N2= 1483)	p
Age (years)		57.5	56.9	NS
Overall endoscopic findings n(%)	Endoscopic aspect of ileitis	0 (0)	71 (5.8)	<0.001
	Abnormal ileal findings on histology	23 (3.4)	169 (11.4)	<0.001
	Diagnosis of Crohn's disease	0 (0)	19 (0.9)	<0.001
Overall histological findings n(%)	Active ileitis	19 (2.8)	147 (9.9)	<0.001
	Focal ileitis	10 (1.5)	89 (6)	<0.001
	Ulcerative ileitis	11 (1.6)	48 (3.2)	0.031
	Erosive ileitis	3 (0.4)	31 (2.1)	0.004
	Architectural distortion	1 (0.1)	16 (1.1)	0.023

Overall ileoscopy findings showed an increased aspect of ileitis on endoscopy (0% in P1 and 5.8% in P2, with p<0.001), correlating with a significant increase in the incidence of histological findings on ileal biopsies (3.4% in P1 vs 11.4% in P2; p<0.001). These histological findings included active, focal and ulcerative ileitis, with more architectural distortion. However, these results corresponded to a less severe ileitis (0.3 vs 2.3%; p=0.001). Nineteen of these patients with positive results of ileitis were diagnosed with Crohn's disease.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Conclusion: This study showed an increase in endoscopic and histologic ileitis on colonoscopy following the Covid-19 era. This could be the result of the direct virologic effect that the virus has on intestinal inflammation, its indirect effect on immunity triggering the onset of enteritis, or the consequence of the mass vaccination campaign held to protect from the virus. Furthermore, histology showed granulomatous inflammation similar to Crohn's disease, which may lead to misdiagnosis and probably overtreatment.

Introduction: Long-term antithrombotic therapy is recommended in short bowel syndrome (SBS) caused by acute mesenteric ischemia (AMI). However, evidence-based recommendations on drug choice, duration and monitoring of treatment are lacking. Also, guidelines are based on data on other artery diseases and overlook the altered drug absorption in patients with SBS. To understand current practices, we aimed to assess the long-term antithrombotic management of AMI.

Aims & Methods: An online survey was sent to centers contributing to the chronic intestinal failure database of the HAN-CIF (Home Artificial Nutrition – Chronic Intestinal Failure) special interest group of ESPEN (European Society on Clinical nutrition and Metabolism), treating patients with SBS post-AMI. The survey featured 10 cases varying in postsurgical intestinal anatomy, revascularization and etiology and focused on drug class, administration route, duration and monitoring of antithrombotic therapy.

Results: The survey was completed by 43 centers. In case of idiopathic AMI leading to SBS, anticoagulation (65.1% of all physicians) or antiplatelet (32.6%) therapy were mostly prescribed (Figure 1; jejunocolic anastomosis, idiopathic).

Antiplatelet therapy was prescribed more often to patients with type 3 anatomy (37.2%, largest absorptive capacity) than to other anatomy groups (30.2 and 32.6% in type 1 and 2 respectively). Antiplatelet drugs (39.5%) or combination therapy (18.6%) were more commonly prescribed in case of revascularization compared to no revascularization (32.6% or 2.3% respectively).

Anticoagulants were very common in patients with atrial fibrillation (90.7%), venous thrombosis (95.3%) and antiphospholipid syndrome (83.7%). More antiplatelet drugs (27.9%) or combination therapy (18.6%) were preferred with concomitant peripheral artery disease. In hypovolemic shock, no therapy (41.9%) or anticoagulants (51.2%) were common.

Parenteral drugs were more prescribed to patients with type 1 anatomy (51.2% of all physicians; lowest absorptive capacity) than to patients with type 2 (44.2%) or 3 (20.9%) anatomy.

Antiplatelet drugs were mainly prescribed lifelong (94.7% of this drug class), while anticoagulants were prescribed for 6 (19.4%) to 12 (16.1%) months or lifelong (51.6%), irrespective of anatomy, revascularization or etiology.

Vitamin K antagonists were consistently monitored, whereas aspirin was not. Monitoring of subcutaneous low molecular weight heparins (no monitoring, 36.8% - always monitoring, 42.1% - in specific circumstances, 21.0%) and non-vitamin K oral anticoagulants varied (no monitoring, 50.0%).

Conclusion: In a case-based survey, anticoagulant versus antiplatelet drug choice depended on the anatomy, revascularization and etiology. However, there was a high variability in case of idiopathic AMI. Administration route depended on anatomy. More detailed practice guidelines are needed.

PREDICTIVE FACTORS IMPACTING THE RESULT OF A GLUCOSE BREATH TEST: A RETROSPECTIVE ANALYSIS OF 2373 TESTS

H. Soliman[1,2], P.-E. Cailleaux[3], C. Desprez[2], A.-M. Leroi[2], C. Melchior[4], G. Gourcerol[2]

[1]Hôpital Louis Mourier - AP-HP, Gastro-enterology Department, Colombes, France, [2]CHU Rouen Hopital C. Nicolle, Dept. of Digestive Physiology, Rouen Cedex, France, [3]CHU Rouen, INSERM UMR 1073, Geriatrics Department, Rouen, France, [4]Rouen University Hospital, INSERM U1073, CIC-CRB-1404, Gastroenterology, Rouen, France

Contact E-Mail Address: heithemsoliman90@hotmail.com

Introduction: Glucose breath test (GBT) is the most commonly used method for the diagnosis of small intestinal bacterial overgrowth (SIBO). SIBO is a common condition with very unspecific symptoms (bloating, abdominal pain, diarrhea or constipation).

Recently, American and European recommandations have been published to standardize the indications and the conditions to perform these tests.[1,2] However, some discrepancies remain between the European and American recommandations, and many statements were supported by

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

low quality of evidence.[1,2] Moreover, several counfounding factors related to the patient's condition may impact the result of the test, leading to a difficult interpretation.

Aims & Methods: This study aimed to assess the factors that could impact the results of a GBT. Therefore, we retrospectively reviewed the results of the GBT performed in our physiology department from 2013 to 2023. The test was performed after ingestion of 75g of glucose, with breath samples collected every 15min during 2 hours. The result was considered positive for hydrogen (H_2) if a rise ≥ 20ppm was observed or positive for methane (CH4) if a rise ≥ 10ppm was observed. Demographic data were collected, such as symptoms and questionnaires during the exam including Rome questionnaire, and the Gastro-Intestinal Quality of Life Index (GIQLI). Severity of symptoms was based on the GIQLI questionnaire, where a higher score represents a better condition. Medical and surgery history, such as drug treatments were then retrospectively collected from medical records, using a computerized research.

Results: A total of 2373 tests from different patients were included. The mean age was 46.0 ± 15.8 years old, with 1727 females (73.7%). The number of positive GBT was 576 tests (24.3%), with 294 tests positive for H_2 only, 214 tests positive for CH_4 only, and 69 tests positive for both. In univariate analysis, a higher age, female sex, and a lower body mass index (BMI) were associated with a positive GBT (Table). A history of diabetes, and a previous gastric surgery (sleeve, or bypass) were associated with a positive test, while proton pump inhibitors (PPI) or opioids intake did not change the outcome (Table). Regarding the symptoms, more severe abdominal bloating and constipation were associated with a positive test (1.28 ± 1.0 vs 1.41 ± 1.1; p=0.02, and 2.67 ± 1.3 vs 2.82 ± 1.2; p=0.03), while abdominal pain and diarrhea were not statistically different (1.57 ± 1.1 vs 1.67 ± 1.1; p=0.07; and 2.23 ± 1.3 vs 2.33 vs 1.4; p=0.14). In multivariate analysis, age (Odds Ratio (OR) = 1.02 [1.01 – 1.03]; p<0.001), BMI (OR=0.93 [0.90 – 0.96]; p<0.001), a previous gastric surgery (OR=9.32 [3.74 – 24.86]; p<0.001) and more severe constipation (OR=0.88 [0.79 – 0.98]; p=0.02) were associated with a positive GBT.

	Negative GBT (n=1797)	Positive GBT (n=576)	p value
Age (years)	44.7 ± 15.5	50.0 ± 16.2	<0.001
Sex (female)	1280 (71.2%)	447 (77.6%)	0.005
BMI (kg/m²)	25.0 ± 5.5	23.9 ± 5.2	<0.001
Diabetes	62 (3.5%)	30 (5.2%)	0.02
Gastric sleeve	8 (0.4%)	14 (2.4%)	<0.001
PPI intake	361 (20.1%)	123 (21.4%)	0.50
Opioids intake	183 (10.2%)	57 (9.9%)	0.91
Irritable bowel syndrome	561 (31.2%)	148 (25.7%)	0.09
Functional dyspepsia	704 (39.2%)	190 (33.0%)	0.08

Conclusion: The result of GBT is more likely to be positive in patients with constipation. A previous gastric surgery is a cofounding factor, leading to a non-interpretable result of the test. A diagnosis of irritable bowel syndrome or functional dyspepsia did not change the result of the test, such as PPI or opioid intake.

THE IMPACT OF GUT MICROBIOTA MODULATION ON THE EVOLUTION OF CELIAC DISEASE

A. Franculescu-Bertea[1], L. Micu[1], E.L. Iliescu[1], I. Copaci[1]

[1]Fundeni Clinical Institute, Center of Internal Medicine, Bucharest, Romania

Contact E-Mail Address: a.franculescu1989@gmail.com

Introduction: The only effective treatment for celiac disease (CD) is lifelong compliance with a gluten-free diet. *Lactobacilli* and *Bifidobacterium* spp. may play a role in the breakdown of gluten. Ithas been demonstrated that *Lactobacilli* can detoxify gliadin peptides after partial digestion by human proteases. These findings could suggest the use of probiotics as complementary therapy for CD.

Aims & Methods: We designed a study to determine the potential effect of a combination of Lactobacillus (acidophilus HA-122, casei HA-108) and Bifidobacterium bifidum HA-132 on perception of symptoms and on the inflammatory-immunological markers in patients with active CD.

25 adult patients were randomized to receive bid of a probiotic combination of Lactobacilus and Biffidobacter for six weeks (13 pts) va a placebo group (12 pts) while being on gluten-free diet. Laboratory studies included routine blood tests, CD specific antibodies, determination of IL-1b, IL-6 and TNF-alpha. CD serology and duodenal histology were performed at baseline, at the end of treatment and at 30 days after therapy. Histological damage in intestinal biopsy samples was graded according to the Marsh modified classification. At baseline and follow-up visit, patients completed the Gastrointestinal Symptom Rating Scale (GSRS) questionnaire. Histological damage in intestinal biopsy samples was graded according to the Marsh modified classification.

Results: 25 pacients, 13 in the probiotic associated arm, 12 in the placebo arm, with median age of 40, BMI 21.2, 18 with symptomatic CD (equal distribuited) and 7 with sublinical CD (4 in the probiotic arm, 9 in the placebo arm). Baseline serology: IGA tTG 1986.6 (group A) vs 1507.1 (placebo group). Baseline hystology (Marsh classification)- Marsh 3a 1 pacient in probiotic group, 2 in the placebo arm. 5 pts Mars 3b3 in group A and 2 in the placebo arm and 17 pts Marsh 3c (9 pts probiotic, 8 pts placebo). IELs density (mean range) was 44.5 in the first group vs 42.5

After treatment: clinical aleviation of indigestion and diareea (p=0.002), constipation (p=0. 0396), gastro-esophageal reflux (p=0.0493) and abdominal pain (p=0.0378)-superior in the probiotic associated treatment.

Serologic parameters: IgA tTG 0,96 in the probiotic arm vs 1,16 in the placebo (p=0.048), IgA EMA 1,05 vs 0,97 (p=0.028), IgG DGP 0,91 vs 1,12 (p=0.21).

Improvement of the inflamatory status: decrease of IL-1b, IL 6 and TNF-a was superior in the probiotic associated group (p=0.071, p=0.083, p=0.078).

Regarding the histologic response: IELs 0,83 vs 1.07 in the placebo arm (p=0.049).

Conclusion: Tests and the lymphocyte infiltrates in the mucosal biopsy specimen in uur study suggests that prebiotic/probiotic treatment may improve symptoms and serology in celiac disease.

Disclosure: I don t have any conflict of interest to declare.

SLEEP DISTURBANCES IN CELIAC PATIENTS UNDER GLUTEN FREE DIET: A PROSPECTIVE STUDY

F. Squeo[1], A. Marotti[1], A. Giangaspero[1], A. Di Leo[1], G. Losurdo[1]
[1]University of Bari, Section of Gastroenterology, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy

Contact E-Mail Address: dott.francescosqueo@gmail.com

Introduction: Celiac disease (CD) is an immune-mediated enteropathy associated with extraintestinal manifestations. It has been hypothesized that sleep disorders may be more frequent in CD patients.

Aims & Methods: The purpose of this study was to investigate the quality of sleep in CD patients and to assess the relationship between poor sleep quality and biochemical parameters.

We included patients with a proven diagnosis of CD at least twelve months prior to enrollment. Patients not fully adhering to a gluten free diet were excluded. All the participants completed the Sleep Scale from the Medical Outcomes Study (MOS sleep scale) and Sleep Problems Index II (SLP9) was calculated. A high SLP9 scale indicated worse quality of sleep and values >20 indicated significant sleep disturbance. Stress was evaluated by PSS-4 scale. Simultaneously, blood samples from each subject were collected and demographic and clinical data were recorded. Linear logistic regression was used for uni- and multivariate analysis, and b coefficient and 95% confidence intervals (CI) were calculated.

Results: We enrolled 53 patients, mean age 42.75±11.19, 84.9 % female. The average hours of sleep per night was 6.47±1.11. Mean SPL9 was 37.44±20.65. Forty patients (75.5%) showed sleep disturbance. At univariate analysis, high SLP9 values (worse sleep) were inversely related to the number of hours of sleep (b=-0.38, 95% CI -11.8 to -2.2, p=0.005) and to vitamin D blood levels (b=-0.57, 95% CI -2.7 to -0.46, p=0.009). In multivariate analysis only serum levels of vitamin D were inversely related to SLP9 (b=-0.47, 95% CI -12.8 to -0.43, p=0.05).

Conclusion: Our study demonstrates that low serum levels of vitamin D are independently associated with poor sleep quality in celiac patients. These findings need to be confirmed in future experimental and clinical studies.

Disclosure: Nothing to disclose.

DIGESTION SUPPLEMENTED WITH COMMERCIAL GLUTENASES: EVALUATION OF THE FATE OF GLUTEN IN PIZZA BY PROTEOMICS AND IMMUNOCHEMISTRY

G. Mazzarella[1], G. D'Auria[2], D.A. Leffler[3], V. Rotondi Aufiero[1], A. Camarca[1], C. Nitride[2], P. Ferranti[2]
[1]Institute of Food Sciences-CNR, ImmunoMorphology, Avellino, Italy, [2]University of Naples Federico II, Department of Agricultural Sciences, Naples, Italy, [3]Beth Israel Deaconess Medical Center (BIDMC), Harvard Medical School, Boston, MA, USA., Celiac Center, Boston, United States of America

Contact E-Mail Address: Daniel.leffler@takeda.com

Introduction: Celiac disease (CD) is an autoimmune disorder caused by gluten in genetically predisposed subjects. Recently, the market has introduced enzymatic supplements, known as glutenases, that individuals can ingest before a meal. These supplements can include single enzymes or mixtures facilitating the digestion; however, their potency is unclear.

Aims & Methods:

We developed an analytical process for assessing the effect of supplements on gluten digestion. A standardized pizza recipe was created and used as substrate in a novel *in vitro* model of gastroduodenal digestion (INFOGEST)[DL1] [GDA2] . 3 different commercial supplements (S1, S2 and S3) were tested. The digestion products were qualitatively monitored in the gastric and duodenal phases using electrophoresis. Primary amines were used to quantify the production of proteinaceous degradation products. Finally, we assessed the digestion resistance of immune-toxic gluten epitopes by using a commercial G12-based ELISA.

Results: Samples treated with supplements showed a reduced number of electrophoretic gluten-related bands [DL3] [GDA4] [GDA5] after gastric digestion as compared with the control. This suggests a faster gluten digestion in the stomach. The highest content of primary amines was determined in the presence of S1 and S2, supplements formulated to contain proteases, peptidases, and starch-degrading enzymes which are active at various pH levels, assisting gluten degradation by gastroduodenal enzymes. The ELISA assay showed a more rapid degradation of G12-immune-toxic epitopes in the presence of S3-a supplement containing prolyl-oligopeptides, that cleave proline-rich motifs.

Conclusion: The developed approach was effective in assessing the ability of commercial glutenase supplements to reduce the potential immune toxicity of gluten-containing ingredients.

Disclosure: This study was supported by an unrestricted grant from Takeda Pharmaceuticals.

THE FREQUENCY OF CELIAC DISEASE AND ITS ASSOCIATION WITH INFERTILITY IN WOMEN REFERRING TO INFERTILITY CLINICS; A CASE-CONTROL STUDY IN SOUTHERN IRAN

E. Rahimpour[1], A.R. Safarpour[2], S. Shojaei-Zarghani[1], S. Amooee[1], B. Geramizadeh[1], M. Mehrabi[1], M. Zahmatkeshan[1]

Contact E-Mail Address: mehrabi.manoosh@gmail.com

Introduction: Celiac disease (CD) is a multifactorial systemic disease causing enteropathy that can cause a wide spectrum of disorders related to infertility.

Aims & Methods: This case-control study aimed to evaluate the frequency of CD and its association with infertility in women.

This study was conducted on women referred to the Ghadir Mother and Child Hospital in Shiraz. Infertile women were considered as the case group, and fertile women were considered as the control group. Blood samples were taken from participants, and tissue anti-transglutaminase (Anti-TTG Ab) levels were measured. Patients with high levels of Anti-TTG Ab were referred for duodenal biopsy.

Results: One hundred subjects were enrolled in the case group and 200 in the control group. Eight patients in the case group had positive serology, and duodenal biopsy results of four were positive for CD. Among the control group, one had a positive serology, and the duodenal biopsy result was negative (*P* for between-group differences: 0.001 for serology and 0.012 for biopsy results). There was a positive association between high levels of Anti-TTG Ab and infertility (odds ratio=17.30, 95% CI: 2.13-140.39), even after adjusting for age and body mass index (odds ratio =9.92, 95% CI: 1.17-84.21).

Conclusion: The frequency of CD among infertile women was higher than that of fertile women. The increased levels of Anti-TTG Ab were independently associated with infertility.

Disclosure: None.

Introduction: There is potential for a paradigm shift from a biopsy- to a serology-based diagnosis of coeliac disease in selected adults. However, it remains unknown if this approach would be acceptable to patients. We aimed to explore patients' views and preferences regarding the no-biopsy approach for coeliac disease diagnosis.

Aims & Methods: We developed a discrete choice experiment survey containing 12 different scenarios with 2 possible alternatives (endoscopy & biopsy or serology), to estimate patient preferences. The scenarios were based on 5 attributes: risk of false positive results, risk of missed diagnosis, waiting time to start treatment, risk of complications, discomfort, or pain. Patient preferences and the relative importance of the attributes were estimated using a mixed logit model.

Results: In total, 385 people (70.6% female, 98.2% white) completed the survey. Respondents preferred a serology-based diagnosis over endoscopy and duodenal biopsies (59% vs 41%, β coefficient = 1.88, $p < 0.001$). Diagnostic test accuracy ($p<0.001$), shorter waiting time to start treatment ($p<0.001$), and discomfort levels during the procedure ($p<0.001$) were the most important attributes to respondents. The risk of complications, including perforation and bleeding, did not significantly influence respondents' choices. Respondents with previous endoscopy experience were more willing to undergo endoscopy compared with those who never had one.

Conclusion: The no-biopsy approach to diagnosing coeliac disease is acceptable and preferred by patients over endoscopy and biopsy. Our findings highlight the importance of patient-centred care and shared decision-making in guiding diagnostic strategies for optimal patient outcomes.

Disclosure: Nothing to disclose.

EXPLORING THE VIEWS OF PRIMARY AND SECONDARY CARE PHYSICIANS ON THE NO-BIOPSY DIAGNOSIS OF COELIAC DISEASE IN ADULTS: A QUALITATIVE INTERVIEW STUDY

M.G. Shiha[1,2], F.J Bowker-Howell[1,2], A.M Harper[1], M. Elwenspoek[2], H.A. Penny[3,4], J. Banks[5], D.S. Sanders[3,4]

Introduction: Despite mounting evidence supporting a no-biopsy approach for the diagnosis of coeliac disease in adults, established clinical pathways in primary and secondary care could hinder implementation in clinical practice. The aim of this study was to identify the barriers and facilitators to a no-biopsy diagnostic pathway of coeliac disease in primary and secondary care.

Aims & Methods: We conducted a qualitative study using semi-structured interviews with gastroenterologists and general practitioners (GPs). We used a pre-defined interview topic guide consisting of open-ended questions and prompts to facilitate discussion about the views of primary and secondary care physicians on the no-biopsy diagnosis of coeliac disease in adults. The interviews were conducted in person or virtually, then transcribed verbatim and analysed using reflexive thematic analysis.

Results: We interviewed 24 physicians (12 gastroenterologists and 12 GPs) across England between February and March 2024. Participants (62.5% male, 58.3% from North of England, and 50% non-white) had different levels of experience ranging between 2 and 30 years. Gastroenterologists were more aware of the no-biopsy approach and the evidence supporting it compared with GPs (100% vs. 50%, $p=0.01$). Both groups were supportive of the no-biopsy approach but acknowledged the lack of clear guidelines as a major barrier to implementation in clinical practice. Increased patient satisfaction, shorter waiting times to start treatment, and reduced endoscopy services pressures and costs were perceived as the main advantages of the no-biopsy approach. However, participants had concerns regarding false positive results, missing concurrent pathology, dealing with persistent symptoms after treatment without biopsy confirmation, and the increased workload in primary care.

Conclusion: Primary and secondary physicians are willing to adopt a serology-based diagnosis of coeliac disease in adults. The safe and effective implementation of this no-biopsy approach depends on developing clear evidence-based clinical guidelines and referral pathways, along with comprehensive education for all healthcare providers involved.

Disclosure: Nothing to disclose.

Introduction: Coeliac disease (CD) is an immune-mediated systemic disorder caused by gluten proteins, affecting approximately 1% of the population. The cardiovascular (CV) and metabolic effects of the disease and the gluten-free diet (GFD) used for its treatment are controversial. Current guidelines suggest that the Mediterranean diet is the most suitable for reducing the risk of CV and metabolic disease, both in terms of primary and secondary prevention. The optimal GFD is based on the Mediterranean diet.

Aims & Methods: Our aim was to assess the body composition and adherence to the Mediterranean diet of CD patients who have been on a GFD for at least 1 year. Body composition was measured with an InBody 770 device and adherence to the Mediterranean diet was assessed with a 14-item questionnaire. Descriptive statistics and Spearman's rank correlation test were applied to analyze our data, provided as mean ± standard deviation.

Results: Data from 105 patients (84 females, 21 males, mean age 36±13 years) were analyzed. Regarding body composition, body weight was 68±17 kg, BMI was 23.9±5.5 kg/m^2, waist-hip ratio was 0.89±0.07, body fat percentage was 27±10%, skeletal muscle mass was 27±7 kg and visceral fat area was 89±50 cm^2 on average. CD patients' Mediterranean diet adherence was low (5.44±1.54 points), due to an inadequate consumption of whole grains (34.3%), fish (22.9%), avocado (13.4%) and red wine (29.5%).

Conclusion: Despite the lack of correlation between body composition parameters and adherence rates, patients with CD have an elevated waist-hip ratio and visceral fat area, as well as insufficient intakes of fibre, fish and red wine. Our data suggest that, in addition to maintaining a GFD, an increased fibre consumption and adherence to a Mediterranean diet are necessary for the prevention of CV and metabolic complications, which should be emphasized during patient follow-up.

Contact E-Mail Address: Daniel.leffler@takeda.com

Introduction: Quality of life (QoL) measures and symptom frequency/severity are common patient-centred outcomes in clinical practice and drug trials. However, the relationship between QoL measures and symptom burden among patients with celiac disease (CeD) is poorly understood. This study evaluated QoL scores in relation to self-reported symptom severity.

Aims & Methods: The Virtual Celiac Symptoms Study (NCT05309330) is a patient survey that followed US adults (≥ 18 years) and adolescents (12–17 years) with CeD currently adhering to a gluten-free diet, for a study period of 12 weeks. Participants self-reported daily symptom severity through the Celiac Disease Symptom Diary 2.1© (CDSD 2.1) and completed the Celiac Disease Quality of Life 20-item questionnaire (CD-QoL) covering a 30-day recall period through a web application. The CDSD 2.1 included five core CeD symptoms (abdominal pain, bloating, diarrhoea, nausea, and tiredness) scored 1 to 5 as none, mild, moderate, severe, and very severe, respectively. The CD-QoL total scores range from 20 to 100, with higher scores corresponding to better QoL. The CDSD 2.1 score was calculated as the daily average symptom severity during the 4 weeks prior to completing the CD-QoL and was categorized as increasing score quartiles; quartile 1 (Q1, reference) represented the lowest possible score and Q4 the highest possible score. In addition, individual CDSD 2.1 symptoms were categorized by severity (none/mild [reference], moderate, and severe/very severe). The mean adjusted percentage difference and 95% confidence interval (95% CI) in CD-QoL scores was estimated by generalized linear regression which included terms for age, sex, race, years since CeD diagnosis, and body mass index.

Results: At Week 7, 404 participants in total had complete information on CD-QoL and CDSD 2.1 scores. The mean (standard deviation [SD]) CD-QoL score was 56.83 (19.21) and the mean (SD) score for CDSD 2.1 was 0.72 (0.56). The CD-QoL scores had a positive linear association with CDSD 2.1 overall scores as well as with individual symptom severity scores. Participants had a 52.7% (95% CI: 39.2%, 67.4%) higher CD-QoL score when comparing those in CDSD 2.1 Q4 (median [min–max] score 1.19 [0.85–3.00]) with those in Q1 (reference; median [min–max] score 0.07 [0.00–0.19]), which was unchanged when tiredness was excluded from the CDSD 2.1 score (53.2% [95% CI: 39.9%, 67.8%]). The positive association between CD-QoL and CDSD 2.1 was mainly driven by abdominal pain, tiredness, and bloating. Comparing participants with severe/very severe symptoms with those with none/mild symptoms, the CD-QoL score was 38.8% (95% CI: 28.2%, 50.2%) higher for abdominal pain, 37.8% (95% CI: 25.5%, 51.3%) higher for tiredness, and 32.2% (95% CI: 21.7%, 43.6%) higher for bloating.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In patients with CeD assessed via a digital platform, those with a higher symptom severity burden, assessed with CDSD 2.1, had significantly greater (worse) CD-QoL scores, which suggests that the CDSD 2.1 might be a good indicator of clinically active disease among patients with CeD.

Contact E-Mail Address: fabiana.zingone@unipd.it

Introduction: The healthcare burden among patients with celiac disease (CeD) following a gluten-free diet is still uncertain. The aim of this study was to compare the frequency of comorbidities, medication use and medical procedures among patients with CeD, pre- and post-diagnosis.

Aims & Methods: This case-control study was conducted in US individuals with and without CeD (1:5 ratio), matched for age, sex, region and diagnosis year using MarketScan claims data (2002-2023). CeD diagnosis was defined as ≥1 inpatient or ≥2 outpatient International Classification of Diseases (ICD)-9/-10 diagnostic codes and all individuals had continuous medical/pharmacy enrolment for 2 years pre-/post-index. Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated by logistic regression comparing CeD cases and controls.

Results: The 21-year data coverage period included 39,814 patients with CeD and 198,961 individuals without CeD (matched controls) with similar baseline demographics (mean age 41.6 years [standard deviation 20.1]; 70.5% female). Comorbidities, medication use, and medical procedures were higher among individuals with CeD versus controls at 2 years pre- and post-diagnosis.

Two years pre-diagnosis, the frequency of depression/anxiety and use of antidepressants and anxiolytics was greater for individuals with CeD versus without CeD (OR: 2.0 [95% CI 1.9–2.0]), 1.5 [1.5–1.5] and 1.5 [1.4–1.5], respectively), and remained higher 2 years post-diagnosis (OR: 2.2 [2.1–2.3], 1.6 [1.5–1.6] and 1.6 [1.6–1.7], respectively).

The odds of medical procedures were higher comparing individuals with CeD versus without CeD, with the strongest associations for video capsule endoscopy and oesophagogastroduodenoscopy (OR: 9.6–19.9 pre- and post-diagnosis).

Conclusion: Comorbidities, medication use, and medical procedures were greater in individuals with CeD than matched controls, both pre- and post-diagnosis, indicating a continued burden for patients with CeD as well as the healthcare system.

Disclosure: MA, SM, VG, SG, RS, DAL, IP and NC are employees and shareholders of Takeda. BL has nothing to disclose. FZ served as a speaker for Werfen and a consultant for Takeda.

Introduction: There is a paucity of data on mesenteric lymph node cavitating syndrome (MLNCS); a rare complication of coeliac disease, characterized by central necrosis within enlarged mesenteric lymph nodes.

Aims & Methods: A case series of all patients with MLNCS at Sheffield Teaching Hospitals, UK between 2000 and 2022.

A further systematic review using PubMed and Google Scholar for patients with MLNCS and coeliac disease until 2022.

Results: In our case series, 5/6 patients were female (mean age:58 years (SD:14.1 years)). Half of patients presented with weight loss, and all were diagnosed by CT scan. Five patients followed a gluten free diet (GFD) and 3 were still alive 1-6years later, 2 died after 5 and 9 years. One did not follow a GFD and died at 1 year.

From the literature 44 patients were identified with MLNCS (52% female, mean age 52 years (SD:14.0 years)) and 16% had refractory coeliac disease (RCD). Common features were persistent villous atrophy (90%), weight loss (82%) and hyposplenism (80%). Forty followed a strict GFD, and 28 had partial or complete improvement of their symptoms whilst 19 died. Twenty-one were treated with steroids and 12 of them died.

The overall mortality was 44% and associated with cachexia (5), lymphoma (4), and infectious complications (4).

Conclusion: MLNCS was indicative of a poor prognosis and commonly presented with weight loss, hyposplenism, persistent villous atrophy and RCD. An early diagnosis and strict GFD may lead to a better prognosis. The role of immunosuppression is unclear and needs further investigation.

Disclosure: Nothing to disclose.

Contact E-Mail Address: lisa.lungaro@gmail.com

Introduction: Celiac disease (CD) is a gluten-related autoimmune enteropathy affecting human leukocyte antigen (HLA) DQ2 or DQ8 positive subjects.[1] CD onset can occur at any age and with several clinical phenotypes. Modern serological markers have significantly improved the diagnosis of the disease, which affects about 1% of the population worldwide.[1-3] Hence, CD serology helps to detect CD in patients with non-classical symptoms or even in those who are asymptomatic.

Aims & Methods: This study aims to analyze the clinical presentation, serology, histology, associated diseases, complications, and death rate of a large cohort of CD patients diagnosed and followed up over forty years. This is a retrospective study on 1547 CD patients (1170 females and 377 males; mean age at diagnosis: 33.1±24.4 years; F:M ratio = 3.1:1), consecutively diagnosed from January 1980 to December 2020 at our referral center (Department of Medical and Surgical Sciences, St. Orsola-Malpighi Hospital, Bologna, Italy). CD diagnosis was established following positive serological tests and confirmed by duodenal histology. The evaluated serological markers included: total immunoglobulin A (IgA), anti-transglutaminase(TG)-2 and anti-endomysium (EmA), both of IgA type; in cases with IgA deficiency, the immunoglobulin G (IgG) antibody anti-TG2 or against deamidated gluten peptides were considered.[4] Comorbidities and complications were recorded at diagnosis and during follow-up.

Results: The rate of CD diagnoses quadrupled after the year 2000. The most prevalent phenotype was the non-classical CD (63.3%), and the most frequent histotype was Marsh 3C (44.7%). Gastrointestinal manifestations, affecting about half of patients (51%), included diarrhea (24.3%), bloating (28%), and aphthous stomatitis (19.7%). Among the CD-associated disorder, osteopenia was the most common (59.9%) and predominantly affecting females (64.3%). Extraintestinal manifestations were anemia (35.8%, with low levels of ferritin and folic acid malabsorption detectable in 87% of patients), cryptogenic hypertransaminasemia (27.9%), and recurrent miscarriages (11.5%). The prevailing CD-related autoimmune disorders were thyroiditis (26.9%), type 1 diabetes mellitus (2.9%), and dermatitis herpetiformis (1.4%). Six patients had inflammatory bowel disease (2 Crohn's disease and 4 ulcerative colitis). Complications occurred in 1.8% of cases, and the mortality rate was 1.9%.

Conclusion: This forty-year, single-center, large cohort analysis showed that the clinical presentation of CD changed over the years, with an increase of non-classical and subclinical phenotypes. Our study highlighted three main aspects: i) the non-classical and subclinical phenotypes prevailed over the classical forms, according to the recently established criteria; ii) modern serological tests allowed an earlier, faster, and more precise CD diagnosis, even at the subclinical stage, thus contributing to explain the increased diagnostic yield; iii) some CD-associated disorders correlated with gender (e.g., osteopenia which prevailed in women). In conclusion, our data confirmed and broadened current knowledge on CD, and help physicians to recognize new CD presentations, thus avoiding diagnostic delay and inappropriate management.

Introduction: Celiac disease (CD) is an immune-mediated systemic disease, triggered by the ingestion of gluten, which only develops in genetically predisposed individuals. The main characteristics of the disease are the gluten-dependent small intestinal mucosal lesion, villous atrophy and crypt hyperplasia, and the production of the specific serum autoantibodies. The gold standard for diagnosis has been based on the biopsy findings. In 2012, new ESPGHAN diagnostic guidelines removed the necessity of duodenal biopsy in symptomatic children showing a high serum transglutaminase 2 titers (TG2-IgA) together with the presence of endomysial antibodies (EmA) and HLA DQ2 and/or DQ8.

Aims & Methods: Our aim was to assess the clinical outcome of the diagnostic change in children by comparing new serology-based diagnosed patients to the biopsy-based ones.

We conducted a retrospective analysis of data collected from the medical charts of the patients diagnosed during a four-year period, from 2010 to 2014, being a time overlapping the guideline change. From a total of 63 patients, 30 were biopsy-diagnosed and 33 diagnoses were based on serology only. Clinical data and laboratory parameters were compared between the groups at diagnosis and at follow-ups at 1 year, 2 years and at their latest follow-up visit during the gluten-free diet (GFD) treatment, median time 8.7 years for the serology-based group and 10 years for the biopsy-based group.

Results: Our results show clear improvement upon GFD in gastrointestinal symptoms in both groups. However, there was a general trend for better treatment outcomes in the biopsy-based group compared to the serology-based group at 1 and 2 years of follow-up. Body mass index Z score was in the biopsy group at baseline -1.5, at 1 year on GFD -0.2 and at 2 years -0.2. The corresponding results in the serology group was -1.51, -0.8 (p=0-056), and -1.35 (p=0.023). Anemia was observed in the serology group

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

at one year as frequently (25%) as at baseline (26.7%) but in the biopsy group improvement from baseline was seen, 27.4% to 7.1 % of patients. At two years, anemia was present in 16.6% of patients. Ferritin values were significantly lower in the serology group at one year (27.5 µg/L vs 59, p=0.040) but not anymore at 2 years. After two years on GFD both TG2-IgA and EmA were often still above the cut-off for positivity in both diagnostic groups (serology group 58.3 % and 50% respectively and in the biopsy group somewhat less, 50% and 28.6% respectively). At long term, no anemia was present anymore. However, 4 children from serology group and 8 from the biopsy group showed antibodies above cut-off even after 8.7 and 10 years of treatment, respectively. Upon long-term follow-up the patients from the biopsy-proven group seemed to be more compliant with the follow-up visits and more adherent to the gluten-free diet.

Conclusion: Both clinical and laboratory results show slow recovery upon gluten-free diet. High percentage of autoantibody positivity still at 2 years on GFD indicates substantial amounts of gluten in the diet. Biopsy-proven patients seemed to have a faster recovery than the serology-diagnosed. Serological diagnosis also appears to negatively influence the adherence and compliance to treatment and follow-up. Novel (drug/vaccine) treatments adjunctive to GFD are an unmet need also in children. Duodenal mucosal recovery results on long-term GFD are warranted.

Disclosure: Nothing to disclose.

Introduction: Anti-Saccharomyces cerevisiae antibodies (ASCA) and anti-neutrophil cytoplasmic antibodies (ANCA) are well recognized as serological markers in inflammatory bowel diseases (IBD). With the growing evidence of a bidirectional association between IBD and celiac disease (CD), there has been an increased interest in identifying shared biomarkers for both conditions.

Aims & Methods: We aimed to assess seroprevalence of ANCA, IgA and IgG ASCA, in newly diagnosed CD patients. CD diagnosis was set according to 2013 ACG guideline and 2019 ESsCD guideline. Serum collected at the time of diagnosis for all CD patients was analyzed for IgA and IgG ASCA, and ANCA concentration, using INOVA Quanta Lite® assays. Positivity cut-off was defined as ≥ 25U for ASCA and > 30U for ANCA.

Results: Altogether 82 newly diagnosed CD patients, 82.9% female, were recruited, all of them having atrophic mucosal injury on duodenal biopsy sampling and one being seronegative CD. While none of the CD patients had positive ANCA, seroreactivity against Saccharomyces cerevisiae was seen in 32.93% of cases for IgG ASCA. A lower prevalence for IgA ASCA was recorded, of 4.88%, due to associated IgA deficiency. Moreover, 7.32% of newly diagnosed CD patients had equivocal result for IgG ASCA.

Conclusion: A high prevalence of ASCA, particularly IgG type, was seen in newly diagnosed, biopsy-proven CD patients. Future research should investigate the clinical significance of the seroreactivity to IBD-specific antibodies in CD patients.

SEROLOGICAL DIAGNOSIS OF COELIAC DISEASE - A WEB-BASED SURVEY AMONG NORWEGIAN GASTROENTEROLOGISTS

N. Gjerstad[1], K.E. Lundin[2]

[1]Institute of Clinical Medicine, Oslo, Norway, [2]Norwegian Coeliac Disease Research Centre, University of Oslo and Oslo University Hospital, Gastroenterology, Oslo, Norway

Contact E-Mail Address: knut.lundin@medisin.uio.no

Introduction: Serological diagnosis of coeliac disease (CeD) is accepted for pediatric patients in Europe [1]. Both the 2019 European guidelines and the 2023 American guidelines from the American College of Gastroenterology required a diagnostic biopsy in adults [2, 3]. In recent years we have seen several studies addressing the no-biopsy approach in adults [4-6]. Wide-spread implementation of no-biopsy approach demands precise instructions on how the diagnosis can be made and by whom.

Aims & Methods: We aimed at investigation the acceptance among clinicians for a no-biopsy approach, and how they follow current guidelines. A digital survey was sent in November 2023 to members of the Norwegian Society for Gastroenterology. It was sent out once, no reminder, and was open for one month. Replies were collected anonymously. The Society has 452 members including 256 gastroenterologists. Almost all specialists are members of this Society.

Results: We received 72 replies. Of the respondents, 48 were male and 22 female, 1 not-binary and 1 did not answer. Five of them were not clinically active. Fifty-eight of 72 adhered to guidelines and routinely took biopsies both from the bulb and the distal duodenum. Forty-five took 4 biopsies from the distal duodenum, only five of them 2 biopsies. Negative serology was considered insufficient to exclude CeD by 52 respondents. All used IgA-TG2 for diagnosis, 41 also IgG-DGP, whereas 6 used endomysium test (EMA) and 4 also anti-gliadin antibodies. We initially asked if positive serology alone could diagnose CeD and received mixed response; 26 supported the notion, 37 did not and 9 did not know. We thereafter provided information on no-biopsy diagnosis for children. With this information, fourty responders supported serological diagnosis without biopsy, 10 were negative and 21 uncertain. The majority (32) requested 2 strongly positive (more than 10 x ULN) IgA-TG2, whereas 14 considered a single strongly positive test as sufficient. Specialists deemed capable of setting the diagnosis was gastroenterology (48 votes), general practitioner (22 votes), internists (21 votes) any doctor (10 votes). However, half of the respondents considered it not necessary to personally meet the patient to make a diagnosis.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The no-biopsy approach receives support; but the precise set-up is not clear. If a no-biopsy approach is agreed upon, we should decide on single or repeated tests, on the use of EMA or rely on only IgA-TG2, and if IgG-DGP has a role. The coeliac community should agree on precise guidelines to minimize misdiagnosis and provide the patients with a clear and definite diagnosis.

Introduction: Celiac disease (CD) is an autoimmune enteropathy triggered by ingestion of gluten in genetically susceptible individuals. It has extremely varied clinical presentations. Diagnosis of celiac disease is made by history and clinical presentation compatible with CD, serological screening compatible with CD, histological findings compatible with CD, obvious clinical and serological response to a gluten-free diet, and exclusion of other clinical conditions mimicking CD. Not much is known about presentation of this disease in Pakistani adults.

Aims & Methods: The study is cross-sectional in nature, gathering data from celiac support communities on social media platforms throughout Pakistan. Patients who were diagnosed cases of Celiac
disease on the basis of serology and/or histopathology were interviewed via a structured questionnaire via non probability consecutive sampling technique. Patient's age, gender, age of diagnosis, diagnostic modality, intestinal and extra-intestinal symptoms, gluten free diet status and response and challenges in gluten free diet were recorded while ensuring patient anonymity. Data was entered and statistical analysis was performed via IBM SPSS version 25.

Results: A total of 340 patients were enrolled in present study. Most predominant intestinal symptom was Diarrhea reported by 46.8% of participants followed by Abdominal pain/Bloating in 44.7% (Figure I). Most common Extra-intestinal features were Anemia reported by 51.5% of patients (Figure II). Of note constipation was reported by 21.5% and Stunted growth by 35.3% of patients. Most common utilized diagnostic modality was Serology in 62.9% of patients (Figure III). 86.8% of patients reported symptom resolution with Gluten free diet. This association was statistically significant. Patients who reported Abdominal pain/Bloating were significantly more likely to report improvement in symptoms following Gluten free diet (Figure IV). Challenges in Gluten free diet were availability issues reported by 37.5% followed by financial issues in 25%, social challenges in 19.2% and other issues including compliance and cross contamination by 40% (Figure V)
Pie & Bar Charts for Abstract

Conclusion: Celiac Disease has an extremely Variable Presentation in Pakistani patients. It can present with Classical Diarrhea and Non classical presentation with abdominal pain and bloating as well. Adherence to Gluten free diet was associated with reduction in Symptoms and improvement.
Financial constraints and limited availability of gluten-free products are contributing factors to non-adherence to gluten-free diet. Further Studies are needed to know more about the Variability of Symptoms in underdeveloped Countries.

Disclosure: Nothing to disclose.

Contact E-Mail Address: michele.dota01@universitadipavia.it

Introduction: The data on the impact of coeliac disease on work loss are still scarce [1-3]. We aimed to evaluate the amount of hours lost at work in adult coeliac patients on a gluten-free diet (GFD), focusing on the reasons behind the work loss (WL), and the relationship with quality of life (QOL) and psychological morbidity.

Aims & Methods: Adult patients with biopsy-proven CD under regular follow-up at two Italian centres were surveyed between October 2022 and January 2024. The survey consisted of specific questionnaires, including the Work Productivity and Activity Impairment questionnaire (WPAI:CD), gastrointestinal symptoms severity score (Visual Analog Scale, VAS), the Coeliac Disease-specific Quality Of Life scale (CD:QOL), the State-Trait Anxiety Inventory scale (STAI-Y1 & STAI-Y2), and the Beck Depression Inventory scale (BDI-II). Amount of hours lost at work in the previous 7 and 30 days were specifically investigated and statistically analysed.

Results: 160 patients on a GFD (121 F, mean age at CD diagnosis 32±14 years, 6% in a GFD for less than 1 year, 63% for more than 5 years, 31% for 1 to 5 years) were enrolled. Eight/160 (6.0%) patients reported having lost working hours in the previous 7 days and 15/132 (11.3%) in the previous 30 days. Reasons for work loss at 30 days included symptoms persistence despite the GFD (40%), attendance of outpatient clinic (40%) and issues with GFD adherence (20%).
The patients had a mean of 3.1 hours of missed work at 7 days and 5.0 hours at 30 days. Focusing on the patients that experienced WL in the previous 30 days, we have found that they were more likely to have on-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

going symptoms despite the GFD (67% vs 93%, p=0.04), scored higher on the survey items regarding depression (median BDI-II score 7.00 vs 12.00, p=0.04), and self-reported a lower QOL (median CD:QOL score 85.00 vs 75.00, p=0.03).

Conclusion: Our clinical data-based study has shown that CD patients can experience a substantial work loss at 30 days, particularly in case of persistence of symptoms despite a GFD, which can have negative impacts on psychological health, as well as overall QOL. This aspect should be considered when trying to develop personalized strategies for the individual follow-ups of coeliac patients.

A DECADE OF COELIAC DISEASE: A COMPARATIVE STUDY OF THE MALTESE ISLANDS (2013-2023)

L. Miruzzi[1], J. Schembri[1], M.D. Grixti[1], P. Ellul[1], M. Sciberras[1]

[1]Mater Dei Hospital, Msida, Malta

Contact E-Mail Address: lara.g.miruzzi@gmail.com

Introduction: Coeliac disease (CeD) is a chronic autoimmune condition affecting the small intestine triggered by gluten.

Aims & Methods: To assess the national management of newly diagnosed CeD patients between 2013 and 2023 in Malta and whether this was carried out in accordance with "European Society for the Study of Coeliac Disease (ESsCD) guideline for CeD and other gluten-related disorders"[1].

The national statistics data of all the newly diagnosed patients with CeD between 2013 and 2023 in the Maltese Islands, were retrospectively analysed. Several factors were considered including patient demographics, serology, histology, imaging and dietitian referral.

Results: 171 patients with newly diagnosed CeD (2013 n=46, 2023 n=125) were recruited. Adults, defined as ≥18 years, accounted for 72.5% (n=124) of the total cohort.

In 2013, 80.4%(n=37) were female while in 2023, 66.4% (n=83) were female (p=0.07), The mean age at diagnosis was 38.5 years (SD19.6) in 2013 and 36.6 years (SD23.4) in 2023. The largest proportion, 17.0%(n=29), were diagnosed in the 31 to 40 age group.

Anti-Tissue Transglutaminase Antibody (anti-TTG IgA-Ab) was taken in 99.4%(n=170), with 92.4%(n=158) having a positive anti-TTG. 4.1%(n=7) had negative anti-TTG IgA-Ab while 2.9%(n=5) had borderline anti-TTG IgA-Ab. Of these 12 patients, 11 patients had biopsies taken with histology confirming the diagnosis of CeD. The other patient was 8 years old with IgA deficiency and had a positive anti-TTG IgG-Ab, with a value of >250 U/mL.

73.1%(n=125) of the total cohort had biopsies taken, with 56.0%(n=70) taken from D2, 3.2%(n=4) taken from D1 and 37.6%(n=47) taken from both D1 and D2. In 3.2%(n=4), the biopsy site was not specified. In 2023, 48.2%(n=41) of patients had D1+D2 biopsies taken, versus only 15%(n=6) in 2013 (p<0.001). Of the remaining 26.9%(n=46) who did not have biopsies taken, 73.9%(n=34) were children.

48%(n=60) of the patients in 2023 were referred to the dietician versus 15.2%(n=7) in 2013 (p<0.001). From the total cohort, only 39.2%(n=67) were referred to the dietician. DEXA scan was carried out in 49.1%(n=84), 40% referred patients in 2023 versus 74% in 2013. 11 patients, 6.4%, required small bowel imaging.

73.7%(n=126) had repeat TTG taken after diagnosis. Only 9 patients, (7.2%), had repeat biopsies taken.

Conclusion: This is the first review of CeD in the Maltese Islands showing a percentage increase over ten years of 171% in diagnosis. The incidence rate was 9.2 new cases per 100,000 in 2013 and 24.3 new cases per 100,000 in 2023. CeD diagnosis was x2.4 times commoner in females. This significant change is also accompanied by the increase in D1 biopsies taken in addition to D2 (p<0.001).

An improvement was noted in the number of dietician referrals carried out from 2013 to 2023. DEXA scan testing was carried out in nearly half the total cohort emphasizing the need to consider this investigation especially in those patients who are at high risk of osteoporosis.

A limitation of this study was the fact that biopsies taken in the private sector were not available for review. Therefore from the total cohort only 7%(n=12) did not have an available biopsy result or review.

A multidisciplinary team approach to the management of CeD is crucial and will help to provide the best outcomes for the patient.

SCREENING FOR COELIAC DISEASE IN INFLAMMATORY BOWEL DISEASE

J. Schembri[1], L. Miruzzi[1], M.D. Grixti[1], N. Sciberras[1], J. Barbara[1], D. Gauci[1], P. Ellul[1], M. Sciberras[1]

[1]Mater Dei Hospital, Msida, Malta

Contact E-Mail Address: lara.g.miruzzi@gmail.com

Introduction: Coeliac disease (CeD) is an autoimmune condition affecting the small intestine. Research has shown a likely bidirectional association between CeD and Inflammatory Bowel Disease (IBD)[1].

Aims & Methods: Our aim is to retrospectively assess whether patients with IBD are screened for CeD in Malta.

284 patients with a histological diagnosis of IBD were randomly selected from the hospital IBD pool. They were grouped into those receiving biological therapy and those solely on immunomodulators. Data collected included age, sex and whether coeliac serology (TTG – IgA or EMA) and/or duodenal biopsies were taken and whether the results were compatible with a diagnosis of CeD.

Results: From 284 patients (58.1% male, mean age 44.5 years SD=16.4). 58.5% had Crohn's disease, 41.5% had Ulcerative Colitis. 65.1%(n=185) were on biological treatment (Infliximab=21.5%, Adalimumab=22.2%, Vedolizumab=17.6%, Ustekinumab=3.9%).

Out of all patients, 79.9%(n=227) underwent CeD immunology tests either at the time of diagnosis or during follow-up, with no difference in gender (p=0.79) or IBD subtype (p=0.32) whether serology was taken or not. Among them, five patients (2.2%) tested positive for coeliac antibodies. However, only three of these individuals proceeded to have duodenal biopsies performed.

One of these patient's biopsies yielded results consistent with Coeliac disease. All these five patients had repeat TTGs, while four of them had DEXA scan performed. 3 patients with positive CeD serology had small bowel imaging. 33.5% of IBD patients had duodenal biopsies taken during upper GI endoscopy.

Conclusion: It's reassuring to observe that a significant majority (79.9%) of patients with IBD underwent testing for CeD. However, despite consistent follow-up in gastroenterology clinics, one-fifth of IBD patients in our cohort were never tested. Our findings reveal a local incidence of CeD in IBD of 0.4%, which is slightly lower than the reported 0.75% [1].

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

This underscores the significance of considering CeD as a potential pathology that may contribute to ongoing symptoms and abnormal blood test results in IBD patients.

EVALUATION OF GLUTEN-FREE DIET ADHERENCE AND QUALITY OF LIFE IN COELIAC PATIENTS

H. Yacoub[1], H. Debbabi[1], D. Cherif[1], H. Hassine[1], H. Kchir[1], N. Maamouri[1]

[1]*La Rabta Hospital, Tunis, Tunisia*

Contact E-Mail Address: yacoubhaythem@hotmail.com

Introduction: As there is currently no drug treatment available to cure celiac disease (CD), treatment is based on a strict, lifelong gluten-free diet (GFD). The GFD is very restrictive and patient adherence is not always a guaranty.

Aims & Methods: The aim of our study was to evaluate adherence to the GFD and the impact of the disease on quality of life.

We conducted a cross-sectional study, includoiong celiac patients followed up at the consultation during the period from January to March 2023. Adherence to the GFD was assessed using the validated Biagi questionnaire, and patients' quality of life was assessed using the CD-Qol questionnaire, which we translated into Tunisian dialect.

Results: We included 33 patients followed for celiac disease with confirmed diagnosis assessed by anatomopathological examination according to Marsh classification. The mean age of included patients was 42.2 years. The sex ratio (M/F) was 0.32. The mean course of the disease was 13.3 years. The dietary survey revealed insufficient macronutrient intake and unbalanced macronutrient distribution (67% of patients). Assessment of adherence to the GFD revealed that 44.4% of patients followed the diet strictly, 33.3% followed the GFD non-strictly, and 22.2% did not follow the GFD at all. The most frequent reason for non-adherence to the GFD was economic issues (87.9%). With regard to quality of life, 57.7% of patients had a good quality of life, as evidenced by a high CD-Qol score > 73. Only 12.1% of patients had poor quality of life (low score < 46). Patients with good adherence to RSG had better quality of life (p=0.027).

Conclusion: Our study demonstrates the link between adherence to the RSG and quality of life in coeliac patients, hence the importance of encouraging patients to follow the diet properly.

Disclosure: No conflict of interest.

PP0319

AWARENESS AND KNOWLEDGE OF CELIAC DISEASE AMONG THE HEALTH CARE PROFESSIONALS: A CROSS-SECTIONAL SURVEY FROM THE LARGEST PUBLIC SECTOR HOSPITAL OF KARACHI, PAKISTAN

M. Mujahid[1]

[1]*Jinnah Postgraduate Medical Center, Gastroenterology and Hepatology, Karachi, Pakistan*

Contact E-Mail Address: murk.mujahid@hotmail.com

Introduction: Celiac disease (CD) is a common chronic illness with various clinical presentations. Despite a rise in prevalence, 95% of patients go undetected, often misdiagnosed or ignored. Inadequate understanding among healthcare professionals contributes to this delay.

Aims & Methods: To evaluate the knowledge of HCPs regarding celiac disease.

Results: Out of 374 participants, 196 (52.4%) were male and 178(47.5%) were female, indicating sample diversity. Furthermore, the split of professional roles demonstrates the vocational diversity of the sample, with nurses comprising the largest group at 147 (39.3%), followed by internees 106(28.3%), house officers 93(24.8%), and medical officers 28(7.49%). The study reveals that a majority of the population perceives the disease as autoimmune, with a higher percentage believing it can be hereditary.

The perception of the illness as lifelong is prevalent, with a high confidence in a cure. A significant proportion acknowledge the potential reversal of symptoms through a strict gluten-free diet, but also associate gluten with sensitivity and allergies.

According to the poll, most people are aware of the symptoms of celiac disease, including chronic diarrhea, bone pain, stomach pain, bloating, exhaustion, weight loss, and skin/nail manifestations.

Conclusion: The study highlights the unsatisfactory knowledge level among HCPs regarding CD, suggesting the need for increased awareness and e-learning activities to improve CD knowledge.

Disclosure: Nothing to disclose.

PP0320

POTENTIAL CELIAC DISEASE IN CHILDREN: HEALTH STATUS ON A LONG-TERM GLUTEN-CONTAINING DIET

R. Mandile[1], L. D'Antonio[1], M. Carpinelli[1], F. Lerro[1], L. Greco[1], R. Troncone[1], R. Auricchio[1]

[1]*University Federico II, Translational Medical Science, Naples, Italy*

Contact E-Mail Address: r.auricchio@unina.it

Introduction: Potential celiac disease (PCD) is a clinical condition characterized by the presence of a positive CD-specific serology and a normal intestinal architecture. Asymptomatic PCD patients are generally addressed to continue on a gluten containing diet (GCD), but long-term risks of this approach have never been explored.

Aims & Methods: In the present study we aim at investigating nutritional and autoimmune complications possibly developing overtime in a cohort of asymptomatic PCD children left on a GCD. We compared parameters of growth, nutritional status, and autoimmunity between time of diagnosis and in occasion of last medical check, after a long-term gluten containing diet.

Results: Altogether we collected data from 171 PCD children with a mean follow-up time of 3 years (*range 0.35-15.3 years)*. During follow-up, despite patients did not reduce the amount of daily gluten intake , anti-tissue transglutaminase (anti-TG2) antibodies spontaneously and significantly decreased. Most of parameters analysed did not change over follow-up (height centile, ferritin, albumin., cholesterol, calcium, alkaline phosphatase , parathormone, vitamin D, p>0.05) or even improved (weight and BMI

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. centile, haemoglobin, blood iron, HDL, glycaemia and HbA1C, p<0.05), always remaining in the limit of normality. Equally autoantibodies for other concomitant autoimmune disorders did not increase overtime. Similar results were obtained excluding from the analysis patients that stopped producing anti-TG2 and those with a follow up < 3 years.

Conclusion: Our pilot study provides reassuring results on the maintenance of a gluten containing diet in asymptomatic PCD children, even when a long term follow-up is considered.

Introduction: The exact molecular pathways contributing to epithelial abnormalities in celiac disease (CeD) remain incompletely understood. Cellular senescence, characterized by cell-cycle arrest and involving oxidative stress (OS), has been associated with the onset of chronic diseases, and attributed to the decline in regenerative capacity and the release of inflammatory agents. However, the potential involvement of senescence and OS in the context of intestinal mucosal damage in CeD remains to be investigated.

Aims & Methods: Aim: To investigate the presence of senescence and OS markers in the duodenal mucosa of both CeD patients and non-CeD controls.

Methods: This was an exploratory study wherein we analyzed duodenal biopsies obtained from 4 adult patients diagnosed with CeD and 5 non-CeD controls. Senescence was analyzed through the expression of the protein p21 and its relevance in terms of cell proliferation was evaluated by the expression of the protein Ki67 (detection with specific primary antibodies and peroxidase immunostaining). Positive cells were semi-quantified in the surface epithelium and crypts according to the percentage of positive cells among the total cells of the analyzed section (no staining reaction = 0; 1-30% stained nuclei = 1; 31–60% = 2; > 60%= 3). Carbonylated proteins were detected using amino-oxyfunctionalized fluorophores. The intensity of fluorescence was quantified in villi and crypts and expressed as relative fluorescence units (RFU) by surface. The statistical analysis was performed by non-parametric tests.

Results: Intestinal biopsies from CeD patients (3 females; median age 26.5 yr; 25%-75% IQR: 21-29) and non-CeD controls (3 females; median age 38 yr; 25%-75% IQR: 33-38) were studied. The percentage of p21-positive cells in the surface epithelium was not different between CeD patients and controls (median [25-75% IQR]): 100% (95-100%) vs 98% (98-100%), respectively (p=0.6).

By contrast, the expression of p21 in the epithelium of crypts was significantly higher in CeD patients vs. controls (45% [40-67.5%] and (0 [0-1]), respectively (p=0.02). Ki-67 expression in the surface epithelium was higher in CeD patients vs. controls (2% [2-3]) and 0% [0–0%]), respectively (p=0.04), while the determinations were similar in the crypts of both groups. Finally, carbonylated proteins were detected with greater intensity in CeD patients compared to controls both in the surface epithelium (5050 RFU [3862-5622]) vs. 2335 RFU [2324-2477]), respectively (p=0.03), and in crypts (2260 RFU [2197-2598]) vs. (1403 RFU 1313-1476]), respectively (p=0.03).

Conclusion: This exploratory study presents the first evidence of senescence and OS in the duodenal mucosa of CeD patients at diagnosis and compared to controls suggesting that these phenomena could be involved in a dysfunctional epithelial regenerative process in CeD. These novel findings offer new perspectives for understanding CeD mucosal damage. However, further confirmation in a larger series of cases is required to validate these findings.

Introduction: Diagnostics of enteropathy with membrane digestion disturbance (EMDD) is based on the evaluation of carbohydrase activity in duodenal mucosa (DM). There is no information about diagnostic value of ileum mucosa (IM) carbohydrases.

Study objective. Assess the diagnostic value of carbohydrases activity in mucous membrane of duodenum and distal ileum in patients with EMDD and irritable bowel syndrome (IBS).

Aims & Methods: The study includes 12 patients with EMDD, 16 patients with IBS and 12 relatively healthy persons (control group). Study design included analysis of food tolerance and evaluation of activity of sucrase (S), glucoamylase (GA), maltase (M) and lactase (L) in mucous membrane of duodenum and ileum based on the method of Dahlquist with N.I.Belostotsky modification. Microsoft Office Excel and STATISTICA 10.0 were used for statistical evaluation of material. Mann-Whitney criterion was used to evaluate the differences between quantitative parameters. The differences were considered to be significant at p <0.05. Control group was used for comparison.

Results: Ratio of carbohydrase activity in duodenum and ileum in control group and patients with IBS and EMDD.

		Glucoamylase	Maltase	Sucrase	Lactase
Control	Duodenum	776 ±163	2664 ±317	175 ±25	83 ±17
	Ileum	714 ±121	2532 ±438	130 ±27	16 ±4
	P	0.763	0.81	0.2	0.001
IBS	Duodenum	590 ±91	2118 ±124	194 ±33	84 ±6
	Ileum	1275 ±158	4142 ±489	191 ±27	14.4 ±6
	P	0.008	0.0004	0.934	0.002
EMDD	Duodenum	164 ±23	859 ±76	69 ±7	27 ±6
	Ileum	858 ±182	3259 ±59.6	143 ±30	10 ±3
	P	0.0014	0.0009	0.03	0.004

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In control group the carbohydrases activity in duodenum mucosa was not significantly statistically different from the one in ileum mucosa.
In patients with IBS glucoamylase and maltase activity parameters in IM were significantly different from activity in DM, which can be interpreted as functional inequality of enzyme activity of various departments of small intestine.
In patients with EMDD GA level in ileum mucosa is 5.2 times higher, maltase level is 3.8 times higher and sucrose level is 2 times higher than duodenum enzyme levels, which demonstrates the possibility of formation of compensatory reaction of adaptive shift type towards distal segments of small intestine, initially described by A.M. Ugolev et al. in 1985
Conclusion: Enzyme activity distribution along small intestine is an adaptor function of its segments. Our study confirmed the need and promising outlook of further investigations in terms of evaluation of proximo-distal gradients of enzyme activity to study compensatory reactions which can be fulfilled by distal segment of small intestine in case of duodenum damage.
The evaluation of carbohydrase activity in ileum mucosa provides additional opportunities for diagnostics of EMDD and its differentiation from IBS, which can be used to improve therapeutic approaches.

WHAT IS THE SIGNIFICANCE OF SYMPTOMS DURING THE GLUCOSE SIBO BREATH TEST IN PATIENTS WITH DISORDERS OF GUT-BRAIN INTERACTION (DGBI)?

C.H. Wilder-Smith[1], A. Materna[1], S.S. Olesen[2,3]
[1]Brain-Gut Research Group, Gastroenterology Group Practice, Bern, Switzerland, [2]Aalborg University Hospital, Department of Gastroenterology, Aalborg, Denmark, [3]Aalborg University Hospital, Department of Clinical Medicine, Aalborg, Denmark

Contact E-Mail Address: info@ggp.ch
Introduction: Small intestinal bacterial overgrowth (SIBO) is a commonly diagnosed finding in diverse conditions ranging from DGBI to GI motility, connective tissue and neurodegenerative disorders (1). A wide spectrum of signs and symptoms have been attributed to SIBO (1,2). Diagnosis is achieved either by direct culture of duodenal aspirate or indirectly, by demonstrating exhaled fermentation gases with ingested sugars, such as glucose or lactulose (3,4). In the breath tests used for carbohydrate intolerances, the symptoms provoked are at least as important for the diagnostic interpretation as the measured gas concentrations. However, the symptoms generated during SIBO breath tests are neither evaluated nor mentioned in most testing guidelines. SIBO exists in asymptomatic populations and the association with symptoms remains uncertain (1,2).
Aims & Methods: We examined the acute relationship between breath gases and the symptoms generated during glucose breath tests in DGBI. A standardised breath test with glucose (50g in 150ml water) was performed after a 24-hour low-FODMAP diet and >8-hour fast. Exhaled hydrogen and methane concentrations were measured and symptom assessments (composite symptom index score, SI used for intolerance breath tests)(5) were performed every 15 minutes for 2 hours in 790 male (30%) and female patients of average age 40.0 years referred to our gastroenterology practice with DGBI (Rome 4 criteria). Breath gas concentration thresholds of >20ppm and >10ppm above baseline were considered positive tests for hydrogen and methane, respectively.
Results: Overall, 59 (7.5%) and 111 (14.1%) DGBI patients were SIBO positive using the hydrogen and methane thresholds, respectively. The composite SI was positive in 208 (26.3%) of patients. The most common individual symptoms were fullness, nausea, tiredness, headache (each in >30% of patients), followed by bloating, flatulence, abdominal cramps or pain, GORD and problems concentrating (each in 20-30% of patients). A positive SI with a negative hydrogen test was seen in 151 (19.1%) of DGBI patients, in 108 (13.0%) with a negative methane test and in 55 (7.0%) with both negative hydrogen and methane tests. A negative SI occurred in 2.4% of patients if either of the gas tests was positive.
Conclusion: During the glucose SIBO breath test, positive gas results and evoked symptoms are closely associated. However, glucose frequently provokes symptoms in DGBI patients with negative hydrogen and/or methane breath test results. This may be due to a discrepancy between breath and intestinal gases, production of gases beyond hydrogen and methane, or the induction of symptoms by glucose or its metabolites via alternative mechanisms.

REDUCING THE NUMBER OF BREATH SAMPLES IS A COST-EFFECTIVE STRATEGY TO OPTIMIZE THE LACTOSE BREATH TEST

G. Scalese[1], A. Cesarini[1], L. Pallotta[1], E. Ribichini[1], L. Spina[1], A. Citarella[2], S. Cammarota[2], C. Severi[1]
[1]Sapienza University, Department of Translational and Precision Medicine, Rome, Italy, [2]LinkHealth Health Economics, Outcomes & Epidemiology S.R.L., Naples, Italy

Contact E-Mail Address: scalese.giulia@gmail.com
Introduction: The lactose breath test (LBT), through the measurement of hydrogen (H_2) and methane (CH_4), is the test of choice in assessing lactose malabsorption (LM). Although direct costs of LBTs are low, indirect costs are high due to the long test duration requiring prolonged involvement of qualified staff and available infrastructures. Sampling frequency represents the principal time-consuming part of the test. The current European guidelines recommend a test duration of 3-5 hours (hrs) and sample intervals of 30-60 minutes (min). In our center, the standard LBT consists of 9 samples collected every 30 min up to 4 hrs after the ingestion of 25 g of lactose.
Aims & Methods: The study aimed to optimize the methodology of LBT either by reducing the test duration by up to 3 hrs (Shortened-test: ST) or reducing the number of breath samples with hourly intervals by up to 4 hrs (Five-sample test: FST). Retrospectively, patients (pts) undergoing LBT at the Gastroenterology Unit from January 2022 to October 2023, were included. Gas peak ≥20 ppm for H_2 and/or ≥10 ppm for CH_4 above baseline was diagnostic for LM. Results of ST and FST were calculated from the standard LBT and compared with them. The delta-ppm (Δ-ppm) and the area under the curve (AUC) were calculated to stratify gas excretion into 3 grades of malabsorption (mild, moderate, severe) according to the percentile distribution. Data were expressed as mean (±DS), and analyzed with Chi-square, Mann-Whitney and Pearson correlation. $p<0.05$ was considered statistically significant. Specificity was always 100% due to the lack of an independent gold-standard test.
Results: Of the 543 pts enrolled (F 71.5%, mean age 43.7 ± 17.6 yrs), 60.4% (328/543) were positive for LM and were significantly older (44.7±17 years) than negative ones (40.5±17.6 years) ($p=0.006$). LBTs were mainly positive for H_2 (80.8% for H_2, 8.2% for CH_4, and 11% for both gasses; $p<0.0001$).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

FST showed higher accuracy than ST. In the ST, the positivity rate was 54.1% (294/543), sensitivity was 89.6% with a false negative rate of 10.4% (34/328) and accuracy was 93.7%. In FST, the positivity rate was 57% (309/543), sensitivity was 94.2% with a false negative rate of 5.8% (19/328) and accuracy was 96.5%.

A statistically positive correlation was found between the Δ-ppm value and the AUC, both for H_2 (r=0.94) and CH_4 (r=0.78). In the FST, according to the percentile stratification of Δ-ppm, 84% (16/19) of negative pts showed mild LM (≤25th percentile) and the remaining 16% (3/19) had Δ-ppm values slightly higher.

Conclusion: Comparing FST and ST, only FST proved to be a cost-effective strategy to optimize LBT without reducing test sensitivity. Extending the interval of breath sampling collection with hourly measurements reduces the indirect costs, by decreasing the involvement of qualified staff and maximizing the procedure by doubling the number of pts who could be tested in a day.

EFFICACY AND QUALITY OF LIFE IMPACT OF INTRAVENOUS FERRIC CARBOXYMALTOSE TREATMENT IN PATIENTS WITH IRON DEFICIENCY ANAEMIA DUE TO IRON MALABSORPTION

S. Scalamonti[1], F.P. Schiavone[1], L. Dottori[1], C. Palumbo[1], E. Dilaghi[1], G. Pivetta[1], I. Ligato[1], M. Pompili[1], M. Magnante[1], B. Annibale[1], E. Lahner[1]

Introduction: Iron malabsorption (FeM) may lead to iron deficiency anaemia (IDA). Its most common causes are celiac disease (CD) due to atrophy of the small intestine mucosa, corpus atrophic gastritis (CAG), and gastric surgery (GS): reduced hydrochloric acid secretion derived from corpus oxyntic mucosa atrophy or surgical resection causes a decreased conversion of Fe(III)ion to Fe(II)ion, the latter being the more easily absorbable form. IDA affects more than two billion people over the world and it can cause troublesome symptoms as asthenia and fatigability. Iron oral supplementation is considered the standard therapy but frequently it leads to side effects reducing long-term compliance. Ferric carboxymaltose (FCM) is an intravenous (iv) preparation shown to be safe and effective in improving the iron status (FeS), but its efficacy in patients with FeM and IDA has not been investigated so far.

Aims & Methods: To evaluate the safety, efficacy and quality of life impact of iv FCM in treating pts with IDA due to FeM. A prospective observational single centre study was conducted on 37 pts with IDA caused by CAG (n=19/51.4%), CD (n=9/24.3%), and GS (n=9/24.3%). Pts with other causes of IDA as GI bleeding were excluded. At baseline (T0), pts were clinically and biochemically evaluated (symptoms, SF12, CBC and FeS: ferritin, iron, transferrin, transferrin saturation (TS)). FCM dosage was calculated according to Ganzoni formula considering Hb values and body weight. If the dosage needed was up to 1000mg, iv infusion was scheduled in a single session, otherwise a 2 nd infusion after 1 wk was planned. After treatment, CBC and FeS were assessed at 4 (T4) and 12 (T12) wks. SF12 was revaluated after 12 wks (cut-off physical component summary (PCS)<44, mental component summary (MCS)<46). IDA was defined as Hb<13 and <12 g/dl for men and women, ferritin<45 ng/dl or TS<15%. Moderate and severe anemia were defined as Hb 8-10 and Hb<8 g/dl. Student's t-test was used to compare CBC and FeS parameters at baseline (T0), 4 weeks (T4) and 12 weeks (T12).

Results: All 37 patients completed 12-wks-follow-up. At T0 Hb was mean±SEM 10.9±0,2g/dl, 18.9% had moderate and 2.7% severe anaemia. In pts treated in a single-session-infusion (64.9%), dosage of FCM was mean±SEM 975±12mg; in pts treated in two sessions (35.1%), FCM dosage was mean±SEM 1400±77mg. One patient reported mild side effects (pruritus, cutaneous erythema) not requiring FCM interruption and reversing after H_2 antagonist treatment within 15 minutes. At T4 and T12, 70.4% and 78.4% of pts recovered from IDA. At T4 mean Hb significantly increased compared to T0 (12.7±0.2 vs 10.8±0.2 g/dl, p<0.0001). At T12 a further increase was observed (13.1±0.2 g/dl, p<0.05). Also, TS increased from 6% at T0 to 20% at T12, p<0.0001. At T4 ferritin levels (ng/dl) significantly increased compared to T0, but slightly decreased at T12 (T0 28.5±11.2 vs T4 188.2±25.7, p<0.0001; T12 124.9±25.7, p=0.10). RDW (%) significantly increased at T4 and significantly decreased at T12(T0 15.4±0.5 vs T4 18.6±0.7, p=0.0003; T12 14.8±0.4, p<0.0001). The proportion of patients with SF12 MCS>46 and PCS>44 scores significantly increased at T12 compared to T0 indicating improved mental and physical health perception after FCM treatment.

Conclusion: In pts with IDA due to FeM, ivFCM is an effective and safe treatment, leading to recovery of IDA in nearly 80% of cases at 12 weeks after treatment and concomitantly to an improved mental and physical health perception. These data show that ivFCM treatment could be considered as a first line treatment for IDA patients with FeM.

CLINICAL AND HISTOLOGICAL SPECTRUM OF MALABSORPTION SYNDROME: INSIGHTS FROM ENDOSCOPIC EVALUATION AND HISTOLOGICAL ANALYSIS

A. Samad[1]

[1]Hamdard University Hospital, Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: samaddhedhi@gmail.com

Introduction: Malabsorption syndrome encompasses a spectrum of gastrointestinal disorders characterized by impaired absorption of nutrients, leading to various clinical manifestations. Endoscopic and histological evaluations play crucial roles in diagnosing underlying etiologies, including celiac disease.

Aims & Methods: This retrospective study aimed to analyze the clinical presentation, endoscopic findings, and histological yield in patients with malabsorption syndrome, focusing on the subset exhibiting villous atrophy to investigate the prevalence of celiac disease. We conducted a retrospective analysis of 100 patients with malabsorption syndrome who underwent endoscopic evaluation between January 1, 2023, and December 31, 2023. Clinical data, endoscopic findings, and histological results were collected and analyzed.

Results: Among the 100 patients, 60 were males and 40 were females. Common presenting symptoms included fatigue (33 patients), recurrent mouth ulcers (15 patients), bloating (12 patients), diarrhea (24 patients), and abdominal discomfort (16 patients). Endoscopic findings revealed normal mucosa in 34 patients, decreased height of duodenal folds in 24,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and fissured mucosa in 42. Histological analysis showed increased intraepithelial lymphocytes in 36 patients, crypt hyperplasia with increased intraepithelial lymphocytes in 20, partial villous atrophy in 22, subtotal villous atrophy in 12, and total villous atrophy in 10 patients. Giardia was detected in histological specimens from 4 patients with partial villous atrophy. Interestingly, only 12 patients had positive celiac serology despite a substantial number exhibiting villous atrophy on histological examination.

Conclusion: This study highlights the diverse clinical presentation and histological spectrum of malabsorption syndrome. Despite significant villous atrophy, celiac disease was diagnosed in only a minority of patients, suggesting the need for further investigation into the etiology of villous atrophy in this subset of patients.

Introduction: Concerns regarding colorectal cancer in short bowel syndrome (SBS) patients receiving teduglutide (TED) treatment have led to the recommendation of colonoscopy for screening and surveillance.[1,2] While there are reports of new small bowel polyps in TED patients, data on small bowel cancer risk and surveillance are lacking.[3,4]

This study aims to evaluate the feasibility and effectiveness of using double-balloon enteroscopy (DBE) for surveillance in SBS patients undergoing TED treatment.

Aims & Methods: Data from patients with SBS in TED treatment who underwent DBE within a year of starting TED at a tertiary referral center for enteroscopy between December 2019 and October 2023 were collected. The primary endpoints were technical success, adverse events, and total enteroscopy rates. Secondary endpoints included the incidence of small bowel polyps and residual small bowel length measurement.

Results: Nine patients (7 female, median age 65.5, IQR 58-79) with SBS (22% type 1, 55.6% type 2, 22.2% type 3-SBS) underwent DBE (10 anterograde, 2 retrograde) under procedural sedation. Crohn's disease (33.3%) and post-surgical complications (33.3%) were the most frequent causes of SBS. The median interval from TED prescription to DBE surveillance was 9.1 months (IQR 3.2-32.9). The median depth of maximal insertion was 85 cm (IQR 50-187). No adverse events occurred during all the procedures. The total enteroscopy rate was 75% (80% [8/10] of anterograde DBEs, 50% [1/2] of retrograde DBEs). Panenteric DBE allowed the estimation of small bowel residual length in all cases (2/2) where this important clinical information was unknown and revealed a different residual small bowel length compared to surgery in 44% of patients. No small bowel malignancies were detected during the study period.

Conclusion: DBE surveillance for small bowel malignancy in SBS patients undergoing TED treatment is feasible and effective. Total enteroscopy can be frequently achieved with a single endoscopy in these patients, allowing easy oncologic surveillance.

Introduction: Peutz-Jeghers polyps (PJPs), seen in Peutz-Jeghers syndrome (PJS), are found throughout the gastrointestinal tracts except for the esophagus. Of these, polyps in the small intestine are likely to become numerously developed and enlarged, resulting in intestinal intussusception which requires surgical treatment. Therefore, endoscopic treatment is recommended to prevent intestinal intussusception.

Recently, endoscopic ischemic polypectomy (EIP) as the strangulation of the polyps using endoclips without polypectomy has been a treatment option for PJPs of the small intestine as well as conventional endoscopic mucosal resection (EMR). However, there has been insufficient data on the clinical utility and safety of EIP compared to EMR, and that needs to be clarified.

Aims & Methods: The purpose of this study was to evaluate the utility and safety of EIP for PJP in the small intestine. We retrospectively recruited PJS patients who underwent ballon-assisted enteroscopy at Chiba University Hospital between February 2010 and December 2023. The clinical information such as patient clinical backgrounds, treatment option, number of polyps, maximum diameter of polyps, and incidence of bowel obstruction after treatment were analyzed in patients who underwent endoscopic treatment for PJPs of the small intestine. The safety profile per-treatment was evaluated using the inverse probability weighting (IPW) method regarding the incidence of bleeding and intussusception after treatment.

Results: During the research period, 55 enteroscopies were performed, of which 37 (20 EMR and 17 EIP) endoscopic treatments were performed for a total of 239 PJPs (diameter 10-40 mm) in 10 PJS patients. The pathological evaluation was performed for 15 lesions (diameter 15-40 mm) treated with EMR, and all were diagnosed as PJPs.

While there was no difference in the total time for endoscopic procedures including insertion and treatment between the EMR and EIP groups (182.5 min vs. 179.1 min, P=0.497), the number of treated polyps at one procedure was significantly higher in the EIP group (3.0±2.1 polyps by EMR v.s. 10.5±13.0 polyps by EIP, P=0.015). Post-treatment complications included bleeding in 5 treatments while no intussusception was observed. IPW analysis revealed that EIP was associated with a significantly lower risk of complications (P=0.017, OR=0.186, 95% CI 0.047-0.738) (Table).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 	OR	95%CI	P value
EIP	0.186	0.047 - 0.738	0.017

Table. Weighted logistic regression analysis of the risk of bleeding after treatment for PJP.

Adjusted for gender, age at treatment, presence of intestinal adhesion, scope approach (via-oral or via anal), endoscopist (expert or non-expert), insert length, number of treated polyps, maximum diameter of polyps, and total time as confounding factors.

Conclusion: EIP for PJPs in the small intestine is a safer treatment option for numerous lesions than EMR.

Introduction: While capsule endoscopy (CE) offers a minimally invasive way to examine the entire digestive tract, current analysis methods are time-consuming and susceptible to errors. Protruding lesions are frequentlyencountered with varying significance throughout the GI tract. This study aims to develop and test a Convolutional Neural Network for panendoscopic automatic detection of protruding lesions on CE exams.

Aims & Methods: A multicentric retrospective study was performed on 1222 CE exams. A total of 191455 images from six different CE device types were evaluated, with 52717 confirmed protruding lesions (epithelial andsubepithelial lesions) after a rigorous triple-validation process. First, we conducted a 5-fold cross validation with exam-split for assessing CNN's robustness. Then, we evaluated CNN's global performance in an exam-split train and test division of data, assessing the latter. Primary outcomes measures were sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value (NPV) and area under the conventional receiver operating characteristic curve (AUC-ROC) and the precision-recall curve (AUC-PR).

Results: Regarding test set, the sensitivity were 90.7% and specificity 94.0%. The PPV and NPV were 95.3% and 88.3%, respectively. The global accuracy was 92.1%. The CNN processed 112 frames per second.

Conclusion: This study aims to address the gap in AI-enhanced capsule panendoscopy by investigating the development of the first CNN for the detection of protruding lesions across the GI tract. AI's improvement of CE's diagnostic accuracy, along with the growing interest in minimally invasive procedures, may contribute to increasing access to this diagnostic tool.

Introduction: Use of antithrombotics including antiplatelet agents and anticoagulants is associated with upper and lower GI bleeding, thus a higher rate of positive findings is reasonable to be expected when patients receiving these drugs undergo SBCE for the investigation of SBB. However, the results of published studies concerning the impact of antithrombotics on the SBCE diagnostic yield remain conflicting. Furthermore, the clinical outcome of patients under antithrombotics who undergo SBCE for the investigation of SBB is not currently known.

Aims & Methods: We aimed to determine the diagnostic yield and outcome of patients receiving antithrombotic drug therapy subjected to small bowel capsule endoscopy (SBCE) for the investigation of small bowel bleeding (SBB). Multicenter retrospective analysis of collected data from all patients undergoing SBCE for the investigation of SBB from March 2003 to June 2023. The diagnostic yield of SBCE was defined as the detection of positive findings that could explain the cause of the patient's bleeding. Rebleeding was defined as evidence of bleeding within 1 year after the index episode.

Results: During the study period, 8401 patients underwent SBCE for SBB investigation. Bleeding lesions were detected in 1103/2535 (43.5%) patients receiving antithrombotics, compared to 1113/5866 (18.9%) not receiving these drugs (p<0.00001). Following capsule endoscopy, a therapeutic intervention was possible in 390/2216 (17.5%) patients with a bleeding lesion. Rebleeding occured in 927 (36.5%) of patients receiving antithrombotics (36.5%), compared to 795 (13.5%) not receiving these drugs (13.5%, p<0.00001).

Conclusion: Both the diagnostic yield of SBCE and the rebleeding rate were higher in patients with SBB receiving antithrombotics. Therapeutic intervention was possible in a real world setting only in a minority of patients with positive findings.

Introduction: Our previous study using capsule endoscopy has demonstrated that low-dose aspirin (LDA) frequently induces small intestinal injury, which is shown to be alleviated by some probiotics. However, the mechanism underlying the effects of probiotics remains elusive.

Aims & Methods: Aim: To clarify the mechanism underlying the alleviating effects of probiotics on LDA-induced mucosal injury using gut microbiota analysis.

Methods: Twenty patients in each of the three groups were recruited: control, received no treatment; PPI, treated with either a proton pump inhibitor (PPI) or potassium-competitive acid blocker (P-CAB); and Aspirin+P, treated with aspirin and PPI/P-CAB. Ileal fluid was collected using colonoscopy for ileal microbiota analysis. All patients were treated with *Lactobacillus paragasseri* OLL2716 (LG) for 6 weeks after colonoscopy, and stool samples were collected for faecal microbiota analysis before and after LG treatment. The participants were asked to complete the Gastrointestinal Symptom Rating Scale (GSRS) questionnaire before (at 0 weeks) and after 6 weeks of LG intake.

Results: Faecal microbiota analysis revealed no significant difference in α-diversity among the three groups before and after LG intake. In contrast, β-diversity indices differed significantly between the control and PPI groups as well as between the control and Aspirin+P groups before LG intake. However, no such significant differences between them were found any more after LG intake. The composition of microbiota structures in the PPI and Aspirin+P groups did not differ before or after LG intake. Ileal microbiota analysis revealed no differences among the three groups. The GSRS scores in the control and Aspirin+P groups significantly decreased after LG intake compared to those before LG intake. However, the GSRS scores in the PPI group did not differ significantly before and after LG intake.

Conclusion: The effect of aspirin itself on the microbiota structure and composition was minimal when combined with PPI or P-CAB. The remodelling effect of probiotics on Aspirin+P-induced dysbiosis may be one of the mechanisms underlying the alleviating effects of probiotics on aspirin-induced mucosal injury.

Introduction: Heyde syndrome is the co-occurrence of aortic stenosis and gastrointestinal bleeding secondary to vascular lesions, including angiodysplasias. Several studies have demonstrated cessation of gastrointestinal bleeding after transcatheter aortic valve implantation (TAVI), but the etiology and effects on vascular lesions are largely unknown.

Aims & Methods: We aimed to establish the effects of TAVI on gastrointestinal vascular lesions and identify the factors associated with recovery. In this prospective, single-center cohort study, patients with iron-deficiency anemia on the TAVI waitlist from September 2020 to February 2022 were assessed by capsule endoscopy. Those with vascular lesions were reassessed six months after TAVI. Endoscopic images were anonymized and evaluated by two independent researchers.

Results: Twenty-four patients underwent capsule endoscopy, and vascular lesions were present in 18 (prevalence 75%). TAVI was performed in 15/18 patients with vascular lesions, of which 11 agreed to a second capsule endoscopy. The mean number of vascular lesions across the gastrointestinal tract decreased from 6.4 (SD 5.6) to 2.0 (SD 2.1) (P = .036). The number of vascular lesions decreased in 9/11 (82%) patients, including 6/11 (55%) who no longer had typical angiodysplasias. Cessation of angiodysplasias was less frequent in patients who had multiple valvular heart disease before TAVI (0/3 [0%] vs 6/8 [75%]) and patients with significant paravalvular leakage after TAVI (2/5 [40%] vs 4/6 [67%]).

Conclusion: Angiodysplasias are present in 75% of anemic patients with severe aortic stenosis. TAVI effectively reduces the size and number of angiodysplasias in these patients.

IS FIT FIT FOR DETECTION OF SMALL BOWEL PATHOLOGY? A PROSPECTIVE STUDY

P. Oka[1], R. Sidhu[2], M. McAlindon[2]
[1]Royal Hallamshire Hospital, Sheffield Teaching Hospitals, Academic Dept of Gastroenterology, Sheffield, United Kingdom, [2]Royal Hallamshire Hospital , Sheffield Teaching Hospitals, Academic Dept of Gastroenterology, Sheffield, United Kingdom

Introduction: The role of faecal immunochemical testing (FIT) as a biomarker to stratify patients with lower gastrointestinal (GI) symptoms is well established. However, its use in patients with iron deficiency anaemia (IDA) is unclear. The aim of this study was to investigate the role of FIT in predicting small bowel (SB) pathology in patients with IDA.

Aims & Methods: This was a single tertiary centre prospective study. Inclusion criteria was adults (>18 years and < 80 years) with IDA who were referred to secondary care for upper and lower gastrointestinal tract (GI) endoscopy. These patients also had a FIT test done in primary care. All participants had a small bowel capsule endoscopy (SBCE) prior to their endoscopic investigations. Participants with subsequent upper or lower gastrointestinal tract malignancy were excluded from the study as this was considered as the most likely cause of IDA. IDA was defined as a Hb < 131g/L for men and < 110 g/L for women with ferritin< 30ug/L and/ or iron levels < 11umol/L.

Results: In total 79 patients were included in the final analysis with a median age of 67yrs (IQR 52-74); haemoglobin 103(IQR 95- 118) and ferritin 11(IQR 6-11). There were 13 patients on NSAID's at the time of their investigations. There were 35 (44%) patients with significant findings on SBCE which was classed as contributing to IDA. These findings included angioectasia in n= 21 (26%) of the patients which was the most common finding. The other findings included erosions= 5 (6.3%); inflammatory strictures= 3 (3.8%); active Crohn's n=1 (1%); visible blood with no clear source n=3 (3.8%); bleeding angioectasia n=1 (1%); and ulcer=1 (1%). A positive FIT (>10) had a sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 34.29%, 54.55%, 37.5% and 51.08% respectively.

Conclusion: Patients with IDA have a high diagnostic yield on SBCE and should routinely have SBCE as part of the work up for IDA. There is a pressing need for biomarkers to help triage SBCE referrals, however FIT is not a reliable biomarker for the presence of small bowel pathology in patients with IDA.

Introduction: Since 2006 at our hospital, lifestyle modification for obese patients has been provided through a team approach with a physician, dietician, nurse, physical therapist and psychologist. From 2016, a surgeon and anesthesiologist were added to the team for metabolic/bariatric surgery (laparoscopic sleeve gastrectomy: LSG).

Aims & Methods: The aim of this study is to clarify the characteristics of obese patients with NAFLD for whom LSG was effective. Of 40 obese patients who were received LSG between 2017 and 2021 with follow-up period of more than 1 year, 19 were male and 21 were female, 24 were with diabetes, 16 with other complications. The diagnosis of NAFLD was made by liver imaging for fat deposit and stiffness by Fibroscan, and liver biopsy in some cases.

Results: The mean preoperative BMI was 43, the mean Fib-4 index was 0.98, and the postoperative insulin resistance (CPI) of diabetic patients improved significantly, with 15 patients in complete remission and 6 in incomplete remission after surgery. One year after surgery, the mean weight loss was 18.3%, the Fib-4 index did not decrease significantly, but the mean AST (U/L) improved from 38 to 18, ALT (U/L) from 55 to 15, GGT (U/L) from 78 to 40, CAP (dB/m) from 348 to 279, and liver stiffness (kPa) from 12.1 to 7.6, significantly. In patients who underwent follow-up biopsy, there was a trend toward improvement in liver fibrosis.

Conclusion: Since LSG significantly improves hepatic markers in obese patients with NAFLD, metabolic/bariatric surgery should be positively considered.

Disclosure: Nothing to disclose.

Introduction: The prevalence of type 2 diabetes has more than doubled in the past 20 years, and literature suggests that nearly 90% of diabetes cases are preventable if risk factors are eliminated early. One of these potential risk factors is hypertriglyceridemia. Given the high prevalence of hypertriglyceridemia (which can affect nearly one-third of the population), the link between the two conditions is of crucial importance. Therefore, we aimed to investigate the dose-dependent effect of hypertriglyceridemia on the development of diabetes mellitus.

Aims & Methods: We carried out a systematic search in three databases (MEDLINE, Embase, and CENTRAL) on the 9th of November, 2023 with no restriction. In the final analysis, we investigated adult population with different triglyceride levels (exposure) and our outcome of interest was the development of diabetes mellitus. We calculated pooled odds ratios (OR) with 95% confidence intervals (CIs) and assessed the risk of bias with the Quality In Prognosis Studies (QUIPS) tool. The protocol was registered in the International Prospective Register of Systematic Reviews (PROSPERO) under the number CRD42023471288.

Results: According to the meta-analysis result of eight cohorts with a total population number of 127431, those who had hypertriglyceridemia had more than a 2-fold higher risk (OR:2.17[CI 1.52-3.10]) of developing diabetes mellitus during the follow-up period than those whose triglyceride levels were below 1.7 mmol/L. Those who had borderline high triglyceride levels at baseline (1.7-2.3 mmol/L) had significantly higher odds of developing diabetes mellitus during follow-up (OR 1.45[CI 1.29-1.63]) according to the data of six cohorts with 36807 patients. Those whose baseline triglyceride levels were higher than 2.3 mmol/L also had significant and even higher odds of the development of diabetes mellitus (OR:2.16 [CI 1.74-2.67]) than patients with normal triglyceride levels, based on the results of 6 cohorts with data on 39068 patients.

Conclusion: Hypertriglyceridemia is a dose-dependent risk factor of diabetes mellitus.

Disclosure: Nothing to disclose.

PP0336

THE IMPACT OF OBESITY ON DEVELOPMENT OF NON-CARDIA GASTRIC CANCER ACCORDING TO SEX IN SOUTH KOREA: A RETROSPECTIVE COHORT STUDY

J. Jang[1], N. Kim[2,3], Y. Choi[2]
[1]National Cancer Center Korea, Research Institute, Division of Clinical Research, Goyang-si, Gyeonggi-do, South Korea, [2]Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam-si, Gyeonggi-do, South Korea, [3]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research institute, Seoul, South Korea

Contact E-Mail Address: jjencc@ncc.re.kr

Introduction: Several studies have recently reported an increased risk of gastric cancer (GC) risk in both underweight and obese population in East Asia. However, the impact of underweight or obesity on the development of non-cardia GC is not fully established yet. In addition, GC is a male dominant cancer, and considering the phenotype differences in body composition between males and females, sex differences must be considered in evaluating the association between obesity and the risk of developing non-cardia GC.

Aims & Methods: Therefore, we aimed to evaluate associations between body mass index (BMI) and non-cardia GC risk with consideration of sex. This study was performed based on a retrospective cohort, which consists of Koreans randomly sampled from participants who underwent the National Health Screening programs and is termed National Health Insurance Service–Health Screening Cohort (NHIS-HEALS). The National Health Insurance system provides health checkups biennially for adults aged ≥20 years through the National Health Screening program. This program covers over 70% of total population in Korea, thus the NHIS-HEALS is a nationwide representative database in South Korea. This study includes a total of 341,999 subjects including 4,103 incident non-cardia GC cases identified during a median follow-up period of 10 years after exclusion of incident GC cases identified within 2 years from the follow-up start. We classified subjects into five groups according to BMI (<18.5, 18.5-22.9, 23.0-24.9, 25.0-29.9, ≥30.0kg/m^2) and evaluated the association between BMI level and GC risk by calculating hazard ratio (HR) and corresponding 95% confidence interval (95% CI) based on the Cox proportional hazard regression.

Results: Increased non-cardia GC risks were observed in severely obese (BMI ≥30.0 kg/m^2) males and obese (BMI 25.0-29.9 kg/m^2) females, respectively (HR, 1.40; 95% CI, 1.11-1.75 for severely obese males; HR, 1.25; 95% CI, 1.06-1.46 for obese females).

Age[1]	Sex	Body mass index (kg/m^2)				
		<18.5	18.5-22.9	23.0-24.9	25.0-29.9	≥30.0
		HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)
<50 years	Total	1.53 (0.74-3.16)	1.01 (0.77-1.32)	1.00	0.88 (0.66-1.17)	1.41 (0.77-2.58)
	Males	1.74 (0.75-4.02)	1.06 (0.77-1.46)	1.00	0.94 (0.69-1.30)	1.91 (1.03-3.55)
	Females	1.39 (0.17-11.02)	0.88 (0.38-2.02)	1.00	0.91 (0.34-2.44)	N/A
≥50 years	Total	1.06 (0.85-1.32)	1.01 (0.93-1.10)	1.00	1.13 (1.04-1.23)	1.17 (0.96-1.44)
	Males	1.09 (0.85-1.39)	0.96 (0.87-1.06)	1.00	1.08 (0.99-1.19)	1.33 (1.04-1.70)
	Females	0.97 (0.61-1.54)	1.17 (0.99-1.38)	1.00	1.30 (1.10-1.53)	0.98 (0.68-2.26)

Table. Association between body mass index and non-cardia gastric cancer risk according to sex in Korea.

Abbreviations: HR, Hazard ratio; CI, Confidence interval
1. Age at BMI measurement

In contrast, evidences supporting that underweight (BMI <18.5kg/m^2) is associated with increased non-cardia GC risk was not found overall (HR, 1.08; 95% CI, 0.88-1.33). In males, the increased risk of non-cardiac GC in the severely obese group remained regardless of age at BMI measurement.

However, the increased risk of non-cardia GC risk related to obesity was confirmed only in elderly females, and was not found in females under 50 years of age. In addition, increased non-cardia GC risk in the normal weight group (18.5-22.9 kg/m^2) was found compared to that in overweight group among females over 50 years of age.

Conclusion: Results suggest that elevated risk of non-cardia GC development might be originated from obesity, especially in elderly populations in East Asia regardless of sex. However, this study proposes that being overweight, which is the pre-obesity stage, may rather have a lower risk of developing non-cardia GC than being normal weight in elderly females.

Introduction: Overweight and obesity present global health challenges, often managed through lifestyle changes and medications like glucagon-like peptide-1 receptor agonists (GLP-1 RAs), which can cause gastrointestinal (GI) adverse events. However, research on their effects in non-diabetic populations is lacking.

Aims & Methods: This review addresses this gap by examining the impact of GLP-1 RAs on GI adverse events in non-diabetic overweight or obese individuals. We systematically reviewed the literature by conducting a search using PubMed and EMBASE, adhering to predefined inclusion and exclusion criteria, to assess GI adverse events linked with GLP-1 RAs in non-diabetic overweight or obese populations. We conducted a dose response meta-analysis to evaluate each adverse event associated with different GLP-1 RAs. The quality of the included studies was appraised utilizing the Cochrane Collaboration's assessment tool.

Results: Our systematic review and meta-analysis encompassed thirty-eight articles, incorporating data from a total cohort of 32,882 individuals. Predominant GI adverse effects observed included nausea, vomiting, diarrhea, constipation, and abdominal pain. Across all evaluated GLP-1 RAs, a notable elevation in nausea risk was noted, with orforglipron exhibiting the highest risk, succeeded by exenatide, tirzepatide, semaglutide, and liraglutide. Moreover, liraglutide, orforglipron, semaglutide, and tirzepatide were associated with heightened vomiting risk, while cagrilinitide and exenatide displayed no significant increase. Exenatide, cagrilinitide, and orforglipron demonstrated no significant association with diarrhea risk. Conversely, semaglutide and liraglutide correlated with an elevated risk of constipation, while cagrilinitide and exenatide did not exhibit a significant increase. Notably, certain GLP-1 RAs were linked to a heightened

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. risk of abdominal pain, with liraglutide, semaglutide, and tirzepatide displaying significant increases, whereas orforglipron showed no significant elevation in abdominal pain risk.

Conclusion: In conclusion, GLP-1 RAs are associated with an increased risk of GI adverse effects, including nausea, vomiting, diarrhea, constipation, and abdominal pain. Importantly, distinct GLP-1 RAs exhibited varying degrees of risk for these adverse effects, underscoring the importance of tailored risk assessment and management strategies in clinical practice.

Contact E-Mail Address: mod2506mod@gmail.com

Introduction: Breastfeeding, recognized for its essential nutrition and health benefits, potentially influences central nervous system development. This study delves into the nuanced relationship between breastfeeding duration and neurodevelopment in five-year-old children.

Aims & Methods: A cohort of 72 children living in Varna, Bulgaria was followed up from birth to age five, all of them being term-born infants with normal birth weight and devoid of perinatal infections or abnormalities. Comprehensive data on demographics and dietary practices were collected. Neurodevelopmental assessments at five years included motor and speech development, articulation, nonverbal intelligence, and behavior, evaluated using the validated NDT5 tool. Children were stratified into 2 groups based on breastfeeding duration (up to age six months vs. over six months). Statistical analysis was performed using Jamovi 2.0.0.0.

Results: Children in both groups exhibited similar demographic characteristics and BMI distributions. Notably, significant differences emerged between the groups in girls' motor development (U=54, p=0.018) and overall development (U=52, p=0.045). Similarly, boys showed disparities in nonverbal intelligence (U=66.5, p=0.008), as evidenced by both intention-to-treat (ITT) and per-protocol (PP) analyses.

Conclusion: Breastfeeding duration appears to exert a discernible influence on neurodevelopment in five-year-old children. Notably, distinct effects were observed in girls' motor development and boys' nonverbal intelligence. Further longitudinal investigations are warranted to optimize neurodevelopmental outcomes based on breastfeeding duration.

PROBIOTIC INTERVENTION IMPROVES QUALITY OF SLEEP – A RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED TELEMEDICAL STUDY

A. Horvath[1,2], N. Feldbacher[1,2], V. Stadlbauer[1,2]
[1]Center for Biomarker Research in Medicine, Translational Precision Medicine, Graz, Austria, [2]Medical University of Graz, Division of Gastroenterology und Hepatology, Graz, Austria

Contact E-Mail Address: angela.horvath@medunigraz.at

Introduction: Poor quality of sleep has detrimental effects on job performance, accident rates and health risks, with a potential link to the gut microbiome composition. First pilot trials have indicated beneficial effects of probiotic modulation of the microbiome on quality of sleep.

Aims & Methods: We conducted a randomized, double-blind, placebo-controlled trial testing the effects of a probiotic intervention on quality of sleep, quality of life and intestinal microbiome.

In total, 130 volunteers with impaired quality of sleep (PSQI>5) were included in the study. They were randomized in a 1:1 ratio to a 28-day intervention with either a multispecies probiotic (Omnibiotic-Stress Repair) or a placebo. Participants completed validated questionnaires to estimate quality of sleep (PSQI), quality of life (SF12, GIQLI) and perceived stress (PSQ20) before, during and after the intervention. Furthermore, stool samples for 16S rRNA gene sequencing were collected before and after the intervention. Ninety-four participants finished the study and could be included in the analysis.

Results: The 50 participants (88.6% female, 41.2±10.6 years old) analysed in the probiotic group and 44 participants (88.0% female, 40.1±10.7 years old) in the placebo group were well comparable at baseline, including the initial PSQI-score (10.1±2.7 vs. 10.5±2.6). After two weeks of intervention, both groups showed a comparable improvement in their PSQI-scores. After four weeks of intervention, the improvement of the PSQI score was significantly more pronounced in the probiotic group compared to the placebo group (6.8±2.9 vs. 7.7±3.1; p=0.036), mainly due to improved sleep efficiency and latency. The intervention did not influence quality of life or perceived stress. Ingested bacteria were partially recovered in the microbiome, causing a slight shift in beta diversity in the probiotic group, while alpha diversity and the overall composition of the microbiome remained unaffected.

Conclusion: In conclusion, the intervention with a multispecies probiotic was able to improve quality of sleep of participants with poor quality of sleep beyond an observable placebo-effect. Participants reported falling asleep more quickly and spending less time awake in bed. This well-powered RCT confirms that the probiotic modulation of the intestinal microbiome can be effective in alleviating sleep disturbances.

Contact E-Mail Address: ma.lopes@unesp.br

Introduction: Inflammatory Bowel Diseases (IBD), including Crohn's Disease (CD) and Ulcerative Colitis (UC), pose significant global health challenges. Nutrient deficiencies and malnutrition are common in both forms of the disease. Dietary supplementation with TGF-β has been suggested to enhance patients' nutritional status, quality of life, and improvement of the symptoms. However, comprehensive evaluations of its clinical impact are needed.

Aims & Methods: This study aims to assess the efficacy of nutritional supplementation in improving clinical outcomes, nutritional status, quality of life, fatigue, disability, and body image among IBD patients.

Methods: Multicenter longitudinal study, enrolling 42 IBD patients in clinical activity and/or at nutritional risk. Patients received the nutritional supplement enriched with TGF-β and underwent assessments before supplementation (M0), at 30 days (M30), and at 60 days (M60) of supplement use. Clinical parameters, disease activity (Harvey-Bradshaw score for CD and partial Mayo score for UC), nutritional evaluation, body composition, presence of fatigue, anxiety and depression, disability, and body image were evaluated. Statistical analyses included descriptive statistics and ANOVA ($p<0.05$).

Results: 42 patients were included: 30 (71%) with CD and 12 (29%) with UC; 48% women, age of 35.1 ± 15.65 years. Among CD patients, 30% were in remission, 16.67% had mild, 43.33% moderate, and 10% severe activity. According to Montreal classification, 36.67% presented ileocolonic disease, 36.67% fistulizing behavior, 26.67% stenosing behavior, 33.33% perianal disease. For UC patients, 41.67% had mild and 58.33% moderate activity; 41.67% presented pancolitis. All patients presented malnutrition or nutritional risk at enrollment. Significant improvements were observed in HBI score comparing M0 (7.97±5.70) vs M30 (4.61±3.16) vs M60 (3.27±1.75), $p=0.0055$. There was also an improvement of the number of bowel movements (5.45±4.65 vs 2.90±2.02 vs 2.65±1.55). Nutritional assessment revealed a significant increase in brachial circumference (24.23±3.68 vs 25.37±3.51 vs 26.03±4.10, $p=0.0182$). Fatigue decreased (40.58±14.07 vs 33.12±15.72 vs 30.38±14.88, $p=0.0293$), as well as disability (51.14±25.34 vs 36±20.89 vs 30.33±22.64, $p=0.0032$). It was observed an improvement of IBD score (135.08±38.88 vs 145.20±48.27 vs 152.71±58.96; $p=0.3737$) and body image (10.78±7.37 vs 9.68±8.42 vs 5.57±6.04; $p=0.1395$), with no significance.

Conclusion: Nutritional supplementation demonstrated notable improvements in clinical and nutritional parameters, as well as reduction in fatigue and disability, underscoring its potential as an adjunctive therapy for IBD management

PREVALENCE OF FOOD ALLERGY AMONG JORDANIAN CHILDREN

E. Altamimi[1], N. Yousef[2], R. Nimer[2], M. Abdelraheem[2]
[1]Jordan University of Science and Technology, Pediatrics, Irbid, Jordan, [2]Jordan University of Science and Technology, Faculty of Medicine, Irbid, Jordan

Contact E-Mail Address: eyadtamimi@gmail.com

Introduction: Food allergy, characterized by an immune reaction to proteins in food, presents a significant global health challenge, especially among children. It is a growing concern worldwide, impacting over 10% of the general population. Epidemiological studies suggest a rising prevalence of food allergy, with estimates indicating that approximately 1 in 10 adults and 1 in 12 children are affected.

Aims & Methods: Our aim was to assess the prevalence of food allergies among schoolchildren aged 5 to 14 years in central and northern Jordan. We conducted a randomized cross-sectional online questionnaire among schoolchildren aged 5 to 14 in central and northern Jordan. A total of 1629 parents completed the questionnaire, providing information on their children's demographic details, feeding history, food allergy occurrences, as well as atopic history for both the child and their family.

Results: The prevalence of parent-reported food allergy was 11.5% (95% CI = 10-13%). Among these cases, 10.1% (95% CI = 8.6-11.7%) were identified as having convincing food allergies, while 5.7% (95% CI = 4.5-6.8%) were diagnosed by a physician. The most common allergens reported were eggs (17.8%), cow's milk (15.8%), peanuts (14.5%), and strawberries (13.8%). A majority (67.1%) reported having a single allergen, while 15.8% reported two allergens, and 17.2% reported more than two allergens.

Among the participants, Food allergy prevalence was higher among children with coexisting atopic diseases and those with a family history of allergies. Regional variations in prevalence were observed, with urban areas showing higher rates.

Conclusion: This study sheds light on the prevalence of food allergy among schoolchildren in Jordan, emphasizing the importance of considering convincing food allergy alongside parent-reported data. The findings underscore the significant burden of food allergy and its association with other atopic conditions, highlighting the need for comprehensive management strategies and further research to understand underlying factors.

Introduction: Sarcopenia is a progressive, systemic skeletal muscle disease associated with aging that severely affects the quality of life and overall health of older adults. Emerging research demonstrates a strong association between the onset of sarcopenia and gut microbiota.

Aims & Methods: 16 out of 30 sarcopenia patients who showed significant skeletal muscle improvement after fecal microbiota transplantation (FMT) were selected and validated by metagenomic, cultured and animal experiments.

Results: Our clinical observations show a marked improvement in sarcopenia symptoms among older patients post FMT, leading to a notable rise in muscle mass ($P < 0.05$). To delve deeper into this occurrence, we conducted metagenomic sequencing of patient fecal samples pre- and post-treatment. FMT distinctly modified the intestinal microbiota composition. Utilizing germ-free animal models and culturomics, we identified Roseburia inulinivorans as a potentially beneficial strain for the alleviation of sarcopenia. Further experimental validation displayed that Roseburia inulinivorans escalated MyoG and MyoD expression ($P < 0.05$), augmented muscle mass ($P < 0.01$) and grip strength ($P < 0.01$) in mice by boosting branched-chain amino acid metabolism within the host, diminishing sarcopenia symptoms in the process.

Conclusion: These outcomes not only validate the intestinal microbiota-sarcopenia relationship but also introduce novel insights and strategies for sarcopenia management.

Introduction: Inflammatory Bowel Disease (IBD), encompassing Crohn's Disease (CD) and Ulcerative Colitis (UC), shares chronic and inflammatory characteristics with Non-Alcoholic Fatty Liver Disease (NAFLD). While their precise pathogenesis remains unclear, emerging evidence implicates dysbiosis and metabolic changes. This study aims to investigate the association between IBD and NAFLD, focusing on metabolic syndrome and its nutritional implications

Aims & Methods: Objective: To evaluate the nutritional status and body composition in IBD patients, comparing groups with and without NAFLD, and identifying the associated factors.

Methods: A cross-sectional study was conducted, assessing clinical data, metabolic syndrome presence, nutritional status, and biochemical markers. Patients were categorized into IBD+NAFLD and IBD-only groups based on hepatic ultrasound findings. Statistical analysis included descriptive statistics and logistic regression.

Results: 127 patients were included, comprising 58 CD and 69 UC, with a mean age of 45.56 years**.** Most patients were female and did not engage in physical activity. Patients were mostly in clinical remission and endoscopic activity. 58 patients (45.67%) had hepatic steatosis on ultrasound, forming the IBD+NAFLD group. The IBD+NAFLD group had higher BMI, fat mass, and all circumference values, Table 1, as well as a higher prevalence of hypertension ($p=0.0446$) and dyslipidemia ($p=0.0377$). It is noteworthy that, although most of these patients were classified as overweight by BMI, considering anthropometric data, most IBD+NAFLD patients were classified as eutrophic. 86.21% of patients in the IBD+NAFLD group met the criteria for MAFLD. No difference was observed regarding medication in use. Regarding biochemical tests, the IBD+NAFLD group had higher values of hematocrit ($p=0.0023$), liver enzymes (AST, $p=0.0141$ and ALT, $p<0.0001$), fasting glucose ($p=0.0107$), glycated hemoglobin ($p=0.0146$), basal insulin ($p=0.0003$), and triglycerides ($p=0.0001$), with lower HDL cholesterol ($p=0.0101$)

Conclusion: The study highlights a significant association between nutritional status and NAFLD in IBD patients. Those categorized as eutrophic had a higher prevalence of hepatic steatosis, potentially linked to dietary factors.

Introduction: Inflammatory bowel disease (IBD) is characterised by a relapsing-remitting disease course, known to be influenced by dietary factors. Therefore, this study aims to examine the relationship between dietary patterns and diet quality with disease activity in IBD patients.

Aims & Methods: From a one-year study of IBD patients from two Dutch hospitals, a cross-sectional analysis of the baseline data was conducted. The GINQ-FFQ[1], an IBD-specific food frequency questionnaire was used to assess dietary intake. Consumed foods were categorised into 26 food groups and analysed for dietary patterns using principal component analysis (PCA)[2]. The Dietary Inflammatory Index (DII), a dietary quality score reflecting inflammatory potential, was calculated according to Shivappa et al.[3], using 28 of the 45 components. Patients were categorised by sex, disease type (Crohn's Disease (CD) or ulcerative colitis (UC)), and biochemical disease activity (remission: CRP ≤ 5 mg/L and/or FCP ≤ 150 µg/g). Mann-Withey U and T-tests were performed to assess differences in dietary patterns and diet quality between patient groups.

Results: A total of 177 patients (52% female, 55.4% CD, median age 50 years) correctly filled out the GINQ-FFQ. Three dietary patterns were identified: a western diet, a flexitarian diet, and a convenience diet. The western diet was high in bread, meat and poultry, pastries and biscuits, cold meats, potatoes and root vegetables, sugar and sweets, sweet sauces, and cheese. It was low in nuts and seeds, vegetables, soups, and fruit. The flexitarian diet consisted of many savoury sauces, eggs, vegetables, potatoes and root vegetables, fats and oils, soups, herbs and spices, savoury snacks and crisps, fish, legumes, and grain products and thickeners. Lastly, the convenience diet was high in grain products and thickeners, composite dishes, non-alcoholic drinks, and meat and poultry, but low in fats and oils, cold meats, alcoholic drinks, and cheese. No differences in consumption of these dietary patterns were observed between patients with active (n=40) and remitted disease (n=137) (p=0.779, p=0.087, p=0.212, respectively). Females adhered less to Western (p=0.001) and convenience food patterns (p=0.009) compared to males. UC patients favoured a flexitarian diet more than CD patients (p=0.030). No differences in DII scores were found (p=0.802). Patients in biochemical remission consumed more alcohol (p=0.04) compared to those with active biochemical disease.

Conclusion: This analysis found no direct association between dietary patterns or dietary inflammatory potential and disease activity. However, patients in remission consumed more alcohol, and a trend towards a flexitarian diet was observed in those with active disease. The full study will follow these patients for a year to assess potential changes in diet and disease activity.

Introduction: Anal fissures are painful benign conditions that significantly impact patients' quality of life (QoL).

Aims & Methods: This study aimed to evaluate the QoL of patients with anal fissures and assess the effectiveness of a high-fiber diet in treatment. A prospective cross-sectional study was conducted over 4 months (September-December 2023) on patients with anal fissures. QoL was assessed using the Hemo/Fiss Burden score and the newly validated REALISE Score. The REALISE Score measures pain severity, post-defecatory pain, analgesic use, bleeding frequency, and impact on QoL.

Results: 62 patients were included, with a female predominance (sex ratio: 1/2). The average age was 54.3 years. Both scores revealed significant impairments in QoL across all domains, including physical discomfort, psychological distress, and sexual dysfunction. A strong correlation was found between the Hemo/Fiss and REALISE scores (r: 0.71; p <10-4), indicating the validity of the REALISE Score for QoL assessment.

Treatment and Effectiveness: All patients were advised to adopt a high-fiber diet, which resulted in healing in 73% of cases within 4 weeks. This improvement is likely due to the softening of stool and facilitation of regular bowel movements, which reduces pain and discomfort associated with anal fissures.

Additionally, the high-fiber diet significantly improved QoL scores compared to those who did not take fiber (p=0.039). Bleeding and pain at defecation were significantly reduced during six weeks of high fiber diet associated to medical treatment compared to those using medical treatment only (p=0.041).

Conclusion: This study demonstrates the significant impact of anal fissures on QoL and highlights the effectiveness of a high-fiber diet in promoting healing and improving QoL. The REALISE Score offers a valuable tool for assessing the severity of anal fissures and monitoring treatment progress.

Introduction: Non-celiac gluten/wheat sensitivity (NCG/WS) is a clinical condition in which gluten/wheat ingestion evokes, while withdrawal ameliorates or reverts gastrointestinal (GI) and extra-GI symptoms. The pathogenetic mechanisms of NCG/WS are poorly understood and no diagnostic biomarker is so far available. NCG/WS diagnosis is established by excluding celiac disease (CD) and wheat allergy (WA), evaluating response to a gluten-free diet (GFD) and the effects of gluten reintroduction. Initial evidence suggests a central role played by the gut microbiota in NCG/WS.

Aims & Methods: This study aimed to identify: i) microbiota species valid as biomarkers for rapid and non-invasive NCG/WS diagnosis; ii) the effects of GFD on microbiota in NCG/WS. Subjects with a clinical suspect of either NCG/WS or CD and healthy volunteers (Ctrl) were enrolled while on a free diet. A thorough work-up (including clinical, endoscopic, allergologic and serological evaluations) was applied to diagnose NCG/WS or CD while excluding WA. Instructions for GFD were provided to all participants. Stool samples for gut microbiome were obtained from NCG/WS and CD before (t0) and after 3, 7, 30 and 200 days of GFD (t1, t2, t3, t4). Stool samples from Ctrl were obtained at t0, t1, t2, and t3. The presence and severity of GI (GI Symptom Rating scale) and extra-GI symptoms of NCG/WS were recorded at each time point (t0-t4). NCG/WS diagnosis was confirmed in participants with a 30% improvement in symptom scores in t3 *vs.* t0. Metagenome from stools was shotgun-sequenced. Data were processed and microbiome profiled with MetaPhlAn v.4.1 (Jun.23). Alpha-diversity (Shannon index, SI), beta-diversity and relative abundances were computed. Principal coordinates analysis was performed (Bray-Curtis dissimilarity test) and groups were compared (PERMANOVA test). Differences in SI at t0 among cohorts were assessed (Mann-Whitney U-test). Species present at any time point in at least 10 subjects were assessed. Candidate biomarkers were validated in newly diagnosed NCG/WS and CD cohorts. Species varying relative abundance during the GFD were identified (linear mixed model and Friedman's ANOVA). P-values were combined with the harmonic mean and corrected for multiple testing (Benjamini-Hochberg method, q-value).

Results: Twenty-eight NCG/WS (F, 37±16 yrs), 11 CD (9 F, 32±15 yrs) and 37 Ctrl (25 F, 33±14 yrs) were enrolled. Alpha-diversity at t0 was comparable (p>0.19) in NCG/WS (SI=4.0), CD (SI=3.7) and Ctrl (SI=4.1), whereas beta-diversity was different among groups (p=0.026). A total of 507 species were identified. The candidate biomarker *Clostridiaceae bacterium* (SGB47672) showed lower abundance in NCG/WS *vs.* Ctrl (q<0.2), data confirmed in validation cohorts (172 NCG/WS, 243 CD). Alpha-diversity was preserved (p>0.05) in NCG/WS and CD up to t4 and in Ctrl (t3) in GFD, whereas concerning changes in relative abundance (q<0.2; p<0.05) we identified a reduction of *Bifidobacterium longum* (SGB17248).

Conclusion: We showed that NCG/WS exhibits a peculiar metagenomic signature with *C. bacterium* (SGB47672) being a potential biomarker for NCG/WS diagnosis. Our study suggests that the use of probiotic supplements can help to restore *B. longum* (SGB17248) deficiency during GFD. Beyond integrating GFD treatment, probiotics containing Bifidobacteria can positively contribute by exerting anti-inflammatory and protective effects on the intestinal epithelial barrier in NCG/WS.

DIET AND EARLY-ONSET COLORECTAL CANCER: VALIDATION OF A NOVEL AD HOC DESIGNED FOOD FREQUENCY QUESTIONNAIRE

M. Puzzono[1], S. Sieri[2], V. Pala[2], A. Mannucci[1], G. Artuso[3], G.M. Cavestro[1]

[1]Gastroenterology and Gastrointestinal Endoscopy Unit, Vita-Salute San Raffaele University, IRCCS San Raffaele Scientific Institute, Milan, Italy, [2]Epidemiology and Prevention Unit, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan, Italy, [3]Vita-Salute San Raffaele University, Milan, Italy

Contact E-Mail Address: cavestro.giuliamartina@hsr.it

Introduction: The incidence of early-onset colorectal cancer (eoCRC), defined as colorectal cancer occurring in young adults under the age of 50, is increasing globally. Questionable eoCRCs' exogenous risk factors are represented by diet and lifestyle, even though a scant literature is available to date. The DEMETRA study is being conducted to assess diet and lifestyle as potential risk factors for eoCRC in various European and non-European countries with populations characterized by large variations in dietary/drinking habits and eoCRC incidence.

Aims & Methods: Therefore, our aims were to (i) develop a unique and shared semi-quantitative food frequency questionnaire (SQFFQ) able to accurately describe dietary and drinking habits of eoCRCs and healthy age-matched controls of different countries at global level that will be involved in the DEMETRA study; (ii) validate the SQFFQ.

We designed an ad-hoc, shared, online SQFFQ to investigate the usual consumption of 329 foods over the past year. These foods were classified in groups and subgroups using the same criteria as the EPIC Italy study [1]. In addition to frequency of consumption, the tool investigates the portions habitually consumed using validated photographs, household measures, and standard units, as well as types of seasoning and methods of cooking and storage. A special software was then developed to analyze responses and link them to food composition tables in order to provide a nutritional

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

breakdown of individual and collective diets. The SQFFQ was then validated for repeatability by administering it twice, 3 weeks apart, to a sample of 30 young adults under 50 years (mean age 35.1 y ± sd 7.71; 63,3% females, 33.3% males, 3% preferred not to answer). To evaluate repeatability, the measurement error for each food group was estimated as the percentage change between the estimates of food consumption for the same individual. Afterwards, the agreement between the two measurements for each food group was measured with Cohen's kappa coefficient.

Results: For 40 out of 65 food groups, the difference between the two SFFQs was less than 20%. The greatest percentage differences were found, as expected, for food groups with sporadic consumption (snacks, barbecue sauces, ketchup, mayonnaise) or consumed in minimal quantities (spices). Agreement levels, represented by the calculation of Cohen's kappa coefficient, were as follows: 12 food groups showed fair/sufficient agreement (Cohen's kappa 20-40), 23 foods exhibited good/moderate agreement (Cohen's kappa >40-60), and 22 food groups demonstrated high substantial agreement (Cohen's kappa >60). Insufficient agreement, with Cohen's Kappa values < 0.21, was observed for only three food groups (snacks, sauces, mayonnaises).

Conclusion: The ad hoc designed SQFFQ provides a reasonably repeatable measure of dietary intake and can be used to assess the dietary and drinking habits of volunteers in this age group. Indeed, most staple foods in the Italian diet, including pasta, fruit, vegetables, legumes, eggs, meat, coffee, and tea, are well estimated by the SQFFQ. However, as yet described in literature, challenges persist in estimating the consumption of foods assumed sporadically (such as snacks) or in small quantities such as spices. Definitive conclusions will be drawn after the completion of the external validation, in which the SQFFQ will be validated against the gold standard, represented by the completion of a 4-day food diary followed by a dietary recall.

Introduction: Sarcopenia is associated with increased morbidity and mortality in IBD. The main objective of thisstudy was to prospectively evaluate sarcopenia by combining morphological and functional criteria inan outpatient IBD population.

Aims & Methods: In a prospective cohort study, we included all IBD patients admitted to the Day Hospital (DH) of ourdepartment between March 1st and 31st, 2023. Patients with short bowel syndrome were notincluded. Muscle mass was assessed using a Bodystat®1500MDD dual-frequency impedance meter,and muscle function was assessed by measuring handgrip strength, Carym® digital dynamometer. Pre-sarcopenia was defined by a handgrip measurement < 16 to 26, and myopenia was defined by anappendicular muscle mass index (AMMI) < 5.5 to 7 kg/m2 or a fat-free mass index (FFMI) < 15 to 17 inwomen or men. Sarcopenia was defined by the association of pre-sarcopenia and myopenia. Patientswere followed-up at 6 months to measure a composite criterion of disease activity combining one ofthe factors: FC > 250µg/g, endoscopic activity, therapeutic change, hospitalization, or IBD-relatedsurgery

Results: In total, 60 patients were included, median age 37 years (IQR 28-54), 55% women, with CD (52%) orUC (48%) diagnosed 9 years (4-17) ago, mostly in remission (67%, n=40). Patients with CD had ileocolic(48%), ileal (35%), or colonic (16%) involvement. Patients with UC had E1 (7%), E2 (41%), or E3 (52%)involvement. A history of digestive surgery linked to IBD was noted in 30% of cases. The biologicsadministered were infliximab (61%),vedolizumab (25%), or ustekinumab (14%). The BMI was 24 (21-27) and serum albumin was 41g/l (39-44). The prevalence of sarcopenia, pre-sarcopenia and myopeniawas 10%, 11% and 20%, respectively. Sarcopenic patients were significantly older (59 vs. 36 years,p=0.01), with older disease (20 vs. 8 years, p=0.003), and associated joint damage (40% vs. 2%,p=0.002) and tended to involve CD more frequently (80 vs. 49%, p=0.36). There was no significantdifference between biologics, BMI or albuminemia in sarcopenic patients, but vitamin D levels tendedto be lower (15 vs. 43, p=0.27). Myopenia was significantly associated with a history of surgery (67 vs.21%, p=0.004), a lower BMI (21 vs. 24, p=0.001) and a more active disease at M6 according to thecomposite criterion (50 vs. 21%, p=0.04 after adjustment for age, sex, and disease activity at baseline). Myopenia indices were strongly correlated with handgrip values(r=0.7, p<0.001)

Conclusion: In a prospective study of Day Hospital IBD patients, sarcopenia was identified by impedancemetry in11% and myopenia in 20% of cases, and associated with an increase in morbidity

Disclosure: No conflict of interest.

Introduction: Inflammatory bowel diseases (IBD) are characterized by recurrent flares and periods of remission. Dietary modifications are commonly made by patients with IBD to manage their symptoms. However, there is no single dietary recommendation for all patients with IBD and little is known about the impact of diet on these patients.

Aims & Methods: This study aimed to identify patients' beliefs, attitudes, and behaviors regarding diet in the management of symptoms and flares in patients with IBD, and to assess the impact on their social life.

Methods: This was a cross-sectional, single-center study involving 50 patients with IBD who were followed up in our department. All patients completed a semi-structured questionnaire.

Results: The majority of patients were male (56%) and had Crohn's disease (84%). Four main themes emerged from the analysis: beliefs about the role of diet in disease onset and flares, attempts to control symptoms through diet, changes in appetite during and outside of flares, and the impact of dietary beliefs on social life. Fifty-six percent (n=28) of patients believed that their diet had triggered their disease, while 84% (n=42) believed that diet could trigger flares. Seventy percent of patients identified specific foods as triggers. Participants described a process of trial and error, identifying foods that worsened their symptoms and others that helped them feel better. Twenty-four percent of patients reported that

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

avoiding fiber improved their symptoms during flares. Two patients used diet as their primary treatment for IBD, but 96% of patients considered diet to be complementary to prescribed medication. Eighty-eight percent of respondents reported having received dietary advice at some point. The majority of patients (68%, n = 34) reported that their disease had changed their enjoyment of food. Appetite was lower during flares than during remission.

Only 8% of patients followed a normal diet during flares. Dietary beliefs and behaviors had an impact on social life for 56% of patients. Avoiding eating out was reported by 56% of patients and not sharing meals with others was reported by 44% of patients.

Conclusion: Our findings confirm those of previous studies that patients with IBD perceive that certain foods can trigger their disease or symptoms, and dietary control is one of the ways they choose to manage their IBD symptoms. We also noted that patients used a personalized approach to diet, combining experience and knowledge.

Disclosure: No conflict of interest.

INCIDENCE AND RISK PREDICTION SCORE OF REFEEDING SYNDROME IN HOSPITALIZED PATIENTS ADMITTED IN A PUBLIC TERTIARY HOSPITAL: A PROSPECTIVE, ANALYTICAL SINGLE CENTER STUDY

J.L. Gargaritano[1], M. Malazarte[1], K. Batoctoy[1]

[1]Vicente Sotto Memorial Medical Center, Internal Medicine - Section of Gastroenterology, Cebu, Philippines

Contact E-Mail Address: janelouegargaritanomd@gmail.com

Introduction: Among critically ill older patients who are hospitalized, malnutrition is prevalent and is also considered a risk factor to develop refeeding syndrome (RFS). There is not enough data on the incidence of refeeding syndrome among them.

This study was conducted to identify the prevalence, severity and risk factors of refeeding syndrome among malnourished hospitalized patients.

Aims & Methods: In this prospective, analytical study conducted in Vicente Sotto Memorial Medical Center in Cebu, Philippines from October 2022 to December 2023, 217 patients were evaluated for malnutrition and risk for developing refeeding syndrome. Malnutrition assessment was conducted using Nutrition Risk Screening 2002 (NRS-2002) through bedside patient interview. The criteria for refeeding syndrome (RFS) were based on the consensus recommendations of the American Society for Parenteral and Enteral Nutrition (ASPEN) for RFS.

Data on electrolyte levels and daily caloric and intake of protein were taken within five days post resumption of nutrition. Significant risk factors in predicting refeeding syndrome were analyzed using Chi-square testing and Pearson rho correlations then subjected to a binary logistic regression to ascertain the effect size.

Results: Among 217 patients, 70 (32%) were at risk for RFS and assessed to have severe nutrition risk with an NRS 2002 score of at least 4 via bedside interview. Refeeding syndrome occurred in 14 patients (20%). Patients with RFS were older (54.71 ± 18.20) than those who were not diagnosed with RFS (50.91 ± 15.77). The total protein (g/day) and total caloric intake of patients who had RFS were significantly lower (41.25g/day ± 12.88 and 884.64 kcal/day ± 559.25, respectively) than those who did not develop RFS (51.20 g/day ± 11.02 and 1275.59 kcal/day ± 295.77, respectively).

Serum albumin (2.59 ± 0.27) and electrolyte levels, particularly, serum phosphorus (1.66 ± 0.29), magnesium (1.96 ± 0.36) and potassium (3.13 ± 0.43) were lower among the RFS patients than the non-RFS group. RFS diagnosis was associated with higher incidence of arrhythmia (50% vs 21%), use of vasopressors (64% vs 32%), ventilatory support (71% vs 23%) and mortality (64.29% vs 21.43%) compared to patients who did not have refeeding syndrome. Predictors of RFS include lower serum magnesium and potassium levels within 5 days of feeding initiation, lower total protein delivered and lower serum albumin level.

Conclusion: Among patients referred to the Section of Gastroenterology and Nutrition Medicine in Vicente Sotto Memorial Medical Center, Cebu City, Philippines, the incidence of refeeding syndrome (RFS) among malnourished patients is 20%. Refeeding syndrome is associated with high morbidity (arrhythmia incidence, use of ventilatory support and vasopressors) and mortality. Parameters such as malnutrition, low total protein intake, low serum electrolyte levels (serum magnesium, serum potassium, serum phosphorus) and low serum albumin were identified to predict the development of refeeding syndrome, with high accuracy, sensitivity, and specificity. However, despite the high morbidity and mortality associated in RFS, most clinicians lack awareness in identifying and managing this syndrome. Clinicians should be able to identify patients at risk to reduce its occurrence.

A RETROSPECTIVE EXAMINATION OF RISK FACTORS FOR CENTRAL LINE-ASSOCIATED BLOODSTREAM INFECTIONS IN HOME PARENTERAL NUTRITION PATIENTS FROM A QUEENSLAND TERTIARY HOSPITAL

P. Hoey[1,2], D. Roche[1,2], P. Chapman[3], V. Kaushik[1], S. Llewellyn[4], N. Adris[1]

[1]Royal Brisbane and Women's Hospital, Department of Gastroenterology and Hepatology, Brisbane, Australia, [2]University of Queensland, Faculty of Medicine, Brisbane, Australia, [3]Royal Brisbane and Women's Hospital, Department of Infectious Disease, Brisbane, Australia, [4]QIMR Berghofer Medical Research Institute, Brisbane, Australia

Contact E-Mail Address: phoey@contexo.com.au

Introduction: A central line-associated bloodstream infection (CLABSI) is a common and potentially life-threatening complication for patients with intestinal failure (IF) receiving home parenteral nutrition (HPN). In uncomplicated infections, The European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines advocate for central venous access (CVC) salvage for venous access preservation (1).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Existing knowledge regarding the risk factors of HPN-related CLABSIs have been extrapolated from European and North American studies (2-4), and the effects of tropical climates and its potentially higher support requirements on the incidence of infection has not yet been studied.

Aims & Methods: We sought to analyse the risk factors of developing HPN-related CLABSI, and assess CLABSI management, in a large Australian state with a highly dispersed population. A retrospective observational cohort study was conducted on 34 adult patients receiving HPN via a central venous catheter (CVC) at a Queensland tertiary referral centre, between 2016 and 2023. CLABSI was defined according to the criteria of the Australian Commission on Safety and Quality in Health Care (5). Patient charts were reviewed, and a univariate cox regression analysis model was used to identify predictors of CLABSI in the first CVC during the study period. Kaplan-Meier analysis was employed to build survival curves of time to CLABSI, and log-rank tests analysed survival between patient and CVC characteristics.

Results: Nineteen patients had ≥1 CLABSI(s) episode, accounting for a total of 39 episodes. Patients with ≥1 CLABSI(s) used regular opioids more than those who did not develop CLABSI (p=0.016) but did not differ by age, gender, body mass index, geography, aetiology of intestinal failure or catheter weeks. Fourteen patients (41%, n=14/34) developed a CLABSI in their first CVC. No patient or line characteristics, including geographical remoteness and tropical climate, were found to be predictive of CLABSI in their first CVC. The overall infection rate was 1.02 per 1000 catheter days. Most CLABSIs were caused by Enterobacterales (22%, n=12/55), followed by coagulase-negative Staphylococcus (18%, n=10/55). Administration of empiric antimicrobials within the standardised 3-hour sepsis timeframe was inadequate (50%, n=14/28), with only 25% (n=7/28) providing adequate cover of causative pathogens. The median time to effective antibiotic therapy was 22.7 hours (IQR 4.8-29.8). There were 3 CVC salvages (8%, n=3/39), all of which were successful.

Conclusion: In this cohort of patients, regular opioid use was associated with an increased risk of developing CLABSI which is consistent with international studies (2-4). We also found a low CVC salvage rate in our cohort, representing potential missed opportunities for venous access preservation. Based on our findings, an empiric antimicrobial regime of vancomycin, cefepime and caspofungin for all HPN-related CLABSI cases would be expected to be effective for 84.6%. We recommend that Australian IF units with a similar antimicrobial distribution and resistance pattern adopt this regime.

EVALUATION OF MALNUTRITION RISK WITH THE MUST SCORE AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE

O. M'solli[1], S. Emna[1], W. Dahmani[1], A. Hammami[1], N. Elleuch[1], M. Ksiaa[1]

[1]*Sahloul University Hospital, Gastroenterology, Sousse, Tunisia*

Contact E-Mail Address: Oussamamsolli7@gmail.com

Introduction: Inflammatory bowel disease patients are at risk of malnutrition due to the nature of the disease, the drugs used, and some dietary restrictions.Several screening tools are available, including the MUST score: the Malnutrition Universal Screening Tool, a simple and an easy-to-use tool.

Aims & Methods: The aim of our study was to assess the frequency of malnutrition risk using MUST score in IBD patients.

We conducted a prospective study that included 142 patients with IBD. All patients with IBD completed a self-administered nutrition screening assessment using the MUST score.Patients with a MUST score of ≥ 2 were concluded as high-risk for malnutrition.

Results: A total of 142 IBD patients were studied over 2 month period. We enrolled a total of 116 (82,1%) patients from outpatient and 26 (18,3%) from inpatient . Risk of malnutrition was identified in 21,1 % of patients according to MUST score. Number of hospitalized patients with malnutrition risk was significantly higher than the outpatient ones (84,6% vs 6.9 %, p<0.01).The frequency of high malnutrition risk was 36,8.% in ulcerative colitis (UC) patients and 15,4% in Crohn's disease (CD) patients (p=0.006). A high MUST score was strongly associated with an elevated Harvey Bradshaw Index score (p<0.01) for patients with Crohn's disease, and with Partial Mayo Index scores (p<0.01) for patients with ulcerative colitis.

Conclusion: In our study, we found that the risk of malnutrition was high in both CD and UC patients, especially inpatients ,and it correlates to the disease activity.Considering the effect of malnutrition on the prognosis of the disease ,IBD patients should be evaluated in terms of malnutrition risk both during their routine follow-ups and during hospitalizations.

Introduction: Etrasimod is an oral, once-daily (QD), selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator for the treatment of moderately to severely active ulcerative colitis (UC). $S1P_1$ receptor modulation is believed to reversibly sequester lymphocytes[1]; its impact on UC intestinal tissue is unknown.

Aims & Methods: We characterised the impact of etrasimod in inflamed colonic biopsy tissue using ribonucleic acid sequencing (RNA-seq) to examine transcriptional-level impacts on disease, in terms of mucosal barrier inflammatory pathways and immune cell populations. In ELEVATE UC 52 (NCT03945188) and ELEVATE UC 12 (NCT03996369), patients (pts) aged 16–80 years with moderately to severely active UC were randomised 2:1 to etrasimod 2 mg QD or placebo (PBO).

Etrasimod treatment effects were characterised by RNA-seq at Week 12 vs baseline (both trials), and in responders achieving clinical remission vs nonresponders. CytoPro (CytoReason) was used for colon-specific cell type deconvolution analysis and single sample Geneset Enrichment Analysis was used for pathway analysis.

Results: At baseline in ELEVATE UC 52/ELEVATE UC 12, colon biopsy samples were available for 245/166 pts receiving etrasimod and 114/84 pts receiving PBO. There were significant reductions in T cell subsets (CD4+, CD8+, helper [Th]1 and Th17), plasma/mature B cell subsets and innate immune cell subsets (monocytes, macrophages, dendritic cells and natural killer cells) in the colon of pts receiving etrasimod (false discovery rate [FDR] < 0.05]); significant changes were not seen among pts receiving PBO. There were also reductions in inflammatory fibroblasts and increases in epithelial cells in the colon of pts receiving etrasimod but not PBO. The change in immune cell populations for responders vs nonresponders at Week 12 was similar to that for etrasimod Week 12 vs baseline. At Week 12, several inflammatory pathways were reduced in responders vs nonresponders to etrasimod; IL-17 signalling was among the most affected (both trials). Nonimmune pathways related to mucosal healing were significantly increased in Week 12 responders.

Conclusion: Decreases in activated immune cell subset and inflammatory signalling pathway changes in responders to etrasimod suggest reductions in local inflammation may contribute to remission and mucosal healing. RNA-seq with cell type deconvolution and pathway analysis contributes to the understanding of etrasimod's mechanism of action.

Introduction: Etrasimod is an oral, once-daily (QD), selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator for the treatment of moderately to severely active ulcerative colitis (UC). S1P receptor modulation reversibly sequesters specific lymphocyte subsets in lymph nodes.[1]

Aims & Methods: This study aimed to better understand immune cell type selectivity of etrasimod using in-depth immunophenotyping of peripheral blood mononuclear cells (PBMC). In ELEVATE UC 52 (NCT03945188) and ELEVATE UC 12 (NCT03996369), patients (pts) aged 16–80 years with moderately to severely active UC were randomised 2:1 to etrasimod 2 mg QD or placebo (PBO). PBMCs were collected and characterised using flow cytometry and epigenetic immune monitoring by Epiontis ID for baseline and Week 12 assessments (both trials).

Outputs were expressed as mean percent change from baseline (%CFB) of cell frequencies. Statistical tests were performed with t-tests at a nominal significance level of 0.05.

Results: In ELEVATE UC 52 and ELEVATE UC 12, 185 (64.0%) and 120 (50.4%) pts receiving etrasimod 2 mg QD, and 98 (68.1%) and 68 (58.6%) receiving PBO, respectively, were included in the biomarker analysis set. Baseline demographics and disease characteristics were similar to the full analysis set.

Using flow cytometry, in both trials, %CFB reductions were observed in total T and B cells with etrasimod (62.24–72.46% decrease) but not PBO. Among CD4+ T cell subsets, the greatest %CFB reductions with etrasimod were for naïve (Tn) cells. Reductions were also seen in central memory (Tcm), helper (Th)2, regulatory, Th1, Th17 and effector memory (Tem) cells (61.00–87.07% decrease) in both trials.

Similarly, CD8+ Tn and Tcm subsets were reduced (69.33–78.48% decrease) with etrasimod; minimal changes were seen in CD8+ Tem cells. For B cell subsets, memory cells and naïve cells were reduced with etrasimod in both trials (62.45–78.03% decrease). In both trials, minimal changes were observed for natural killer cells. With Epiontis ID, etrasimod induced significant reductions in peripheral CD3+, CD4+, GATA3+, IL17A+, FOXP3+, CCR7+ and LRP5A+ cells vs PBO (both trials; Table).

	ELEVATE UC 52		ELEVATE UC 12	
n, mean CFB, % (SD)	PBO (N = 98)	Etrasimod 2 mg QD (N = 185)	PBO (N = 68)	Etrasimod 2 mg QD (N = 120)

PP0356

EVALUATION OF FECAL SHORT-CHAIN FATTY ACIDS CONTENT IN PATIENTS WITH ULCERATIV COLITIS.

M. Stoikevych[1], T. Tarasova[1], I. Klenina[1]
[1]SI "Institute of Gastroenterology of the National Academy of Medical Sciences of Ukraine", Department of intestinal diseases, Dnipro, Ukraine

Contact E-Mail Address: stoykevich.marina@gmail.com

Introduction: It is known that disorders of the intestinal microbiota in patients with ulcerativ colitis (UC) lead to increased intestinal permeability, impaired production and intestinal absorption of short-chain fatty acids (SCFA). The ratio of fecal SCFA is an important indicator of the integrity of the intestinal microbial community. The study of the concentrations of SCFA is a very attractive approach to broadening the understanding of the pathogenesis of UC.

Aims & Methods: To study the content of SCFA in the coprofiltrate of patients depending on the degree of severity of the course of UC.

We included in this study 86 patients with UC with a mean age of 43.2 ± 1.8 years. They were divided according to the Mayo index: 7 milds, 64 moderate and 15 severe. The control group consisted of 7 relatively healthy people. The diagnose UC were established according to generally accepted diagnostic standards in gastroenterology. Determination of SCFA was carried out by the method of chromatographic research. Was determined anaerobic index (AI) - the ratio of the sum of propionic and butyric acids concentrations to the concentration of acetic acid. AI values are used as an indicator of the infrastructure of the microbiocenosis - the ratio of anaerobic and aerobic microorganisms.

Results: The total content of SCFA did not show significant changes in patients with mild and moderate severity of UC (only a moderate tendency to decrease by 1.6 times (p>0.05) and 1.8 times (p>0.05), respectively), while in severe severity there was a statistically significant decrease by 3.9 times (p=0.008) compared to control. Also, in severe UC, this indicator had a pronounced tendency to decrease by 2.4 times (p>0.05) and 2.2 times (p>0.05), respectively, compared with mild and moderate severity, respectively. In mild and moderate severity of the disease, only a weak tendency to reduce the content of acetic acid in the coprofiltrate of patients by 1.4 times (p>0.05) and 1.3 times (p>0.05), respectively, and in severe severity - a significant decrease by 1.7 times (p=0.02), compared to the control. The content of propionic acid in the experimental samples of patients did not change significantly, there was only a moderate/weak tendency to its decrease by 1.6 times (p>0.05), 1.3 times (p>0.05) and 1.2 times (p>0.05), respectively, for the three severity levels of UC compared to the control. A significant decrease in the content of butyric acid in the coprofiltrate of patients with moderate and severe UC severity was found by 2.1 times (p=0.049) and 10.4 times (p=0.001), respectively, compared to the control. It is characteristic that in severe UC, the content of butyric acid was significantly reduced by 5.7 times (p=0.034) and 5 times (p=0.022), respectively, compared with mild and moderate severity of this disease.

IA significantly decreased by 1.5 times (p=0.028) and 1.9 times (p=0.033) in moderate and severe UC severity compared to the control group.

Thus, in severe UC severity, there was a marked decrease in the total content of FFAs mainly due to a significant decrease in butyric acid and a moderate decrease in acetic acid.

Conclusion: The obtained results showed that changes in SCFA concentrations in patients with UC differed significantly from the control group, what can lead to deterioration of the course and prognosis of UC. Estimation of the ratio of SCFA fractions with the calculation of the anaerobic index may be useful for the diagnosis of violation of the quantitative and qualitative composition of the intestinal microbiota in patients with UC.

Introduction: Collagenous colitis (CC) is a form of microscopic colitis (MC), the others being lymphocytic colitis (LC), incomplete CC and incomplete LC (1). It is an inflammatory disease of the large bowel that causes chronic watery diarrhoea, abdominal pain, faecal incontinence, nightly defecation, and weight loss, resulting in significantly impaired quality of life (2). Incidence of MC has increased significantly during the past decades in some countries and the main reason for this increase is thought to be an enhanced disease recognition (3). The diagnosis of MC is challenging as it can only be diagnosed upon histological examination of colonic biopsies taken from normal or near normal appearing mucosa (1).

Histological interpretation of biopsies involves subjective evaluation leading to inter-rater variability discrepancies in diagnosis and treatment plan. Deep learning-based assistance system can objectivise diagnostic key feature selection leading to minimisation of inter-rater variability and improvement of diagnostic accuracy.

Aims & Methods:

The aim of this pilot study was to develop an algorithm for robust segmentation of light microscopy images of histological specimen slides (tissue slides) emphasizing key diagnostic features of CC.

Histological specimens were fixed with formalin, embedded in paraffin, cut into 3 µm sections, and stained with haematoxylin and eosin (H&E) for histological examination. Images were taken using OLYMPUS IX71 light microscope (x20 magnification) equipped with Q IMAGING EXI aqua camera at (1392 x 1040 pix.) resolution and 24-bit pixel encoding. Registered image pixel values were normalized in RGB colour space by histogram alignment using empty tissue-less areas using an algorithm described previously (4).

Superpixel technique using Simple Linear Iterative Clustering algorithm (5) was used for initial segmentation of the images. All 1000 superpixels defined in each image were annotated by the expert, indicating ones containing thickened subepithelial collagen layer as the sought class among the others containing the rest of the tissue indicated as normal class. The

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. feed – forward neural network (implemented in MatLab environment) was trained to classify superpixels using their normalized histogram bin-counts of the pixel values as a feature.

Due to significant inequality in the data set, where the number of sought class superpixels was significantly smaller than the number of the remaining ones, the training set was formed by equalising it to the lowest class case's value (18761). Only randomly selected cases of the bigger class were included in the training set.

Results: The proposed algorithm was tested on images from 5 treatment-naive patients with newly diagnosed CC. Patients' histological specimens were rated by an expert pathologist and 50 images were chosen (with changes characteristic of CC and without). The classification training process with extracted data set took 0.13 seconds on personal computer with an AMD Ryzen Threadripper 3970X 32-Core, 3.70 GHz processor and 128GB of RAM memory, epochs for training was set to 30 (after tests the model was not improving after 30 epochs) and data shuffling was set to every-epoch. The algorithm showed 0.807 accuracy, 0.801 sensitivity and 0.813 specificity.

Conclusion: The shown ability of deep learning algorithm to classify histology image segments can assist the diagnostic process of CC emphasizing thickened subepithelial collagen layer – the essential diagnostic feature.

A MULTI-OMICS ANALYSIS REMINDS THE RELATIONSHIP AMONG GUT MICROBIOTA, BILE ACID METABOLISM, AND THE DISORDER OF INTESTINAL BARRIER FUNCTION IN CROHN'S DISEASE

J. Jiang[1], L. Chen[2], Y. Liu[1], W. Chen[1], H. Chen[2]

[1]Southeast University, School of Medicine, Nanjing, China, [2]Zhongda Hospital, Southeast University, Department of Gastroenterology, Nanjing, China

Introduction: Crohn's disease (CD) is a complex chronic intestinal inflammatory disease with unknown etiology[1]. Gut microbiota is involved in the bile acid metabolism in the intestine and the regulation of intestinal mucosal immunization to maintain intestinal homeostasis[2]. The histological changes in the intestinal mucosa of CD are closely related to impaired intestinal barrier function[3-5]. Abnormal gut microbiota and metabolic disorders can destroy the normal intestinal barrier function and intestinal homeostasis, thereby continuously aggravating the inflammatory reactions[6,7].

Aims & Methods: To further explore the related factors affecting the incidence and provide essential guidelines for clinical prevention and treatment of CD, the prospective case-control study conducted a multi-omics analysis of gut microbiota, fecal bile acid profiles, serum cytokines and intestinal barrier function in patients with active CD, patients in remission and normal controls.

Results: The study found that CD patients had unique gut microbiota and fecal bile acid profiles compared with normal controls, which were related to the disease activity. The beneficial bacteria represented by Romboutsia were positively correlated with the concentrations of fecal secondary bile acids, while negatively correlated with the concentrations of primary bile acids. When patients were active, their gut-beneficial bacteria decreased, affecting the bile acid metabolism. The variation of CD patients' bile acid profile was increased. The production of secondary bile acids was decreased. The levels of proinflammatory cytokines in peripheral blood were increased, such as FC, ESR, CRP and HBP, with P values all below 0.001. And the CD active group had significantly higher levels of IL-6, IL-8, IL-10 and IL-1β than those in remission, with P values of <0.001, 0.005, 0.04 and 0.044, respectively. The intestinal physical barrier and mucosal barrier were damaged with disease activity of CD.

Conclusion: The study suggested that the occurrence and development of CD might be caused by the interaction between gut microbiota and the metabolic product bile acid, which leads to the consequence of immune response in the body and the damage to the intestinal barrier.

THE CONTACT SYSTEM - AN INFLAMMATORY CONTRIBUTOR IN ULCERATIVE COLITIS

M.L. Halling[1,2,3,4], S.T.D. Pham[4], M. Wirenfeldt[3,5], Y. Palarasah[2,4], T. Knudsen[1,3]

[1]Esbjerg and Grindsted Hospital, Department of Internal Medicine, Section og Gastroenterology, Esbjerg, Denmark, [2]Esbjerg and Grindsted Hospital, Department of Clinical Biochemistry, Unit for Thrombosis Research, Esbjerg, Denmark, [3]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark, [4]University of Southern Denmark, Department of Cancer and Inflammation Research, Institute for Molecular Medicine, Odense, Denmark, [5]Esbjerg and Grindsted Hospital, Department of Pathology, Esbjerg, Denmark

Contact E-Mail Address: morten.halling@rsyd.dk

Introduction: Previous research indicate the contact system (CAS) is associated with ulcerative colitis (UC). The activation of coagulation factor XII leads to the activation of plasma kallikrein. Plasma kallikrein generates bradykinin and cleaved H-kininogen (cHK) by cleaving H-kininogen. Bradykinin induces inflammation.

C1 inhibitor (C1-INH) is the most important regulator of CAS, while activated factor XII and plasma kallikrein are the accelerators. Interestingly, experimental colitis can be induced and alleviated in UC animal models by respectively activating and inhibiting CAS[1-3].

Increased activity of CAS in plasma and colonic tissue was detected in patients with active disease[4, 5].

Human studies are still limited. We, therefore, aimed to characterise CAS in patients with active UC by employing our unique panel of CAS assays.

Aims & Methods: We included adults with active UC at the Section of Gastroenterology, Esbjerg and Grindsted Hospital, Denmark from May 2021 to June 2023. Inclusion criteria were: Patient reported outcome 2 (PRO2) score ≥1, Mayo endoscopic subscore (MES) ≥1 and negative stool culture. The PRO2 considers stool frequency and passage of blood.

Pregnancy and conditions influencing CAS or inflammation was prohibited. Patient were not allowed to use oral contraceptives, non-steroid anti-inflammatory drugs, systemic corticosteroids or anticoagulants. Controls were gender-matched blood donors recruited at the Unit for Thrombosis Research, Esbjerg and Grindsted Hospital, Denmark from 2019 to 2021. In- and exclusion criteria were the Danish blood donation criteria. We used the Montreal classification, MES, Nancy histological index, PRO2, CRP, and fecal calprotectin to describe the UC activity.

Biochemical assays determined the kallikrein generation and plasma concentrations of coagulation factor XII, prekallikrein, H-kininogen, C1-INH and cHK (a surrogate marker of bradykinin generated by plasma kallikrein).

Results: We included 94 patients and 100 controls. Patients were primarily female (n=53) non-smokers (n=91) with a median age of 43 years and limited comorbidity (n=26). Half of the patients had proctitis. Patients displayed mild to moderate disease with medians: MES 2, Nancy histologic index 2, PRO2 4, CRP 2.5 mg/L and fecal calprotectin 515 mg/kg.

Although, patients and controls generated similar amounts of plasma kallikrein, patients still had higher cHK levels in plasma than controls (1.38 [0.21-3.98] µg/mL vs 0.83 [0.02-2.88] µg/mL, p <0.0001). The same applied for C1-INH levels (0.22 [0.14-0.33] g/L vs 0.21 [0.16-0.29] g/L, p =0.0340).

The remaining CAS components were similar in patients and controls. Nor, did CAS correlate to UC extension or severity. Interestingly, cHK remained higher even in patients displaying mild disease (see Table 1).

Patient subgroups	cHK in patients	cHK in controls	p-value
Proctitis, n=50	1.40 [1.13-1.70]	0.83 [0.64-1.16]	<0.0001
Mayo endoscopic subscore 1, n=14	1.35 [1.07-1.61]	0.83 [0.64-1.16]	0.0012
Nancy histological index grade ≤1, n=24	1.29 [0.90-1.56]	0.83 [0.64-1.16]	0.0013
Patient reported outcome 2 score ≤2, n=19	1.33 [0.92-1.61]	0.83 [0.64-1.16]	<0.0001
CRP in plasma ≤5 mg/L, n=63	1.40 [1.13-1.61]	0.83 [0.64-1.16]	<0.0001
Fecal calprotectin ≤250 mg/kg, n=20	1.45 [1.13-1.76]	0.83 [0.64-1.16]	0.0004

Results are expressed as medians [interquartile range 25-75%]. Significance was tested with the Mann-Whitney U test.

Table 1 Cleaved HK in patients with mild disease vs controls.

Conclusion: This is currently the largest study to profile CAS in patients with UC. By employing unique and novel assays, we can conclude that CAS contributes to active UC as verified by increased plasma levels of cHK and C1-INH in patients. Further, cHK might be useful as a serological marker for distinguishing patients with UC from healthy subjects.

Contact E-Mail Address: Samehsam888@gmail.com

Introduction: Postoperative recurrence (POR) in Crohn's disease (CD) affects nearly half of patients one year after surgery. The identification of histological features, predictive of POR is relevant. Although it has been suggested that the presence of plexitis is associated with an increased risk of POR, it is not yet common practice to look for plexitis during pathological examination. Therefore, the predictive value of myenteric and submucosal plexitis in POR remains unclear.

Aims & Methods: The aim of our work was to evaluate the histopathological and clinical factors associated to POR after bowel resection in CD patients. We conducted a retrospective study using the Database of the Department of Pathology of Habib Thameur hospital (Tunis). Patients with ileocolonic or ileal resection for CD between 2000 and 2020 were included. The proximal resection margin was analyzed to detect the presence of myenteric and/or submucosal plexitis and assess its grade and the inflammatory cells involved. Plexitis was evaluated based on the appearance of the most severely inflamed ganglion or nerve bundle. Endoscopic recurrence was defined as a Rutgeerts score of ≥ i2 during a colonoscopy performed

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

between the 6th and 12th month after anastomotic surgery . Clinical recurrence was defined as the reappearance of disease-related symptoms, confirmed by endoscopy and imaging.

Results: Seventy patients were included in the study. The mean age was 35 ± 10.7 years and the sex ratio was 1.33. Endoscopic recurrence occured in 56% of cases. Clinical POR concerned 50% of patients within 62 ± 49.2 months. The time to onset of clinical recurrence was significantly shorter in case of endoscopic recurence (p=0.05). Age > 30 years at the time of surgery increased the rate of endoscopic POR (p=0.02) and its severity (p=0.015). Endoscopic recurrence was more frequent in cases of a previous bowel resection (p=0.03). An ileal resection > 30 cm was associated with clinical POR (p=0.012). Ileocolic disease location was associated with a significant increase in clinical POR (p=0.04). A macroscopically affected proximal margin was associated with endoscopic (p=0.017) and clinical (p=0.024) recurrence. Histologic activity at the proximal margin was present in 28% of cases and was associated with endoscopic POR (p=0.042). Myenteric plexitis was reported in 49% of cases. Submucosal plexitis was present in 21% of patients.

The presence of myenteric plexitis and its grade did not increase endoscopic (p=0,28) and clinical (p=0,54) POR. However, plasma cell plexitis was associated with clinical POR (p=0.043). The presence of submucosal plexitis and its grade were not significantly related with a higher risk to endoscopic and clinical recurrence (p=0,94, p= 0,31 respectively).

Inflammatory cells involved in submucosal plexitis had no influence on endoscopic and clinical recurrence (p=0,18, p=0,5 respectively). In multivariate analysis, factors associated with endoscopic POR were age > 30 years at the time of surgery (Odds ratio (OR) = 1.069; 95% CI 1.002 to 1.14; p = 0.044) and the presence of histologic activity (OR= 4,969; 95% CI 1,175 to 21,01; p=0,029). Ileal resection > 30 cm was independently associated with clinical POR (OR= 1,043; 95% CI 1,002 to 1,086; p=0,04).

Conclusion: In this present study, histologic activity at proximal margin, age > 30 at surgery and ileal resection > 30 cm were associated with POR. No association was revealed between myenteric/submucosal and POR. Looking for plexitis should be more regular with a common search methodology to better assess its predictive value in POR.

Disclosure: Nothing to disclose.

Introduction: Patients diagnosed with inflammatory bowel disease (IBD) may have damage in different parts of the gut. The development of this disease involves an intricate interaction between a host with genetic susceptibility, environmental factors, an imbalanced immune response, and intestinal microbiota. Several studies have revealed discrepancies in the composition of gut microbiota between IBD patients and healthy individuals, especially concerning microbial diversity and relative abundance of specific bacteria.

Nonetheless, previous research typically involves patients who have undergone immunosuppressive treatment, potentially altering the microbiota and affecting the integrity of study findings.

Aims & Methods: The aim of this study was to elucidate the differences in the microbiota of newly diagnosed patients with Crohn's disease (CD) and ulcerative colitis (UC) compared to healthy controls (HC), based on the location of the affected area. Stool samples were obtained from IBD patients who had not yet initiated treatment for the disease, and from HC. Each sample underwent shotgun metagenomic sequencing, followed by bioinformatic analysis using the Cutadapt, Kraken2, and Bracken programs. Shannon index (α-diversity) and Bray-Curtis dissimilarity (β-diversity) were used as tests of within-species diversity and within-group diversity, respectively.

Results: We included 103 patients with CD, 144 with UC and 49 HC. Patients with CD, which have been classified depending on disease location (ileal, colonic and ileocolonic), showed lower α-diversity compared to HC in each subgroup, showing the lowest index in those with ileocolonic location. In UC patients, divided according to disease extension (proctitis, left-sided colitis and extensive colitis), those with extensive involvement,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

exhibited the lowest α-diversity compared to HC and other groups. β-diversity in CD patients revealed the highest differences between the comparisons ileal vs ileocolonic and colonic vs ileocolonic, suggesting that patients with ileocolonic pattern showed a more different microbiota profile compared to the other groups studied; however, there were no differences in UC patients.

Examination of taxonomic abundance revealed a decrease in *Phocaeicola coprocola* and several species of *Adlercreutzia*, and an increase in *Shigella flexneri*, in CD patients, compared to HC. In UC patients, an increase in *Toxoplasma gondii* and *Gemella morbillorum* was observed in all three extension subgroups compared to HC. However, several species of *Adlercreutzia* and *Alistipes* were decreased in patients with extensive colitis compared to HC.

Conclusion: Our data suggest that newly diagnosed CD and UC patients showed relevant differences in the microbiota depending on the location of the disease, with a reduction in beneficial genus such as *Adlercreutzia* and *Alistipes*, and an increase in pathogenic species.

Introduction: Crohn's disease (CD) is a chronic inflammatory disorder of the gastrointestinal tract, with its etiology involving genetic, microbial and environmental factors. Dysregulated autophagy, high-fat (HF) diet and abnormal colonization of adherent-invasive *E. coli* (AIEC) have been identified as risk factors for CD. Physical activity (PA) represents a fundamental intervention that offers significant health benefits and has been associated with a reduced risk of developing various diseases, including CD. Although PA has been shown to induce autophagy in different tissues, exerting beneficial effects for the organism, its impact on autophagy in the intestine and its ability to suppress the deleterious effects of HF diet *via* the modulation of autophagy have not been investigated.

Aims & Methods: This study aims to:

(i) explore the influence of PA on the autophagy process in intestinal tissue, and;

(ii) assess the potential of PA to restore intestinal homeostasis and decrease inflammation caused by HF consumption.

Mice deficient for the autophagy-related gene *Atg16l1* specifically in intestinal epithelial cells (*Atg16l1*$^{flox/flox}$*CreVillin*, called by *Atg16l1*$^{\Delta IEC}$ mice) or wild-type mice (WT or *Atg16l1*$^{flox/flox}$) were fed either a control or HF diet for 12 weeks, and then engaged in spontaneous PA on running wheels (active group) or not (sedentary control group) for the same duration. The travelled distance (km), and the speed (m/min) on the wheels were recorded continuously. At the end of the experiment, total fat mass and fat-free mass were measured with echoMRI. The weight of total mesenteric and epididymal adipose tissues were also determined post-mortem. Levels of autophagy markers were assessed by Western blot and qRT-PCR. Intestinal inflammation was assessed by quantification of fecal lipocalin-2 and intestinal pro-inflammatory cytokine levels.

Results: Under HF diet, both *Atg16l1*$^{\Delta IEC}$ and WT mice exhibited substantial weight gain compared to the groups fed the control diet. Spontaneous PA notably attenuated weight gain, particularly in the HF diet-fed groups. Spontaneous PA also diminished the increase in total fat mass and the weight of mesenteric adipose tissue induced by HF consumption, while concurrently augmenting total fat-free mass. HF diet-fed mice exhibited a lower total running distance over the 12 weeks compared to those fed the control diet. Importantly, HF diet consumption led to increased fecal lipocalin-2 level compared to control diet, with a more pronounced effect in *Atg16l1*$^{\Delta IEC}$ *versus* WT mice, and this level was reduced with spontaneous PA. In the absence of PA, HF diet-fed *Atg16l1*$^{\Delta IEC}$ mice exhibited increased *E. coli* abundance compared to other mouse groups, and this was not observed in the active groups.

Compared to control diet, HF diet led to dysregulation of expression levels of several autophagy markers and autophagy flux in intestinal tissues, and this was corrected by PA. In particular, there was a positive correlation between the total travelled distance and levels of several autophagy-related mRNAs.

Conclusion: Spontaneous PA can correct the dysregulation of autophagy and mitigate intestinal inflammation induced by the HF diet. This suggests that combining spontaneous PA with other therapeutic interventions may be a valuable strategy for CD patients with dysregulated autophagy.

Introduction: Inflammatory bowel diseases (IBD), comprising Crohn´s disease (CD) and ulcerative colitis (UC), are characterised by chronic, relapsing and remitting inflammation of the gastrointestinal tract. Despite significant efforts to understand the pathogenetic mechanisms of IBD, the elucidation of its etiopathology and progression remains incomplete. This study aimed to clarify IBD pathogenesis using a multiomic approach in serum, urine, intestinal tissue and stool samples.

Aims & Methods: We performed a multiomic analysis (transcriptomic, proteomic, metabolomic and metagenomic) in a discovery cohort of 53 patients with active CD, 50 patients with active UC, and 33 healthy controls (HC). Transcriptomic and proteomic analysis of intestinal tissue was performed by RNA-seq and liquid chromatography-mass spectrometry, respectively. Serum and urine samples were used for metabolome study using nuclear magnetic resonance, and metagenomic analysis of stool samples was performed by 16rRNA gene sequencing.

Results: Gene expression profiles showed a detailed transcriptome landscape of intestinal tissue in patients with CD and UC. A total of 4,105 proteins were identified in mucosal biopsies, of which 2,128 were differentially expressed (DE) between CD and HC, 2,715 proteins DE in UC compared with HC, and 1,653 proteins DE between CD and UC. Metabolomic analyses revealed metabolites and pathways related to ketone, amino sugar and methyl histidine metabolism, Warburg effect, and ammonia recycling deregulated in IBD patients. Moreover, metagenomic results indicated that CD and UC differ in their microbial populations according to beta diversity. In comparison to HC, the microbial population in CD was different, and its alpha diversity was significantly lower.

Conclusion: The results showed that some of the identified analytes could play essential roles in the pathogenesis of CD and UC. New potential key mechanisms that could help to understand the information of omics layers that underlies the pathogenesis of IBD have been outlined.

LIVER FIBROSIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A CASE-CONTROL STUDY FROM AN IBD CENTER

D. Feijó[1], C. Borges Chaves[1], S. Mendes[1], M. Ferreira[1], S. Lopes[1], M. Ferreira[1], F. Portela[1], P. Figueiredo[1]

Introduction: Inflammatory Bowel Disease (IBD), comprising Crohn's disease (CD) and ulcerative colitis (UC), is a chronic inflammatory condition affecting the gastrointestinal tract. Although primarily associated with intestinal symptoms, IBD has also been linked to various extraintestinal complications, including liver fibrosis (LF). Additionally, metabolic-associated steatotic liver disease (MASLD), a common liver condition driven by metabolic risk factors such as obesity and insulin resistance, could intersect with IBD, given its systemic nature.

While both LF and MASLD are prevalent among the general population, their incidence and associated risk factors in IBD patients remain underexplored. Understanding these liver-related complications is crucial for developing effective screening and management strategies for patients with IBD.

Aims & Methods: We aimed to assess the prevalence of LF and MASLD in IBD patients compared to matched controls. In this cross-sectional, case-control study, we enrolled consecutive IBD patients from an IBD referral center and matched controls from the general population based on age, sex, type 2 diabetes (T2D) status, and body mass index (BMI) in a 1:1 ratio. Liver fibrosis and MASLD were confirmed through shear-wave elastography (SWE) measurements of stiffness and attenuation coefficient. Potential risk factors were analyzed using multivariate logistic regression.

Results: We included 378 participants, comprising 200 IBD patients (106 with CD and 94 with UC) and 178 controls. There were no statistically significant differences regarding distribution by gender, age, T2D status and BMI. The prevalence of LF (SWE ≥ 6.78 kPa) and advanced LF (SWE ≥ 9.15 kPa) was 42.5% and 16.0%, respectively, in IBD patients (48.1% in CD vs. 36.2% in UC; p=0.088) and 28.1% and 9.0%, respectively, in the control

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. group (p<0.05). For UC, history of complicated disease (OR 7.5, CI95% 1.2-46.2 p<0.05) and multiple hospitalizations due to acute disease (OR 5.6, CI95% 1.3-24.8; p<0.05) were significant risk factors. As for CD, previous hospitalizations (OR 9.7, CI95% 1.4-65.8; p<0.05) and heavy smoking habits (OR 4.9, CI95% 2.0-12.4; p<0.001) were the main risk factors.

Extraintestinal manifestations, higher fecal calprotectin level at the time of liver stiffness measurement and latest endoscopic activity were not associated with presence of LF. MASLD was not significantly different between IBD and control group (42.0% vs. 51.7%, respectively; p>0.05). Higher BMI, higher waist circumference, higher abdominal wall thickness and metabolic syndrome were significant risk factors for MASLD (p<0.001).

Conclusion: Our case-control study demonstrates that patients with IBD have a higher prevalence of liver fibrosis compared to matched controls, with significant risk factors including a history of complicated disease, multiple hospitalizations, and heavy smoking habits.

Conversely, the prevalence of MASLD does not significantly differ between IBD patients and controls, suggesting that metabolic factors might play a more substantial role in MASLD risk. Given these findings, it is critical for clinicians to implement routine liver fibrosis surveillance in IBD patients, especially in those with identified risk factors. Proactive management strategies aimed at reducing risk factors, such as smoking cessation and minimizing hospitalizations through effective disease management, could mitigate liver fibrosis risk in this population. These insights emphasize the need for integrated care approaches that address both IBD-related complications and associated liver health.

Introduction: Ulcerative colitis (UC) is an inflammatory bowel disease marked by chronic inflammation of the colon's inner lining. Its pathogenesis involves a multifactorial interplay between genetic and environmental factors, dysregulated immune responses, and alterations in the gut microbiome. MicroRNAs (miRNAs) have emerged as critical regulators of gene expression implicated in UC pathogenesis.

Understanding the differential expression of miRNAs in colonic epithelial cells and their extracellular vesicles (EVs) during bacterial exposure could offer potential insights into the interplay between gut microbiota and epithelial cell-mediated inflammatory responses.

Aims & Methods: The objective of this study was to investigate the expression of UC-associated miRNAs in colonic epithelial cells and their EVs, using UC patients and control subjects-derived colonic epithelial cells co-cultures with *Escherichia coli* and *Phocaeicola vulgatus* bacteria.

Colonic stem cells from healthy controls (HC) (n=10) and patients with active UC (n=10) were used to generate 3D colonic epithelial organoids, which subsequently served as a cell source for constructing polarized monolayers of colonic epithelial cells. These monolayers were co-cultured with commensal *E. coli* or *P. vulgatus* bacteria for 2 hours, washed, replenished with fresh culture medium, and further incubated for an additional 24 hours. EVs from cell-conditioned media were isolated using precipitation method and characterized by ELISA (CD63, HSP70, Apo-A1), Dynamic Light Scattering and cryo-TEM. RNAs from colonic epithelial cells and precipitated EVs were isolated using silica-column based method. MiRNAs expression was evaluated by TaqMan qPCR. Statistical analysis and visualization of the results were performed using R studio.

Results: Although statistically insignificant, but the expression of miR-183-5p and miR-135b-5p in epithelial cells of HC group was tended to decrease after contact with *E. coli* compared to untreated cells (resp. FC=0.84 (p=0.574) and FC=0.87 (p=0.798)), while miR-146a-5p increased (FC=1.37 (p=0.798)). In the EVs samples of HC, the same trends were observed. Interestingly, in the UC patients' cells, after incubation with *E. coli*, the expression of all studied miRNAs - miR-183-5p, miR-135b-5p, miR-146a-5p - tended to increase (resp. FC=1.53 (p=0.730), FC=1.71 (p=0.666), and FC=2.39 (p=0.258)).

Similar expression changes were observed in the EVs of colonic epithelial cells from UC patients following stimulation with *E. coli* (resp. FC=1.32 (p=0.730) (miR-183-5p), FC=1.32 (p=0.666) (miR-135b-5p), and FC=2.07 (p=0.258) (miR-146a-5p)).

After culturing colonic epithelial cells with *P. vulgatus* the expression of all investigated miRNAs, compared to unstimulated cells, remained almost unchanged, both in HC and in UC patients' monolayers. Meanwhile, in both the HC and UC groups, a decrease in miR-183-5p and miR-135b-5p expression was observed in EVs following contact with *P. vulgatus*, compared to control conditions (in the HC group resp. FC=0.59 (p=0.382) and FC=0.51 (p=0.234); in the UC group resp. FC=0.70 (p=0.605) and FC=0.73 (p=0.489)). However, the expression of miR-146a showed a decreasing trend only in the HC group compared to unstimulated cells (FC=0.53 (p=0.161)).

Conclusion: Due to the considerable variation in the response between study subjects, the observed expression changes did not reach statistical significance**.** The experimental study revealed a tendency that the expression of miRNAs associated with UC can be modulated by commensal gut bacteria, particularly *E. coli*, both in colonic epithelial cells and their EVs.

Introduction: Mucosal healing, defined as the resolution of inflammation and restoration of the intestinal epithelial barrier[1], is believed to cause long-term remission in patients treated for Inflammatory bowel disease (IBD). However, most current therapeutic strategies only alleviate the symptoms and induce endoscopic remission rather than directly addressing histological and molecular healing, and little is known about how IBD drugs may contribute to epithelial repair in the colon[2].

During homeostasis, epithelial renewal is maintained by leucine-rich repeat-containing G-protein coupled receptor 5+ (Lgr5+) intestinal stem cells in the crypts, producing proliferative progenitors that gradually cease to divide as they move towards the surface and differentiate into mature cytokeratin 20 (CK20) expressing colonocytes. Inflammation is a major effector of intestinal mucosal damage in IBD and has been found to affect epithelial stemness, regeneration and cellular functions[3].

Thus, we need more knowledge about how IBD drugs, developed to modulate immune cells, also affect intestinal epithelial cells. Here, we used human colon organoids (colonoids) to recapitulate important features of colonic epithelium in a donor-specific manner[4].

Aims & Methods: Our hypothesis is that mechanisms of action (MOA) of IBD drugs in intestinal epithelium are relevant for homeostasis, and drug classes such as targeted small molecules and broad-spectrum first-line corticosteroids will have distinct MOA and varied effects among patients. Here, we use colonoids from healthy donors and ulcerative colitis patients to elucidate MAO for budesonide and the pan-JAK inhibitor tofacitinib, especially their impacts on stemness in differentiated cells.

The effects of tofacitinib and budesonide treatment during differentiation were examined in uninflamed and TNF+Poly(I:C) stimulated colonoids. Colonoid growth, stemness, cell death, and chemokine release were analyzed by brightfield and confocal imaging, immunohistochemistry, western blot, 40-chemokine plex, and single ELISAs. Scripts were developed for automated size and protein quantifications.

Results: When added during the differentiation process, tofacitinib led to an increase, while budesonide resulted in a decrease in colonoid size. Tofacitinib treatment was associated with increased Ki67 expression in general and specifically in mature CK20-positive cells. We observed large inter-individual differences, but tofacitinib treatment enhanced expression of the stem cell markers LGR5 and EPHB2 receptor in colonoids from most donors. Budesonide treatment did not seem to affect proliferation or stemness consistently. Neither tofacitinib nor budesonide pre-treatment showed definite harmful or protective effects on TNF+Poly(I:C) induced cell death in colonoids, but both drugs attenuated TNF+Poly(I:C) induced chemokine release from colonoids.

Conclusion: Although both budesonide and tofacitinib show anti-inflammatory effects in colonoids, their effects on stemness may differ. Notably, our study represents the first to demonstrate that treatment of colonoids with the pan JAK-inhibitor tofacitinib during differentiation promotes a heightened tendency for proliferation in terminally differentiated colonoids.

Furthermore, our research reveals that tofacitinib enhances the expression of stem cell markers. Our study also demonstrates the utility of human colonoids in investigation of drug effects and inter-individual variations in the intestinal epithelium.

Introduction: Inflammatory bowel disease (IBD), encompassing Crohn's disease (CD) and ulcerative colitis (UC), is characterized by chronic inflammation of the gastrointestinal tract. Emerging evidence suggest critical role of gut microbial metabolites in IBD progression. Among these, valeric acid (VA), a short-chain fatty acid (SCFA) produced by bacterial fermentation, is known to be decreased in the feces of IBD patients and to exert an anti-inflammatory effect on macrophages. However, it remains underexplored whether VA could alleviate intestinal inflammation and improve the epithelial barrier in IBD.

Aims & Methods: This study aimed to investigate the effects of VA on intestinal epithelial barrier function and delineate its molecular mechanisms in IBD. VA pathway-related gene expression in human colon biopsies was measured by bulk and single-cell RNA sequencing. In addition, we investigated changes in microbial enzymes involved in VA biosynthesis via microbiome sequencing.

Furthermore, we used human colon organoid *in vitro* model to examine the effects of VA on the intestinal epithelial inflammatory response.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Results: Expression of VA receptors (*Ffar2, Ffar3, Hcar2*), transporters (*Slc5a8, Slc16a1*), and histone deacetylases (*HDACs*) are altered in the colonic mucosa of IBD patients, compared to healthy individuals. The abundance of microbial enzymes responsible for VA synthesis shows significant differences in the microbiota of IBD patients.

Finally, VA treatment decreases the secretion of the inflammatory IL-8 cytokine in a dose-dependent manner and downregulates genes such as *Ffar2* and *Cxcl8* in the colon organoids model.

Conclusion: VA is involved in IBD pathogenesis by affecting the epithelial barrier and modulating immune response.

Introduction: Current IBD therapy regimens are still frequently inefficient, can exert severe side effects, and loss of treatment response is common. Thus, the development of novel therapeutic approaches is an unmet clinical need – especially for patients featuring a primary non-response, refractory disease and/or severe side effects.

Here we assessed novel small molecule inhibitors targeting a4b7 integrin or IRAK4 regarding their efficacy to relieve colitis in a model of spontaneous intestinal inflammation either as a stand-alone treatment or in combination.

Aims & Methods: IL-10 knockout (IL-10KO) mice, which develop spontaneous immune-driven intestinal inflammation resembling human IBD, were used for all studies. Mice with established disease were fed for three weeks *ad libitum* with control chow or chow containing the inhibitors at two previously defined concentrations: a higher concentration intended to induce optimal treatment response or a lower, sub-optimal concentration that did not induce therapeutic effect as stand-alone therapy.

Results: When administered as stand-alone treatment at the higher dose, a4b7 and IRAK4 inhibitors both significantly reduced colitis severity (reduced endoscopic and histological colitis scores [p<0.001 and p<0.01], reduced disease activity index scores [p<0.001]). This effect was accompanied by a normalization of immune cell populations in the colonic lamina propria.

Particularly, we found reduced numbers of granulocytes, Th1, Th17, and cytotoxic T cell sin a4b7 and IRAK4 treated mice. Furthermore, mRNA and protein levels of inflammatory cytokines (IFNg, IL17, TNFa and IL-1b) were normalized in intestinal tissue of a4b7 and IRAK4 inhibitor-treated mice (p<0.01, each). When administered in lower concentrations, however, the a4b7 and IRAK4 inhibitors were not able to reduce disease activity as a stand-alone treatment. Of note, a combination of the low doses of the a4b7 inhibitor and the IRAK4 inhibitor significantly reduced the disease severity as evidenced by reduced endoscopic and histologic colitis scores [p<0.001, each], reduced disease activity scores [p<0.01] and a normalization of immune cell infiltrates (reduced levels of granulocytes [p<0.001], Th1 cells [p<0.001], Th17 cells [p<0.001] and less IFNg+ CD8 T cells [p<0.001]).

Furthermore, while low doses of anti-IL12/23 p40 antibody were not able to reduce disease severity as a stand-alone treatment, combination of low-dose anti-IL12/23 p40 with the low dose of the a4b7 inhibitor resulted in amelioration of colitis (normalized endoscopic [p<0.001] and histologic [p<0.01] colitis scores, reduced infiltration of granulocytes, Th1, Th17 and IFNg+ CD8 T cells [p<0.01, each], normalization of IFNg, TNFa and IL-1b protein and mRNA levels in the intestine).

Conclusion: Our results demonstrate that small molecule inhibitors for a4b7 and IRAK4 were efficient in reducing colitis in a model of spontaneous immune-cell driven intestinal inflammation. Combination of the a4b7 inhibitor with low doses of the IRAK4 inhibitor or sub-optimal doses of an anti-IL12/IL23 antibody was effective to relieve the disease in the IL-10-KO model. This indicates that combination treatment of a4b7 inhibition with other immune-modulatory drugs, such as IL12/23 neutralization or IRAK4 inhibition might be a promising approach for patients that do not respond to single therapies.

Furthermore, our results indicate that combination therapy is able to induce significant disease-relieving effects when the drugs are administered in low concentrations what could minimize side effects without interfering with treatment response.

TACROLIMUS OPTIMIZES OXIDATIVE METABOLISM OF COLONOCYTES IN EXPERIMENTAL COLITIS

W. Lv[1], L. Liu[1]

[1]West China Hospital of Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

Contact E-Mail Address: lvweieg@163.com

Introduction: It has emerged that the energy metabolism of colonocytes shapes the gut microbiota, and loss of epithelial hypoxia accompanied by respiration-dependent dysbiosis is observed in experimental colitis[1,2].

The inhibitory effect of tacrolimus on inducible nitric oxide synthase (iNOS), a vital protein in nitrate respiration, was reported in human colonic epithelial cell lines[3].

Our previous study reported that tacrolimus significantly alleviated colitis in mice and induced beneficial alterations of the gut microbiome[4]. However, the mechanism of how tacrolimus improves the gut microbiota in colitis remains to be elucidated.

Aims & Methods: In this study, we aim to explore the effects of tacrolimus on colonocyte metabolism in colitis. Male C57BL/6J mice aged 8 to 10 weeks were employed. Solutions of 2.5% dextran sulfate sodium (DSS) were prepared in the drinking water to induce colitis for 7 consecutive days. Tacrolimus (Tacro) at a dose of 10 mg/kg was administered via gavage, while aminoguanidine hydrochloride (AG), the selective iNOS inhibitor, was given intraperitoneally at a dose of 100 mg/kg per day. The body weight was observed daily. For hypoxia detection, mice were treated with 60 mg/kg of pimonidazole HCl intraperitoneally 1 hour before euthanasia. Colon lengths were measured, and the colon samples were fixed in 4% paraformaldehyde for subsequent hematoxylin and eosin staining and hypoxia staining. Total RNA and protein were extracted from the isolated colonocytes for the measurement of iNOS expression. For the in *vitro*

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

study, the human colorectal adenocarcinoma cells (Caco-2) were incubated with 10 ug/mL tacrolimus or 0.1% DMSO for 4 hours, then the oxygen consumption rates were measured on the Seahorse XFe24 Analyzers according to the manufacturer's protocols.

Results: Hypoxia in the colonic epithelium was significantly disrupted in DSS-induced colitis mice, which was partially restored by tacrolimus treatment. The iNOS expression on both mRNA and protein levels was significantly upregulated by DSS and downregulated after tacrolimus administration, while the addition of AG enhanced the effects of tacrolimus.

Compared with the individual tacrolimus intervention, the combined treatment of tacrolimus and AG achieved a better remission in weight loss, colonic shortening, and colonic pathological changes including the disruption of crypt-villus structure, goblet cell loss and immune cell infiltration. In *vitro* measurement of mitochondrial oxidative phosphorylation showed that tacrolimus significantly enhanced oxygen consumption, and promoted ATP production and spare respiratory capacity in Caco-2 cells.

Conclusion: Our results indicated that tacrolimus improved the oxidative metabolism of colonocytes in experimental colitis, which could be an important contributor to the alterations in the gut microbes induced by tacrolimus. The observed effect of tacrolimus in colonocytes may be associated with the inhibition of iNOS.

Introduction: Most current approaches for therapy for Inflammatory Bowel Disease (IBD) focus on inhibition of excessive inflammation. However, with clinical remission rates for IBD plateauing, new approaches, are needed. The protease, Activated Protein C (APC), can exert a broad range of cytoprotective actions including inhibition of inflammation, stabilization of endothelial and epithelial barriers and suppression of apoptosis. APC shows therapeutic effects in various inflammatory diseases, and its cytoprotective functions often require biased cleavage of protease-activated receptor (PAR)1 and PAR3.

Biparetide is a bivalent PAR1:PAR3-derived peptide formed by covalent linkage of PAR1-residues 47-55 to PAR3-residues 51-65 via a 10-mer oligo-Gly peptide. Biparetide in vitro mimics APC's anti-inflammatory activity.

Aims & Methods: Aim: Our objective was to assess the in vivo therapeutic benefits of intrarectal and intraperitoneal administration of biparetide in a murine preclinical 40kDa dextran sulfate sodium (DSS) model of colitis.

Methods: Eight-week-old female C57Bl/6N mice were given 2% (weight/volume) DSS in drinking water for three 7-day cycles followed by 7 days of regular drinking water to induce colitis. Both biparetide (1, 10 and 50 mg/kg) and scrambled biparetide (peptide with randomized amino acid sequence) were given daily from day 18 to day 41 by concomitant intrarectal (half volume) and intraperitoneal (IP) injection (half volume).

Anti-TNFa was administered IP 15mg/kg 3 times per week from day 18 to day 41. Prednisolone was administered IP (1mg/kg) once daily from day 18 to day 42. Control groups included healthy mice and DSS-treated animals receiving only vehicle. Colitis severity was monitored using a disease activity score (DAI) based on daily evaluation of weight, stool consistency, and presence of blood; at study end, endoscopic scoring was performed. Colon length and weight were measured, and histological analysis on formalin-fixed paraffin sections was performed by a blinded pathologist.

Results: DSS effectively induced chronic colitis. Biparetide dose-dependently reduced body weight loss compared to vehicle-dosed DSS-treated mice from day 24 ($p<0.01$). Biparetide at both 10 and 50 mg/kg significantly improved body weight loss compared to prednisolone ($p<0.01$) and anti-TNF-a from day 31 ($p<0.01$), and it was associated with a dose-dependent, significant reduction in DAI score compared with vehicle-dosed DSS-treated mice, e.g., from day 24 (for 10 mg/kg, $p<0.01$). Biparetide significantly reduced DAI compared with prednisolone ($p<0.01$) and reduced DAI similar to anti-TNF-a. The peptide's protective effects against chronic colitis observed at both 10 and 50 mg/kg were accompanied by improvements in colon length shortening and in colon weight/length ratio ($p<0.01$), with effects comparable to anti-TNF-a. Amelioration of histological and endoscopic parameters of colitis was seen with anti-TNF-a and biparetide (10 and 50mg/kg) treatments.

Conclusion: In this DSS-induced colitis model, biparetide gave dose-dependent improvement in clinical signs and symptoms, reducing body weight loss and improving DAI score. These significant improvements were seen at 10mg/kg and 50mg/kg peptide. Similar improvements were observed during endoscopy and upon histological assessment.

Here we demonstrate proof of concept that biparetide is a novel anti-inflammatory peptide that mimics APC's previously reported in vivo benefits for DSS-induced colitis. Moreover, these data suggest that biparetide merits further evaluation for clinical translation for inflammatory pathologies.

TRANSCRANIAL DIRECT CURRENT STIMULATION (TDCS) MODULATES ENTERIC NERVOUS SYSTEM (ENS)-CELL EXPRESSION PATTERNS AND INTESTINAL BARRIER IN CHRONIC DSS COLITIS

J.J. Wiese[1], F. Weiß[1], S. Manna[1], S. Krug[1], M. Bubeck[2], C. Günther[2], J. Patankar[2], B. Siegmund[1], M. Prüß[1], N. Hering[1], M. Schumann[1]

Introduction: Chronic visceral pain is a clinical challenge in >50% of Inflammatory Bowel Disease (IBD) cases (Morrison et al., 2013). A randomized controlled trial (RCT) demonstrated that transcranial direct current stimulation (tDCS) can modulate brain activity and effectively alleviate chronic abdominal pain associated with IBD (Neeb et al., 2019).

To elucidate the underlying mechanism of tDCS, we implemented this technique in a mouse model of inflammatory, chronic DSS colitis.

Aims & Methods: The tDCS protocol, including a total of 10 stimulations, was designed based on established human tDCS studies. An anodal direct current (0.5 mA, 20 min) was administered to both primary motor cortices over two separate periods with each period consisting of five consecutive days of stimulation, separated by a two-day break. The study was controlled by including a sham-treatment-group (0.5-minute sham stimulation).

For histology, H&E stained FFPE-sections of colon were assessed by scoring (Koelink et al., 2018). Barrier integrity was analysed by Ussing chamber experiments. To confirm that tDCS was affecting murine activity, mice were tracked in home cages using subcutaneously injected RFID-chips. Myenteric plexus (MP) cells of the murine small intestine, primarily the terminal ileum, were isolated and cultivated for 10 days.

Staining with beta3-tubulin and S100B was performed confirming neuronal cell identity. Bulk-RNA sequencing was conducted using the NovaSeq Xplus system (read length 150 bp, read depth 30 million copies/run).

Results: The distal colon of DSS-treated mice revealed significantly stronger inflammation in the H&E scores compared to control mice (mean±SEM: Ctrl: 0.14±0.08; DSS: 1.52±0.19; MWU: p=0.0005). Only a tendency towards less inflammation was observed in tDCS-treated mice compared to sham-tDCS.

The DSS caused an inflammation-driven thickening of the colon wall, resulting in an increased transmural resistance. This effect was ameliorated by the tDCS-treatment (mean±SEM: DSS+sham-tDCS: 72.2±8.2 $\Omega \cdot cm^2$; DSS+tDCS: 48.1±2.1 $\Omega \cdot cm^2$; MWU: p=0.007).

DSS colitis was associated with a reduced activity, which was partially recovered by tDCS (mean±SEM: DSS+sham-tDCS: 70.7±15.2 relative distance units/day; DSS+tDCS: 205.9±40.4 relative distance units/day; MWU: p=0.029).

Neuronal cell identity was confirmed in isolated murine MP cells by immunostaining (beta3-tubulin, S100B). Bulk-RNAseq revealed a clear separation of tDCS and sham-tDCS treated colitis mice by PCA. Subsequently, 739 differentially expressed genes (DEGs) were identified in tDCS-treated DSS colitis mice compared to a sham-tDCS-treatment (622 upregulated, 117 downregulated genes; log2(fold-change)≥1.5; padj<0.05), *Table 1*.

Analysis of KEGG and GO pathways revealed involvement in several biological processes, comprising neuroactive ligand-receptor interaction ($p=7.94 \cdot 10^{-3}$), gated channel activity ($p=2.4 \cdot 10^{-7}$), substrate-specific channel activity ($p=1.99 \cdot 10^{-7}$), and leukocyte migration ($p=3.99 \cdot 10^{-7}$).

Gene name	Differential expression	Log2(fold-change)	Adjusted p-value
Nos1, Nitric oxide synthase 1	upregulated	$2.68 \cdot 10^{14}$	$5.32 \cdot 10^{-08}$
Fos, FBJ osteosarcoma oncogene	upregulated	$2.21 \cdot 10^{13}$	$4.04 \cdot 10^{-07}$
Ncam2, Neural cell adhesion molecule 2	upregulated	$2.29 \cdot 10^{14}$	$2.66 \cdot 10^{-04}$
Chrnb4, Cholinergic receptor, nicotinic, beta polypeptide 4	upregulated	$1.69 \cdot 10^{14}$	$3.69 \cdot 10^{-04}$
Cend1, Cell cycle exit and neuronal differentiation 1	upregulated	$1.67 \cdot 10^{14}$	$6.71 \cdot 10^{-03}$

Table 1 Selection of neurologically relevant DEGs.

Conclusion: In colitis, transcranial direct current stimulation (tDCS) has the capacity to modulate activity of DSS-treated mice and alters gene expression in MP cells. This reveals another layer of evidence for the impact of central pathways on the gut / brain-gut-axis.

DOES A TRANSCRIPTIONAL SIGNATURE COMPOSED OF TWELVE METALLOPROTEINASES PREDICT THE RESPONSE TO ANTI-TNF THERAPY IN PATIENTS WITH ULCERATIVE COLITIS?

L. Arosa-Garcia[1], M. Camba-Gomez[1], I. Bastón-Rey[2,1], R. Ferreiro-Iglesias[1,2], C. Calviño-Suarez[2,1], M.d.S. Porto-Silva[3], L. Nieto-García[3], J.E. Domínguez Muñoz[2,1], M. Barreiro de Acosta[1,2], J. Conde-Aranda[1]

Introduction: Failure of anti-TNF therapy contributes to the socio-economic burden of inflammatory bowel disease (IBD). This is particularly relevant when new drugs targeting α4β7 integrin, IL-12/IL-23, Janus kinases or sphingosine-1 are added to the IBD therapeutic armamentarium. Anti-TNFs are the usual first-line biologic agents and, therefore, pre-treatment discrimination of patients who will be refractory to these therapies is important to prevent IBD patients from being exposed to multiple therapeutic failures. Many studies have reported predictive biomarkers for response to anti-TNF therapy.

However, the implementation of easily readable biomarkers in daily clinical practice is an unmet need. Due to the active role of the metalloproteinase (MMP) family in the development of intestinal inflammation, we wanted to isolate robust and reproducible transcriptional markers capable of specifically predicting response to anti-TNF therapy by comprehensive analysis of these proteases.

Aims & Methods: We analysed the expression of twelve MMPs in publicly available microarray and RNAseq datasets from the Gene Expression Omnibus and the European Bioinformatics Institute: GSE12251, GSE16879,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. GSE73661 and E-MTAB-7845 for colon biopsies from ulcerative colitis (UC) patients before anti-TNF or vedolizumab therapy. The R package was used for differential expression analysis and receiver operating characteristic (ROC) calculation. Cytoscape software and Morpheus (broadinstitute.org) were used for network data integration and visualisation.

In addition, we evaluated the expression of these twelve MMPS by RT-qPCR in peripheral blood mononuclear cells and polymorphonuclear cells from a local cohort of UC patients (n=21).

Results: We isolated a colonic transcriptional signature consisting of twelve MMPs that is highly associated with disease activity. Most of the transcripts of this signature were significantly up-regulated in colon biopsies of non-responders to anti-TNFs before treatment in three different microarray datasets, but not in vedolizumab-treated patients. ROC curves of the twelve MMPs showed variability in correlation with anti-TNF response in all datasets analysed.

However, the combination of MMP2, MMP3, MME and PHEX efficiently discriminated patients who failed anti-TNF therapy (ROC AUC = 84%). Interestingly, this four-gene signature was not able to predict the response to vedolizumab (ROC AUC = 63%).

For completeness, we observed that of the twelve MMPs analysed, only MME showed increased expression in peripheral mononuclear cells from patients refractory to anti-TNF therapy, confirming that this MMP could be a feasible biomarker in both colonic tissue and peripheral blood.

Conclusion: Overall, our study reveals a novel and robust colonic transcriptional signature consisting of four MMPs associated with anti-TNF, but not vedolizumab, therapy response.

Furthermore, MME levels in peripheral blood cells emerge as a novel, easily readable predictive biomarker of anti-TNF response. Nevertheless, our results should be confirmed in independent cohorts of UC patients to test their efficacy and sensitivity in the clinical setting.

Disclosure: Nothing to disclose.

Introduction: Ulcerative colitis (UC) is a chronic, idiopathic inflammatory bowel disease (IBD), with mucosal inflammation affecting the rectum (proctitis, E1), left side of the colon (E2), or whole colon (pancolitis, E3). Proctitis is considered a mild disease, and often excluded from clinical trials due to heterogeneity in accessing the affected area of the colon.

Proximal extension of the disease is associated with a more severe clinical course. We compared the disease burden of patients with UC according to disease extent.

Aims & Methods: THEFAR is a cross-sectional, observational, multicentre study, including adult patients with UC treated with advanced therapy (AT; biologics or Janus kinase inhibitors). Gastroenterologists across 41 centres included consecutive patients during routine clinic visits.

They completed medical and therapeutic management data, including disease activity (partial Mayo score) using an electronic case report form (eCRF). Patients completed self-reported quality of life (EQ-5D-5L), disability (IBD-Disk), incontinence (Wexner score), bowel urgency (Urgency Numeric Rating Scale, UNRS), and Work Productivity and Activity Impairment UC (WPAI:UC) questionnaires.

Results: 293 patients with UC (mean age 44 ± 16 years; 50% [147/293] male) were enrolled, with 292 self-reported questionnaires returned for analysis; 45 (15%) patients had proctitis (E1), 117 (40%) left-side colitis (E2), and 131 (45%) extensive colitis (E3). Former smokers were more common in E2 (25%) and E3 (28%) than E1 (11%) subgroups (p=0.01). Comorbidities, including chronic rheumatological disease and cardiovascular diseases, were similar across all subgroups (p>0.05). Disease duration was related to the extent of disease: mean duration of 5.3 years (E1) to 8.8 years (E3) (p=0.02). Age at diagnosis was lowest in E3 (33 years) compared to E1 and E2 (38 years each) subgroups (p=0.02). Regardless of subgroup, there was a similar incidence of flares over the past year, presence of extra-intestinal manifestations, and disease activity per partial Mayo score (all p>0.05). There was no proof of difference in current treatment allocation, duration or lines of advanced therapies, or corticosteroid use (p>0.05 for all [except golimumab]) between subgroups. The proportions of hospitalized patients were significantly different in subgroups: E1 (11%), E2 (21%), and E3 (46%) (p<0.0001).

There was no between-group difference for EQ-5D-5L, IBD-Disk, or WPAI:UC scores (all p>0.05). UC-related patient-reported outcomes were similar across subgroups according to both the Wexner score (p>0.05) and UNRS (p>0.05; Table).

Conclusion: In this cohort of patients with UC treated with AT, there was no association between the extent of disease and quality of life, disability, treatment allocation, work impairment, incontinence, or bowel urgency. However, the extent of disease was associated with hospitalizations. Patients with proctitis treated with AT experience similar disease burden and require a comparable level of treatment as those with left-sided colitis and pancolitis.

Demographics and disease characteristics of study participants	E1	E2	E3	p-value
EQ-5D-5L Utility, mean (SD)	0.871 (0.162)	0.893 (0.147)	0.889 (0.174)	0.38
UNRS, mean (SD)	3.5 (3.3)	3.1 (2.9)	2.8 (2.9)	0.46
Wexner Score, mean (SD)	8.4 (4.9)	7.4 (5.1)	8.2 (4.3)	0.35
Total IBD-Disk Score, mean (SD)	36.4 (24.8)	33.5 (25.0)	32.6 (26.1)	0.69
WPAI:UC scores (on people employed*)				
Absenteeism, mean % (SD)	11.1 (29.9)	8.1 (17.6)	7.7 (21.7)	0.52
Work impairment (loss of productivity), mean % (SD)	26.7 (27.1)	22.8 (26.5)	19.4 (26.1)	0.51
Activity impairment, mean % (SD)	27.2 (25.7)	20.1 (23.6)	22.3 (27.0)	0.47

*44 patients in E1, 117 in E2 and 131 in E3 completed the WPAI:UC questionnaire. E1, proctitis, E2; left-sided colitis; IBD, inflammatory bowel disease; UNRS, Urgency Numeric Rating Scale; WPAI-UC, Work Productivity and Activity Impairment-UC; SD, standard deviation. Utility was calculated using the French value set for EQ-5D-5L.

ML-DERIVED, QUANTITATIVE HISTOLOGIC FEATURES OF THE INFLAMMATORY MICROENVIRONMENT AFTER ADALIMUMAB INDUCTION TREATMENT ALLOW PREDICTION OF RESPONSE IN PATIENTS WITH ULCERATIVE COLITIS

J. Shamshoian[1], F. Najdawi[1], S. Degryse[1], C. Jayson[1], J. Brosnan-Cashman[1], K. Kolahi[2], A. Shrotre[2], H. Guay[2], F.S. Laroux[2]

[1]PathAI, Boston, United States of America, [2]AbbVie, South SanFrancisco, United States of America

Contact E-Mail Address: john.shamshoian@pathai.com

Introduction: Ulcerative colitis (UC) is a chronic disease characterized by inflammation. Despite the advent of anti-inflammatory biologics, most patients do not achieve a deep response to therapy. Furthermore, predicting response to therapy is challenging. Quantitative histologic features of the inflammatory microenvironment in UC have potential to inform treatment selection and maintenance efficacy once a regimen has started.

To address this hypothesis, we compared such features derived from machine-learning (ML) models with endoscopic response status (Mayo endoscopic score; MES<2) in patients with UC treated with adalimumab (ADA).

Aims & Methods: A retrospective analysis of a phase III clinical trial of ADA (NCT02065622) was performed. A suite of ML models, collectively known as IBD Explore™ (PathAI, Boston[1])* previously trained to quantify tissue regions (e.g., granulation tissue) and cells (e.g., goblet cells) were deployed on 345 hematoxylin and eosin (H&E)-stained whole slide images (WSI) of biopsies from the rectum and sigmoid colon at ADA end-of-induction (week 8). Human interpretable features (HIFs) were extracted from each WSI. Features were then correlated with end-of-maintenance (week 52) region-level endoscopic response status (MES<2) using univariate logistic regression.

Multivariable logistic regression predictive models were also developed on a subset of the samples (277 WSIs). Predictive accuracy was assessed on a held-out test dataset (66 WSIs).

Results: Of the 657 model-derived HIFs assessed at end-of-induction, 251 were associated (p<0.05) with end-of-maintenance region level MES response status after applying Benjamini-Hochberg (BH) false discovery rate correction. Some example HIFs and their associated odds ratio with end-of-maintenance MES response are noted in Table 1.

Feature	Odds ratio	BH p-value
Median density of goblet cells in crypts	2.85	< 1e-10
Median area ratio of goblet cell mucin to epithelium + crypt abscess in crypts	2.50	< 1e-9
Proportion of neutrophils within 20 µm of goblet cells	2.40	< 1e-8
Proportion of inflamed crypts	0.46	< 1e-7
Proportion of plasma cells + intraepithelial lymphocytes in mucosa	0.66	< 1e-3
Area proportion of granulation tissue in mucosa	0.72	0.032
Heterogeneity of crypt area	0.71	0.01

Table 1: Example HIFs taken at end-of-induction and associated odds ratio to end-of-maintenance MES response.

To develop predictive models of region-specific end-of-maintenance endoscopic response, 5-fold cross validation was used. Biopsies from each subject were placed in a single split to minimize data leakage. The selected model (L1 penalized, class balance weighted) achieved a sensitivity and specificity of 0.64 and 0.67, respectively, on WSI not seen during predictive model development.

Conclusion: A quantitative understanding of the histologic changes in the colonic microenvironment shortly after treatment initiation is critical to advance our collective knowledge of UC and may aid in the prediction of a patient's response. Here, quantitative features of goblet cells and goblet cell mucin were especially predictive of endoscopic response from end-of-induction. ML-derived quantitative histology features have the potential to guide therapeutic decisions in UC that leverage mechanistic rationale derived from histology, contributing to precision medicine in immunology.

THE CAUSAL EFFECTS OF INFLAMMATORY BOWEL DISEASE ON SKIN CARCINOMA: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

L. Luo[1], X. Zhong[1], X. Tang[1], X. Hu[1], L. Li[1], J. Xu[1]

[1]Affiliated Hospital of Southwest Medical University, Luzhou, China

Contact E-Mail Address: luolian5309@163.com

Introduction: Observational studies have indicated that inflammatory bowel disease (IBD) patients have higher incidence of skin carcinoma (SC), including melanoma skin carcinoma (MSC) and nonmelanom skin carcinoma (NMSC) than healthy people. However, whether the correlation is causal remains unclear.

The purpose of this study was to evaluate the causality of IBD on SC using the mendelian randomization (MR) analysis.

Aims & Methods: We performed a two-sample MR analysis with public genome-wide association studies (GWAS) data. Eligible instrumental variables (IVs) were selected according to the three assumptions of MR analysis. The inverse-variance weighted (IVW) method was the main method. Complementary methods included the MR-Egger regression, the Weighted Median, the Weighted Mode and MR pleiotropy residual sum and outlier (MR-PRESSO) methods.

Results: Genetically predicted IBD (IVW OR = 1.07, 95% CI: 1.02-1.13, P = 0.011) and ulcerative colitis (UC; IVW OR = 1.09, 95% CI: 1.03-1.16, P = 0.003) was associated with an increased risk of MSC. Results of complementary methods were consistent with those of the IVW method except Weighted mode. In addition, Crohn's disease (CD; IVW OR = 1.04, 95% CI: 0.99-1.08, P = 0.128) had not a causal effect on MSC. Moreover, IBD (IVW OR = 1.03, 95% CI: 1.00-1.07, P = 0.034) and CD (IVW OR = 1.03, 95% CI: 1.00-1.06, P = 0.045) were associated with a higher risk of NMSC. However, UC (IVW OR = 1.00, 95% CI: 0.97-1.04, P = 0.803) was not associated with NMSC.

Conclusion: Our study revealed genetically predicted associations of IBD on MSC and NMSC in European populations. Additionally, UC increased the risk of MSC, and CD increased the risk of NMSC. But the influence of the use of immunosuppressive agents or biologics cannot be ruled out.

Introduction: Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), and endometriosis are two nosological frameworks affecting young women. They share a spectrum of abdominal symptoms and partially common pathophysiological mechanisms involving immune system dysregulation. It is described that women with endometriosis have a higher risk of developing IBD. However, the impact of endometriosis on IBD is poorly understood.
The aim of our study was to evaluate the impact of the coexistence of both diseases on the phenotype and evolution of IBD.
Aims & Methods: We conducted a retrospective cohort study in 18 GETAID (Groupe d'Étude Thérapeutique des Affections Inflammatoires du tube Digestif) centers between June 2022 and March 2023. Any patient with both endometriosis and IBD was eligible for inclusion. They were then randomly matched to 1 or 2 patients with IBD without endometriosis, according to the following criteria: type of IBD (CD or UC), year of birth (± 5 years), year of IBD diagnosis (± 4 years), and date of the last consultation (± 2 years). Data from non-exposed patients (IBD alone) were collected from a single center (CHU de Lille).
The evolution of IBD was assessed using a composite severity criterion including intestinal damage (stenosis, fistula, or intra-abdominal abscess) or the need for intestinal resection surgery. The use of immunosuppressants and biologics was also recorded.
Results: In total, 207 patients with both endometriosis and IBD (149 CD and 58 UC) were included and matched to 409 patients with IBD alone. The median age of patients at the diagnosis of IBD was 23 years [IQR 18; 29]. The median follow-up duration for IBD was 10 years [5.75; 17]. For patients with CD, there was no difference between the two groups regarding disease location, disease phenotype, and anoperineal involvement. For patients with UC, there was a difference in disease extent with more rectal involvement in the endometriosis group (29.3% vs 12.6%; p=0.03). Patients exposed to endometriosis had significantly less use of immunosuppressive treatments (UC p < 0.01; CD p < 0.001) and biologics (UC p < 0.01; CD p < 0.001), both anti-TNF (UC p=0.01; CD p < 0.001) and non-anti-TNF (UC p=0.04; CD p=0.001). In the actuarial analysis according to the composite severity criterion, patients exposed to endometriosis had a more favorable evolution of their CD than non-exposed patients (HR=0.68; 95% CI [0.50; 0.92]; p=0.011). In the subgroup of patients with CD who underwent surgery for their endometriosis during follow-up (n=72), a less severe progression was also observed (HR=0.65; 95% CI [9.42; 1]; p=0.05). The luminal surgery rate for CD in these patients was lower (32.2% vs 43.9%; p=0.01) in the "exposed" group.
No difference was observed for anoperineal manifestations (p=0.16) and the use of anoperineal surgery (p=0.82). For the UC group, those with endometriosis seemed to have a less favorable disease course, according to the composite severity criterion (HR=1.73; 95% CI [0.74; 4.00]; p=0.20). However, the rate of colectomy was not significantly higher for exposed patients (19.0% vs 11.5%; p=0.20).
Conclusion: Although patients with endometriosis are at a higher risk of developing IBD, it does not negatively influence the course of IBD. On the contrary, patients with CD appear to have a less severe progression, with significantly less exposure to immunosuppressants and biologics. However, both conditions have a major impact on patients, requiring multidisciplinary follow-up to ensure symptom control and improve their quality of life.

Contact E-Mail Address: amalia.dip@unica.it
Introduction: Xanthine oxidase (XO) is involved in the last steps of purine metabolism; indeed, it catalyzes the oxidation of hypoxanthine to xanthine and xanthine to uric acid (UA) with the production of superoxide anion. The accumulation of UA has been shown to initiate the inflammatory process through NLRP3 inflammasome and the production of reactive oxygen species (ROS) contributes to inflammation-related tissue damage. In murine models of colitis, XO inhibitors, allopurinol or febuxostat, reduced the expression of proinflammatory cytokines supporting the involvement of XO in the intestinal inflammatory process.
Aims & Methods: This study aims to conduct a thorough investigation of the role XO plays in IBD pathogenesis and to explore the potential of XO inhibition as a therapeutic strategy.
Biopsies from the sigmoid colon of 15 Healthy Controls (HC), 20 Ulcerative Colitis (UC), and 15 Crohn's Disease (CD) patients, as well as from the ileum of 10 HC and 10 CD patients, were collected at the University Hospital of Cagliari. Disease activity was assessed using Mayo and SES-CD scores. XO expression levels were evaluated using Real-Time PCR and validated by GEO database (GSE11223, GSE117993). XO enzymatic activity was

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

quantified spectrophotometrically in protein extracts from the biopsies. XO and NLRP3 inflammasome activation pathway, including NLRP3, ASC, and CASPASE1, was investigated using immunohistochemistry (IHC). Biopsies samples were lysed in RIPA buffer and Capillary Western analyses were performed with ProteinSimple Jess System utilizing 1:10 dilution for XO, NLRP3, ASC, and Caspase 1; 1:100 dilution for Beta-actin as primary antibodies. Ex-vivo organ culture were assayed with Intestinal biopsies from UC and CD patients. Briefly, the biopsies were cultivated with or without XO inhibitors, allopurinol and febuxostat, for 24 hours in a 24-well plate with 250 µL RPMI at 37°C with 95% O 2 /5% CO 2 atmosphere. After 24h the biopsies were used for IHC analysis of NLRP3 pathways.

Results: Increased XO mRNA expression was found in UC and CD sigmoid colon mucosa compared to HC in the GEO database. This finding was further confirmed by Real-Time PCR in our patients, with a Relative Quantification (RQ) of 1.93 vs. 0.99 (p=0.004) for UC and CD sigmoid colon, and RQ of 2.72 vs. 1.26 (p=0.004) for CD ileum. XO activity was higher in UC and CD sigmoid colon (3.86 nmol UA/min/mg in UC, 4.82 in CD vs. 1.03 in HC, p<0.001) and CD ileum (8.41 vs. 1.83 in HC, p<0.001). IHC and Western analysis confirmed that XO and the NLRP3 inflammasome pathway are more expressed in IBD patients than in HC, predominantly within epithelial cells. The ex-vivo organ culture of CD patients, and UC patients, showed a reduced UA levels and reduced NLRP3 pathways activation after treatment with XO inhibitors.

Conclusion: XO expression was higher in UC and CD patients than in HC individuals. Alongside this increase in XO activity, there was a concurrent hyperactivation of the NLRP3 inflammasome. The inhibition of XO activity in ex-vivo organ culture resulted in reduced activation of the NLRP3 inflammasome pathway. These findings support the hypothesis that XO plays a critical role in the pathogenesis of IBD and highlight its potential as a therapeutic target.

Introduction:

The complexity of Inflammatory Bowel Diseases (IBD) presents challenges for the management of these diseases. Predicting treatment outcomes remains difficult, leading to suboptimal outcomes and high costs. Emerging evidence suggests the potential of the gut microbiome in predicting response to biologic treatments (1,2). In this prospective study we aimed to predict treatment response to vedolizumab and ustekinumab in 79 IBD patients by integrating clinical data, gut microbiome profiles and fecal metabolites and validating these findings in a replication cohort of 47 IBD patients.

Aims & Methods: Treatment response was defined as either continuation or discontinuation of biologic therapy after six months. We performed whole genome metagenomic shotgun sequencing on the baseline fecal samples to identify microbial and functional profiles. Additionally, abundances of over 1000 metabolites were captured through untargeted metabolomic profiling. Baseline diversity, dissimilarity and differential abundance analyses compared responder and non-responder groups. The prediction tool CoDaCoRe was used to identify predictive log-ratio biomarkers. We tested the identified ratios in an external cohort and attempted to replicate the microbiome-based signals of previous studies. Finally, we used a neural-network framework to model the relationship between metabolites and microbes, comparing identified clusters in responders and non-responders and tested our approach with different definitions of response.

Results: We identified 7 differentially abundant metabolites between responders and non-responders (FDR < 0.05), and no significant differences in bacterial species or pathways. Our prediction analysis indicated only marginal predictive utility of the gut microbiome and fecal metabolites for treatment response, when compared to a clinical model using fecal calprotectin, disease duration and disease activity, among other factors (AUC only clinical features: 0.71±0.13, AUC microbial and clinical features: 0.73±0.12). The main predictive features of these models were the high abundance Phocaeicola vulgatus, Bacteroides uniformis and Alistipes onderdonkii, and low abundance of Ruminococcus gnavus and Faecalibacterium prausnitzii. Testing our identified ratio of 10 species in an external cohort of 47 IBD patients reinforced the lack of predictive power of the microbiome. No replication of previously published predictive signals of the microbiome was observed. Additionally, we identified two metabolite and one microbiome cluster associated with response, and observed that predictors were highly dependent on the definition of response.

Conclusion: While previous studies of similar size have shown that microbial features can predict response to either vedolizumab (VedoNet, 1), or vedolizumab, ustekinumab and anti-TNF (2), our comprehensive study found no significant differences in the gut microbiome at baseline between responders and non-responders among IBD patients treated with ustekinumab or vedolizumab. Microbial features added no predictive power to drug response in our IBD patient cohort or an independent replication cohort. Addition of metabolite features did not improve predictive power. These findings suggest minimal impact of the gut microbiome on treatment outcomes with these medications in IBD patients at this disease stage. Generalizability beyond initial study cohorts is limited, leaving predictors for individualized IBD-medication selection unidentified, but based on this work, likely do not lie in the fecal microbiome.

PROTECTIVE EFFECT OF FOOD EMULSIFIERS CARBOXYMETHYLCELLULOSE (CMC) ON MICE COLITIS MODEL IN HIGH-MILK-FAT DIET

L. Shao[1], J. Liu[1], L. Liu[1]
[1]West China Hospital, Sichuan University, Department of Gastroenterology and hepatology, Chengdu, Sichuan, China

Contact E-Mail Address: m18267952034@163.com

Introduction: Inflammatory bowel disease (IBD) is a complex chronic and relapsing inflammatory disorder of the gastrointestinal tract with unclear pathogenesis. Accumulating evidence suggests food emulsifiers as a risk factor for the development of IBD. It is indicated that food emulsifiers carboxymethylcellulose (CMC) can alter gut microbiota and promote intestinal inflammation in IBD under normal diet. Since high-fat diet is the main life scenario for CMC use, little is known about the effect of CMC on colitis model in different high-fat diet.

Aims & Methods: *C57/BL6* mice (3-5 weeks old) were randomly divided into three high-fat diet (HFD) groups, which only differed by fat composition (40 %), derived from corn oil (HCO, n-6 polyunsaturated fatty acids), olive oil (HOO, monounsaturated fatty acids) and milk fat (HMF, saturated fatty acids), and exposed to CMC (1.0% w/v) in drinking water for 4 weeks before the establishment of dextran sulfate sodium (DSS) induced acute colitis mice model. Colon inflammation severity was evaluated using survival rate, HE staining, colon length, body weight change and DAI score. Ki67 and TUNEL assays were performed to detect proliferation and apoptosis.

Results: Compared with the CMC+DSS group, the HMF+CMC+DSS group markedly increased survival rate (P=0.013), colon length (P=0.027) and body weight (day4, day5, day6 and day7, P<0.05, respectively), and relieved DAI score (day4 and day6, P<0.05, respectively) and histological damage (P<0.0001). The HOO+CMC+DSS group seemly had no significant difference from the CMC+DSS group. In contrast, the HCO+CMC+DSS group developed more aggressive colitis with increased DAI score (day5, P<0.01) and decreased body weight (day1, day2, day5 and day6, P<0.05, respectively). In terms of maintaining homeostasis of the intestinal barrier, the HMF+CMC+DSS group showed the highest Ki67 (P=0.012, P=0.0002 P=0.042, respectively) and TUNEL positive cells (P=0.324, P<0.0001, P<0.0001, respectively) compared with the CMC+DSS, HOO+CMC+DSS or HCO+CMC+DSS group. Between CMC+DSS and HOO+CMC+DSS or HCO+CMC+DSS group, there was no difference in Ki67 positive cells, while TUNEL positive cells significantly decreased (P=0.002, P=0.008, respectively).

Conclusion: The function of CMC on DSS colitis varies in different high-fat. Unexpectedly, CMC protects against the development of high-milk-fat related colitis by maintaining homeostasis of proliferation and apoptosis.

References: The function of CMC on DSS colitis varies in different high-fat. Unexpectedly, CMC protects against the development of high-milk-fat related colitis by maintaining homeostasis of proliferation and apoptosis.

Introduction: Inflammatory bowel diseases (IBD), which includes Crohn´s disease (CD) and ulcerative colitis (UC), are complex and heterogeneous diseases characterized by a multifactorial etiology. IBD prevalence is increasing worldwide. The availability of diverse treatments with different mechanisms of action have revolutionized the ability to achieve clinical

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

remission and endoscopic healing. The aim of this study was to achieve a deeper understanding of the mechanism of action and response to different IBD treatments using a multiomic approach.

Aims & Methods: We analysed the metabolome of serum and urine, metagenome of stool samples and transcriptome and proteome of mucosal biopsies from 53 patients with moderate-to-severe CD and 50 UC patients initiating biologic therapy (anti-TNF, ustekinumab or vedolizumab) or tofacitinib. Patients were assessed at 14 weeks for endoscopic remission and were categorized into responders or non-responders. The methodologies employed in this study were RNA-seq analysis, liquid chromatography-mass spectrometry, nuclear magnetic resonance, and 16S rRNA gene sequencing.

Results: The multiomic analyses revealed substantial alterations in the transcriptome, proteome, metabolome and metagenome of both responders and non-responders IBD patients before and after treatment (14 weeks) to different biologics and tofacitinib. Gene enrichment analysis showed noteworthy differences in all study comparisons, except for patients with CD and UC who did respond to anti-TNF and tofacitinib. Functional enrichment analysis of differentially expressed proteins indicated several processes that could be potentially involved in the mechanisms of action of different treatments. More differences were observed in lipoproteins than in serum and urine metabolites in the different study comparisons. Finally, metagenomic findings indicated changes in the composition of gut bacteria communities among CD patients treated with ustekinumab and UC patients treated with tofacitinib (responders vs non-responders at 14 weeks).

Conclusion: The present study provides novel insights into the mechanisms of action of different IBD treatments from a multiomic approach. Nonetheless, multiomic data integration and validation studies are needed to confirm these findings within a more extensive and independent cohort of patients.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) is a chronic multi-factorial disease characterized by inflammation of the gastrointestinal tract. Currently, the mechanisms underlying the disease are far from being elucidated. Thus, the study of proteins involved in its pathogenesis would allow further insights into the molecular mechanisms underlying IBD.

Aims & Methods: The serum and intestinal mucosa (ileum and left colon) proteomic profiles of patients with Crohn´s disease (CD) and ulcerative colitis (UC) and healthy controls (HC) were analyzed through label-free relative quantitative proteomic profiling using nLC MS/MS. Data mining and pattern recognition techniques were performed to identify hidden relationships that are not detectable using classical linear classifiers, and thus identify potential markers able to discriminate between the different study groups. Six candidate biomarkers were selected for further validation using enzyme-linked immunosorbent assay (ELISA) and immunohistochemistry (IHC) in serum and intestinal tissue samples, respectively.

Results: Comparison of serum proteins between UC patients and HC revealed statistically lower levels of protein 1 and 2 and higher levels of protein 3. The comparison of potential biomarkers between CD and HC group showed lower levels of protein 1 and higher levels of protein 3. In addition, protein 4 was differentially upregulated in CD patients compared to UC. Regarding the intestinal biopsies, protein 5 showed higher intensity in the

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. IHC staining of ileum from CD patients compared to HC, whereas protein 6 was significantly decreased in left colon and ileum from CD and UC patients compared to HC. These proteins are involved in thyroxine transport, regulation of chemotactic chemokine activity, inflammatory processes, triglyceride homeostasis, oxidative stress and regulation of NF-kappa-B activation in the cytosol.

Conclusion: In this study, we have identified a panel of six potential biomarkers that could help to elucidate mechanisms involved in IBD pathogenesis. Their roles in the pathophysiology need to be clarified in further experiments.

FETAL THIOPURINE SENSITIVITY IN A MOUSE MODEL BASED ON NUDT15 GENE POLYMORPHISM

T. Imai[1], S. Nakao[1], Y. Yokota[1], S. Shintani[1], M. Ohno[1], A. Nishida[1], O. Inatomi[1]

Introduction: Thiopurines are vital therapeutic agents for inflammatory bowel diseases but often cause severe myelosuppression. The NUDT15 polymorphism, particularly p.Arg139Cys (NUDT15R139C), is strongly linked to severe leukocytopenia and is prevalent in Asian populations. Despite thiopurine use during pregnancy, it remains unclear if NUDT15R139C affects fetal thiopurine sensitivity.

Aims & Methods: The human and murine NUDT15 proteins share 89% homology with the preservation of arginine at codon 139 of human NUDT15 in codon 138 of murine Nudt15. We established a knock-in mouse model with a point mutation (c.412C>T) generating p.Arg138Cys (*Nudt15*^{R138C}), mimicking the human phenotype. In the current study, we investigated offspring generated from *Nudt15*$^{+/R138C}$ or *Nudt15*$^{+/+}$ female mice that were mated with *Nudt15*$^{+/R138C}$ male mice and simultaneously administered with mercaptopurine (MP).To evaluate the effects of thiopurine on the fetus, we evaluated the number of hematopoietic stem cells in the fetal liver, which is the center of fetal hematopoiesis.

Results: In administration with the tolerable MP dose (0.5 mg/kg) for adult *Nudt15*$^{+/R138C}$ mice, genotypes of the genotypes of neonatal mice born from breeding between *Nudt15*$^{+/R138}$ male mice and *Nudt15*$^{+/R138}$ female mice were 35 (37.2%) *Nudt15*$^{+/+}$, 59 (62.8%) *Nudt15*$^{+/R138C}$, and 0 *Nudt15*$^{R138C/R138C}$. On embryonic day 14.5, *Nudt15*$^{R138C/R138C}$ fetal mice showed shorter body lengths and fewer hematopoietic stem cells in the fetal liver than *Nudt15*$^{+/+}$ fetal mice. The number of fetal HSCs was not altered in any of the *Nudt15* genotypes without MP treatment. However, it was significantly reduced by MP treatment in *Nudt15*$^{+/R138C}$ fetal mice ($p< 0.01$, mean number 1104 in DMSO and 577 in MP) and in *Nudt15*$^{R138C/R138C}$ fetal mice ($p< 0.01$, mean number 927 in DMSO and 402 in MP), but not in *Nudt15*$^{+/+}$ fetal mice ($p= 0.39$, mean number 1004 in DMSO and 820 in MP). The number of HSCs in *Nudt15*$^{R138C/R138C}$ fetal livers was significantly reduced to less than 50% of that in *Nudt15*$^{+/+}$ fetal livers by MP treatment during gestation ($p= 0.0089$). In administration with the tolerable MP dose (1.0 mg/kg) for *Nudt15*$^{+/+}$ adult mice, genotypes of neonatal mice born from breeding between *Nudt15*$^{+/R138}$ male mice and *Nudt15*$^{++}$/female mice were 23 *Nudt15*$^{+/+}$ and 0 *Nudt15*$^{+/R138C}$. Without MP administration, neonatal mice were born in a Mendelian fashion.

Conclusion: Fetal toxicity may arise if the fetus has more NUDT15 R139C alleles than the mother, despite safe thiopurine doses for the mother. Analysis of the father's NUDT15 genotype may enable safer thiopurine use during pregnancy, emphasizing the importance of considering parental genotypes in therapeutic decisions.

Introduction: The gut microbiome has been implicated in inflammatory bowel disease (IBD), with functional defects leading to disturbances in important classes of metabolites, including bile acids. Bile acids are molecules produced by the liver that help aid in the digestion of dietary fats. While most are reabsorbed in the small intestine, approximately 5% escape into the colon and are metabolized by bacteria in the colon. Bile acids are important signalling molecules and have been implicated in both inflammation and colorectal cancer. More information is needed to understand how dysbiosis modifies bile acid profiles in patients with IBD.

Aims & Methods: This is a bioinformatic analysis of whole metagenomic sequences that searched for bacteria and genes involved in the transformation of primary bile acids into secondary bile acids. The population

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. consisted of 215 IBD patients who were previously recruited from France. The faecal samples and metagenome sequences were obtained for each patient. The data was processed through a metagenomic pipeline using HUMAnN 3.0 and MetaPhlAn 3.

Results: Cluster analysis previously revealed 3 distinct patient groups based on their gut microbiome composition, one of which, cluster 3, was strongly associated with bile acid dysmetabolism. *Firmicutes CAG:103* and *Firmicutes CAG:83*, previously uncultured co-abundance groups, most strongly positively correlated with secondary bile acid levels in the dataset. *Firmicutes CAG:103* has previously been identified as a potential dominant secondary bile acid producer in metagenomic surveys. Notably, these bacterial groups were almost completely absent in cluster 3 subjects, implicating them as potential actors in secondary bile acid depletion in IBD patients.

Conclusion: This study suggest loss of *Firmicutes CAG:103* and *Firmicutes CAG:83* could be a driving factor for bile acid dysmetabolism in IBD patients. Further research is underway to validate these findings using metagenome-assembled genomes.

Introduction: Inflammatory bowel disease (IBD), are characterized by chronic inflammation of the intestine, and affects millions of people worldwide. There are two main classifications of IBD: Crohn's disease and ulcerative colitis with different mechanisms and etiology of disease progression. IBD is multifactorial; the incidence of this disease may be associated with a dysregulated immune response, genetics, environment, and interactions with the host microbiome. The gastrointestinal epithelium acts as a barrier against harmful stimuli, and defects in its integrity are a precursor for the development of IBD. Our laboratory has shown that the conditional deletion of the Hepatocyte nuclear factor 4A (HNF4A) in the mouse intestinal epithelium (*Hnf4a)* leads to chronic intestinal inflammation. However, the functional impact of HNF4A on epithelial barrier integrity is still controversial.

Aims & Methods: To evaluate the impact of *Hnf4a* deletion on barrier integrity during acute inflammation.

We used a tamoxifen-inducible Cre^{ER}-loxP system to delete *Hnf4a* in the adult intestinal epithelium. Intestinal permeability was assessed in *Hnf4a*$^{\Delta IEC\text{-}ind}$ and control littermate mice in the collected serum after oral gavage of FITC-dextran. Mice were infected with an invasion-attenuated strain of *Salmonella* Typhimurium (SB103 (invA::strep)). *S.* Typhimurium loads were scored in the feces, liver, and spleen by plating homogenates on LB agar supplemented with streptomycin. Histological assessment was performed by various staining. In addition, we used a model of T-cell-induced enteropathy triggered by a T-cell activating monoclonal anti-CD3 Ab. Control and *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice received an intraperitoneal injection of 50 µg monoclonal antiCD3ε Ab (145-2C11). Mice were assessed for clinical signs of enteropathy and sacrificed 1-, 3-, and five days post-injection. Gene expression levels of selected targets were measured by RT-qPCR. Also, Ki67+ staining was performed in the small intestinal tissue

Results: FITC-dextran assay showed a significant increase of intestinal permeability in uninfected *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice compared to controls. In contrast, an oral infection with an invasion-deficient *Salmonella* Typhimurium strain did not differentially impact tissue bacterial loads or epithelial damage between groups. Likewise, the loss of epithelial HNF4A led to increased Muc2 transcripts expression in the ileum of infected *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice. Histological examinations at four days post-infection showed an elevated number and size of goblet cells in the ileal crypts of *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice. Bacterial localization using the general bacterial probe EUB388-cy3 (red) staining showed that infected *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice tended to enhance barrier mucus layer thickness compared to the controls. On the contrary, acute T cell activation with anti-CD3 mAb induced a significant increase of *Cxcl1* transcripts in the small intestine of *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice. H&E staining showed elongated ileal crypts in *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice compared to controls after anti-CD3 injection. Moreover, five-days after inflammatory stimulus, the ki67+ staining showed a proliferative phenotype located in the hyperplastic crypts of *Hnf4a*$^{\Delta IEC\text{-}ind}$ mice.

Conclusion: Altogether, these results support that HNF4A could play a crucial adaptive role in modulating the small intestine epithelial barrier function and controlling the immune system during acute inflammatory stress.

Introduction: Intestinal stem cells (ISCs), located at the intestinal crypt base, are exposed to diverse signals that contribute to their proliferation and differentiation. These signals originate from the stem cell niche, which is comprised of epithelial cell types, enteric neurons, myofibroblasts or endothelial cells. Acetylcholine (ACh) is an important neurotransmitter of the enteric nervous system (ENS), which activates muscarinic (mAChRs) and nicotinic receptors (nAChRs). Mammalian mAChRs consist of five main subtypes (M1–M5) which are coupled to G-proteins. In addition to cells of the ENS, mAChRs are prominently expressed by intestinal epithelial cell (IEC) types including Lgr5-positive ISC. We could previously show that the modulation of mAChRs altered small intestinal differentiation and the cellular activity of Lgr5+ ISCs.

Aims & Methods: We investigated the role of mAChRs in colonic epithelial homeostasis and regeneration by utilizing male and female Vil-Cre×M3R fl/fl mice with epithelial ablation of M3R. The colonic *Lgr5*-expressing ISC

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

number was assessed in Vil-Cre×M3R fl/fl and C57bl/6 mice by *in situ* hybridization (ISH). Intestinal inflammation was induced by treating C57bl/6 and Vil-Cre×M3R fl/fl mice with 1% (v/v) DSS in drinking water for 7 days, followed by 5 days of normal drinking water. Epithelial cell proliferation rate and numbers of Lgr5+ ISC were assessed in colonic organoids treated with 250 nM bethanechol (Beth), a muscarinic agonist, for 4 days.

Results: Epithelial deletion of M3R in vivo revealed sex-based differences in colonic *Lgr5*- expressing ISC cell numbers. While male Vil-Cre×M3R fl/fl mice exhibited a severe reduction in colonic *Lgr5*-expressing ISCs, female mice showed the opposite phenotype with a moderate expansion of *Lgr5*-expressing cells. This translated into exacerbated DSS-induced colitis in male Vil-Cre x M3R fl mice as compared to very mild inflammation in female Vil-Cre x M3R fl mice normalized to respective age- and gender matched C56BL WT controls. In vitro, pharmacologic muscarinic agonism using Bethanechol similarly induced sex-specific changes to epithelial proliferation as well as Lgr5-positive ISC counts employing murine colonic organoids. Interestingly, Bethanechol treatment induced increased proliferation and an expansion of Lgr5-positive ISC in vitro in colonoids from female mice, which did not occur in treated organoids from male mice.

Conclusion: In summary, our study highlights the significant role of mAChRs, particularly M3, in ISCs and colonic health. The sex-based disparities observed in Lgr5+ ISC populations and responses to inflammatory stimuli emphasize the potential intricate interplay between mAChRs and sex hormones in intestinal physiology. These findings suggest potential therapeutic targets for intestinal disorders, emphasizing the importance of understanding sex-specific mAChR signaling for personalized treatments.

Introduction: Inflammatory bowel disease (IBD) describes two chronic inflammatory intestinal diseases: Ulcerative Colitis (UC) and Crohn's Disease (CD). Treatment of these conditions is often through immunosuppression to induce remission then maintenance. Cytomegalovirus (CMV) is a virus commonly found latent in all humans with seroprevalence rates existing between 40-100% depending on geographical location (1). Pathological reactivation of CMV is triggered by inflammation and immunosuppression; both present in the pathogenesis and treatment of IBD respectively (2). Consequentially, CMV reactivation occurs in IBD flare-ups around a rate of 25% (2) and greater than 30% in steroid-refractory patients (1, 3). Whether CMV reactivation is associated with escalating medical therapy, further hospital admissions, and worse clinical outcomes such as toxic megacolon or colectomy when compared to non-CMV associated flare-ups remains controversial. As such, the aims of this study were to follow up patients with IBD following an index episode of CMV colitis and analyse disease progression, relapse of CMV colitis, and clinical outcomes.

Aims & Methods: As such, the aims of this study were to follow up patients with IBD following an index episode of CMV colitis and analyse disease progression, relapse of CMV colitis, and clinical outcomes.

A retrospective study of patients treated at Royal Melbourne Hospital, Parkville, Australia treated between 2018-2023 was completed. Patients were included if they had a diagnosis of IBD, had positive immunohistochemistry for CMV on biopsy, and were treated with Ganciclovir or Valganciclovir for CMV colitis. Data collected included
demographic details and laboratory investigations at time of first episode of CMV colitis. Data regarding treatment for IBD and CMV colitis at time of CMV colitis was also collected. Outcome results were collected at 6-month and 12-month time points after first episode of CMV colitis. Fourteen patients were included in this study; 13 with UC and 1 with CD.

Results: Recurrence of CMV colitis occurred in 21% of cases at 6 months and 29% at 12 months. Additional courses of corticosteroids remained constant at 21% of cases at 6 and 12 months. Forty-three percent of patients had changed their biologic at 6 months and this stayed constant at 12 months. Similarly, 29% of patients had escalated their biologic dose at 6 months which was the same at 12 months. At 6 months, 43% of patients had been re-hospitalised due to IBD or CMV including 2 colectomies. At 12 months, these figures increased to 36% and 3 respectively. Disease remission was only achieved by 7% of patients at 6 months, increasing to 29% at 12 months.

Conclusion: While a descriptive study, our results when compared with previous studies (4) suggest that CMV colitis is a negative prognostic marker in patients with IBD, resulting in higher rates of hospitalisation, failed medical therapy requiring medication change or dose escalation, and colectomy. These risks may be greater at <6 months from index episode of CMV colitis. Further research regarding effective management of CMV colitis is needed to minimise poor outcomes in these patients.

sociated with an overactivation of the immune system and a dysbiosis of the gut microbiome. An important step towards a better understanding is the characterization of epithelial lesions. Their severity is classified by the Mayo score system based on their macroscopic appearance. While previous studies analysed cellular changes within the colon in UC patients, a detailed characterization of different UC-associated lesions are still missing, which is the aim of our study in collaboration with Sanofi Pharmaceuticals.

Aims & Methods: We recruit patients with active disease at our endoscopy unit and collect different biopsies from multiple regions within these patients to compare the reproducibility of single cell RNA sequencing (scRNAseq) results of similar appearing lesions within and between patients. For the sample preparation, we performed a cellular enrichment step for immune, epithelial and stromal cells before performing 10x scRNAseq to obtain equal numbers for each cell fraction from every sampled area. Additionally, we collected stool samples and endoscopic brushes to determine the associated microbial communities by 16S rRNA sequencing.

Results: Our cellular isolation strategy allows successful recovery of fibroblast, epithelial and immune cell fractions from each lesion. All expected epithelial cell types as previously described are detected in our dataset as well. Moreover, our experimental setup to obtain comparable numbers of fibroblasts, epithelial and immune cells enables us now to investigate cell-cell communication differences within different Mayo score lesions. For example, CXCL signals increased with the severity of macroscopic lesions and involves multiple cell types.

Additionally, we are in the middle of correlating microbial diversity with the corresponding disease conditions.

Conclusion: Our results provide exciting insights into cell-cell communications at an unprecedented depth, which identifies aberrant signalling pathway that may contribute to treatment failure in the clinics.

Disclosure: We have nothing to disclose.

LACK OF DNA METHYLTRANSFERASE DNMT3A IN FIBROBLASTS IMPAIRS CELL GROWTH AND WOUND HEALING

C. Escudero-Hernández[1], E. Hübner[1], S. Núñez-Torvisco[1], A. Rodríguez-Peña[1], J. Montague[1], P. Rosenstiel[2]

[1]University Hospital Schleswig-Holstein / Institute of Clinical Molecular Biology (IKMB), Cell Biology, Kiel, Germany, [2]Kiel University, University Hospital Schleswig-Holstein, Institute of Clinical Molecular Biology (IKMB), Kiel, Germany

Contact E-Mail Address: celia.escher@gmail.com

Introduction: Fibrosis in Crohn´s disease (CD) is a complication of chronic inflammatory processes that may result in impaired gastrointestinal function and bowel strictures. However, exact pathomechanisms leading to intestinal fibrosis in CD are not fully understood. Since the de novo DNA methyltransferase DNMT3A is involved in cellular differentiation processes and genetic variants have been associated with increased risk for CD, we sought to characterize how DNMT3A loss might affect fibroblasts, the key mesenchymal cells involved in fibrosis.

Aims & Methods: We stably deleted Dnmt3a in 3T3 fibroblast cell line using CRISPR-Cas9 technology and subsequently selected GPF-positive clones using FACS sorting. Cell cultures were performed in cell culture plates with or without 0.2% gelatin coat. Reverse transcription quantitative PCR, western blot, and immunofluorescence were used to confirm Dnmt3a gene deletion and characterize wild-type (WT) and knockout (KO) cells. Cell adhesion was evaluated by fluorescence levels of calcein acetoxymethyl ester (CAM)-labelled cells that attached to cell culture plates after 1h of culture and subsequent wash. Collagen lattice assays in presence of proinflammatory and profibrotic stimuli served to assess fibroblast contractibility.

Results: 3T3 fibroblasts lacking Dnmt3a acquire an activated myofibroblast phenotype (increased alpha-SMA expression) that also overexpress tissue remodeling matrix metalloproteinase Mmp3, and the inflammation-induced necroptosis marker RIPK3 when compared to their WT counterparts. In addition, Dnmt3a-depleted 3T3 cells adhere more strongly to cell culture plates. In presence of transforming growth factor (TGF)-beta, cells embedded in a 3D collagen matrix and lacking Dnmt3a build an interconnected cellular network and contract up to a 77.78% (compared to interconnected cells that reach up to 13.73% contraction by WT cells). This contraction was independent of the presence of interleukin (IL)-11. Profibrotic factors such as bleomycin prevent intercellular network formation in both WT and KO cells; hence, incapacitating cells to contract the collagen matrix.

Conclusion: We conclude that Dnmt3a is crucial for fibroblast homeostasis, including cell activation and functionality. Furthermore, TGF-beta induces higher fibroblast contractibility when Dnmt3a is lacking. Thus, additional characterization of Dnmt3a depletion in fibroblasts will deepen the understanding of fibrosis and may point towards new therapeutic approaches for this untreatable complication.

HIGH SERUM LIPOCALIN-2 EXPRESSION AT THE DIAGNOSIS IN CHILDREN WITH ULCERATIVE COLITIS: A PILOTSTUDY

G. D'Arcangelo[1], C. Petrella[2], M. Fiore[2], M. Distante[1], F. Zucconi[1], S. Rotulo[1], A. Gravina[1], M. Aloi[1]

[1]Sapienza University of Rome, Pediatric Gastroenterology Unit, Rome, Italy, [2]Institute of Biochemistry and Cell Biology (IBBC-CNR), Rome, Italy

Contact E-Mail Address: giuliadarcangelo87@gmail.com

Introduction: Lipocalin-2 (LCN2) is a pleiotropic mediator of various inflammatory processes. Upon gastrointestinal damage, bacterial infection, or intestinal inflammation, LCN-2 is strongly upregulated, resulting in high concentrations of this molecule.

Aims & Methods: We determined the serum levels of LCN-2 in a cohort of newly diagnosed UC children, and we compared them with healthy controls.

We conducted a prospective cross-sectional observational study conducted at the Pediatric Gastroenterology Unit of the Umberto I Hospital and at the IBBC – Institute of Biochemistry and Cell Biology – CNR in Rome. All children aged 6-18 years of age, newly diagnosed with UC were consecutively enrolled. Blood withdrawal was conducted upon diagnosis. Human serum LCN-2 (Cat. No. DY1757) was measured using a sandwich enzyme-linked-immunosorbent assay (ELISA) kits (R&D Systems, Minneapolis, MN, USA), according to the protocols provided by the manufacturer. Clinical, demographic, biochemical and endoscopic data were recorded.

Results: Thirty-two children with a new diagnosis of UC [11 (34%) female, mean age 12,7 ± 4] and 38 age- and sex-matched healthy control [21 (55%) females, mean age 11.71 ± 4] were consecutively enrolled. Serum LCN-2

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

levels were significantly higher in cases compared to controls (280 ± 152 ng/mL vs 66 ± 55 ng/mL), p < 0,001]. Among UC children, significantly higher LCN2 levels were measured in pancolitis (363.7± 155.2 ng/mL) compared to proctitis, left-sided and extensive colitis (184.9 ± 74.65 ng/mL; P = 0.0003). A significant inverse correlation was observed between LCN-2 and albumin levels at the diagnosis by the Spearman coefficient correlation (r = −0.455; P = 0.03) and a significant direct correlation was observed between LCN-2 and CRP values at the diagnosis (r = 0.44; P <0.05).

Conclusion: Serum LCN-2 levels are significantly higher in children with UC compared to the healthy control group, with the highest levels observed in children with the most extensive disease. Such results as well as and its correlation with the actual disease monitoring tool, make this protein an interesting candidate biomarker.

Disclosure: Nothing to disclose.

Introduction: Limited evidence is available about predictors of response to specific medications for ulcerative colitis (UC). OCTN1, an organic cation transporter, with its variants, could modulate the inflammatory response and potentially predict individual response to immune-modulatory therapy (anti-TNFα and vedolizumab).

Aims & Methods: We first confirmed the ability of OCTN1 to differentially modulate IL1β secretion under different stimuli in a human leukemia monocytic cell line (THP-1) and in human peripheral blood mononuclear cells. We therefore prospectively enrolled a cohort of UC patients starting either anti-TNFα or vedolizumab, determined their OCTN1 genotype and evaluated their clinical features at baseline and clinical response to therapy after six months, as well as two years therapy persistance.

Results: OCTN1-deficient THP1 cells showed reduced IL-1β secretion in response to peptidoglycan (PGN) and Fusobacterium nucleatum (Fn), whilst primary monocytes bearing OCTN1 503F variant displayed an increased production of IL-1β in response to PGN and live bacteria. We therefore enrolled 90 patients, of which 50 starting anti-TNFα and 40 vedolizumab. At the multivariate analysis, an overall better response to therapy was observed with the mutated 503F variant (OR=16.72, p=0.011) in comparison to wild type (503L) and heterozygous variants; nevertheless, a significant reduction of clinical response after six months was observed in patients with 503F variant treated with vedolizumab (OR=0.02, p=0.04). Furthermore, the same trends were observed the two years steroid free therapy persistence wa taken inot consideration.

Conclusion: Mutated OCNT1 genotype (503F) could favor an increased IL1β secretion from human leukocytes, thus suggesting a worse disease course and lower response to vedolizumab as compared to homozygous 503L and heterozygous.

Introduction: Endothelial dysfunction is seen in chronic inflammatory diseases and also associated with inflammatory bowel disease (IBD).(1-3) Similarly, subclinical cardiac dysfunction has also been seen in children with IBD.(4) This has not been studied in adults with IBD.

Aims & Methods: This study aims to assess the prevalence of endothelial and subclinical cardiac dysfunction among patients of IBD.

Adult patients with active IBD, IBD in remission and healthy control (age and sex matched) were recruited. Diagnosis of IBD was based on clinical, endoscopic, and histological findings. Ulcerative colitis (UC) severity was evaluated with Total Mayo Score (MS) and Crohn's Disease (CD) with Crohn's Disease Activity Index (CDAI). All participants underwent investigations to assess disease severity, presence of anemia and dyslipidemia. Conventional 2D and speckled echocardiography was done to assess subclinical cardiac dysfunction. Endothelial dysfunction was detected using endothelium dependent flow mediated dilation (FMD). Vascular doppler ultrasound of brachial artery was done to assess FMD.

Group comparisons of numerical data were done with one-way ANOVA test or Kruskal-Wallis test, depending on the normality of the data. Holm-Sidak test was used as post hoc test for multiple assessment. Proportions were compared using the chi-square test. Statistical significance was determined when the p-value was less than 0.05.

Results: 90 subjects were analyzed in the study (30 with active IBD, 30 IBD in remission and 30 healthy controls). 55 patients had UC and 5 patients had CD. The median duration of disease was 24 (48.3) months and was similar in both active IBD and IBD in remission.

The median FMD was 13.7 %, 22.9% and 23.3% in active IBD, IBD in remission and controls respectively. FMD was significantly lower in patients with active IBD as compared to controls (p=0.025) and IBD in remission (p=0.048). There was no difference in FMD between controls and IBD in remission (p=0.707).There was no correlation between impaired FMD and disease duration (Pearson's r = -0.104, p=0.21). Cardiac evaluation revealed comparable ejection fraction (EF) among different groups. The global longitudinal strain (GLS) was significantly lower in active IBD [-18.0 (5.73)%] (p=0.002) and IBD in remission [-18.0 (3.30)%] (p=0.034) as compared to controls [-20.2 (1.95)%]. GLS was similar in IBD in remission and active IBD (p=0.933). The prevalence of subclinical cardiac dysfunction based on GLS was 4% (4/30) in controls, 14.4% (13/30) in IBD in remission and 15.6% (14/30) in active IBD. The difference among the groups was significant (p=0.011). FMD was not different between subjects with normal and abnormal GLS (p=0.936).

Outcome Median (IQR)	Active IBD	IBD in remission	Controls	p Value	p1	p2	p3
FMD (%)	13.7 (16.3)	22.9 (15.1)	23.3 (6.4)	0.017	0.048	0.025	0.707
GLS	-18.0 (5.73)	-18.0 (3.30)	- 20.2 (1.95)	0.003	0.99	0.002	0.003

Comparison between: p1 –Active IBD and IBD in remission; p2 –active IBD and controls, p3 – IBD in remission and controls

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Conclusion: Endothelial dysfunction was more in active IBD compared to IBD in remission and controls. It was similar in IBD in remission and controls. Subclinical cardiac dysfunction was also more in IBD patients. Endothelial dysfunction did not correlate with disease duration. We also found no correlation between Endothelial Dysfunction and presence of subclinical cardiac dysfunction.

Introduction: Crohn's disease (CD) poses a clinical challenge due to its unpredictable post-operative recurrence and the necessity for effective therapeutic interventions. The molecular mechanisms governing recurrence are poorly understood, although oxidative stress (OS) has been implicated in CD pathogenesis. However, its specific role in recurrence remains elusive. This study aimed to analyze the gene expression signatures regarding OS and their implications for CD recurrence using transcriptomic analysis.

Aims & Methods: Ileal mucosa samples were obtained from the prospective mutlicentrique cohort of CD patients undergoing surgery. They were collected from ileal resection margins (n = 196) at the time of surgery (M0) and in the neo-terminal ileum (n = 121) 6 months after surgery (M6) while patients were classified as in remission (Rem) or recurrence (Rec) based on the Rutgeerts score. Endoscopic recurrence was defined as a Rutgeerts score ≥i2b. Gene data sets (Affymetrix microarrays) were issued on a princeps paper*. Pathway analysis was conducted to identify significant OS pathways using the Ensemble of Gene Set Enrichment Analyses (EGSEA) method and through unsupervised signature generation (Independent Component Analysis) from M0 and M6 genes dataset. Statistical analyses were carried out to assess differential gene expression and pathway enrichment between Rem and Rec patients at M0 and M6.

Results: No significant genes were differentially expressed between Rem and Rec groups at M6 and M0. However, using EGSEA at M6, of the 1766 significant pathways, 40 were related to OS and predominantly overexpressed in the Rec group, indicating a potential association between OS resolution and pressure relief. At M0, of the 2556 significant pathways, 40 were related to OS and equally distributed between the Rem and Rec groups, and therefore did not predict recurrence at M6. Applying unsupervised signature generation, 140 signatures were identified and 8 were annotated as OS pathways. Theses OS pathways were upregulated at M6 in the Rec group and at M0 in the Rem group.

Conclusion: The study highlights the role of OS in CD progression and post-operative relapse. The significant increase in OS pathways at M6 in relapsed patients and at M0 in patients who remain in remission suggests that resolution of OS is necessary to counteract CD relapse. Further research is needed to delineate the role of oxidative stress in CD recurrence and to identify new therapeutic targets tailored to individual patient profiles.

THE E3 UBIQUITIN LIGASE RNF31 MEDIATES THE DEVELOPMENT OF ULCERATIVE COLITIS BY REGULATING NLRP3 INFLAMMASOME ACTIVATION

C. Zeng[1], P. Wang[1], C. Tang[1], J. Li[1], Y. Chen[1], Peng Wang, ChaoTao Tang, Jun Li, Youxiang Chen

Introduction: The NLRP3 inflammasome is a multiprotein complex consisting of the receptor protein NLRP3, the linker protein ASC, and the effector protein caspase-1. Activation of NLRP3 can lead to increased production of proinflammatory cytokines, which disrupt intestinal barrier function and induce the development of ulcerative colitis.

Aims & Methods: Whether RNF31 regulates the expression of the NLRP3 inflammasome is not known. In this study, we examined the expression of RNF31, and NLRP3 in ulcerative colitis tissues by GEO database analysis and immunohistochemical assays, and subsequently determined that RNF31 can regulate NLRP3 inflammasome expression by constructing an RNF31-deficient cell model, and elucidated the role of RNF31 in the development of ulcerative colitis.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Results: We found that the expression of NLRP3 decreased after the addition of MG132 inhibited the level of ubiquitination. a cycloheximide (CHX)-chase analysis showed that RNF31 was able to make NLRP3 more stable, which was most likely due to the fact that RNF31 changed the level of ubiquitination on NLRP3. Multiple co-immunoprecipitation (CO-IP) assays showed that there was an interaction between RNF31 and NLRP3 and that this interaction increased the level of ubiquitination on NLRP3. And CO-IP experiments using truncated RNF31 plasmids showed that the RBR structural domain interacted with NLRP3, increasing the level of ubiquitination on NLRP3 and making NLRP3 more stable. By constructing a cell model with RNF31 deletion as well as overexpression and using CO-IP experiments we found that the K63 ubiquitination chain plays an important role in stabilizing NLRP3.

Finally, we constructed RNF31-deficient mouse models using adenovirus and showed that the expression of NLRP3 and inflammatory factors IL-18 and IL-1β were reduced in the absence of RNF31.

Conclusion: Our study shows that RNF31 can interact with NLRP3 through the RBR structural domain and increase the level of the K63 ubiquitin chain on NLRP3 thereby making NLRP3 more stable and activating the assembly of the inflammasome, elucidating how RNF31 is involved in the mechanism of colitis development.

Introduction: Inflammatory bowel disease (IBD), encompassing Crohn's disease (CD) and ulcerative colitis (UC), often manifests around the fertile age. It is known that disease activity affects pregnancy outcomes. However, little is known about how IBD affects pregnancy outcomes and vice versa. Both IBD and pregnancy complications, particularly those in which placental insufficiency is implicated, are accompanied by oxidative stress. Oxidative stress is defined as an imbalance between reactive oxygen species (ROS) production and antioxidant availability. Free thiols (FT) are circulating biomarkers of oxidative stress since they readily scavenge ROS. Previous research has shown reduced levels of FT in both IBD[1] and pregnancy complications[2]. Classical biomarkers of placental insufficiency include soluble FMS-like tyrosine kinase-1 (sFlt-1) and placental growth factor (PLGF), and their ratio is reflective of maternal pregnancy complications[2]. However, the behavior of these biomarkers in pregnant women with IBD remains unclear.

Aims & Methods: In this study, we aimed to investigate the relationship between FT, sFlt-1, and PLGF and the occurrence of pregnancy complications in patients with IBD, and to assess their dynamics before, during, and shortly after pregnancy.

In this retrospective clinical pilot study, we investigated a cohort of pregnant women with IBD and healthy pregnant controls who were pregnant between 2000 and 2023. Serum samples taken before (IBD n=41), during (IBD n=33, controls n=14), and after (IBD n=25) pregnancy were analyzed for PLGF, sFlt-1 and FT levels. FTs were measured using a colorimetric detection method. sFlt-1 and PLGF were measured using an immunofluorescent assay. Extensive clinical data were collected, including data about pregnancy complications such as pre-eclampsia, fetal growth restriction, and gestational diabetes, and IBD disease parameters, including fecal calprotectin and clinical disease scores.

Results: In total, 40 patients (n=32 CD, n=7 UC, and n=1 IBD-U) with 47 pregnancies and 14 non-IBD control pregnancies were included. Comparing patients with IBD to controls during pregnancy, serum FT levels were significantly reduced in patients, even after adjustment for gestational age (p=0.043). FT levels significantly decreased during pregnancy compared to preconception (p=0.001), suggesting increased systemic oxidative stress during pregnancy. The sFlt-1/PLGF ratio was significantly higher in IBD compared to controls (p=0.011), which was partially due to a difference in gestational age (median (IQR): controls 32.6 weeks (29.4-33.1) vs. 15.4 weeks (7.0-22.7) in IBD). In total, 32 patients (56%) and 3 controls (21%) developed pregnancy complications. The sFlt-1/PLGF ratio was higher in those developing maternal complications, almost reaching significance (p=0.053), while FT showed a trend towards decreased levels in those developing maternal complications (mean (SD): 368.9 μM (38.7) without vs. 349.1 μM (21.9) with maternal pregnancy complications, p=0.082).

Conclusion: This study provides evidence for increased systemic oxidative stress (reflected by lower systemic FT levels) during pregnancy in IBD, when compared to both healthy controls and their own pre-conceptional levels. These results suggest a difference in redox status between pregnant women with IBD compared to those without. Further research is necessary to substantiate these findings and evaluate the utility of these biomarkers in predicting pregnancy complications and guiding clinical decision making in IBD pregnancy.

Introduction: Renal disorders are among the extra-intestinal manifestations of inflammatory bowel disease (IBD), and treatments may also lead to renal failure. However, the incidence of end-stage renal disease (ESRD), defined as the need for renal replacement therapy (dialysis and/or renal transplantation (RT)), is poorly known. The primary objective of our study was to assess the incidence of ESRD in IBD patients, and to compare it with the general health insurance scheme population.

Aims & Methods: We conducted a prognostic cohort study based on data from the French National Health Insurance Database(SNDS). Prevalent cases of IBD affiliated to the general health insurance scheme during the period 2011-2020 were identified on the basis of declarations long-term diseases ALD 24 or the presence of 2 hospital stays for IBD with ICD-10 codes or a single stay with reimbursement of specific treatments. Incident cases of ESRD were identified on the basis of a stay with a RT or a period with dialysis sessions for at least 45 days. Crude incidence rates of ESRD were calculated over the period for the IBD and the non-IBD population, with their 95% confidence intervals.

Results: A total of 280,283 IBD patients were included in the study over the period 2011-2020, 134,567 with ulcerative colitis(UC) and 145,716 with Crohn's disease(CD). The mean age at study inclusion was 39.8 (± 17.1) years. The M/F sex ratio was 0.9. The mean age at incidence of ESRD in the non-IBD population was 65.0 (±17.0) years, the M/F sex ratio cases was 1.7. Among IBD patients, 534 patients began replacement therapy by dialysis or RT, they were younger than non-IBD patients (60.3(±16.7)years, P<0.001).The mean incidence rate of ESRD over the period was 26.4 per 100,000 person-years (IC95% 23.1-29.6), 480 (89.9%) patients entered ESRD by dialysis, and 54 (10.1%) by preemptive RT. In the non-IBD population the mean rate of ESRD was 15.9 per 100,000 person-years (IC95% 14.8-17.1; P<0.0001 compared with IBD): 79,606 (94.5%) patients entered ESRD by dialysis, and 4,634 (5.5%) by RT (as compared with IBD,P<0.001). In subgroup analysis, the mean incidence rate of ESRD was 22.8 per 100,000 person-years (IC95% 18.9-26.7) in UC patients and 29.5 (IC95% 25.3-33.6) in CD patients (P<0,0001). The rates of preemptive RT were 12.4% in UC patients (87.6% dialysis) and 8.6% in CD patients (91.4% dialysis).

Over a median follow-up of 6.8 years, the survival rate after ESRD was 40.8% in ESRD-IBD patients VS 34.2% in ESRD non-IBD patients (P<0.001). This difference remained significant for patients under 65 (p<0.0073).

No significant difference for the risk of re-hospitalization after RT (p=0.84), of retransplantation during the follow-up period in RT patients (p=0.67), or for the risk of hospitalization for severe infection (p=0.97) after RT in patients from the general population compared with IBD patients. The same was true for the type of severe infections after RT (p= 0.068) and for the risk of solid and haematological cancer after RT (p=0.48). However, there was a significant difference in the type of first severe infection after RT(p=0.003), but we are waiting for the results to tell us which one.

Conclusion: The incidence of ESRD is significantly higher in IBD than in the general data base population, confirming the need for regular monitoring of renal function in our patients.

Survival after ESRD onset, is higher in IBD patients.

The high incidence of RT in the IBD population confirms that access to transplantation is not restricted in this
population.

Introduction: There is an unmet need for new therapies to promote mucosal healing and restoration of epithelial barrier function in the inflammatory bowel diseases (IBD). The development of novel approaches to specifically deliver a therapy to the gut has the theoretical advantage of optimizing benefit while limiting side effects. Adenoviral (Ad) gene therapy has been successful in treating cancer and has recently been used in clinical trials as a vaccine for SARS-Cov2. Ad vectors can be modified to target specific tissues and therefore may be more effective vehicles for gene therapy for diseases like IBD than other systemic therapeutics. We propose that gene therapy using adenovirus has promise to achieve these goals in IBD. As a proof of concept, we developed an approach to deliver IL-22 via Ad gene therapy. IL-22 plays an important role in maintaining the epithelial barrier at mucosal sites like the skin, airway, and intestine. Epithelial cells are the primary target of IL-22 signaling, where it activates transcription of genes involved in cell proliferation and promotes antimicrobial functions.

Aims & Methods: We hypothesize that gene therapy with Ad vectors to deliver IL22 directly to the intestine could be an effective therapeutic for IBD by promoting intestinal wound healing and microbial homeostasis. To test this hypothesis, we injected human adenovirus serotype 5 (huAd5) expressing *Il22* (Ad-CMV-Il22) intravenously into 6-week-old C57BL/6 mice.

Results: IL-22 protein levels in the serum, liver, ileum, and colon were increased with Ad-CMV-Il22 compared to the empty vector control (Ad-CMV-GFP). We analyzed transcription of genes downstream of IL-22 signaling and found Ad-CMV-Il22 increased relative expression of *Lcn2* in the liver, ileum, and colon, as well as increased expression of *Mt1* and *Mt2* in the liver and colon. Ad-CMV-Il22 induced increased crypt depth and goblet cell count in the ileum and colon, and increased villus length in the ileum compared to Ad-CMV-GFP. Changes to the stool microbiome included increased abundance of the pro-tolerogenic family Lachnospiraceae-Ruminococcaceae with Ad-CMV-Il22 in both colon and ileum. It is known that huAd5 has liver tropism and gene therapy with hAdv5 has been associated with liver toxicity. We also observed higher levels of IL-22 in the liver than in the serum, ileum, or colon after Ad-CMV-Il22 treatment. To reduce liver tropism, we modified the vector to incorporate myeloid-binding peptide (MBP) on the virus fiber, which re-targets the virus to the intestine and

vascular endothelium. Incorporation of MBP significantly reduced IL-22 protein levels in the liver by nearly 10-fold. The ratio of IL-22 protein levels in the ileum and colon was 1.35 and 1.81 times higher with the targeted vector compared to untargeted virus. Increased colon and ileal crypt depth (45%) as well as villus length (9%) were seen with Ad-CMV-MBP-Il22 as compared to the untargeted virus.

Conclusion: Together, these data suggest that IL-22 gene therapy in the intestine can promote cell proliferation and microbial homeostasis. In the future, this adenoviral gene therapy could be modified further to increase *Il22* gene delivery specifically to intestinal tissues.

IMPACT OF PHYSICAL ACTIVITY ON THE QUALITY OF LIFE OF PATIENTS WITH IBD: PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

S. Mechhor[1], M. Cherkaoui Malki[2], H. El Bacha[1], N. Benzzoubeir[2], I. Errabih[2]

[1]Hopital ibn sina / universite mohamed v / faculte de medecine, gastroenterologie et hepatologie, Rabat, Morocco, [2]Ibn Sina Hospital, Department of Gastroenterology, Hepatology and Proctology « Medicine B »; Ibn Sina University Hospital, Rabat, Morocco, Rabat, Morocco

Contact E-Mail Address: salmamechhor@gmail.com

Introduction: Chronic inflammatory bowel diseases (IBD) are chronic conditions that profoundly affect the quality of life (QoL), and their evaluation has become essential during IBD follow-up. Regular and tailored physical activity (PA) can contribute to improving QoL; however, engaging in PA may be limited during these diseases.

The aim of this study was to describe the factors associated with PA practice and its impact on QoL.

Aims & Methods: This was a descriptive and analytical prospective study conducted on a sample of 85 patients followed in IBD consultations. We collected data regarding the disease and assessed PA intensity using the International Physical Activity Questionnaire (IPAQ), which distinguishes between three activity levels: light, moderate, and vigorous. We assessed QoL using the Inflammatory Bowel Disease Questionnaire (IBDQ), calculating sub-scores for digestive symptoms, systemic symptoms, emotional disorders, social function, and overall score. Statistical analysis was performed using SPSS 20.0 software. Qualitative variables were compared using the Chi-square test and McNemar's test. Factors associated with PA practice were identified using a binary logistic regression model in univariate and multivariate analysis.

Results: We collected data from 85 patients. The mean age was 35 +/- 3.4 years. The female-to-male ratio was 1.23. Crohn's disease was reported in 65 (76.47%) patients, while 20 (23.53%) had ulcerative colitis. 68 (80%) patients were in remission. Two patients (3.3%) were smokers. The prevalence of joint manifestations was 13.3%. 12 patients (14.1%) had undergone surgery as part of their disease management. 51 (60%) patients were on biologic therapy with a mean treatment initiation of 3.5 +/- 1.2 years; 13 (15.29%) patients were on thiopurines alone, 19 (22.3%) were on salicylates, and 2 (2.35%) were on corticosteroids. Among our patients: 58 (80%) engaged in light PA, 18 (21.1%) in moderate activity, and 9 (10.58%) in vigorous activity. The mean sub-score for digestive symptoms was better in patients engaging in moderate to vigorous activity compared to those engaging in light activity, with respective values of 31.3 +/- 1.16 vs. 29.15 +/- 2.11, $p < 0.001$. The mean sub-score for systemic symptoms was also better in patients engaging in moderate to vigorous activity: 34.6 +/- 3.61 vs. 28.52 +/- 1.21 in cases of light PA, $p = 0.003$. In multivariate analysis, engaging in moderate to vigorous PA was associated with clinical remission (OR 1.06; [1.02; 3.15]; $p = 0.002$) and absence of joint manifestations (OR 2.93; [1.24 - 3.05], $p < 0.001$). Smoking and a history of digestive surgery did not influence PA. Patients engaging in moderate to vigorous activity had a better quality of life than those engaging only in light activity, with mean overall IBDQ scores of 198.3 +/- 21.3 vs. 151.11 +/- 25.3, $p = 0.0003$. The emotional sub-score was better with moderate to vigorous activity: 33.7 +/- 5.1 vs. 31.05 +/- 4.51 in patients with light PA, $p = 0.002$. Similarly, the social function sub-score was better with moderate to vigorous activity: 29.04 +/- 7.16 vs. 26.23 +/- 4.61, $p < 0.001$.

Conclusion: In our study, engaging in moderate to vigorous PA among patients with IBD was associated with better quality of life. Certain factors limit its practice, notably disease flare-ups and joint manifestations. The importance of physical activity should therefore be evaluated during consultations, and patients with IBD should be encouraged to engage in regular and tailored PA according to their disease profile

Introduction: Chronic inflammatory bowel disease (IBD) is at high risk of thromboembolic events (TEA), which are a significant cause of morbidity and mortality.

They are attributed to a pre-thrombotic state caused by the inflammatory activity of this disease.

The objective of our study was to evaluate the prevalence and risk factors (FDR) of ATEs in patients with IBD, to determine their clinical and evolutionary particularities while specifying the existence or not of a gender effect.

Aims & Methods: This is a retrospective descriptive and analytical study carried out at the hepato-gastroenterology and proctology department "Médecine B" CHU Ibn Sina Rabat, between January 2001 and July 2023, including all patients who presented during their follow-up with an ATE confirmed by imagery (thoracic angioscanner/ cerebral angio MRI/ doppler ultrasound).

We collected demographic, clinical and paraclinical data.

The Chi-2 test was used to compare categorical variables.

Results: During the study period, among the 1643 IBD cases collected in the department, we recorded 21 cases of IBD complicated by ATE, a prevalence of 1.27%.

The mean age was 42.7 years (23-61 years), with a male predominance of 12 men (57%) and 9 women (43%), with a sex ratio of M/F : 1.3.

Among the 12 men, 7 (58%) had Crohn's disease and 5 (42%) UC, with a mean disease duration of 8 years and 4 months. Among the 9 women, 6 (67%) were being followed for Crohn's disease and 3 (33%) for UC.

The occurrence of a thrombo-embolic complication during hospitalization for a disease exacerbation was more frequent in men than in women (8 (67%) Vs 5 (55%); p=0.3).

Deep vein thrombosis (DVT) was more common in women than in men (6(67%) Vs 1(8%); p= 0.003).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Cerebral thrombophlebitis was found in 2 men (17%) and 2 women (22%). Budd Chiari syndrome was found in 1 woman (11%).

Pulmonary embolism was found in 3 men (25%), portal thrombosis in 3 men (25%), renal artery thrombosis in 2 men (17%), superior mesenteric vein thrombosis in 1 man (8%). None of the women had these manifestations.

Thrombophilia testing revealed decreased anti-thrombin activity in women, associated with protein C deficiency in 2 patients (22%). In the men, we noted protein C deficiency in 1 patient (8%) and 1 case (8%) of protein S deficiency.

Hyperhomocysteinemia was positive in one patient (11%), with no cases in men.

All patients were treated with anti-coagulants for curative purposes.

The absence of thrombosis and good revascularization was confirmed by follow-up imaging after 6 months of treatment in 5 men (42%) and 3 women (33%); p= 0.4.

A complication in the form of extensive cerebral ischemic necrosis of thrombosed vessels was noted in 1 man (8%).

A single case of death was reported in 1 man (8%) following a severe pulmonary embolism. No cases of death were recorded in women.

Conclusion: Patients with chronic inflammatory bowel disease have a non-negligible risk of developing TEA, particularly during the active phase of the disease, underlining the importance of preventing thromboembolic disease when managing patients during relapses.

CANDIDA YEASTS IN CROHN'S DISEASE: PREVALENCE, ASSOCIATED FACTORS, AND IMPACT ON DISEASE PROGRESSION

M. Sabbah[1], F. Kahlaoui[1], A. Bouratbine[2], M. Ben Abid[2], N. Bibani[1], H. Jlassi[1], S. Soua[1], K. Aoun[2], D. Gargouri[1]

Introduction: Crohn's disease (CD) has a complex etiopathogenesis involving the intestinal fungal microbiota which appears to have a significant impact on the development and progression of the disease.

Aims & Methods: The objectives of our study were to investigate the prevalence of *Candida* yeasts and the factors associated with their presence, as well as their impact on the course of CD. A prospective study involving patients with CD [June 2020 - March 2021] was conducted at the gastroenterology department of HHT in collaboration with IPT. A mycological examination of stool samples was performed to identify *Candida* yeasts.

Clinical and laboratory follow-up was conducted to assess disease progression. Unfavorable evolution was defined in the presence of flare-ups, complications (abscesses, collections, surgical intervention for CD), and therapeutic escalation.

Results: Fifty-two patients with a mean age of 40.7 years [18-67] and a gender ratio (M/F) of 1,59 were included. Yeasts were detected in 71,2% of patients, with *Candida* genus present in 55,8%.

The isolated species were *Candida albicans* (45%), *Candida parapsilosis* (32%), *Candida glabrata* (10%), *Candida tropicalis* (6%), and *Candida krusei* (7%).

Two patients harbored two *Candida* species simultaneously: *C. krusei* and *C. parapsilosis*, and *C. albicans* and *C. parapsilosis*, respectively.

The presence of *Candida* was associated with a history of diabetes (p=0,001), ileal (p=0,018) and ileocolonic (p=0,017) disease locations, and clinical disease activity as assessed by CDAI (p=0,03).

C. albicans was associated with both stenosing and fistulizing phenotypes of CD (p=0,04) and a CRP > five mg/L (p=0,005). *C. glabrata* was associated with ileal localization (p=0,01), and *C. tropicalis* was associated with the occurrence of collections (p=0,049) and therapeutic escalation (p=0,01).

Conclusion: *Candida* genus yeasts are common in CD and are associated with disease activity and an unfavorable disease course. We suggest their systematic investigation during MC, although their treatment is not consensual.

Contact E-Mail Address: luciamv_20@hotmail.com

Introduction: Infection by Leishmania spp. in patients diagnosed with inflammatory bowel disease (IBD) is an uncommon infectious complication. The use of anti-TNF-α is well known risk factor for Leishmania infection (LI), particularly in some endemic areas, but only a few case series have been reported in the literature, mainly in the Mediterranean basin.

Aims & Methods: Aim: To evaluate the main demographic, IBD-disease features and risk factors as well as LI disease characteristic and required treatment among IBD patients who develop LI.

Methods: This is a retrospective, observational, multicenter study conducted in twenty-five Spanish hospitals, promoted by the Young Group of GETECCU, including patients diagnosed with IBD and subsequent diagnosis of LI.

Results: We collected a total of 73 patients, 48 of them were men (65.8%) with a mean age of 48 ± 15.06 years. 92% of patients resided in the Mediterranean basin, an endemic area of Leishmania. Only 1 patient was born outside of Spain. Nineteen percent of patients were smokers and 16.4% had some comorbidities.

Fifty patients had Crohn's disease (CD) (68.5%) with ileocolonic involvement (30.1%) and inflammatory behaviour (45.2%) and 42.9% had perianal disease. 94% of CD patients were on clinical remission at the time of LI diagnosis. In addition, 23 patients had ulcerative colitis (UC) (31.5%), being extensive colitis the most frequent extent (78.3%), and all of them were on clinical remission or had mild disease activity. 69 patients (94.5%) were under immunosuppressive and/or biologic treatment during the 6 months prior to the LI. 6.8% were on immunosuppressants monotherapy, 42.5% in combotherapy and 38.4% under biologic monotherapy. Regarding biological treatment, 97% of patients were under AntiTNF and only 2 patients were under treatment with Ustekinumab.

Regarding the characteristics of LI, 62 patients presented cutaneous involvement (85%), 9 visceral (12%) and the rest presented mucocutaneous involvement.

Symptoms associated to LI were fever (9.6%), abdominal pain (4.1%) and constitutional syndrome (8.2%), moreover 24.7% required hospital admission. Regarding the location of the skin lesions, the most frequent were the upper limbs (35.6%) followed by lower limbs (30.1%).

The treatment used for LI was systemic amphotericin in 60.3% of patients and pentavalent antimonials in 35.4%; the remaining patients were treated with other treatments, including miltefosine. LI solved at one month in 33 patients (45.2%) and at one year in 95.3% of patients, and only 11% of patients had recurrent LI.

Treatment was stopped temporarily in 38.4% of patients and definitively in 27.4%, starting Ustekinumab (36.8%), Vedolizumab (15.8%) and antiTNF (10.6%) and the rest of the patients remained without biological treatment after the LI.

Conclusion: The usage of antiTNF is associated to LI in IBD patients, but LI could also happen under inmunossupresants or ustekinumab therapy. Although cutaneous involvement is the most frequent manifestation, 12% of patients have visceral involvement or LI recurrences. This infectious complication should be considered in IBD patients in endemic areas.

Disclosure: No Conflict of Interest.

PP0404

INTERLEUKIN-8 AS A POSSIBLE PREDICTIVE MARKER OF LONG-TERM RESPONSE IN ULCERATIVE COLITIS PATIENTS TREATED WITH VEDOLIZUMAB

A. Mínguez Sabater[1], P. Ripoll[1], A. Aguerri[2], V. Argumánez Tello[1], I. Navarrete[1], A. Garrido[1], M. Aguas[1], M. Iborra[1], E. Cerrillo Bataller[1], P. Nos Mateu[1], G. Bastida[1]

Contact E-Mail Address: alejandromsab11@gmail.com

Introduction: Vedolizumab has demonstrated efficacy in moderate-severe Ulcerative Colitis (UC). To date, few tools are available to predict medium- and long-term response to the drug. The aim of the study is to characterise the profile of circulating cytokines associated with the pathophysiology of inflammatory bowel disease (IBD) to identify markers of immune response to vedolizumab in UC patients. As a secondary objective,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

we analysed the possible involvement of baseline characteristics such as smoking and disease duration until drug initiation, previous exposure to other biologics, and baseline faecal calprotectin (FCP) and C-reactive protein (CRP) values in the response to the drug.

Aims & Methods: Retrospective single-centre cohort study including 28 patients diagnosed with UC with inflammatory activity objectified by clinical and biochemical data who started treatment with vedolizumab in the period from 2015 to 2022. Participants consented and authorised the collection of biological samples. Plasma samples were collected prior to drug initiation and response to treatment was assessed at the end of follow-up.

Response to treatment was based on clinical remission (pMAYO < 3 with no subscore >1) together with a biochemical response (reduction in FCP and/or CRP > 50%) at the end of follow-up. In patients where colonoscopy was available, endoscopic response was defined as an endoscopic Mayo of 0 or 1. Cytokines were determined by Magpix® Luminex using a Milliplex® Human High Sensitivity T Cell Magnetic Bead Panel containing 12 proteins.

The cytokines studied were (interferon-gamma, interleukin 10, interleukin 12, interleukin 13, interleukin 17A, interleukin 10, interleukin 2, interleukin 21, interleukin 23, interleukin 7, interleukin 8, TNF-alpha).

Results: Twenty-eight patients with UC (100% pancolitis or left colitis) and S2+S3 94.7% were included in the study. 85.2% were bioexposed (infliximab in 75%). 50% of patients received concomitant corticosteroid therapy at the start of vedolizumab.

Vedolizumab response was seen in 13 patients (46.4%) after a median overall treatment duration in both cohorts of 2.79 years (IQR 7.55). The responder group was on vedolizumab treatment for a median of 5.58 (IQR 6.9) years vs 1.17 (IQR 5.13) years in the non-responder group, p=0.005. There were no baseline differences between responders in pMayo or in FCP and CRP values. Active smoking, disease duration until vedolizumab initiation and previous exposure to other biologics were not associated with response/non-response to vedolizumab treatment.

Vedolizumab responders had significantly lower median interleukin 8 (IL8) levels at baseline than vedolizumab non-responders (median IL8 1.67 pg/mL versus 3.03 pg/mL, p=0.016). No statistically significant differences in baseline concentrations were found in any of the other interleukins analysed.

Conclusion: In our series of UC patients treated with vedolizumab, patients with long-term response to the drug show lower plasma IL8 levels than non-responders at baseline. Therefore, IL8 could serve as a predictive marker of long-term response to vedolizumab in UC patients. These results should be confirmed in prospective studies with larger sample sizes.

Disclosure: Nothing to disclose.

CAUSAL ASSOCIATION BETWEEN CIRCULATING IMMUNE CELL COUNTS AND INFLAMMATORY BOWEL DISEASE: A BIDIRECTIONAL TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

C. Liang[1], Z. Wang[1], Y. Yuan[1], M. Wang[1], Y. Liu[1], W. Zhang[1], Y. Li[1], X. Lu[1], Z. Lin[1], J. Li[1], T. Mao[1]

Introduction: Inflammatory bowel disease (IBD) is a chronic recurrent inflammatory bowel disease, whose cause involves the interaction between genetic and environmental factors. At present, the pathogenesis of IBD has not been fully understood. Although there is a recognized link between immune response and IBD, the causal relationship between circulating immune cell counts and IBD remains controversial.

Aims & Methods: This study aimed to elucidate the causal relationship between genetically predicted circulating immune cell counts and IBD. We conducted a bidirectional two-sample Mendelian randomization (MR) study using aggregated statistics from genome-wide association studies. The causal relationship between five circulating leukocytes cells (monocytes, lymphocytes, eosinophils, basophils and neutrophils) counts and IBD, including Ulcerative colitis (UC) and Crohn's disease (CD) was analyzed. Inverse variance weighting (IVW) was used as the primary MR analysis method, and horizontal pleiotropy test and heterogeneity test were used to ensure the stability of the results.

Results: Our findings indicated that monocytes, lymphocytes, eosinophils, and basophils count were not significantly associated with IBD, however, elevated circulating neutrophils count was significantly associated with higher risk of IBD [odds ratio (OR): 1.002; 95% confidence interval (CI): 1.001–1.003; p = 0.009] and UC [OR: 2.465; 95%CI: 1.236–4.916; p = 0.01].

In addition, we also found that IBD [OR: 12.07; 95% CI: 1.909-76.316; P = 0.008] and UC [OR: 2.465; 95% CI: 1.236 - 4.916; P = 0.01] were significantly associated with higher circulating neutrophils count in reverse MR.

Conclusion: This MR study provides genetic evidence for the causal relationship between the genetically predicted increase in circulating neutrophils count and the risk of IBD (UC and CD). This finding stresses the need for further exploring physiological functions of neutrophils in order to develop effective strategies against IBD.

Disclosure: The authors state that the study was conducted in the absence of any business or financial relationships that could be interpreted as potential conflicts of interest.

THE EFFECT OF VEDOLIZUMAB ON THE LEVEL OF ADHESIVE MOLECULES ICAM-1, ICAM-2, SL-SELECTIN IN ULCERATIVE COLITIS

V. Pavlenko[1], A. Pavlenko[1]

[1]» Stavropol State Medical University of the Ministry of Health of the Russian Federation, Chair of Propaedeutics of Internal Diseases, Stavropol, Russian Federation

Contact E-Mail Address: pavlenkovv@yandex.ru

Introduction: A deeper understanding of the pathogenesis of UC has led to the emergence of new therapeutic strategies. One of them consists of targeted exposure with biological drugs to certain molecules that regulate the interaction between leukocytes and endothelial cells in the inflammatory zone (mainly leukocyte integrins and endothelial cell adhesion molecules of the immunoglobulin superfamily).

Aims & Methods: Purpose of the study: To study the content of adhesion molecules ICAM-1, ICAM-2 and L-selectin in the peripheral blood of patients with ulcerative colitis (UC) and the effect of vedolizumab (Intivio) on their levels.

We examined 12 patients with moderate and severe forms of UC and the ineffectiveness of previous standard therapy. The severity of the UC attack was calculated according to the Mayo index. Antivio® 300 mg was administered to patients intravenously according to the attached instructions. The content of adhesion molecules in the peripheral blood was studied before and 6 weeks after the first injection of vedilizumab. The control group consisted of 15 healthy volunteers. The content of ICAM-1, ICAM-2 and L-selectin in blood serum was determined by multilayer ELISA analysis (Bender med.Systems, Austria). Statistical processing of the obtained results was carried out using SPSS 13.0 software.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: It was found that the initial levels of ICAM-1 (461.9±28.4 ng/ml), ICAM-2 (323.3±18.4 ng/ml) and sL-selectin (1650±12.25 U/ml)) in the peripheral blood of patients with UC were increased (P<0.05 with control), the Mayo index was 9 points. After four infusions of Vedolizumab (week 14), the levels of soluble molecules decreased in 4 patients, with a predominant decrease in sL-selectin (201±9.32 ng/ml, 197±8.54 pg/ml and 1008±15.3 U/ml respectively). The Mayo index was 5 points. In 8 patients, by the 6th week of treatment, the levels of the studied adhesive molecules did not change, although the Mayo index decreased by 3 points.
Conclusion: The initial level of ICAM-1, ICAM-2 and sL-selectin in the peripheral blood of patients with severe forms of UC is increased. The dynamics of the synthesis of adhesive molecules by immunocompetent cells under the influence of the fourth administration of Vedolizumab may predict the possibility of continuing the administration of the drug.

Contact E-Mail Address: julien.kirchgesner@gmx.com
Introduction: Inflammatory bowel disease (IBD) prevalence is steadily increasing worldwide, particularly in developed countries. In parallel, the medical treatment of IBD evolved significantly with the marketing approval of advanced therapies over the last decade. The aim of this study was to describe the epidemiology of IBD and to assess treatment patterns in real-life management in France.
Aims & Methods: This was an observational study using the French National Health Databases (SNDS) including all adult patients diagnosed with Crohn disease (CD) or ulcerative colitis (UC) meeting at least one of the following criteria between 2014 and 2021: i) long term disease (LTD) related to IBD ii) at least 2 hospital stays for IBD iii) one hospital stay for IBD and 3 or more IBD treatment deliveries. A look-back period of at least 5 years prior to index date was considered to assess epidemiology and patients' characteristics, and a follow-up period of at least 12 months to describe treatment patterns.
Results: In the study period, 274,694 IBD patients were identified: 139,001 CD patients (including 45,939 (33.0%) incident patients), and 135,693 UC patients (including 53,939 (39.8%) incident patients). CD prevalence varied from 193.5 per 100,000 person-years (py) in 2014 to 234.4 per 100,000 py in 2021, while incidence varied from 12.1 to 9.7 per 100,000 py respectively. UC prevalence and incidence varied respectively from 173.1 to 229.2 per 100,000 py and from 13.7 to 11.8 per 100,000 py.
Prevalent CD patients were 56.7% female, median age was 42 years (IQR 31-56) and median follow-up was 8.0 years (IQR 4.6-8.0). Among patients with at least 1 year of follow up, 42.3% were exposed to at least one biologic: 96.9% received an anti-TNF in first line, 1.6% an anti-interleukin, 1.4% an anti-integrin and 36.4% received a concomitant immunosuppressant. Among incident CD patients (54.6% female, median age of 37 years (IQR 26-53) and median follow-up of 3.9 years (IQR 2.0-5.9)), 50.8% of patients with at least 1 year of follow-up were exposed to at least one biologic. The treatment distribution in first line was similar to prevalent patients.
Prevalent UC patients were 50.8% male, median age was 49 years (IQR 36-62) and median follow-up was 8.0 years (IQR 3.9-8.0). Among patients with at least 1 year of follow up, 20.3% were exposed to at least one biologic: 94.0% received an anti-TNF in first line, 5.3% received an anti-integrin, 0.4% an anti-interleukin, 0.3% a JAK inhibitor (JAKi) and 34.5% received a concomitant immunosuppressant. Among incident UC patients (50.9% male, median age of 43 years (IQR 31-58) and median follow-up of 3.8 years (IQR 1.9-5.8)), 23.5% of patients with at least 1 year of follow-up were exposed to at least one biologic, with comparable treatment distribution in first line as in prevalent patients.
After a switch or a swap from an anti-TNF in first line for CD, the use of anti-TNF in second line tends to decrease (from 92.8% in 2014 to 36.2% in 2020) in favor of anti-integrins (from 2.3% to 16.7%) and anti-interleukins (from 4.9% to 47.1%). The same trend is observed for UC, for anti-TNF (from 93.8% to 30.0%), mostly in favor of anti-integrins (from less than 5.6% to 57.0%).
Conclusion: This study reports an increase in prevalence and a slight decrease in incidence of IBD in France between 2014 and 2021. Treatment patterns evolved with an increased use of advanced therapies and a swap out of class in the second line.

OUTPATIENT CARE FOR CROHN'S DISEASE IN BRAZILIAN HEALTHCARE PUBLIC SYSTEM: FROM COST TO REFUND

L. Rosevics[1], E. Lima Júnior[1], O. Ramos Júnior[1]
[1]Complexo Hospital de Clínicas - Universidade Federal do Paraná, Curitiba, Brazil, [2]Universidade Federal do Paraná, Curitiba, Brazil

Contact E-Mail Address: le.rosevics@yahoo.com.br
Introduction: Crohn's disease (CD) is characterized by a rare, chronic disease that requires lifelong treatment, representing a burden on healthcare systems. Considering that in Brazil, through the Unified Health System (SUS), patients have access to all treatment, it is important to know how the costs are being distributed in these patients, to better plan they care.
Aims & Methods: The present study aims to evaluate the costs for the hospital and SUS reimbursement for outpatient treatment of patients with CD. This is a retrospective cohort of patients with CD followed between 2006 and 2020 in a Brazilian public tertiary hospital. Patients over 18 years of age and with complete information in their medical records were in-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cluded. Through medication and exams carried out during follow-up, SUS reimbursement values were calculated using the SIGTAP-SUS table and hospital costs using the table provided by the hospital. The values for the acquisition of medications were provided by the State Health Department. Conversion to dollars was carried out each year, as well as correction for inflation. The statistical difference was evaluated across disease phenotypes according to the Montreal classification using the ANOVA test and the Scheffe post hoc test.

Results: One hundred and ninety-one patients were included, 50.26% being female. The SUS reimbursement cost was $6741.40 ± 2526.87, the hospital cost was $7162.88 ± 2732.30, and adjusted for inflation was $11274.36 ± 5806.85. In post hoc analysis, there was a statistical difference between groups A2 and A3 (age at disease onset between 16 and 40 years and over 40 years) in the reimbursement group, and between the inflammatory and fistulizing phenotypes in the cost and reimbursement groups.

Conclusion: In Brazil, the treatment of CD has lower costs but maintains differences between phenotypic profiles similar to international studies. Showing the difference in cost, reimbursement and inflation, questions are raised about the updating of SIGTAP-SUS tables and the credibility of cost studies and its management planning.

Disclosure: Nothing to disclose.

Introduction: The identification of colonic stricture in patients with Crohn's disease (CD) often leads to surgery due to concerns about associated neoplasia. Nevertheless, information regarding the neoplastic risk associated to colonic stricture is still limited.

Aims & Methods: The objective of this study was to assess both the incidence of colonic stricture in pediatric-onset CD and the associated neoplastic risk at the population-based level. All patients diagnosed with CD before age 17 between 1988 and 2011, and included in a population-based registry, were followed until 2013. Colonic stricture was defined as a narrowing of the digestive lumen observed on endoscopic or radiological examination. Excluded were stricture in the ileocaecal valve, anal canal, or low rectum. Univariate risk factors for colonic stricture were explored using Cox proportional hazards models with time-dependent variables, and a multivariable Cox model analysis was performed.

Results: A total of 1,007 patients diagnosed with CD between 1988 and 2011 were included. Median age at diagnosis was 14.5 years [IQR: 12.0-16.1]. Throughout the follow-up period (median follow-up, 8.8 years [4.6-14.2]), patients were predominantly exposed to 5-aminosalicylates (88.1%), immunosuppressants (70.6%), and biologics (47.9%). Colonic stricture was diagnosed in 52 patients, including 11 at CD diagnosis. The cumulative incidence of colonic stricture in CD was 2.9% [1.8%-4.0%] at 5 years. The overall incidence rate of colonic stricture in CD was 5.4 cases/1000 person-years, 95% CI [4.1-7.1]. In multivariable analysis, an increased risk of colonic stricture was observed during periods of active disease (HR = 2.62, [1.40-4.89], p<0.01).

Conversely, the absence of colonic involvement at diagnosis (HR = 0.18, [0.04, 0.80], p<0.05) or treatment with aminosalicylates (HR = 0.39, [0.19-0.79], p<0.05) was associated with a lower risk of colonic stricture. After a median follow-up of 6.4 [2.4-12.7] years, colonic stricture surgical resection was performed in 29 patients (55.8%). Colon adenocarcinoma was detected in one patient (1.9%) within 6 months after the diagnosis of colonic stricture.

Conclusion: In this population-based study of pediatric-onset Crohn's disease, 52 patients (5%) experienced colonic stricture, with a 2.9% incidence rate observed after 5 years of follow-up. Additionally, one patient (2%) presented with an associated adenocarcinoma.

Introduction: Axial spondyloarthritis (axSpA), characterised by chronic inflammation of the sacroiliac joints (SIJs) and spine, is a common extraintestinal manifestation in Inflammatory Bowel Disease (IBD). It is associated with poor outcomes and a substantial impact on quality of life. Thus,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

early detection is important to optimally tailor treatment and suppress the inflammation in all disease domains. However, the prevalence and pattern of axial involvement have not been described in early IBD.

Aims & Methods: We aimed to describe the prevalence and distribution of axial symptoms, clinical findings and MRI-determined inflammatory and structural lesions in the spine and SIJs of patients with newly diagnosed IBD. Patients with newly diagnosed IBD from a prospective population-based inception cohort were consecutively included. Structured rheumatological interview collecting data on peripheral and axial symptoms and clinical evaluation were performed. MRI assessment for spine and SIJ inflammation and structural lesions was based on validated and widely applied scoring systems [1,2]. Further, an expert assessment of the MRIs as +/- indicative of axSpA applying standardized definitions was performed [3,4].

Results: Of 110 included patients (mean age 42 years, 40% male, 40 with Crohn's disease (CD), 70 with ulcerative colitis (UC)), 74 had active IBD. At the time of evaluation, 4 patients received treatment with systemic glucocorticoid and one received TNF-inhibitor. Nine patients were HLA-B27 positive. None were previously diagnosed with SpA.

Back and/or buttock pain was reported by 48(44.9%) patients and inflammatory back pain by 10(9.1%). In 23(21.5%) patients the pain could not be better explained by competing conditions (for example degenerative disc disease, nerve root compression, osteoporosis or fibromyalgia) according to the assessing rheumatologist. The axial symptoms were accompanied by peripheral joint and/or entheseal symptoms in 30(62.5 %) patients and 33(68.8%) had tender and/or swollen joints and/or entheses.

According to the MRI expert, MRIs of 17(16.7%) patients were indicative of axSpA (spine and SIJs evaluated together), while 11(10.8%) of the spine-MRIs and 13(12.7%) of the SIJ-MRIs were indicative of axSpA. Only 10 of the 17 patients with typical axSpA MRI findings had axial symptoms. There was no difference in symptoms or MRI findings between patients with UC and CD, or between patients with active and inactive IBD.

Spine bone marrow oedema (BME) in ≥1 slice was present in 30(30.3%) patients. SIJ BME in ≥1 slice was found in 27(26.5%) patients, erosion was present in 24(23.5%) patients, fat lesions in 12(11.8%) and ankylosis in 3(2.9%). The definition of positive MRI for sacroiliitis was fulfilled in 12 (11.8%) patients of whom six had axial symptoms. The Assessment of Spondyloarthritis International Society (ASAS) classification criteria for axSpA were met in 11 cases.

Conclusion: One out of six patients with newly diagnosed IBD had findings indicative of axSpA on spine and SIJs MRI. Since only 60% of these patients were symptomatic, we conclude that axSpA may be an underdiagnosed early-occurring condition among IBD patients. Our results indicate a low threshold for performing MRI of the spine and SIJs and a need for multidisciplinary collaboration to ensure early detection of axial involvement to enable an optimal therapeutic strategy and prevent future structural damage and disability.

INNOVATIONS IN HEALTHCARE: AI'S IMPACT ON INFLAMMATORY BOWEL DISEASE AND DIGESTIVE HEALTH

R. Rammohan[1], M. Joy[1], S.G. Magam[1], D. Natt[1], W. Lau[1], S.R. Magam[1], L. Pannikodu[1], A. Tadikonda[1], J. Desai[1], K. Subramani[1], P. Mustacchia[1]

[1]*Nassau University Medical center, Department of Gastroenterology, East Meadow, United States of America*

Contact E-Mail Address: rrammoha@numc.edu

Introduction: Artificial Intelligence (AI) has significantly changed the landscape of healthcare, particularly in the diagnosis and treatment of Inflammatory Bowel Disease (IBD) and various digestive conditions. Key AI tools like ChatGPT and Google Gemini have the ability to decode endoscopic images, examine various samples, streamline administrative tasks, and aid in the evaluation of medical imagery and device automation. These AI solutions improve the management of digestive diseases by tailoring treatments and predicting potential adverse reactions. The incorporation of AI into healthcare allows patients to make informed decisions through the assessment of personalized treatment options.

Aims & Methods: The aim of the study was to assess the accuracy of two popular chatbots, ChatGPT and Google Gemini, in addressing medical management inquiries. Each chatbot was given a set of questions to answer, with their responses rated on a 1-10 Likert scale, where 1 represented a low score and 10 was high. To ensure fair evaluation, two neutral evaluators examined the responses of each bot. The research sought to highlight the abilities of these chatbots by methodically evaluating their performance in terms of accuracy and reliability. The use of two evaluators and the Likert scale method was instrumental in reducing potential biases, thereby validating the results.

Results: Our research evaluated the effectiveness of ChatGPT and Google Gemini in the realm of medical management. ChatGPT outperformed, attaining a 71% accuracy rate compared to Google BARD's 39% ($p = 0.032$), and surpassed in information reliability with 58% against Google BARD's 29% ($p = 0.021$). This study emphasizes the critical role of accuracy and reliability in the development of chatbots for managing IBS. ChatGPT's impressive performance suggests its potential as a reliable tool, yet it also points to the continuous need for research and improvement in this area.

Conclusion: AI has profoundly transformed healthcare, especially in the diagnosis and management of IBD. ChatGPT and Google Bard stand out as crucial AI instruments for interpreting medical imagery, evaluating samples, and enhancing efficiency. Our study assessed the accuracy and reliability of these chatbots within medical management contexts. ChatGPT outshone Google Bard by achieving 71% accuracy and a 58% reliability rate in information. ChatGPT demonstrates significant promise as a dependable AI tool for IBD care, yet our findings also underline the ongoing need for further research and development in the field.

BRIDGING THE GAP: ETHNIC VARIATIONS IN IBS OUTCOMES AFTER BARIATRIC SURGERY

R.m. Ram mohan[1], S.G. Magam[1], M. Joy[1], D. Natt[1], S.R. Magam[1], W. Lau[1], A. Tadikonda[1], L. Pannikodu[1], R. Jiyani[1], S. Sheikh[1], J. Desai[1], K. Subramani[1], P. Mustacchia[1]
[1]Nassau University Medical center, Department of Gastroenterology, East Meadow, United States of America

Contact E-Mail Address: rrammoha@numc.edu

Introduction: Bariatric surgery emerges as a powerful intervention for obesity, promoting enhanced metabolic health. However, substantial evidence indicates a rise in Irritable Bowel Syndrome (IBS), primarily following such surgical interventions. The effect of race on the occurrence of IBS after surgery has yet to be investigated. Given the widespread occurrence of IBS and its confirmed connection to bariatric surgery, examining the effect of racial disparities is crucial. This study seeks to ascertain whether racial differences impact the probability of an individual developing IBS post-bariatric surgery. Revealing this relationship is vital for improving patient results and optimizing postoperative care.

Aims & Methods: We executed a retrospective study to analyze patients who underwent bariatric surgery at our facility between 2009 and 2022. Data about comorbidities, insurance statuses, surgical techniques, colonoscopy and pathology reports, and initial patient attributes were collected through ICD and CPT codes. Patients who developed IBS post-surgery were monitored until 2023 and categorized by gender, race, and duration post-surgery. We used propensity score matching to balance baseline characteristics. Participants with a previous diagnosis of IBS were excluded from the study. Kaplan-Meier survival analysis and Cox proportional hazards models were leveraged to examine the onset of IBS among different racial groups. Additionally, odds ratios were employed to discern independent variables influencing the study outcomes

Results: Between 2009 and 2022, 960 bariatric surgeries were performed at our institution. Of these, 39 patients, equating to 0.04%, were diagnosed with IBS, typically around 40±9.2 months post-surgery. The subjects' average age was approximately 39±8.7 years, with females constituting 51.2% of the participants. Regarding racial breakdown, 29.2% were African Americans, 33.5% were Whites, 21.8% were Hispanics, and 15.5% were Asians. Notably, White patients manifested symptoms of IBS significantly earlier compared to other racial groups (23±5vs 36±7, 31±8, 29±6) (Breslow: 12.46, p=0.015). Additionally, a heightened risk of IBS was observed among individuals with lower educational attainment (OR: 1.25, P=0.025).

Conclusion: This research aims to bridge the prevailing knowledge void relating to the influence of race on the emergence of IBS following bariatric surgery. Our retrospective analysis of 960 surgeries from 2009 to 2022 highlighted a 0.04% occurrence of IBS, generally identified around 40 months after surgery. Notably, White patients experienced the onset of IBS in considerably less time than other racial groups, with individuals with lower educational levels exhibiting increased risks. These insights emphasize the importance of considering racial and other sociodemographic elements in refining postoperative care

Introduction: Some epidemiological studies suggest that long-term exposure to environmental air pollutants, such as particulate matter (PM), could have a role in inflammatory bowel disease (IBD) incidence and pathogenesis. However, less is known about the potential effect of short-term air pollution exposure. The aim of this study is to investigate whether short-term exposure to environmental air pollution is associated with the occurrence of IBD flares.

Aims & Methods: Anonymized hospital discharge records (HDR) with ICD-9-CM codes 555 (Crohn's disease) and 556 (ulcerative colitis) for years 2002-2009 from all hospitals of the Lombardy region were collected. All HDR of adult patients (18-75 years) resident in Milan were included, except for recurrent hospitalizations within 6 months.

Each record was assigned daily PM ≤10 µm (PM10) concentrations at municipality level by averaging PM10 levels of the day of admission with the levels of the day before (lag01) and of each preceding day up to six days before (lag06).

To evaluate the association between PM10 and IBD-related hospitalizations, a time-stratified case-crossover study design was applied. Conditional logistic regression models, calculating Odds Ratios (OR) and 95% Confidence Intervals (95%CI) per increments of 10 µg/m3 of PM10, were performed.

Results: Overall, 2,176 hospital admissions (males=1,137, Crohn's disease=1,264, ulcerative colitis=912) were included. In the entire population no clear association between PM10 and IBD-related hospitalization was identified, notwithstanding a small risk increase for males (OR: 1.03; 95%CI: 0.99-1.08 at lag04).

When further stratifying for ICD code, an increased risk of hospitalization for "left-sided ulcerative colitis" (ICD code: 556.5) was found in males only, for exposures in all days preceding hospitalization up to lag04 (1.28; 1.05-1.28; 59 cases, 207 controls) (Figure 1). In females, the association was weaker, although positive (1.14; 0.91-1.42; 49 cases, 164 controls). No relevant findings emerged when looking at other ICD codes.

Conclusion: We observed an increased risk of IBD-related hospitalization in male patients with left-sided ulcerative colitis per increasing levels of air pollution in the days preceding hospital admission. Although preliminary, our findings suggest the possible role of sex as an effect modifier of the influence that air pollution might exert on IBD flares.

Further studies are needed to better comprehend the complex framework characterizing the interplay between environmental and individual factors contributing to IBD.

TESTING MACHINE LEARNING WITH FINNISH REGISTER DATA TO PREDICT NON-RESPONSE TO CONVENTIONAL TREATMENT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

T. Kovalainen[1], J. Mehtälä[1], K. Elomaa[2], H. Loponen[1], P. Kamble[3], T. Ylisaukko-oja[1], P. Szolovits[4]

Contact E-Mail Address: kaisa.elomaa@takeda.com

Introduction: Inflammatory bowel disease (IBD), including both Crohn's disease (CD) and ulcerative colitis (UC), are difficult to diagnose due to a broad symptoms spectrum.1,2

If symptoms remain uncontrolled with conventional therapy (CT), patients are transitioned to biologics. Little is understood about which CD and UC patients will respond to CT and which patients may have a more aggressive disease progression, and therefore should be treated with biologic therapies sooner.

Aims & Methods: We aimed to develop and evaluate machine learning (ML) models to identify non-responders to CT based on patients' demographic characteristics and on data available before their treatment with CT. The study cohort included all Finnish patients ≥18 years of age, with a diagnosis for CD or UC between 1.1.2000–31.12.2019. Data were collected from electronic health records and national healthcare and prescription registers. CT drugs included corticosteroids (CS), immunomodulators and 5-aminosalicylic acids. CT failure outcomes are defined in *Table 1*.

A set of 6,782 predictive features including demographic and clinical characteristics, comorbidities, healthcare visits, procedures, laboratory measurements, and medication were created for three different baseline periods. A Lasso model was run both separately and in combination for each period, splitting the data into training and testing subcorpora ten different times to estimate the error bounds.

Results: After applying specific attrition criteria, the final analysis cohort included 12,818 CD and 30,178 UC patients. In total, 64.2% of CD and 61.1% of UC patients experienced CT failure (*Table 1*).

For CD, CS at baseline and young age (0–18 and 18–30 years) were the highest predictors of CT failure. For UC, the model selected 78 predictive features, the strongest being: baseline CS use, age (0–18, 18–30, and 65+ years), gastrointestinal and schizoaffective disorders, and secondary care visits to rheumatology, general medicine, and emergency.

The key findings of the Lasso model were:

1) The performance of CD-models was slightly better than the UC-models (median test accuracy was 0.65 [CD] and 0.62 [UC]);

2) a slight discrepancy between test and training statistics suggested overfitting, and;

3) most features appeared in all ten splits indicating their relevance.

CT failure outcomes	CD, n	CD, %	UC, n	UC, %	Total, n	Total, %
Prescription for biologics[1]	718	5.6%	828	2.7%	1,546	3,6%
IBD-related surgery	803	6.3%	728	2.4%	1,531	3.6%
90-day gap in CT medication (5-ASA[2], IM[3])	2,339	18.2%	5,325	17.6%	7,664	17.8%
≥2 corticosteroid[4] prescriptions	6,347	49.5%	14,302	47.4%	20,649	48.0%
IBD-related inpatient stay	1,339	10.4%	2,160	7.2%	3,499	8.1%
IBD-related ED visit	193	1.5%	398	1.3%	591	1.4%
Any of the above	8,223	64.2%	18,453	61.1%	26,676	62.0%

[1]adalimumab, vedolizumab, infliximab, golimumab, ustekinumab, and tofacitinib; [2]mesalazine, olsalazine, and sulfasalazine; [3]methotrexate, mercaptopurine, azathioprine, cyclosporine, and metronidazole; [4]prednisolone, hydrocortisone, budesonide, methylprednisolone, prednisone, and dexamethasone. Abbreviations: CD, Crohn's disease; CT, conventional therapy; ED, emergency department; IBD, intestinal bowel disease, IM, immunomodulators; UC, ulcerative colitis; 5-ASA, 5-aminosalicylic acid

Table 1. CT failure outcomes (within one year from CT initiation) for CD, UC, and combined cohorts.

Conclusion: Data quality is critical to build high-performance models. Even though Finnish registries provide access to comprehensive longitudinal data allowing the generation of relatively large analysis cohorts, our ML model demonstrated a weak predictive potential, with low AUCs and accuracies (0.6 range), in line with previous findings.3 Due to scarcity of information on additional clinical variables available in the Finnish IBD registry, their use did not improve prediction of CT failure.

Additional prediction difficulty is introduced by non-standardized data recording practices. Confounding factors and random chance affect complicated outcomes, such as CT failure, making them especially difficult to predict.

Introduction: Several viral respiratory infections have been implicated in the exacerbation of immune mediated inflammatory diseases (IMID)[1-3]. There has however been limited investigation and conflicted findings of the long-term outcomes in inflammatory bowel disease (IBD) following COVID-19[4]. We therefore performed a systematic review and meta-analysis of the long-term impact of SARS-CoV-2 infection on the disease course of IBD.

Aims & Methods: To understand the impact of early SARS-CoV-2 variants and to be better prepared for future variants, we aimed to carry out a meta-analysis of the available evidence. We searched MEDLINE and EMBASE for studies investigating the risk of adverse IBD-related outcomes (IBD flares, change in disease activity, change in medication, IBD-related hospitalization, and surgery) following a SARS-CoV-2 infection, compared to IBD patients without a SARS-CoV-2 infection. ROBINS-E for observational studies was used to assess the risk of bias in the included studies. We used random effects model (REM) meta-analysis to calculate pooled hazard ratios (HR) for the risk of adverse IBD outcomes following the acute phase of COVID-19 infection. Subgroup meta-analysis was carried out to assess the risk of the outcomes by IBD subtype (Crohn's disease (CD) and ulcerative colitis (UC)). Meta-regression was undertaken to assess whether sex or duration of follow-up were significant predictors of IBD-related outcomes.

Results: A total of 3119 studies were identified of which 5 studies were eligible for inclusion after screening using the pre-defined inclusion criteria. The studies were based on cohorts from Denmark, Italy, the US, and a pan-European consortium including a total of 34,977 SARS-CoV-2 positive IBD patients and 53,270 IBD patients without a recorded SARS-CoV-2 infection.

Two studies were assessed as having a high risk of bias. REM meta-analysis did not show an increased risk of adverse IBD-related outcomes in IBD patients with a recorded SARS-CoV-2 infection compared to those without (HR:1.05, 95% CI:0.75-1.46) and substantial between-study heterogeneity was identified in the included studies (I2=91%, p<0.01).

There was no significant difference in adverse IBD-related outcomes between CD and UC patients (CD HR: 0.91, 95% CI: 0.82-1.02; UC HR: 0.83, CI: 0.75-0.90). Following meta-regression, neither sex nor duration of follow-up were found to be significant predictors of individual study effect size.

Conclusion: In this systematic review and meta-analysis, we find that SARS-CoV-2 infection does not increase the risk of long-term adverse IBD-related outcomes. High-quality studies with longer follow-up periods are required to understand the long-term impact of SARS-CoV-2 infection on IBD outcomes.

Introduction: Chronic fatigue (CF) is prevalent among patients with ulcerative colitis (UC) and Crohn's disease (CD), but the influence of the disease activity is not established.

Aims & Methods: The primary aim of this study was to evaluate the prevalence and probability of chronic fatigue (CF) in patients with CD and UC one year after diagnosis, stratified by different measures for disease remission (symptomatic, biochemical, endoscopic, and histological). Additionally, we aimed to evaluate factors associated with chronic fatigue among patients in endoscopic/radiological remission.

Patients ≥18 years with CD and UC were recruited from the Inflammatory Bowel Disease South-Eastern Norway (IBSEN III) study, a population-based, observational inception cohort. Fatigue was assessed using Fatigue Questionnaire (FQ), and CF was defined as a dichotomized score of ≥4 with a duration of ≥6 months. Only patients with complete FQ data, without history of colectomy, were eligible for inclusion. Binary logistic regression analyses were used to examine the probability of CF for various indicators of remission, including i) symptomatic remission (Harvey–Bradshaw index score <5 for CD and Simple Clinical Colitis Activity Index score <3 for UC), ii) biochemical remission (Fecal calprotectin ≤ 250 µg/g), iii) endoscopic/radiological remission (Mayo endoscopic score 0 in UC, and endoscopically verified absence of inflammation combined with normal intestinal MRI/CT in CD), and iv) histological remission (normal histology in all mucosal biopsies). Additionally, in patients with endoscopic/radiological remission, associations between CF and selected clinical factors were evaluated using binary logistic regression analysis.

Results: In total, 711/1416 patients with CD or UC diagnosis were included (CD: 33.8%, UC: 66.2%). Among them, 619 (87.1%) underwent colonoscopy, intestinal MRI/CT and/or fecal calprotectin testing. Prevalence of CF stratified by different indicators of remission is presented in table 1. In univariate binary logistic regression analysis regarding measures for disease remission, the probability of CF was only significantly reduced in patients with UC in symptomatic remission (OR: 0.48 (0.30, 0.77), p=0.003). Among patients with CD and UC in endoscopic/radiological remission (n=181), CF was independently associated with current biological treatment (OR: 2.92 (1.002, 8.49), p=0.05) and sleep disturbance (OR: 6.23 (2.03, 19.14), p=0.001) in multivariate logistic regression.

	CD (% (n/n total))	UC (% (n/n total))
Symptomatic remission	33.6 (51/152)	30.0 (85/283)
Biochemical remission	33.3 (25/75)	34.6 (62/179)
Endoscopic/radiological remission	40.4 (21/52)	33.3 (33/99)
Histological remission	36.8 (14/38)	35.0 (28/80)

Abbreviations and table legends: CD: Crohn's disease. UC: Ulcerative colitis. Symptomatic remission: Simple Clinical Colitis Activity Index (SCCAI) score <3 for UC / Harvey–Bradshaw index (HBI) score <5 for CD. Biochemical remission: Fecal calprotectin ≤ 250 µg/g. Endoscopic/radiological remission: Mayo endoscopic score 0 in UC and absence of intestinal disease on endoscopy and/or intestinal MRI/CT in CD. Histological remission: normal histology in all mucosal biopsies.

Table 1: Prevalence of chronic fatigue among CD and UC patients with different measures for remission one year after diagnosis.

Conclusion: The probability of CF one year after diagnosis was not associated with either low fecal calprotectin level, normal endoscopic/radiological examinations, or normal histology. Among patients with UC, but not CD, symptomatic remission was associated with a reduced probability of CF. For patients in endoscopic/radiological remission, CF was independently associated with sleep disturbances and current biological treatment.

Disclosure: Nothing to disclose.

Contact E-Mail Address: AGNESEFAVALE@ICLOUD.COM

Introduction: The nutritional status of patients affected by inflammatory bowel disease (IBD) is often impaired. Although a link between inflammation-related pathophysiologic mechanisms and malnutrition in IBD has been proposed, the role of dietary regimen and adherence to Mediterranean diet, known to have anti-inflammatory properties, is under investigated.

The aim of this study was to assess quality of diet and adherence to Mediterranean diet in a cohort of Sardinian IBD patients.

Aims & Methods: We conducted a case-control study in which IBD patients, both Crohn's disease (CD) and ulcerative colitis (UC), were compared with healthy controls matched for age, sex and BMI at a 1:2 ratio. Diet Quality Index (DQI) and Medi-Lite questionnaires were collected from IBD patients and controls to assess individual diet quality and adherence to Mediterranean diet, respectively. Subgroup analysis by disease phenotypic characteristics and use of biologic or small molecules as proxy of

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

disease severity was also performed. Differences between groups were analyzed by descriptive statistics and non-parametric tests were used to assess statistical significance of the observed differences.

Results: Fifty CD and an equal number of UC were matched each with 100 healthy control subjects. Both DQI and Medi-Lite scored significantly lower in IBD patients as compared to controls (DQI: CD 34.5 [IQR 33-37] vs CTRL 40 [IQR 38.5-43] p<0.0001; UC 34.5 [IQR 33-37] vs CTRL 42 [IQR 40-44] p<0.0001; Medi-Lite CD 7.5 [IQR 7-9] vs CTRL 9 [IQR 7-10] p=0.0379; UC 8 [IQR7-10] vs CTRL 9 [IQR 8-10.5] p=0.0046). In CD, DQI was consistently lower than controls independently of disease localization and behavior.

However, Medi-Lite score was significantly lower in patients with stricturing phenotype and ileo-colonic localization. In UC patients, DQI was consistently lower as compared to controls independently of disease extent. Among these patients, Medi-Lite score was significantly lower only in those with extensive colitis.

Finally, DQI was lower in both CD and UC independently of the use of concomitant biologic or small molecules, while Medi-Lite resulted significantly lower in UC but not CD patients undergoing major therapies.

Conclusion: IBD was associated with an overall low quality of diet independently of disease type and phenotype.

However, Medi-Lite score detected a lower adherence to Mediterranean diet in patients affected by ileo-colonic stenosing disease and in UC patients with extensive colitis suggesting that the potential benefit of Mediterranean diet may be deemed by low acceptance in specific IBD patient subgroups.

Disclosure: Nothing to disclose.

Introduction: When starting immunosuppressive therapy in patients with inflammatory bowel disease (IBD), screening test for latent tuberculosis infection (LTBI) and subsequent preventive treatment for positive patients are recommended to reduce the risk of tuberculosis reactivation especially in moderate-burden countries like Japan. However, the prevalence of LTBI and TB in patients with IBD and its influence in the selection of immunosuppressive therapy remain uncertain.

Aims & Methods: Our multicenter study group (IBD-Quality team; IBD Q-shu all institutional study team) conducted a retrospective study to clarify the prevalence of LTBI and the difference in therapeutic management according to the LTBI status in Japanese patients with IBD. Electronic clinical records of each institution during the period between July 2010 and June 2020 were reviewed to assess patients' clinical profile and subsequent medication after screening test of LTBI. LTBI was defined as positive when interferon γ release assays (IGRAs) or tuberculin test was positive with normal chest X-ray.

Results: This retrospective study included 10 institutions of IBD-Quality team, where 4257 IBD patients (Crohn's disease: CD 1646, Ulcerative colitis: UC 2611) were treated during the study period. LTBI was diagnosed in 69 patients (1.62%), and their mean ages of the diagnosis of IBD and LTBI were 40.9 ± 2.2 years and 51.8 ± 2.1 years, respectively. Of the 69 patients, 47 patients (68%) were having clinically active IBD, 3 patients (4.4%) had been treated for TB before the diagnosis of IBD, and 5 patients (7.3%) had a family history of TB.

After the diagnosis of LTBI, 57 patients (82.6%) were treated for LTBI (LTBI treatment group), whereas the remaining 12 patients were followed up without treatment of LTBI (non-LTBI treatment group). In LTBI treatment group, patients were treated with anti-TNFα antibody in 40 cases (70.2%), JAK inhibitors in 3 cases (5.2%), ustekinumab in 12 cases, and vedolizumab in 5 cases.

During the observation period, two patients (1 CD and 1 UC) developed TB 9 and 18 months after completing LTBI treatment, and they were treated with anti-TNFα antibody and JAK inhibitor, respectively. On the other hand, patients in non-LTBI treatment group were treated with ustekinumab in 2 cases, vedolizumab in 1 case, and other drugs in 9 cases, however, neither anti-TNFα antibody nor JAK inhibitors were used. No patient developed TB in the non-LTBI treatment group during the observation period.

Conclusion: The prevalence of LTBI was 1.62% (95% CI; 1.28-2.05) and the rate of developing TB during IBD treatment was 0.05%(95% CI; 0.013-1.17). No cases of TB were observed in the LTBI-negative group during the study period. Although rare, TB can develop in patients with IBD treated with immunosuppressive treatment even after LTBI treatment. Careful follow-up with imaging modalities for TB seems to be mandatory, and further research is required to determine the possible influence of immunosuppressive therapies for the development of TB in patients with IBD.

Disclosure: Nothing to disclose.

Introduction: There is a scarcity of population-based studies investigating therapeutic strategies and the long-term disease outcomes in inflammatory bowel diseases (IBD) amongst the elderly. This is a population population-based cohort from Veszprem Province, Hungary, with a follow-up of the incidence and disease course for over 40 years.

Aims & Methods: Our aim was to analyze long-term disease course, surgery rates, medication exposures (especially biological therapy) in a prospective population-based cohort of incident, elderly onset Crohn's disease and ulcerative colitis patients.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Patient inclusion was between January 1,1977 and December 31,2018. Patient follow-up ended December 31, 2020. Elderly-onset IBD was defined if diagnosis was established at more than 60 years of age. Disease outcomes and surgery rates were compared based on time of diagnosis: 'pre-biological era', 1977-2008; vs. 'biological era', 2009-2018. Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up.

Results: Data of 840 CD and 1,295 UC patients were analyzed, 58 and 183 of which were elderly-onset IBD patients, respectively. Proportion of patients with colonic (L2) disease location and stenosing behavior (B2) at diagnosis were higher in the elderly population compared to adult-onset CD (p=0.014 and p=0.017, respectively). In UC, the prevalence of extensive colitis was less amongst the elderly (p=0.001).

In time dependent analysis, the probability of biological therapy was 0.0±0% and 3.2±3.2% at 1 and 5 years from diagnosis in elderly CD patients, 7.8±3.3% and 16.6±4.8% among elderly UC patients, respectively. Biological therapy was significantly lower in elderly patients compared to adult-onset disease in CD [pLogRank=0.003], but similar exposure was seen amongst UC patients [pLogRank=0.770].

The cumulative probability of resective surgery in the elderly CD population was 31.1±6.1%, 32.9±6.2%, and 35.3±6.4% after 1, 5 and 10 years. There were no statistically significant differences in resective surgery rates between the elderly and adult-onset cohorts in CD [pLog Rank=0.838]. The cumulative probability of colectomy in elderly UC patients was 2.2±1.1%, 3.4±1.4%, and 3.4±1.4% after 1, 5 and 10 years, respectively. Colectomy rates in the elderly and adult-onset cohorts were similar [pLog Rank=0.435].

The probability of disease behavior progression in CD patients with luminal (B1) behavior into stenosing or penetrating phenotype (B2/B3) was lower among elderly patients, compared to adult-onset CD. [pLogRank=0.015]. Similarly, disease extent progression (E1/2>>E2/3) in elderly UC patients was also lower [pLogRank=0.022].

Logistic regression model showed that male gender (OR 0.22; 95%CI 0.07-0.72; p=0.013) stenosing or penetrating disease (B2/B3) behavior (OR 8.69; 95%CI 2.17-34.85; p=0.001) and ileal or ileo-colonic (L1/L3) location (OR 9.71; 95%CI 2.41-39.13; p=0.001) were predictors of resective surgery in elderly CD patients. Whereas, extensive colitis (E3) (OR 7.17; 95%CI 1.63-31.52; p=0.011), continuous disease activity (OR 11.07; 95%CI 2.28-53.77; p=0.010), and anaemia (OR 10.13; 95%CI 1.97-52.13; p=0.004) were predictors of colectomy in elderly UC.

Conclusion: Elderly patients represent an increasing proportion of the IBD population. Biological therapy use was lower in elderly CD, however no different in elderly UC compared to adult-onset populations. There were no significant differences in resective surgery and colectomy rates between the elderly and adult-onset cohorts, whereas disease phenotype progression was slower in the elderly.

IBD HEALTH EQUITY SUMMIT: A CALL TO ACTION

M. Doyle-Scharff[1], C. Jimenez[1]

[1]*Pfizer Inc, Institute of Translational Equitable Medicine, New York, United States of America*

Contact E-Mail Address: maureen.doyle-scharff@pfizer.com

Introduction: Pfizer's Institute for Translational Equitable Medicine and our Chief Medical Officer, Aida Habtezion, MD, hosted an IBD Health Equity Summit at DDW 2023 in Chicago, Illinois on May 5, 2023 with a group of 22 key opinion leaders in the gastroenterology field. The purpose of the Summit was to uncover health equity research gaps and quality of care gaps that will enable Pfizer and our partners to determine future directions in IBD research and contribute to achieving healthcare equity by providing opportunities to improve patient outcomes, as well as address practice-based disparities.

Aims & Methods: A full day Summit was designed and developed, bringing together thought leaders and experts (representing research, HCPs and patients) to discuss health disparity gaps and possible solutions. The day was split into two parts: a morning session focused on research, with IBD researchers presenting different facets of the research construct with follow-on discussion with the audience. The afternoon was dedicated to clinical care and also included IBD experts addressing Health Equity concerns and opportunities. A follow-on summary report was developed, distributed and serves as the basis for current and future strategies aimed at closing disparity gaps among IBD patients.

Results: Several overarching themes emerged, highlighting IBD as a global affliction, and challenges that transcend geographical borders. Addressing these challenges will require solutions tailored to local and regional contexts that consider factors such as race, ethnicity, socio-economic status, culture, diets, and sexual orientations. It was also recognized that many of the challenges posed by IBD are not unique to this disease, and that valuable insights can be gained by examining other complex disease states to improve the quality of care and address health disparities in patients with IBD.

Conclusion: IBD Research

Key gaps include low clinical trial participation of patients from diverse communities due to lack of healthcare literacy, low historical representation, bias in recruitment, lack of diversity in providers.

Strategies to address these gaps include improving health literacy, workforce development and educating providers, adequate compensation for time, flexibility for participating in trials, and incorporation of digital health tools for follow-ups.

Clinical Care

There are groups of patients in several regions that lack any care, and addressing healthcare disparities in IBD care for these patients cannot be done online but will need to be done on a local and regional level on the ground.

When addressing health inequities, the heterogeneities within underserved populations like Black and Hispanic patients need to be considered.

Gaps in data on the effectiveness of therapies in specific patient populations (ie, response to anti-TNFs in black patients and patients with comorbidities).

Sponsorship is lacking to establish efforts in underserved communities on a global level; There is an opportunity to provide connection for minority physicians to resources.

By identifying gaps and potential strategies to close them, the participants have provided Pfizer and our partners a roadmap to address health disparities among IBD patients worldwide. These data and information have served as the basis for a go-forward plan to support and invest in

change initiatives to close gaps. Our desire is to enlist additional partners and collaborators through a Call to Action to identify solutions at the local level that can accelerate improved IBD care and outcomes for some of the most vulnerable populations in the world.

Introduction: Significant advances have been made in identifying biomarkers to predict IBD onset. With the use of predictive testing to identify individuals at risk of developing the disease, it would be possible to intervene and try to mitigate that risk. However, the feasibility of such strategy would depend on whether individuals at risk of developing IBD would be willing to undergo predictive testing and preventive interventions.

Aims & Methods: An anonymized electronic survey was created in eight different languages and disseminated by clinicians and patient's associations; patients with IBD, patients with an at-risk first-degree relative (offspring), and their first-degree relatives were invited to provide their feedback.

The survey had four main sections – participants' characterization, knowledge of disease, predictive tests and preventive interventions. Univariate and multivariate logistic regression were used to assess factors associated to acceptance of predictive testing and preventive interventions.

Results: Overall, 2034 participants (73% women, mean age of 43±13 years old) from 66 different countries (80% from Europe), participated. Most participants (52%) were parents with IBD with healthy at-risk children. 51% of individuals with IBD had Crohn's disease, 56% were undergoing treatment with biologics, 28% had a history of surgery, and 61% reported a significant impact on their quality of life caused by disease. 73% recognized IBD as a disease with no defined genetic transmission, but with an increased risk among FDR of affected patients.

Most participants (82%) would be willing to undergo, predictive testing, or to have their children undergo them, mainly with minimally-invasive blood (91%), stool (90%) or saliva tests (78%), or intestinal ultrasound (68%); 46% would accept a colonoscopy.

The main benefits recognized with predictive testing were the possibility of starting preventive interventions to minimize the risk of developing IBD (69%) and to obtain an earlier diagnosis (58%). The main disadvantage was anxiety generated from a positive result (57%).

Overall, 97% of participants were willing to accept preventive interventions. The most accepted were dietary modification (82%), physical exercise (79%) and probiotics (71%). Overall, 40% and 34% would accept oral or intravenous/subcutaneous immunosuppressive treatment, respectively; provided that the risk of minor adverse events was negligible to acceptable (23%), while 44% considered that the risk of major adverse events should be <1% to be acceptable. In multivariate analysis, factors associated with less acceptance of predictive testing were older age ($p<0.001$) and treatment with thiopurine ($p<0.001$).

Factors only associated with less acceptance of preventive interventions were having ulcerative colitis ($p=0.004$) or undetermined colitis ($p<0.001$) and being treated with mesalazine ($p<0.001$). Having a disease with low impact in their/their family members' quality of life were associated with less acceptance of both predictive testing and preventive interventions ($p<0.001$).

Conclusion: The vast majority of parents with children at-risk for IBD, or first-degree relatives at risk for IBD development would accept minimally-invasive predictive testing for IBD. The vast majority expressed acceptance of non-pharmacological interventions, however, more than one-third would be willing to accept immunosuppressive medications, particularly if associated with a low risk of minor and major adverse events. This data provides useful and important information for the development of prediction and prevention strategies.

Disclosure: Nothing to disclose.

PP0423

FINANCIAL IMPLICATIONS OF FIXED DOSING OF SUBCUTANEOUS INFLIXIMAB IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Jang[1], H. Yoo[1], T. Kwon[1]
[1]Celltrion, Incheon, South Korea

Contact E-Mail Address: minyoung.jang@celltrion.com

Introduction: In Australian patients receiving intravenous (IV) infliximab (IFX) treatment, 44% of patients do not respond to standard regimen and require dose escalation within a year. The REMSWITCH (6-month evaluation) and REMSWITCH-LT (18-months evaluation) investigated the effectiveness of switching from IV to subcutaneous (SC) IFX in patients with inflammatory bowel disease (IBD) who received standard and dose-escalated IV regimen.

The two studies concluded that a fixed dose of 120 mg Q2W is feasible, safe and well-accepted leading to a low risk of long-term relapse in patients with escalated IV doses except for those on 10mg/kg/4weeks regimen. In this study, we developed a model to estimate the financial implications of switching.

Aims & Methods: Clinical efficacy parameters were derived from the REMSWITCH and REMSWITCH-LT studies and applied to the Australian context. Number of Australian patients who are on IFX, the proportion of patients on dose escalated regimen, and cost parameters were identified from the published literature or publicly available resources. A financial model was developed based on the assumption that a cohort of patients will receive either IV or SC IFX, and the analysis concluded with the cost difference.

Results: The model assumes that a total of 5.6K patients are receiving IV IFX, with 44.2% of them receiving dose escalation and/or shortened interval of IV IFX. The model produced 6 months and 12 months results, suggesting savings between 582 and 882 AUD per patient, respectively, and equates to a yearly societal savings of 5 million AUD.

Conclusion: IFX SC deserves premium over IFX IV, given that the novel formulation offers tangible and intangible benefits that originator Remicade and biosimilars cannot provide. There is a concern regarding the affordability of SC IFX because it is generally priced higher than IV IFX, which has many biosimilars on the market.

However, this study asserts that fixed dosing of 120mg of IFX is cost-saving for society, considering highly prevalent practice of dose escalation and/or shortened intervals of IFX regimen.

Disclosure: Nothing to disclose.

Introduction: Environmental factors have only been partially implicated in the aetiopathogenesis of inflammatory bowel disease (IBD). The role of indoor radon, a radioactive gas, has not been formally studied and may play a role in the pathogenesis of the disease.

Aims & Methods: The aim of this study is to analyse the role of individual residential radon exposure on the incidence of IBD in a radon-prone area, also characterised as a high incidence IBD region, and whether this exposure is associated with the development of the disease.

Methods: A case-control study was developed in the health area of Santiago de Compostela (Galicia, Spain) between June 2020 and September 2023, including all consecutive incident cases with IBD. Controls were selected by frequency matching based on sex and age and without IBD. All participants had to have lived in the same home for at least 5 years. All cases were followed up for one year to assess disease progression. Endoscopic index, imaging techniques and analytical parameters were collected. In patients with IBD, hospitalisations related to the disease and the number and severity of flares (measured by Partial Mayo Score and Harvey-Bradshaw) were recorded. Radon levels measured in participants' homes over three months were compared between cases and controls, and between different types of IBD. Each individual was provided with a home radon meter (an RSKS trace detector), which was delivered and read by the Galician Radon Laboratory, a certified radon laboratory. Radon concentrations were categorised into three groups: 0-99 Bq/m3, 100-299 Bq/m3 and >299 Bq/m3. The results are expressed as odds ratios with their 95% CIs obtained by logistic regression.

Results:

RADON LEVELS (Bq/m^3)	IBD PATIENTS (%)	CONTROLS (%)	OR (95%CI)
0-99	34.3	19.8	1
100-299	45.2	55.8	0.5 (0.3-0.8)
>299	20.5	24.4	0.5 (0.3-0.9)

**OR = Odds Ratio; CI = Confidence Interval.*

178 incident cases and 178 controls were included, with a median age of 51 years (IQR 40-59.5). 51.7% were female. 136 IBD patients completed one year of follow-up (78 ulcerative colitis, 52 Crohn's disease and 6 unclassified colitis). The median radon level in the homes of the IBD patients was 144.5 (IQR 83 - 260) and the median radon level in the homes of the controls was 189.5 (IQR 112 - 292.5). After adjustment for age and sex, high radon levels showed a negative association with the development of IBD (taking levels of 0-99 Bq/m3 as reference, OR 100-299 Bq/m3 is 0.5 (95%CI 0.3-0.8) and OR >299 Bq/m3 is 0.5 (95%CI 0.3-0.9). The results are shown in Table 1. Taking into account the different types of IBD, radon levels show

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the same negative association, but without statistical significance. There were no statistically significant differences in radon levels, taking levels of 0-99 Bq/m3 as reference, between hospitalised and non-hospitalised patients (OR 0.8 95%CI 0.3-2.1 for 100-299 Bq/m3, OR 1. 7 95%CI 0.6-5.0 for >299 Bq/m3), nor in patients with a flare compared with patients without a flare during the follow-up year (OR 0.4 95%CI 0.0-4.5 for 100-299 Bq/m3, OR 5.4 95%CI 0.8-34.3 for >299 Bq/m3). Radon levels were also not associated with the number of flares (OR 0.6 95%CI 0.3-1.7 for 100-299 Bq/m3, OR 1.5 95%CI 0.5-4.5 for >299 Bq/m3). Stratification by type of IBD did not alter the results.

Conclusion: High radon levels may be a protective factor against the development of IBD, and indoor radon levels do not appear to be associated with the development of IBD in terms of hospitalisations or flares.

Disclosure: Nothing to disclose.

PP0425

IMPACT OF THE FASTING MONTH OF 'RAMADAN' ON DISEASE ACTIVITY IN EMIRATI PATIENTS WITH INFLAMMATORY BOWEL DISEASE AT A TERTIARY REFERRAL CENTER IN ABU DHABI, UNITED ARAB EMIRATES: RESULTS OF RETROSPECTIVE COHORT STUDY

K. Altenaiji[1], S.W. Khan[2], H.A. Ahmed[2], M.N. Alzaabi[2], A. Alali[3], T. Swaid[2], M. Alahmad[4], K.K. Kumar[2], Y. Ghoris[5], T.A. Malik[6]
[1]Sheikh Shakhbout Medical City, Abu Dhabi, United Arab Emirates, [2]Sheikh Shakhbout Medical City, Gastroenterology, Abu Dhabi, United Arab Emirates, [3]Sheikh Shakhbout Medical City, Abudhabi, United Arab Emirates, [4]Sheikh Shakhbout Medical City, Gastroenterology, Abudhabi, United Arab Emirates, [5]Arizona State University, Arizona, United States of America, [6]Mayo Clinic, Arizona, United States of America

Contact E-Mail Address: Dr.khalifa14@gmail.com

Introduction: Current Literature examining how Ramadan affects gastrointestinal disorders indicates that individuals with inflammatory bowel disease (IBD) generally face a low likelihood of worsening symptoms, although older men with ulcerative colitis (UC) are more susceptible to exacerbations during fasting. Moreover, individuals with duodenal ulcers have a heightened risk of experiencing bleeding following fasting during Ramadan (1).

Aims & Methods: Aim: To study the impact of 'Ramadan' on Inflammatory bowel disease (IBD) activity in an Emirati cohort.

Methods: We designed a retrospective cohort study of adults (> 16 years) with IBD seen at our tertiary care IBD referral center in Abu Dhabi, the United Arab Emirates (UAE) for IBD related emergencies, IBD related hospitalizations and in-person clinic visits during Ramadan, the Islamic lunar calendar month of fasting vs. during the preceding month of Shaban in the year 2023. Exposure of interest was the month (30 days) of 'Ramadan' and the unexposed cohort was the month (30 days) of 'Shaban'. Chi-square testing was used to compare emergency department (ED) visits and hospitalizations.

Logistic regression was used to assess the impact of Ramadan vs. Shaban on the risk of active clinical disease during in-person clinic visits. Statistical analysis was performed using R (version 4.0.2) and a p-value of <0.05 was considered statistically significant. IRB approval was in place for this study.

Results: A total of 294 encounters in the cohort (130 in Ramadan vs. 164 in Shaban) During Ramadan, 12 of 130 (9%) IBD encounters were ED visits for an IBD related emergency vs. 4 of 164 (2%) patients during Shaban (X^2 = 5.25, 95%CI 0.06-0.13, P=0.02). During Ramadan, 16 of 130 (12%) IBD encounters led to hospitalization vs. 16 of 164 (10%) during Shaban (X^2=0.26, 95%CI -0.054-0.1, P=0.61). In Ramadan, during 33/77 (43%) in-person clinic visits, patients had active disease vs. 24/106 (23%) in Shaban (X^2=7.59, 95%CI 0.055-0.35, P=0.006). Logistic regression model adjusted for age and gender demonstrated that during Ramadan, the risk (likelihood) of active clinical disease was approximately 3 times higher compared to during Shaban (OR 2.70, 95% CI 1.41-5.25, P= 0.003).

Conclusion: This is the first study examining the effect of the fasting month of 'Ramadan' on disease activity among Emirati patients with IBD. We found that during Ramadan, there was higher likelihood of ED visits, hospitalizations and active clinical disease when compared to during Shaban. This risk was profound and statistically significant regarding ED visits and likelihood of active clinical disease. There may be several factors underlying these significant findings.

For example, in the UAE during Ramadan, there are limited meal and drink options during the day, there occurs a sudden drastic change in diet patterns and there are limited working hours that reduce access to the IBD Clinic. IBD practices in the UAE could try to mitigate the risk of flares during Ramadan by increased dietary and lifestyle counseling of patients in preparation for the month, encourage patients to hydrate adequately and perhaps by increasing access when needed to the IBD clinic during Ramadan.

INFLAMMATORY BOWEL DISEASE AND CONCOMITANT ENDOMETRIOSIS: FREQUENCY AND CHARACTERISTICS IN A MULTIDISCIPLINARY APPROACH

M. Fiorillo[1], B. Neri[1], F. Iacobini[2], R. Mancone[1], S.C. Schiavone[1], C. Russo[2], M. Franchin[1], C. Exacoustos[2], L. Biancone[1]

Contact E-Mail Address: fiorillo93@gmail.com

Introduction: Inflammatory bowel disease (IBD) and endometriosis are both immuno-mediated chronic inflammatory diseases, sharing some common clinical manifestations (i.e. abdominal pain). A possible association between IBD and endometriosis has been suggested but is currently still undefined.

Aims & Methods: In a multidisciplinary prospective single-center study, we aimed to assess the frequency of undiagnosed endometriosis in IBD patients by searching for symptoms compatible with this condition (dysmenorrhea, dyschezia, dyspareunia, dysuria, heavy menstrual bleeding, HMB).

Secondary end point was to compare symptoms compatible with endometriosis in IBD patients with vs without a subsequent diagnosis of endometriosis. In a prospective study, all female IBD patients in childbearing age with symptoms compatible with endometriosis, as revealed by filling a questionnaire during a scheduled visit at our IBD center, were enrolled. After informed consent, gynecological evaluation and transvaginal ultrasonography (TVUS) was performed by our referral dedicated gynecologist, in order to search for pelvic endometriosis.

Inclusion criteria:

1) female gender;
2) age ≥18 and ≤50 years;
3) well-defined diagnosis of IBD;
4) ≥1 symptom compatible with endometriosis;
5) written informed consent.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Exclusion criteria:
1) pregnancy;
2) menopause.
Characteristics of endometriosis and adenomyosis were reported according to standard classifications. Data were expressed as median [range].
Results: The study population included 51 IBD patients (age 37 [23-53] years, body mass index 21.6 [17.3-41.6]). In IBD, there were 24 (47.05%) Crohn's Disease (CD) and 27 (52.9%) Ulcerative Colitis (UC) patients.
At enrollment, questionnaires revealed dysmenorrhea in 43 (84.3%), dyschezia in 18 (35.3%), dyspareunia in 31 (60.8%), dysuria in 4 (7.8%), HMB in 33 (64.7%) patients. At TVUS, endometriosis in any form was observed in 35 (68.6%) IBD patients, adenomyosis in 26 (51%).
Both diseases were concomitantly detected in 22 patients (43.1%). In patients showing endometriosis, deep infiltrating endometriosis was diagnosed in 33 (94.3%) IBD patients, and 7 out of these 33 (21.2%) patients showed rectal endometriosis.
Among the 35 patients with endometriosis, IBD included CD in 16 (45.7%) and UC in 19 (54.3%).
The frequency of the tested 5 symptoms compatible with endometriosis were then compared between IBD patients with vs without a subsequent diagnosis of endometriosis. Dysmenorrhea (32 [91.4%] vs 11 [68.75.4%]; p=0.04) and HMB (26 [74.3.%] vs 7 [43.75%]; p=0.04) were more frequent in IBD patients with endometriosis.
Differently, the other considered symptoms were comparable between IBD patients with vs without endometriosis: dyspareunia (24 [68.6%] vs 7 [43.75.%]; p=0.09), dyschezia (11 [31.4%] vs 7 [43.7%]; p=0.39), dysuria (3 [8.6%] vs 1 [6.25%]; p=0.77).
No significant differences were observed between UC and CD patients in terms of characteristics of endometriosis, when excluding a higher frequency of endometriosis involving the uterosacral ligament in UC vs CD (16 [84,2%] vs 6 [36.5%]; p=0.005).
Conclusion: Findings from a prospective multidisciplinary study suggest that endometriosis may be highly underestimated in IBD and that specific symptoms, particularly dysmenorrhea and HMB, should be carefully searched in young patients. In IBD, endometriosis was mostly represented by deep infiltrating endometriosis and a higher frequency of rectal endometriosis, potentially leading to rectal bleeding was observed.

Introduction: The relationship between obesity and inflammatory bowel disease (IBD) is currently undefined. The clinical outcome of obese and non-obese IBD patients is apparently comparable. However, evidences at this regard are conflictual.
Aims & Methods: Primary aim was to compare, in a prospective study, IBD characteristics between overweight or obese and non-obese consecutive IBD patients. Secondary aim was to compare the frequency of immunomodulator therapies, IBD-related surgery and hospitalizations between overweight or obese and non-obese patients.
In a prospective, single-center study, consecutive IBD patients undergoing scheduled outpatients visit between September 2022 and January 2023 were enrolled. Demoghaphic and clinical data including body mass index (BMI) were recorded. Inclusion criteria: 1)defined diagnosis of IBD; 2)age ≥18 years; 3)regular follow up (≥2 visits/year). Exclusion criteria: 1)BMI <18.5 mk/m^2, 2)incomplete data. Data were expressed as median [range]. Normal distribution of continuous variables tested by the Kolmogonov-Smirnov test. Comparisons assessed by Student-t test, Mann-Whitney u-test and Chi-squared test.
Results: Out of 300 IBD patients assessed, 284 were enrolled (141 [49.6%] Crohn's Disease (CD); 143 [50.4%] UC). The median age of IBD group was 51 [20-87] and male gender was observed in 157 (55.3%) patients. The median IBD duration was 13.5 [1-57] years. Overall, 170 (59.8%) IBD patients were normal-weight and 114 (40.2%) were overweight or obese.
Among the 141 CD patients enrolled, 89 (63.1%) normal-weight patients and 52 (36.9%) overweight or obese patients were observed. Lesions distribution and behavior was comparable between normal-weight and overweight or obese patients (L1: 62 [70%] vs 35 [67.3%], p=0.77; L2: 8 [9%] vs 4 [7.7%], p=0.79; L3: 19 [21%] vs 13 [25%], p=0.61; L4: 7 [7.9%] vs 2 [3.8%], p=0.34; B1: 24 [27%] vs 13 [25%], p=0.79; B2: 44 [49.4%] vs 32 [61.5%], p=0.16; B3: 21 [23.6%] vs 7 [13.5%], p=0.74, respectively). Perianal disease was more frequently observed in overweight or obese vs normal-weight patients (9 [10.1%] vs 12 [23%], p=0.03). Immunosuppressive (ISS) or biologic use was comparable between groups (ISS: 33 [37%] vs 19 [36.5%], p=0.94; biologics: 23 [25.8%] vs 17 [32.7%], p=0.38). Lack of response to biologics was more frequently observed in overweight and obese vs normal-weight patients (0 [0%] vs 4 [23.4%], p=0.01). Loss of response and adverse events were comparable between groups (11 [47.8%] vs 5 [29.4%], p=0.23; 13 [56.5] vs 8 [47.1%], p=0.55).
Among the 143 UC patients enrolled, 81 (56.6%) normal-weight patients and 62 (63.4%) overweight or obese patients were observed. Proctitis and extensive UC were more frequently reported in overweight or obese vs normal-weight patients (E1: 18 [29%] vs 11 [13.6%], p=0.02; E3: 35 [56.4%] vs 31 [38.3%], p=0.03). Left-sided UC were more frequent in normal-weight then in overweight or obese patients (E2: 39 [48.1%] vs 19 [30.6%], p=0.03). ISS use was comparable between groups (14 [17.3%] vs 7 [11.3%], p=0.31) while biologics were more frequent in normal-weight then in overweight or obese patients (15 [18.5%] vs 4 [6.4%], p=0.03). Lack of response, loss of response and adverse events were comparable between groups (6 [40%] vs 1 [25%], p=0.58; 5 [33.3%] vs 1 [25%], p=0.75; 6 [40%] vs 0 [0%], p=0.12).
Conclusion: In the tested population, overweight or obese CD patients showed a higher frequency of perianal disease and refractoriness to biologics than normal weight patients. These preliminary findings in CD suggest that BMI and phenotype may influence responsiveness to biologics.

INSIGHTS INTO MICROSCOPIC COLITIS: A COMPREHENSIVE ANALYSIS FROM LONDON'S PREMIER TEACHING HOSPITAL IN THE UNITED KINGDOM

S. Hoque[1], J. Kottwitz[1], K. Giaslakiotis[1]
[1]Barts Health NHS Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: samihoque@nhs.net

Introduction: Microscopic colitis is a cause of chronic watery, non-bloody diarrhoea diagnosed mainly on histology after taking biopsy from macroscopically normal colonoscopy. Thereby mainly two subtypes can be identified: Lymphocytic and collagenous colitis. So far, no biomarkers for the diagnosis of microscopic colitis have been identified. Here, we looked at, risk factors and treatment outcome of microscopic colitis in a large series of cases.

Aims & Methods: In this study, we analysed all cases of microscopic colitis diagnosed from 2018-2022 in the Northeast London from 5 different teaching hospitals in the UK. 225 cases (121, Lymphocytic, 124 cases are collagenous colitis) were identified and their electronic health record from hospital and from the primary General Practitioner (GP) were manually reviewed.

Results: In this cohort, 32% male, 68% female with ratio of (1:3, P < 0.036) with mean age of 64years. Thirty three percent were active or ex-smoker, Disease symptoms were significantly different compared to non-smoker (p< 0,007). PPI uses were associated with in 81% cases. While NSAIDS and statin were associated in 57% and 49% cases, respectively. We also found that SSRI use was associated in about 31% cases.

Painless watery diarrhoea was the main cause for referral in 90% of cases, while complaint of abdominal pain noted in only 39% cases. Thirty-five (25%) cases noted to have history of weight loss. Forty-eight (48%) patients received treatment with Budesonide, 46% treated with loperamide, 5% with Immunomodulator or Biologics and 1% Bismuth Subsalicylates respectively. Other autoimmune disease was associated in 6% cases and 2% cases were associated with Coeliac disease. in Nineteen (19%) of cases symptoms improved immediately after stopping above associated drugs without any specific therapy.

Twenty-five (25%) percent relapses 6 months after stopping of therapy. Patients present with abdominal pain, and arthralgia were significantly (p<0.001) higher risk of relapsing compared to patients with other symptoms.

Conclusion: In this large series of microscopic colitis, we found that in addition to associated drug use is not only risk, but patient also presents with abdominal pain and arthralgia have higher risk of relapse, after stopping of therapy of microscopic colitis. Further studies are needed to identify biomarker of this frustrating disease which has significant impact on patients of quality of life.

Introduction: The management of inflammatory bowel disease (IBD) has traditionally focused on controlling symptoms and reducing or even clearing inflammatory burden. However, the Selecting Therapeutic Targets in Inflammatory Bowel Disease (STRIDE)-II statements have expanded the targets to include health-related quality of life (HRQoL) as a long-term outcome. Despite this, the predictive factors for worse HRQoL have yet to be fully completely determined. Alongside psychosocial status, it has been hypothesized that illness perception may also influence HRQoL. Additionally, a bidirectional relationship between sleep quality and IBD has been observed.

Aims & Methods: We thus aim to investigate the potential association between self-reported sleep quality and HRQoL in patients with IBD and to identify other predictors of HRQoL to so that these factors can be integrated into the evaluation of IBD patients. We conducted a prospective single-center cohort study at a tertiary center. From January 2024 to March 2024, patients previously diagnosed with IBD were invited to complete a comprehensive questionnaire assessing HRQoL using the Short Inflammatory Bowel Disease Questionnaire (SIBDQ), self-reported sleep quality using the Pittsburgh Sleep Quality Index (PSQI), and illness perception using the revised version of the Illness Perception Questionnaire. Demographic, clinical (including history of psychopathology), and symptomatology (evaluated using the Harvey Bradshaw Index (HBI) and Partial Mayo Score), as well as analytical parameters (fecal calprotectin), were assessed at the time of questionnaire completion. Clinical remission was defined as HBI<=3 or Partial Mayo Score<=1. Poor HRQoL was defined as SIBDQ<50 and poor sleep quality defined as PSQI>5. Logistic regression was used to performed both univariate and multivariable analysis. Predictors with p<0.1 in the univariate analysis were included in the multivariable analysis.

Results: A total of 272 patients were included, with 53.3% being male. The median age was 48 years (interquartile range [IQR] 38-58). Ulcerative colitis was present in 184 (68%) patients, while the remaining patients had Crohn's disease. A history of psychopathology was noted in 35 (12.9%) patients. The majority of patients were in clinical remission (245 (90.1%) patients). Poor QoL was reported by 87 (32.7%) and poor sleep quality was reported in 185 (70.1%). Univariate analysis revealed a statistically significant association between female gender, Crohn's disease, absence of clinical remission, self-reported poorer sleep quality, and illness perception (higher scores in four components: timeline cyclical, illness consequences and coherence, and emotional representation of IBD) and worse HRQoL. Multivariable analysis confirmed younger age, absence of clinical remission, worse sleep quality, and illness perception (illness consequences, coherence, and emotional representation of IBD) as independent predictors of poor HRQoL.

Conclusion: HRQoL in IBD is influenced by factors beyond disease activity. Sleep quality emerges as a significant determinant of HRQoL, alongside the patient's illness perception. Therefore, integrating sleep quality assessment into patient clinical evaluation is paramount. Moreover, addressing patients' understanding of their disease, perspective on consequences, and emotional response to the condition is crucial for improving HRQoL.

CAN THE IBD DISK ADEQUATELY ASSESS PSYCHOLOGICAL BURDEN IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE?

R. Limam[1], N. Elleuch[1], H. Kallel[1], W. Dahmani[1], A. Hammami[1], A. Ben Slama[1], A. Braham Ep Krifa[1], H. Jaziri[1], M. Ksiaa[1]
[1]*Sahloul Gastroenterology Departement, Sousse, Tunisia*

Contact E-Mail Address: limamrihab33@gmail.com
Introduction: Inflammatory bowel disease (IBD) is often diagnosed in early adulthood and can lead to a substantial decline in quality of life. It has been suggested that patients with IBD are at increased risk of depression and anxiety disorders.
The IBD Disk is a validated 10-question, self-administered visual questionnaire that includes characterisation of psychosocial disease burden. Whether scores in these domains correlate with traditional measures, such as the Hospital Anxiety and Depression Scale (HADS), is not known.
Aims & Methods: The aim of this study was to assess the prevalence of anxiety and depression in IBD patients, and the correlation between IBD-Disk and traditional measures.
We conducted a cross-sectional study over 3 months between April and June 2023. IBD patients responded to the IBD-Disk and HADS questionnaires.
HADS Scores are out of 21; with 0–7 normal, 8–10 mild, 11–15 moderate and 16–21 severe.
Results: We enrolled 57 patients (50.9% men) with a median age of 38 years [31-48].
Thirty-eight patients (66.7%) had Crohn's disease (CD). It was ileal in 14 patients (36.8%), ileocolic in 15 (39.5%), and colonic in 9 (23.7%). Ano-perineal involvement was present in 36.8% of cases. Nineteen patients (33.3%) had ulcerative colitis. Pancolic involvement was noted in 13 patients (68.4%).
Thirteen patients were depressed (22.8%) and 16 patients were anxious (28.1%).
In univariate analysis, depression was significantly associated with clinical disease activity (p=0.002), hospitalization at the time of interview (p<0.001), anemia (p=0.01), elevated CRP (p=0.015), hypoalbuminemia (p=0.016) and corticoresistance profile (p=0.01).
Anxiety was significantly associated with clinical activity (p=0.043), hypoalbuminemia (p=0.023) and high CRP (p=0.043). In multivariate analysis, only hospitalization at the time of interview and corticoresistance were independent risk factors for depression (OR=15.169, p<0.001; OR=5.577, p=0.042 respectively). The only independent risk factor for anxiety was clinical disease activity (OR=3.437, p=0.049). A significant correlation was noted between the IBD-Disk global score, the anxiety score and the depression score (respectively r=0.511 and r=0,524, p<0.001).
Conclusion: IBD patients tend to have a higher prevalence of depression and anxiety disorders than the general population. The IBD disk is an easy tool that correlates well with HADS scores. Its utilisation in clinic allows holistic assessment, particularly in patients with active disease.
Disclosure: Nothing to disclose.

Introduction: The prevalence of primary sclerosing cholangitis (PSC) among ulcerative colitis (UC) is known to be lower in Eastern Asia, including Japan, than in Western countries. There have been few studies describing the details of ulcerative colitis-associated colorectal cancer (CAC) in UC with PSC (PSC-UC) in Japan so far, owing to its rarity.

Aims & Methods: This retrospective study aimed to evaluate the clinicopathologic features and prognosis of CAC in PSC-UC in the largest nationwide cohort of its kind in Japan. A total of 797 eligible patients diagnosed with CAC from 1983 to 2020 were categorized into those with PSC (PSC-UC group, n = 26) and those without PSC (UC-alone group, n = 771). Clinicopathologic features, 10-year overall survival (OS) and 10-year cancer-specific survival (CSS) were compared between the two groups.

Results: In PSC-UC group, duration of UC was shorter (12.8 vs 17.0 year, p=0.042), and age at CAC diagnosis was younger (47.8 vs 53.4 years old, p=0.042) compared to UC-alone patients. Right-sided colon cancer was significantly more common in PSC-UC group than in UC-alone group (34.6% vs 15.5%, p=0.032). Left-sided colon cancer (38.5%) and rectal cancer (26.9%) accounted for a similar proportion with right-sided colon cancer in PSC-UC group. There were no differences between the two groups in terms of sex, age at UC diagnosis, disease extent of UC, medical therapies for UC, diagnostic opportunity for CAC, histological types, and pathological stages of CAC. PSC-UC group showed a comparable 10-year OS (70.6% vs 83.1%, p=0.072) and 10-year CSS (84.1% vs 87.6%, p=0.50) as UC-alone group.

Conclusion: Our study highlighted the differences and the similarities of CAC between UC with PSC and without PSC patients. In patients with PSC-UC, it may be beneficial to start surveillance colonoscopy earlier because of the shorter duration of UC before the CAC diagnosis.

Disclosure: Nothing to disclose.

Introduction: Anemia is a common extraintestinal manifestation of inflammatory bowel disease (IBD) with an important impact on patients' quality of life. The prevalence is uncertain (6% to 74% depending on the definition and on the subgroup of patients examined). In Italy a prevalence of anemia at the diagnosis of 13.6% among the adult IBD outpatients is reported.

Aims & Methods: We aimed to determine the prevalence of anemia and its characteristics at the diagnosis in children with IBD and to investigate its trend during follow-up.

This was an observational, multicenter cohort study including data of IBD children with anemia at the diagnosis prospectively enrolled in the Italian Society of Pediatric Gastroenterology, Hepatology and Nutrition (SIGENP) IBD registry. Data were collected at the diagnosis and anemia trend was evaluated at 1-year follow-up. Anemia was diagnosed based on the WHO criteria and classified as mild, moderate, and severe accordingly. Based on serum ferritin and CRP level and/or transferrin saturation (TNSat), anemia was defined as iron deficiency anemia (IDA), anemia of chronic disease (ACD) or inflammatory IDA (InflIDA).

Results: Five hundred eighty-nine [295 CD (50%) and 294 UC/IBDU (50%)] out of 1634 children with IBD presented with anemia, resulting in a prevalence of 36%. Anemia rate was higher in CD than in UC (39% vs 33%, p = 0.009) and most patients had moderate anemia (55%). Iron deficiency anemia and InflIDA were diagnosed equally in 42% of children, while only 15.4% presented with ACD. Children with CD showed higher rates of mild anemia (38% vs 33%,p<0.0001) and a higher frequency of ACD compared to UC patients (26.5% vs. 4.5%, p < 0.0001). A severe form of anemia was more common in UC (13% vs 6%, p= 0.001) as well as the IDA (53% vs 31%,p<0.0001). Younger age and lower albumin levels significantly correlated with the severity of the anemia in CD. In UC, females were more likely to experience severe anemia (69% vs 47%, p=0.02) and an extensive disease was prevalent in children with moderate and severe anemia than in those with mild anemia (p=0.01 and p=0.03, respectively).

At 1 year, 99 children (17%) were still anemic. At the multivariable logistic regression analysis, baseline wPCDAI and SES-CD significantly correlated with the risk of the persistence of anemia at 1 year in CD. No variables correlated with the persistence of anemia in UC.

Conclusion: More than one-third of pediatric patients presents with anemia at the diagnosis of IBD, most commonly moderate. A severe anemia is most common in UC compared to CD. IDA (alone or in its form of ACD) is the most common cause of anemia in children with IBD. One out of five is still anemic after 1 year from the diagnosis.

Disclosure: Nothing to disclose.

Introduction: Chronic abdominal pain (CAP) occurs in up to 50% of patients with Inflammatory Bowel Disease (IBD), even in remission[1]. Previous studies demonstrate that CAP is associated with fatigue, depression and reduced quality of life in IBD patients[2].

These studies, however, are mostly retrospective questionnaire based which are subject to recall bias.

The Experience Sampling Method (ESM) is a digital patient reported outcome measure (PROM) allowing real-time assessment of current symptoms and reduces recall bias compared to end of day or end of week surveys[3,4]. ESM has not been used in IBD patients to evaluate the relationship between pain, psychological profile and autonomic symptoms.

Aims & Methods: 69 patients with newly diagnosed IBD within the last 12 months were included in the analysis. Patients completed an ESM-based PROM (with a maximum of 10 buzz questionnaires per day) for 7 consecutive days. Within each of the ESM questionnaires, patients reported on current abdominal pain, anxiety, mood, and autonomic symptoms on a scale from 0 (not at all) to 10 (very much). The mean score across the 7 days was calculated for each of the symptoms. Only patients who had completed >25% of the ESM questionnaires (18/70) were included in the analysis.

Results: 63 patients completed >25% of the ESM questionnaires (age range 18-62, 34 male, 29 female) and were included in the analysis. 39 patients (62%) had no abdominal pain (mean pain score 0-1), 15 patients (24%) had mild pain (mean pain score 1-4), whilst 9 patients (14%) had moderate/severe pain (mean pain score 4-10).

The mean scores for low mood (2.35, 95% CI 1.69-3.00) and anxiety (1.57, 95% CI 0.78-2.37) were higher in the mild pain group compared to the mean scores for low mood (1.25, 95% CI 0.75-1.76) and anxiety (1.01, 95% CI 0.59-1.43) in the no pain group (p < 0.01). Likewise, the mean scores for low mood (4.59, 95% CI 2.93-6.25) and anxiety (3.59, 95% CI 1.64-5.53) were higher in the moderate/severe pain group compared to the mild pain group (p < 0.05)

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

There was a higher mean score for palpitations and dizziness in both the mild pain and moderate/severe pain groups compared to the no pain group ($p < 0.01$). The mean score for dyspnea was higher in the moderate/severe pain group compared to no pain group ($p < 0.05$), however it was similar between the mild pain and no pain groups ($p = 0.39$).

Finally, the mean score for sweating was similar between the three groups ($p = 0.34$).

A strong positive correlation ($r = 0.84$) between pain intensity and low mood intensity was found ($p < 0.01$).

Similarly, there was also a strong positive correlation ($r = 0.82$) between pain intensity and anxiety intensity ($p < 0.01$).

Conclusion: Newly diagnosed IBD patients experiencing moderate to severe abdominal pain are more likely to have lower mood, higher levels of anxiety as well as more symptoms of dysautonomia.

Further evaluation of the ESM data will provide a greater insight into the course of symptoms as well as potential triggers for the abdominal pain.

Introduction: Up to half of inflammatory bowel disease (IBD) patients experience chronic pain despite disease remission. The factors affecting the development of chronic pain are poorly understood and pain-directed therapies are scarce.

Our study aimed to compare the clinical features and psychological characteristics of patients with and without chronic abdominal pain (CAP). The current analysis focuses on patients with IBD in remission and used REDCap to capture electronic data [1].

Aims & Methods: This is a cross-sectional online questionnaire-based study of 2381 IBD patients aged 16 years and above. The Rome IV questionnaire was used to diagnose irritable bowel syndrome (IBS). Remission was defined as Harvey Bradford Index (HBI) < 5 for patients with Crohn's disease (CD) or Simple Colitis Activity Index (SCAI) < 3 for patients with ulcerative colitis (UC) [2]. Participants in remission with at least weekly abdominal pain for at least three months were defined as the cohort with chronic abdominal pain, and the rest were categorised as the pain-free cohort.

The independent samples t-test was used to compare mean Body Mass Index (BMI) and age at diagnosis, and the independent samples Mann Whitney U test to compare the non-parametric scale data of the two cohorts. Spearman's correlation was used to compare the pain intensity and pain interference scores from the Brief Pain Inventory with scale data from the following scales: Big Five Personality Questionnaire (BFPQ), Highly Sensitive Person Scale (HSPS), General Anxiety Disorder-7 (GAD7), Patient Health Questionnaire 9 (PHQ9), and Cognitive and Behavioural Response Questionnaire (CBRQ). Cronbach's alpha was used to assess the reliability of these scales.

Results: 1191 participants in remission were studied. Their ages ranged from 17 to 92, with a mean age of 51, and 52.6% were male. Eighty-eight percent were of White British ethnic origin and 40% were current or previous smokers.

25.9% (308) of those in remission reported CAP, with a mean age of 47 years, and 41.6% of them were males. The mean age at diagnosis of IBD was 35 years in those with CAP in remission, versus 30 in those without CAP (t= -4.548, p <0.001, 95% CI -6.598 to -2.621). In the CAP group, the prevalence of IBS was 73.1% compared to the total prevalence of 18.9% in

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the remission cohort. The prevalence of CD and UC were 72.4% and 27.6% respectively in the CAP in remission cohort, compared to 61.3% and 38.7% in all remission participants. 34.4% of people with CAP in remission had previous surgery.

There was a significant difference between the CAP and non-CAP cohort median scores with p values < 0.001 for neuroticism from the BFPQ, Ease of Excitation (EoE) from the HSPS, GAD7, PHQ9. The CBRQ components of fear avoidance, embarrassment avoidance, symptom focusing, all-or-nothing behaviour score, and avoidance/resting behaviour score also showed differences between the CAP and non-CAP groups (p <0.001, 95 % confidence interval).

Pain intensity and pain interference scores showed positive correlations significant at the 0.01 level with neuroticism, EoE, GAD7, PHQ9, and all components of the CBRQ except catastrophisation score within the CAP in remission group.

Conclusion: Our results demonstrate that an older age at diagnosis, IBS prevalence, Crohn's disease, neurotic personality type, and certain behavioural and psychological profiles are significant features of IBD patients with chronic abdominal pain in remission. Further studies will help to develop management strategies and to establish causality.

EXPLORING THE RELATIONSHIP BETWEEN HORMONAL CONTRACEPTIVE USE AND ULCERATIVE COLITIS FLARES: A LONGITUDINAL ANALYSIS

B. Gros[1,2], C. Frutos[1], J.M. Benítez[1], P. Soto[1], S. Marin[1], E. Iglesias-Flores[1]

Introduction: Numerous studies have implicated hormonal contraceptive therapy (HCT) as a potential trigger for IBD onset. However, data regarding disease flares in hormonal contraceptive users are limited in ulcerative colitis (UC). This study aims to explore this association.

Aims & Methods: Female patients who were diagnosed with UC after 1st January 2014, and born between 1966-2008 were included. The Andersen-Gill extension of the Cox proportional hazards model was used to account for recurrent events within the same subjects. Two models were employed: the first included each patient corresponding to only one cohort, while in the second one those who initiated HCT after diagnosis, were included twice, one from diagnosis to HCT as non-exposed and as exposed thereafter.

Results: Among 2359 patients in our local database, 545 were women with UC, of whom 132 met the inclusion criteria for analysis. The majority had UC proctitis 57 (43.2%) with 24 (18.2%) were smokers. The median age was 32.5 (23.3-42) years.

Of the cohort, 52 (39.1%) women exposed HCT, with a median exposure duration of 1.5 (0.5-5.0) years. Of these, 33 (25%) were exposed to HCT during follow-up.

Over 518 person-years of follow up, 178 flares and 198 courses of steroids were observed with 56 admissions and one colectomy, differences were observed among the incidence rates between groups Table 1.

Additionally, there were 24 pregnancies documented.

No differences in time to first flare (log-rank test p=0.83). However, the Cox proportional hazard model showed that HCT was associated with higher cumulative risk of flares in both models (HR 1.53, 95%CI 1.05-2.22, p=0.029) and (HR 1.47, 95%CI 1.019-2.11, p=0.039), Figure 1A and 1B. No adverse events associated to HCT occurred during follow-up.

N=132	All N=132	No OCP n=99	HCT n=33	Incidence rate ratio (95%CI)	p
Age at diagnosis, median (IQR)	32.5 (23.3-42)	36 (27-45)	25 (20.5-32)		0.0001
UC extent, n (%)					
E1	57 (43.2)	40 (40.4)	17 (51.5)		0.38
E2	40 (30.3)	33 (33.3)	7 (21.2)		
E3	35 (26.5)	26.3 (26.3)	9 (27.3)		
Time to 1st flare	493 (182-1187)	481 (177-1210)	522 (184-1226)		0.83
Person-year follow-up	517	458	56		N/A
Flare rate (nºevent/person-year follow-up)	167/518=0.34	132/458=0.29	35/56=0.63	0.46 (0.32-0.69)	<0.0001
Hospitalization rate	56/518=0.11	39/458=0.09	17/56=0.3	0.28 (0.16-0.53)	<0.0001
Surgery rate	1/518=0.002	1/458=0.002	0	0.002 (-0.01-0.01)	0.73
Steroid courses rate	198/518=0.38	158/458=0.35	40/56=0.72	0.48 (0.34-0.70)	<0.001

Conclusion: Our study suggests that HCT is associated with an increased cumulative risk of flares, steroid prescription and hospitalization rates in ulcerative colitis patients. Furthermore, no safety signals were observed with the use of HTC in this cohort.

PRIORITIZING PATIENT PERSPECTIVES: IDENTIFYING KEY SYMPTOMS IN CROHN'S DISEASE AND ULCERATIVE COLITIS TO ENHANCE CLINICAL TRIAL DESIGN

C. Carmichael[1], L. Lucats[2], E. Brown Hajdukova[2], K. Jones[2], S. McKee[1], T. Hemrike[2]
[1]Clarivate, Boston, United States of America, [2]Sanofi, R&D, Paris, France

Contact E-Mail Address: Tessa.Hemrika@sanofi.com

Introduction: Due to the diverse symptoms experienced by patients living with Crohn's Disease (CD) and Ulcerative Colitis (UC), it can be challenging to understand how best to assess the benefit of new therapeutics for these conditions. Identifying priority symptoms that significantly impact patient's well-being and functioning is essential to inform the development of new therapies that truly improve their quality of life. Qualitative interviews with patients are a fundamental step in collecting this critical data, ensuring patient-focused drug development.

This study aimed to identify the most pertinent concepts (signs, symptoms, and impacts) from the patient perspective to provide an in-depth understanding of what aspects of their condition they prioritize.

Aims & Methods: A total of 24 qualitative interviews were conducted with US adult patients with UC or CD. Concept elicitation was conducted remotely using an IRB-approved, semi-structured guide. Participants rated the bothersomeness on a 10-point scale from 0 (no bother) to 10 (greatly bothersome); the average rating of bothersomeness for each symptom was calculated and combined with the total number of incidence reports to assess the saliency of each identified concept.

Data were analyzed in Atlas.ti and then visualized in a graphical format using Microsoft Excel. Salience was assessed for the present time ('at the interview') and at worst.

Results: Twelve UC adults (mean age: 39.5 years, 7 female, 7 white, 4 with only high school education) participated. The average time since UC diagnosis was 5.3 years, with 10 receiving one UC treatment at the time of the interview. Patients with UC most frequently reported rectal bleeding (N=12), fatigue (n=9/12), abdominal pain (n=9/12bowel urgency (n=9/12), and diarrhea (n=8/12).

The symptoms identified as most bothersome in a ranking task were abdominal pain (n=7/12), bowel urgency (n=5/12), rectal bleeding (n=4/12), and diarrhea (n=4/12). In symptom salience tasks 'at its worst', rectal bleeding (bothersomeness, 8.7/10) and bowel urgency (bothersomeness, 9.3/10) were identified as most salient. Most frequently reported UC impacts were diet change (N=12, worrying (n=10/12) and increased need for rest (n=10/12).

Twelve CD adults (mean age: 40.3 years, 8 female, 10 white, 4 with only high school education) participated. The average time since CD diagnosis was 10.3 years, with 11 receiving one CD treatment at the time of the interview. Patients with CD most frequently reported fatigue (n=11/12 bowel urgency (n=9/12), abdominal pain (n=8/12), and diarrhea (n=7/12).

The symptoms identified as one of the most bothersome to patients in a ranking task were fatigue (n=8/12%), frequent bowel movements (n=6/12), diarrhea (n=4/12), bowel urgency (n=4/12) and abdominal pain (n=8/12). In symptom salience tasks 'at its worst', fatigue (bothersomeness, 8.3/10) was identified as most salient. Most frequently reported CD impacts were inability to leave home (n=10/12), low mood (n=10/12) and planning around bathroom use (n=10/12).

Conclusion: The UC and CD patients reported priorities and concerns that may not be adequately assessed by the Mayo score (fatigue, abdominal pain and bowel urgency are not assessed) and CD Activity Index (CDAI) (fatigue, bowel urgency and diarrhea are not assessed) currently used in UC and CD clinical trials, respectively.

This underlines a need to increase patient experience data collection and to investigate whether inflammatory bowel disease (IBD) drugs in development (as well as those already approved) adequately address patients' priorities.

CLOSTRIDIOIDES DIFFICILE INFECTION IN ADMITTED PATIENTS WITH ULCERATIVE COLITIS: ANALYSIS OF 23 YEARS THROUGH PROPENSITY SCORE MATCHING

B. Gros[1], P. Alañon[1], B. Carrillo[1], S. Marin[1], P. Soto[1], E. Iglesias-Flores[1], J.M. Benitez Cantero[2]
[1]Reina Sofía University Hospital, Gastroenterologist, Cordoba, Spain, [2]Hospital Universitario Reina Sofia, Gastroenterology, Cordoba, Spain

Contact E-Mail Address: begrosal@gmail.com

Introduction: Clostridioides difficile infection (CDI) represents the leading cause of nosocomial diarrhea in the Western world. Patients with ulcerative colitis (UC) have a higher risk of developing this infection, which has been associated with an increased risk of flare-ups, need for surgery, and mortality. The aim of the present study was to evaluate the impact of this infection in patients hospitalized for a UC flare-up.

Aims & Methods: Retrospective case-control study including all patients hospitalized for a UC flare-up at Reina Sofía Hospital in Córdoba between January 2000 and January 2023. To avoid potential selection biases, Propensity Matching Score (PMS) adjusted for age, gender, duration, and extent of the disease, with a 1:2 ratio was used. Primary objective was to assess the need for treatment intensification (initiation or dose escalation of biologics/small molecules or immunosuppressant). Secondary endpoints included readmission rate, colectomy, mortality, and CDI risk factors identification.

	All patients				PMS		
	Overall N=419	CDI n=46	NO CDI n=373	p	CDI n=46	NO CDI n=92	p
Length of admission, days, median (IQR)	11 (7-16)	11 (8-15)	11 (7-17)	0.79	11 (8-15)	8 (5-15)	0.107
Albumin <3.5gr/L, n (%)	145 (34.6)	17 (37)	128 (34.3)	0.83	17 (37)	31 (33.7)	0.848
Need for blood transfusion, n (%)	45 (10.7)	9 (19.6)	36 (9.7)	0.042	9 (19.6)	10 (10.9)	0.203
Therapy intensification, n (%)							
- During admission	225 (53.7)	19 (41.3)	206(55.7)	0.065	19 (41.3)	46 (50)	0.366
- Within 3 months	59 (14.1)	8 (17.4)	48 (14.6)	0.49	9 (20.9)	14 (15.2)	0.655

Readmission within 12 months, n (%)	80 (19.1)	17 (37)	63 (16.9)	0.001	17 (37)	16 (17.4)	0.009
Complications during admission, n (%)	66 (15.3)	5 (10.9)	61 (16.4)	0.34	5(10.9)	17 (17.7)	0.39
- Toxic megacolon	26 (6)	3 (6.3)	23 (6.2)		3 (6.3)	7 (7.3)	
- Bowel perforation	5 (1.2)	0	5 (1.3)		0	1 (1)	
- Severe bleeding	7 (1.6)	1 (2.1)	6 (1.6)		1 (2.1)	2 (2.1)	
- Other	26 (6)	1 (2.1)	25 (6.5)		1 (2.1)	7 (7.3)	
Colectomy, n (%)	49 (11.7)	3 (6.3)	46 (12.3)	0.25			
- During admission	14 (3.2)	3 (6.3)	10 (2.7)	0.19	3 (6.3)	11 (12)	0.385
- Within 1st year	11 (2.5)	3 (6.3)	8 (2.1)	0.09	6 (13)	6 (6.6)	0.214
Death within 12 months, n (%)	8 (1.9)	3 (6.5)	5 (1.3)	0.047	3 (6.5)	1 (1.1)	0.108

Table 1. Hospitalisation characteristics, evolution and complications

Results: During the study period, 419 patients were hospitalized for a UC flare-up, of whom 251 (59.9%) were men, with a median age of 41 (IQR 28-55) years and disease duration of 0.89 (0-5.8) years. Of all admissions, 46 (11%) had CDI. After PMS, CDI was associated with increased therapeutic intensification between 3-12 months after discharge (27.5% vs. 11.7%, p = 0.004) and a higher risk of readmission at 12 months (37.5% vs. 13.7%, p = 0.009) but not to risk of colectomy or mortality (Table 1). Infection recurrence was detected in 8 (16.7%) patients.

Classical risk factors for CDI were not found to increase the risk of CDI

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

among UC patients, however antiTNF therapy was associated to CDI in both models: full cohort (OR 3.52, 95%CI 1.46-8.49) and PMS (OR 4.63, 95%CI 1.32-16.31).
Chi-square test or Fisher test were used to compare categorical variables. U-Mann Whitney test was used to compare continuous variables.
PROPENSITY SCORE MATCHING ANALYSIS: Cohort matched adjusting for: age, gender, disease duration and disease extension.
Conclusion: CDI in UC was associated with a greater need for therapeutic intensification and a higher readmission rate at one year. There was no evidence of an increased risk of colectomy or mortality in these patients. Classical risk factors for CDI were not identified but patients on antiTNF were at higher risk of CDI.

GENE-ENVIRONMENT INTERACTIONS IN INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW OF HUMAN EPIDEMIOLOGIC STUDIES

J. Bai[1], D.G. Bouwknegt[1], R.K. Weersma[1], G. Dijkstra[1], K. van der Sloot[1], E.A.M. Festen[1,2]
[1]University Medical Center Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands, [2]University Medical Center Groningen, Department of Genetics, Groningen, Netherlands

Contact E-Mail Address: j.bai@umcg.nl
Introduction: While genetic susceptibility and environmental exposures are known contributors to the pathophysiology of Inflammatory Bowel Disease (IBD), their complex gene-environment interactions (GXE) remain elusive. This systematic review aims to summarize the current evidence of GXE in IBD.
Aims & Methods: PubMed, EMBASE, Web of Science and Scopus were systematically searched from inception through July 20, 2022 to identify publications examining the interaction effect of genetic variants and environmental factors in IBD. All eligible studies were graded using the STREGA guideline.
Results: 4,305 publications were identified and screened, resulting in 36 eligible studies. 17 studies reported statistically significant interactions. *NOD2*-smoking interaction was most frequently investigated and showed variant-specific effects at rs2066847 regarding the risk of Crohn's disease. Gene-smoking interactions were further identified in other IBD risk genes (*ATG16L1, IL23R,* and *CALM3*), detoxification genes (*GSTP1* and *HMOX1*), smoking-associated genes (*CHRNA3, CHRNA5, PPP1R3C,* and *BDNF*), and the inflammatory cytokine (*IL1B*) through a candidate gene approach. Immunochip-wide interaction analyses yielded 64 smoking interacting variants. Gene-diet interactions were observed across multiple nutritional measures, including fatty acid intake with *CYP4F3* and *FADS2*, serum selenium with *SEPHS1* and *SEPSECS*, potassium intake with *IL21*, alcohol consumption with *IL12B*, heme iron intake with *FCGR2A* and serum vitamin D with *VDR*.
Conclusion: Although previous studies have provided valuable insights into potential roles of GXE in the etiology of IBD, current evidence is sparse and inconclusive due to limited statistical power and lack of replication. Further studies, including genome wide environment interaction studies (GWEIS) and genotype-based nutrition/lifestyle clinical trials, are needed to unravel the missing heritability influenced by environmental exposures, and to construct personalized recommendations of lifestyle/dietary modification based on an individual genetic background.

Introduction: The prevalence of gallstone disease in patients with ulcerative colitis (UC) is higher than in the general population. However, risk factors of gallstone disease in these patients remain unclear. Thus, we investigated the prevalence and risk factors of gallstone disease in Korean patients with UC.
Aims & Methods: Patients diagnosed with UC who underwent abdominal imaging between 1997–2020 were investigated using a well-established referral center-based large volume inflammatory bowel disease cohort. The prevalence and clinical characteristics of patients with gallstone disease were evaluated and compared with those without gallstone disease.
Results: Overall, 2811 patients with UC were enrolled. During the follow-up period (mean 5.7 years), 198 (7.0%) patients were diagnosed with gallstone disease and compared with those without gallstone disease (n = 2613). The proportion of extensive colitis at maximum extent, primary sclerosing cholangitis (PSC), history of cytomegalovirus, corticosteroid use, immunomodulatory use, colectomy, and appendectomy were significantly higher in the gallstone group (all $P < 0.05$). In multivariate analyses, age ≥ 60 years at gallstone evaluation (odds ratio [OR] 1.027; 95% confidence interval [CI] 1.002–1.052; $P = 0.033$), PSC (OR 6.304; 95% CI 3.162–12.565; $P < 0.001$), and history of colectomy (OR 2.494; 95% CI 1.222-5.087; $P = 0.012$) were significant risk factors for gallstone disease in patients with UC.
Conclusion: The prevalence of gallstone disease in Korean patients with UC was 7.0%, and age ≥ 60 years at gallstone evaluation, PSC, and history of colectomy were significant risk factors for UC patients with gallstone disease.

Introduction: Transition of adolescents with inflammatory bowel disease (IBD) to adult care is a challenge for patients, families, and healthcare providers. Considering that ~ 25% of IBD patients are diagnosed before the age of 16 years, and that these patients are at higher risk for poorer clinical disease outcomes. interest in the transition of care has been increasing considerably in the last decade. To assess the main clinical and epidemiological features of a single centre pedriatic population of IBD patients at diagnosis and at the time of transition to the adult center

Aims & Methods: From June 2014 to June 2023 we performed a multicenter, observational, cross-sectional study that included pediatric patients with IBD enrolled in the only pediatric IBD reference center in Sardinia. Data were obtained from the patients' medical records and from a questionnaire administered at the inclusion visit.

Results: Sixty-five IBD patients were enrolled (UC 40, CD 25, M 32, F 33). Median age at diagnosis was 13 years (IQR 2-18). After a median disease duration of 8 years (IQR: 1-25), no UC patients experienced proximal estension of proctitis or left-sided colitis, and no CD patients experienced new localizations of disease. Fifteen patients developed extraintestinal manifestations. No significant difference was found in median diagnostic delay (DD) between UC [4 months (IQR: 1-84)] and CD patients [4,5 months (IQR: 1-48)]. At the transition visit, overall, twenty-nine patients (44,6%) were exposed to one biologic agent (vs 3% at baseline; p<0.02); 0 patients (0%) were exposed to two biologic agents. 4,6% of patients (3/ 65) underwent surgery

Conclusion: Our results provide important insights into the clinical and epidemiological features of paediatric IBD population, and while waiting for a nation Italian registry, present eligible data on the IBD population in Sardinia

Disclosure: Nothing to disclose.

PP0443

IMPACT OF VITAMIN D LEVEL ON OUTCOMES IN ULCERATIVE COLITIS IN THE EMIRATI PATIENT POPULATION AT A TERTIARY CARE CENTER IN ABU DHABI, UNITED ARAB EMIRATES: RESULTS OF A RETROSPECTIVE COHORT STUDY

Introduction: Vit D is a known immunomodulator and is essential in maintaining immune balance as well as controlling processes observed in inflammatory disorders like ulcerative colitis (UC) [1,2].

Aims & Methods: Aim: We previously completed a study looking at the effect of vitamin-D on Crohn's disease activity and noted a marginal beneficial effect. In this study, we sought to investigate the association between Vitamin D (VitD) levels and Ulcerative Colitis (UC) activity in the Emirati patient population of the United Arab Emirates (UAE).

Methods: We designed a retrospective cohort study using a sample population of patients (16-85 years) with UC, who were followed for at least one year in the Division of Gastroenterology at our tertiary care center in Abu Dhabi, between January 2021 and October 2023.

Demographics were collected on patients retrospectively identified in the EMR. Eligibility criteria were applied that included patients who had their VitD levels recorded at baseline and whose disease outcomes were measured between 1-12 months post-baseline visit. VitD was documented as a continuous variable and dichotomized into low vs. adequate level categories.

The primary outcome was clinical disease activity measured dichotomously. Summary statistics were calculated. Unadjusted logistic regression analysis was employed to examine the association between VitD level as a continuous variable and when categorized into low vs. adequate levels on clinical disease activity in UC.

Multivariable logistic regression looked at the independent effect of VitD levels by adjusting for covariates of effect size >20%. Statistical analysis was performed using R (version 4.0.2) and a p-value of <0.05 was considered statistically significant. IRB approval was in place for this study.

Results: We identified 89 patients with UC. Of these, 75 met our eligibility criteria, out of which 47 had their Vit D levels recorded at baseline, and 18 were noted to be deficient. 34 (45%) were women. The mean age of the cohort was 36 years. Detailed summary statistics were done. Unadjusted logistic regression analysis revealed that VitD did not appear to impact disease activity.

However, in the multivariable logistic regression analysis, when the model was adjusted for variables with an effect size of greater than 20% (age, BMI, duration of disease, steroid use), a marginal association between VitD as a continuous variable and active clinical disease was observed (OR 0.96 95%CI 0.93-0.99 P=0.039).

Conclusion: This is the first study looking at the impact of VitD on Emirati patients with UC. While there are previous studies in other cohorts that have suggested an association between VitD level and disease activity in UC, it appears that having adequate VitD levels, similar to our experience with Emirati patients with CD has a positive effect. The results of this study highlight the need for IBD practices in the UAE to consider VitD level sampling at baseline and replacement when necessary but discourage the frequent use or overuse of VitD testing in the UC population in the UAE.

Introduction: Colorectal neoplasias developing from ulcerative colitis mucosa (CRNUCs) can be divided into ulcerative colitis-associated neoplasias (UCANs) and sporadic neoplasias (SNs); however, it is often difficult to distinguish between UCAN and SN from biopsy.

We previously reported the utility of cancer genomic analysis for differentiating UCAN from SN in post-resection CRNUC samples (Inflamm Bowel Dis. 2021).

Aims & Methods: This study investigates whether genomic analysis can differentiate UCANs from SNs using CRNUC biopsy tissues. In the first step, of the 36 early-stage CRNUCs (high-grade dysplasias and T1 carcinomas) resected at Hiroshima University Hospital between June 1998 and July 2018, and examined for genetic landscapes in the resection specimens, 14 CRNUC samples that underwent biopsy before endoscopic or surgical resection were analyzed.

The genomic landscape of the biopsy and resection specimens was examined for concordance. In the second step, the relationship between the genomic status and pathological diagnosis was investigated using biopsy specimens from 26 CRNUC cases, not included in the first step, which provided sufficient DNA for genomic analysis.

A custom panel of 27 genes, previously identified as mutated in CRNUC studies, was used for deep sequencing analysis of the cancer genome. In the evaluation of biopsy specimens, UCAN diagnosis using p53 immunostaining (IHC) was defined as cases exhibiting strongly positive p53-IHC results, and UCAN diagnosis based on *TP53* mutations was defined as cases with pathogenic mutations. UCAN diagnosis, combining hematoxylin and eosin (HE) staining with p53-IHC or *TP53* mutation analysis, was defined as follows: cases diagnosed with UCAN based solely on HE staining of the biopsy specimen, or cases with strongly positive p53-IHC or a pathogenic *TP53* mutation when HE staining alone was insufficient for a UCAN or non-UCAN diagnosis.

Results: After the first step of analysis, 14 out of the 27 candidate genes were found to be mutated. The concordance rate for pathogenic mutations across all 14 genes between the biopsy and resected specimens was 29% (4/14), whereas that for pathogenic mutations in *TP53* and *KRAS* was 79% (11/14). After the second step of analysis, the accuracy of diagnosing UCAN/non-UCAN using only HE staining of biopsy specimens was 38% (10/26), whereas p53-IHC achieved an accuracy of 73% (19/26, p=0.026), and *TP53* mutation analysis achieved an accuracy of 77% (20/26, p=0.012). The combination of HE pathology with other methods improved UCAN diagnosis. Specifically, combining HE pathology with p53-IHC in biopsy specimens achieved a sensitivity of 73% and an accuracy of 85% (22/26), while combining HE pathology with *TP53* mutation analysis resulted in a sensitivity of 87% and an accuracy of 88% (23/26).

Conclusion: Both p53 immunohistological staining and *TP53* mutation analysis of biopsy tissue were found to be useful for diagnosing UCAN, with *TP53* mutation analysis demonstrating comparable accuracy to p53 immunohistological staining for UCAN diagnosis.

Contact E-Mail Address: siri.saterstad@ntnu.no

Introduction: Most immune-mediated disorders display a degree of heritability, with specific genetic variants linked to disease susceptibility. Variants in Endoplasmic Reticulum Aminopeptidase 2 (*ERAP2*) have been associated with numerous inflammatory conditions, including Inflammatory Bowel Disease (IBD). As several species (rodents included) lack the *ERAP2* gene, functional studies have been relatively limited. Several immunological functions of ERAP2 beyond peptide trimming have been proposed, yet most of these findings have been reported in immune cell populations. As the epithelial involvement in IBD pathogenesis is getting increasingly recognized, we set out to explore the impact of epithelial ERAP2 presence during inflammatory encounter using human-derived colonoids as a model system. To investigate the effect of genotype on *ERAP2* expression in different disease states, patient material from a IBD cohort was used to correlate genotype to *ERAP2* expression in inflamed and noninflamed colonic biopsies.

Aims & Methods: Two single nucleotide polymorphisms (SNPs) linked to ERAP2 expression (rs2910686/rs2248374) were analyzed in a cohort of IBD patients. Genotypes for both SNPs were correlated with colonic *ERAP2* expression levels in noninflamed and inflamed biopsies. Based on rs2910686

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

genotype, ERAP2-proficient (*n*=4) and ERAP2-deficient (*n*=4) colon organoids were established to study differential expression between proficient and deficient donors after proinflammatory stimulation.

Results: Conditioning on genotype reveals upregulation of *ERAP2* in the inflamed colon of IBD patients. ERAP2 expression proficiency correlates with rs2910686 genotype. IFNγ induces colonic epithelial ERAP2 expression. Western blot confirms that mechanisms independent of the frequently studied SNP rs2248374 can cause ERAP2-deficiency. A total of 586 genes involved in various molecular mechanisms are differentially expressed between ERAP2-proficient and -deficient colonoids upon proinflammatory stimulation, including *AOC1, CPE, ANPEP* and *MEP1A* (catalytic activity), *TNFSF9, MDK, GDF15, ILR6A, LGALS3* and *FLNA* (regulator activity), *SLC40A1* and *SLC5A1* (transmembrane transporter activity), *FGL2, HMCN2,* and *MUC17* (extracellular matrix structural constituents).

Conclusion: Our findings demonstrate that ERAP2 expression is significantly upregulated in the inflamed colon of IBD patients, and expression levels correlates with rs2910686 genotype. Although rs2248374 is commonly used to assess ERAP2 expression proficiency, our findings confirm that mechanisms independent of rs2248374 can lead to ERAP2-deficiency. We further demonstrate that stratifying organoid donors based on genotype is a useful way of exploring the impact of genetic variants. Our data support that ERAP2 play a multifaceted role in modulating the inflammatory response in epithelial cells.

Introduction: Maintaining intestinal homeostasis relies on the interplay between individuals and their unique gut microbiota. Disruptions may result in chronic inflammation and Inflammatory Bowel Disease (IBD) [1]. This study delves into this interplay, emphasizing the characterization of diet-derived microbiome-associated metabolites and prioritizing them based on their effects on epithelial barrier integrity and inflammatory status.

Aims & Methods: Diet-derived microbiome-associated metabolites – epigallocatechin-gallate, gallic acid (GA), protocatechuic acid (PCA), ellagic acid (EA), and urolithins (Uro-A, B, C, D) – were selected through extensive literature research. In the commercial colon cell model (Caco-2) and 3D epithelial organoids from primary adult intestinal-epithelial stem cells, inflammation was induced with TNF-alpha and IFN-gamma (25ng/ml and each) to mimic IBD conditions. The expression of inflammatory cytokines genes (TNF-alpha, CXCL-9, MCP-1, IL-8) and epithelial barrier integrity markers (ZO-1 and OCLN) were evaluated by qRT-PCR. Epithelial barrier integrity was visualized using FITC-dextran assay.

Results: The induction of inflammation significantly increased in key inflammatory markers by an average 7.5-fold change (±1.8SD) in Caco-2 and 3D IBD organoid models. Metabolite analysis in Caco-2 cells showed that GA exhibited a 1.24-fold increase in TNF-alpha (p=0.036) and a -7.22-fold decrease in MCP-1 (p=0.049) gene expressions. EA decreased the expression of TNF-alpha and MCP-1 genes by -1.59-fold (p=0.045) and -3.59-fold (p=0.036) respectively, whereas IL-8 was reduced by -7.62-fold (p=0.01). Uro-A uniquely decreased MCP-1 gene expression by -7.16-fold (p=0.004) but increased IL-8 by 8-fold (p=0.01). PCA demonstrated a statistically significant decrease in all tested inflammatory markers (p<0.05). Analysis of 3D IBD organoids highlighted unique effects in restoring the epithelial barrier and expression of inflammatory marker genes.

Conclusion: Our findings demonstrate the anti-inflammatory properties of gallic acid, ellagic acid, protocatechuic acid, and urolithin-A in both Caco-2 and 3D organoid models. This research elucidates the complex interrelationships within the nutrition-microbiome-metabolome axis and its consequential impact on gut health.

Introduction: The SELECTION trial (NCT02914522) demonstrated that filgotinib (FIL), a once-daily, oral, Janus kinase 1 preferential inhibitor, was effective at inducing and maintaining clinical remission in patients with moderately to severely active ulcerative colitis (UC).[1]

A *post hoc* analysis of FIL responders identified five unique patient groups with different trajectories of response modelled from partial Mayo Clinic Score (pMCS) data, ranging from sustained improvement to rebound of symptoms.[2]

Aims & Methods: We investigated the underlying biology associated with these pre-defined symptomatic trajectories using colon biopsies collected during SELECTION; the trial design has been reported previously.[1] Using group-based trajectory modelling, FIL responders (defined as patients treated with FIL who were in clinical remission or with a Mayo Clinic Score response at week 10) were clustered into trajectories based on similar changes in pMCS from baseline to week 58.[2] RNA was extracted from colonic mucosal biopsies collected at baseline and week 10, and RNA

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. sequencing was performed as per standard protocols. Trajectory-specific transcriptional changes were assessed at baseline by differentially expressed gene (DEG) analysis.

Key comparisons were:

a) Each trajectory at baseline versus the average of the other trajectories and'

b) The change from baseline to week 10, assessed separately for each trajectory group.

Results: Comparison of DEGs between each trajectory group demonstrated minimal transcriptional differences between the groups at baseline. However, the number of DEGs from baseline to week 10 differed between the trajectory groups (*Table*). Interestingly, trajectories associated with greater symptomatic improvement beyond week 10 had higher numbers of DEGs.

Conclusion: We identified transcriptional differences in the change from baseline to week 10 in DEGs between trajectory groups, aligning with symptomatic improvement beyond week 10 in patients receiving FIL. A qualitative analysis of DEGs is under investigation, for which preliminary results support the potential for personalized medicine in UC, by identifying differences in underlying pathophysiology associated with differential response to targeted therapy. These findings could further help to identify blood biomarkers that predict treatment outcomes in patients with UC on FIL.

GENOME WIDE ANALYSES UNRAVEL NOVEL INTERACTIONS BETWEEN TOBACCO SMOKING AND GENETIC VARIANTS IN CROHN'S DISEASE AND ULCERATIVE COLITIS

J. Bai[1], R.K. Weersma[1], G. Dijkstra[1], K. van der Sloot[1], E.A. Festen[1,2]
[1]University Medical Center Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands, [2]University Medical Center Groningen, Department of Genetics, Groningen, Netherlands

Contact E-Mail Address: j.bai@umcg.nl

Introduction: The divergent impact of tobacco smoking in Crohn's disease (CD) and ulcerative colitis (UC) has been widely observed, but it's not completely understood whether the effect of smoking may be modified by genetic makeup.

Our present study aims to systematically identify the genetic modifiers of tobacco smoking in relation to CD and UC disease risk based on genome wide screening.

Aims & Methods: We performed a case-only genome wide association meta-analysis to examine the multiplicative interaction effect between tobacco smoking and single nucleotide polymorphisms (SNPs) in two independent IBD cohorts, the 1000IBD cohort (N=990) and the Dutch Parelsnoer-IBD cohort (N=2540). Imputed Global Screening Array genotype datasets combined with classical HLA alleles were used to compare the genotype frequencies between ever versus never smokers, current versus never smokers, and former versus never smokers in patients with IBD. We further separated entire analyses for CD and UC to characterize interactions where opposite direction was observed.

Functional mapping and annotation of smoking interaction variants were conducted using FUMA, including positional mapping, eQTL mapping and chromatin interaction mapping.

Results: A total of 572 lead SNPs showed consistent evidence of interaction with tobacco smoking between two independent cohorts (meta-analysis P<5e-5, heterogeneity Q test>0.05). Thirty SNPs exhibited opposite associations with smoking behaviors between CD and UC. (Effect size ratio>5 or <0.1) An HLA Class II haplotype (HLA-DRB1*03:01~HLA-DQA-1*05:01~HLA-DQB1*02:01) showed lower frequency in IBD smokers than never smokers.

Functional mapped genes were significantly overrepresented in various immune-response regulation pathways as well as collagen metabolic processes and showed enrichment in specific cell types, such as fetal intestine myeloid cells and midbrain neurotypes. These implicated genes also significantly overlapped with the risk genes for mental disorders, including autism spectrum disorders, schizophrenia, and major depressive disorders.

Conclusion: Our findings indicate that the influence of smoking behaviors on IBD risk depends on individual genetic background. Genetic modifiers of tobacco smoking with opposite directions may explain the differential impact of smoking on the susceptibility to CD and UC. Overrepresentation of these mapped genes in multiple mental disorders reflected complex pleiotropy.

Disclosure: Nothing to disclose.

EARLY VEDOLIZUMAB DRUG LEVELS PREDICT ENDOSCOPIC IMPROVEMENT IN BIOLOGICAL-NAIVE PATIENTS: A SINGLE-CENTER EXPERIENCE

B. Smolović[1], M. Lukic[2], O. Sekulić[2], T. Antunović[3], M. Jakšić[4]
[1]Faculty of Medicine, University of Montenegro; Clinical Center of Montenegro, Internal Clinic, Department of Gastroenterohepatology, Podgorica, Montenegro, [2]Clinical Center of Montenegro, Internal Clinic, Department of Gastroenterohepatology, Podgorica, Montenegro, [3]Clinical Center of Montenegro, Center for Clinical-Laboratory Diagnostic, Podgorica, Montenegro, [4]Institute for Children's Diseases, Clinical Center of Montenegro, Department of Laboratory Diagnostics, Podgorica, Montenegro

Contact E-Mail Address: petar.s@t-com.me

Introduction: Inflammatory bowel diseases (IBD) are chronic gastrointestinal diseases that include ulcerative colitis (UC) and Crohn's disease (CD). IBD is a major public health concern, affecting approximately 6 million people globally (2). Although more common in industrialized countries, the prevalence of IBD is rising in emerging countries as a result of lifestyle changes.

Unfortunately, there is no official data on the occurrence of IBD in Montenegro, either for children or adults. Vedolizumab is a humanized monoclonal antibody that selectively targets α4β7 integrin and was approved for the treatment of adult patients with moderately to severely active UC and CD. The effects of therapeutic drug monitoring or a target serum concentration for vedolizumab are not fully established at this time. It is assumed that higher serum concentrations of vedolizumab lead to a higher probability of clinical response or remission.

Aims & Methods: The aim of the study was to investigate the relationship between vedolizumab serum concentrations (measured at week 6th after beginning of treatment) and clinical and endoscopic responses in IBD patients (evaluated at week 14th). The trial included 22 biologic-naive IBD patients (15 - UC, 7- CD), who received vedolizumab as a first-line treatment. We evaluated endoscopic scores (Mayo Score for UC and Simple Endoscopic Score (SES) for CD) as well as the clinical disease activity scores (Ulcerative Colitis Disease Activity Index (CDAI), Partial Mayo Score (PMS) for UC, and Harvey Bradshaw Index (HBI) for CD). Endoscopic response was defined as a 50% decrease in SES-CD score from the baseline value and Mayo endoscopy subscores of 0 or 1 were considered satisfactory. Clinical remission was defined as an HBI < 5, Mayo Score ≤ 2, and no individual subscore > 1. Clinical response was defined as a decrease in HBI ≥ 3, a decrease in Mayo Score ≥ 30%, and ≥ 3 points from the induction baseline, with a rectal bleeding subscore of 0 or 1.

Results: In the 14th week of therapy, a statistically significant clinical and endoscopic response was achieved, surpassing the overall response of patients with UC and CD (p<0.001). Furthermore, a statistically significant reduction in individual clinical scores (CDAI, HBI, and PMS) was observed in the 14th week of drug application (p=0.004; p=0.026, p=0.005, respectively). The endoscopic response was statistically significant in patients with UC (Mayo endoscopic score, p=0.003) in the 14th week, but not in patients with CD (p=0.176).

The difference in vedolizumab concentration was statistically significant between patients who achieved an endoscopic response in the 14th week and those who did not (p=0.02). Additionally, the difference in drug concentration was close to statistical significance (p=0.088) between patients with UC (28.6±13.6) and CD (21±9.7).

In biologic-naïve IBD patients, a vedolizumab serum concentration of 25.6 mcg/mL or greater at week 6th demonstrated a sensitivity of 88.9% and a specificity of 100% in predicting an endoscopic response at week 14th.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Early determination of vedolizumab serum concentration in biologic-naive IBD patients, primarily UC, can be a promising predictor of endoscopic improvement in these patients.

THE ULTRASOUND MEASUREMENT OF PSOAS MUSCLE AS AN INDEX OF SARCOPENIA IN A COHORT OF PATIENTS AFFECTED BY INFLAMMATORY BOWEL DISEASE: CORRELATIONS WITH THEIR CLINICAL HISTORY AND VARIABLES

F.M. Stalla[1], G. Pecorella[2], M. Mendolaro[1], E. Morello[1], D. Stradella[1], R. Rocca[1], M. Daperno[1]

Contact E-Mail Address: francesco.stalla@gmail.com

Introduction: Sarcopenia is a progressive disorder characterized by reduced musculoskeletal mass leading to reduced strength and poor physical performance. Nutritional status is critical to therapeutic success in Crohn's Disease (CD) and Ulcerative Colitis (UC) but it is clear how traditional weight and body mass index (BMI) scores are poorly representative of these.[1,2]

Sarcopenia could better reflect the degree of malnutrition.[3]

In inflammatory bowel disease (IBD) sarcopenia has been associated with refractory to medical treatment, prolonged hospitalization, increased rate of surgery and increased frequency of post-operative complications.[4–6]

Recently the measurement of the psoas muscle (PM) by ultrasound (US) has been proposed as a surrogate of sarcopenia obtaining an high concordance with the reference standard CT scan.[7]

Aims & Methods: Our preliminary prospective study aims to identify correlations between US measurement of PM in a cohort of 57 patients with IBD and their clinical history and variables. The transverse area of the PM in cm^2 (US-TPA) and the same divided the square height in $cm^2/m2$ (US-PMI) were measured in the right iliac fossa using a low frequency probe: General Electric Logiq P8 (Boston, USA) for outpatients whereas Esaote MyLab One/Touch (Genova, Italia) for inpatients.

Results: Normal weight patients have significantly higher US-TPA and US-PMI values (p=0.032 and 0.031) than underweight (BM<18.5 kg/m^2) or overweight (BMI>25 kg/m^2). CD patients have significantly lower US-TPA (p=0.03) than UC patients. Patients with history of fistulizing perianal disease or who have at least two surgeries have significantly lower US-TPA and US-PMI values than the rest of the population (p=0.02). Patients with severe disease activity (Mayo Partial 5 or Harvey-Brashaw Index>8) have lower US-TPA and US-PMI (p = 0.0003 and 0.0004) than those in clinical remission or mild-moderate activity. As well as for patients with disease activity of any degree (Mayo Partial >2 or HBI>5) compared to remission (p= 0.001 and 0.002). With due caution, we have empirically applied the US-PMI cut-offs proposed by Kobayashi[8] in their cirrhotic cohort of 1.89 cm^2/m^2 for males and 1.81 cm^2/m^2 for females: 13 (23%) of our patients were found to be sarcopenic.

Of these, 46% of patients were admitted at the time of inclusion, 50% clinically active and 77% clinically severe. The higher frequency of sarcopenia observed in these groups was statistically significant with OR 5.42 (IC 95% 1.4-21.8) and p=0.017, OR 5.4 (IC 95% 1.4-21.2) and p=0.02 and OR 19.3 (IC 95% 3.2-116) and p=0.0002 respectively. Underweight and overweight subjects (BMI <18.5 kg/m2 or >25 kg/m2) were more frequently sarcopenic according to the same cut-off than normal weighted with OR 3.97 (95% IC 1.08 - 14.53) and p=0.037.

Conclusion: US is a simple and reproducible method of measuring the PM as a surrogate for sarcopenia, an independent nutritional index that could affect therapeutic responses and outcome in IBD. Our study has found a correlation between the so quantified sarcopenia and the disease activity and clearly demonstrates how such a state of malnutrition is linked to both underweight and overweight. The widening of the population will allow us in future to emphasize associations and differences. The impact and predictive role of sarcopenia on IBD outcomes will be investigated. It will be necessary to identify PM US cut-off for IBD, validated and related by nutritional parameters or other quantitative or qualitative methods.

MONITORING STRUCTURAL BOWEL DAMAGE IN PATIENTS WITH CROHN'S DISEASE: CAN IT REVERSED BY BIOLOGICAL TREATMENT?

S. Albert Palomares[1], P. Marqués García[1], M. Fquihi Chetouani[1], J.R. Lorente Montoro[1], J. Torrente Sánchez[1], A.A. Pérez Ibáñez[1], E. Peiró García[1], A. Rabadán Mata[1], J.M. Paredes Arquiola[1]
[1]*Hospital Universitario Dr Peset, Gastroenterology, Valencia, Spain*

Contact E-Mail Address: saraalbert44@gmail.com

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease, characterized by a progressive course that leads to structural bowel damage (SBD). There is no clear definition of SBD. The Lémann index has been proposed, but it's too complicated to calculate. However, the presence of detectable complications through imaging techniques, such as strictures, fistulas or abscesses is widely accepted to describe SBD. Their presence is strongly associated with the severity of the disease and predicts the risk of hospitalization and surgery. Therefore, reversing structural bowel damage is an emerging medical goal in the time of biological treatments.

Aims & Methods: The main objective of this study was to assess the ability of biological treatments to reverse structural bowel damage monitored by intestinal ultrasound (IUS) and compare the disease course of patients with CD with inflammatory behaviour vs complicated behaviour (stricturing or penetrating -abscesses and fistulas-).

This was a longitudinal observational study, which included patients with CD who started a biological treatment in our center and that were monitored with IUS. Clinical, laboratory and ultrasound variables were collected at the beginning of biological treatment, after 12 weeks and after one year of treatment in order to study the evolution of the disease.

To achieve our objective, we compared the transmural healing (TH) at 12 weeks and one year after starting biological treatment. TH is defined as intestinal parietal thickness ≤3 mm, with no detectable Doppler signals and absence of complications.

As a secondary objective, we compared the need for medical treatment, hospital admission and surgery during the first year of biological treatment

Results: A total of 137 patients with CD were included in this study. Their characteristics and treatments are shown in Table 1.

Variables		Absolute frequency (%)
Male		67 (48.9%)
Initial bowel damage	Stricturing	31 (22.6%)
	Abscesses	11 (8%)
	Fistula	21 (15.3%)
Montreal Classification	Age	≤16 years: 12 (8.8%) 17-40 years: 79 (57.7%) ≥ 41 years: 46 (33.6%)
	Location	Ileal: 75 (54.7%) Colonic: 19 (13.9%) Ileocolonic: 43 (31.4%) Upper disease: 1 (0.7%)
	Behaviour	Inflammatory: 53 (38.7%) Stricturing: 30 (21.9%) Penetrating: 54 (39.4%)
Indication for initiating biologic treatment	Stenotic complication	25 (18.2%)
	Penetrating complication	22 (16.1%)

Table 1.

At the beginning of biological treatment, 50 patients (36.5%) exhibited a complicated behaviour (strictures, abscesses, and fistulas).

After 12 weeks of treatment, TH was achieved in 22.9% of all evaluated patients. By groups, 8.2% of patients with complicated CD and 31.3% with an inflammatory behavior achieved TH, being the last difference statistically significant (p 0.02). After one year of treatment, TH on IUS was achieved in 46% of all evaluated patients. 31.8% of these patients had a complicated EC and 45.1% presented an inflammatory behavior, without reaching statistical significance (p 0.159).

Furthermore, the group with complicated behavior exhibited a significantly higher need for corticosteroid therapy, hospital admission, and surgery.

Conclusion: Patients with SBD showed a significantly lower rate of TH compared to patients with an inflammatory behaviour after 12 weeks of biological treatment.

Additionally, the need for corticosteroid therapy, hospital admission, and surgery was significantly higher in patients with a complicated CD. However, after one year, the TH rate showed no differences between groups. This suggests that reversing structural bowel damage is possible but that the treatment of these patients is more complex.

TYPE 2 DIABETES AND INFLAMMATORY BOWEL DISEASE: IS THERE A POSSIBLE LINK?

M. Mtir[1], M. Ayari[1], A. Chehaider[1], I. Abdelaali[1], M.H. Douggui[1], J. Mohamed Taieb[1]
[1]*Internal Security Forces Hospital, Gastroenterology department, La Marsa, Tunisia*

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Nowadays, it is widely recognized that the gastrointestinal tract plays an important role in the homeostasis of glycemic metabolism. Some studies suggest that the presence of chronic intestinal inflammation is associated with an over-risk of type 2 diabetes (T2D), due to dysbiosis (1).

However, the impact of diabetes on chronic inflammatory bowel disease (IBD) has been insufficiently studied.

The aim of our study was to compare the clinical and therapeutic features as well as the evolutionary character of IBD according to the presence or not of T2D.

Aims & Methods: We conducted a monocentric retrospective study, including patients with Crohn disease (CD) or ulcerative colitis (UC) IBD, over a 7-year period [2014 - 2021]. Clinico-biological data, disease severity as well as the long-term therapeutic and evolutionary data were collected. Patients were compared according to the presence or absence of diabetes. They were divided into two groups:

- Group 1 (N=21): diabetic patients with IBD
- Group 2 (N=79): non-diabetic patients with IBD.

The statistical study was carried out by using SPSS V23 software.

Results: We enrolled 100 patients with IBD: 50% with CD and 50% with UC. The mean age was 46.5 years [extremes: 11 - 82], with a noticeable male predominance (M/F sex ratio of 2.5). The prevalence of T2D in our population was 21%, essentially affecting patients with UC in two-thirds of cases (N=14) versus seven diabetic patients with CD.

The comparison of these two groups showed no significant difference in terms of sex ratio (p= 0.961), smoking habits (p=0.731), duration of disease progression (p=0.744) or association with extraintestinal manifestations. However, the mean age was higher in cases of diabetes (p=0.017), with a cut-off of 51 years. Among diabetic patients, we observed a higher rate of complications such as acute severe colitis in 38.1% versus 15.2% of non-diabetic patients (p=0.020).

The number and severity of IBD flare-ups were not associated with diabetes. Nevertheless, bacterial or viral superinfection during relapses was significantly more frequent in case of diabetes (38.1% versus 15.2%, p=0.020). It was mainly due to superinfection with Escherichia Coli. Thromboembolic complications also occurred more frequently in diabetic patients (14.3% versus 1.3%, p=0.028). As for the therapeutic component, there was no significant difference between the two groups regarding the use of systemic corticosteroid therapy (p=0.458), immunosuppression (p=0.101) or biotherapy (p=0.803). Nonetheless, we found that side effects of corticosteroids were more important among diabetic patients (21.4% versus 2.3%, p=0.013). The risk of undergoing surgery was similar in both groups (33.3% versus 34.2%, p = 0.944).

In multivariate studies, type 2 diabetes was an independent factor in the occurrence of superinfection during relapses (OR=4.8; 95% CI [1.096 - 21.747]; p=0.038), as well as the side effects of corticosteroid therapy (OR=17.6 95% CI [1.281 - 243.006]; p=0.032) among IBD patients.

Conclusion: In our study, type 2 diabetes seems to have a negative impact by increasing the risk of superinfections and cortico-induced side effects during IBD, justifying increased surveillance in these patients. However, it does not appear to have a significant effect on the prognosis and long-term course of the disease.

PREDICTIVE VALUE OF THE MOBILE HEALTH INDEX IN DIFFERENT RISK GROUPS IN INFLAMMATORY BOWEL DISEASES: SIX-MONTH OUTCOMES OF A PROSPECTIVE COHORT STUDY

L.J. Koppelman[1], N.M. Althuis[1], J.P. Maljaars[1], P.W. Voorneveld[1], R.J. Jacobs[2], A.E. Van Der Meulen - De Jong[1]

Introduction: Patients with inflammatory bowel disease (IBD) require long-term, intensive care. To optimise future healthcare delivery, identifying patients suitable for remote monitoring is crucial. Patient-reported outcome measures integrated within eHealth systems, such as the 4-item Mobile Health Index (mHI)[1], offer potential for predicting disease activity. This study explores the predictive value of the mHI within the e-health system DEARhealth[2] at a Dutch university medical centre.

Aims & Methods: This multi-centre prospective cohort study tracked IBD patients within the e-health system. Patients were categorised into high-, intermediate-, and low-risk groups based on current and past biochemical disease activity. High-risk patients had current biochemical disease activity (FCP > 150 µg/g and/or CRP > 5 mg/L), intermediate-risk patients were in remission but experienced a biochemical flare within the last three years, while low-risk patients had been in biochemical remission for at least three years.

A personalised care pathway, considering both risk group and medication usage, dictated the frequency of outpatient visits and lab tests. Over a 24-month period, patients are monitored according to standard of care (biochemical disease activity; endoscopic disease activity) and with mHI scores at both pre-defined time points and patient-initiated moments. These preliminary results focus on assessing the predictive value of the mHI, above a validated cut-off value[1], at baseline for predicting a flare within six months. Sensitivity, specificity, and predictive values are calculated alongside simple logistic regression and Kaplan-Meier analyses.

Results: Out of 319 patients (56.7% Crohn's Disease (CD), median age 43 years, median disease duration 15 years), 89 exhibited biochemical disease activity at baseline and were excluded from the current analysis. Among the 230 patients in remission at baseline, 51 (21.3%) scored above the mHI cut-off point at baseline and 79 (34.3%) experienced a biochemical flare-up within six months of follow-up. The relative risk of experiencing a disease flare in Ulcerative Colitis (UC) patients with a baseline mHI score above the cut-off point was 2.44 (p = 0.04) with sensitivity of 42.1%, specificity of 82.4%, positive predictive value of 40.0%, and negative predictive value of 83.6%. In CD patients, this relative risk was 1.62 (p = 0.39) with sensitivity of 38.5%, specificity of 73.4%, positive predictive value of 14.7%, and a negative predictive value of 90.9%. Logistic regression analysis revealed a significant association between a mHI score above the cut-off point and disease flares in UC patients (OR = 3.394, 95% CI: 1.110-10.330, p = 0.03), whereas in CD patients, such an association was not significant (OR = 1.724, 95% CI: 0.487-5.603, p = 0.37). Similarly, Kaplan-Meier analysis demonstrated a longer flare-free survival in UC patients with a baseline mHI score below the cut-off point (p = 0.03), while no significant difference was observed in CD patients (p = 0.14).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Conclusion: This study indicates that the mHI could be a valuable tool for predicting disease activity, and particularly quiescent disease, in UC patients. However, this predictive capability was not observed in patients with CD. These results underscore the potential utility of mHI in enhancing the management of IBD patients, with implications for personalised care and resource allocation within healthcare systems.

Further research should explore repeated mHI measurements in combination with biomarkers like calprotectin for a more comprehensive approach.

Introduction: The Rutgeerts score is the most commonly used score for assessing endoscopic recurrence after ileocolic resection in Crohn's disease. However, a significant drawback of this score is that it combines lesions localized to the anastomosis with those in the neo-terminal ileum in the same category, assigning them equal prognostic significance.

Aims & Methods: The aim of this study was to evaluate the performance of the REMIND score in predicting postoperative recurrence of Crohn's disease and compare its performance with the Rutgeerts score.

We conducted a monocentric, retrospective, evaluative study of patients operated for Crohn's disease. All patients had a follow-up colonoscopy within one year of surgery.

The REMIND score was derived from endoscopic details documented in the colonoscopy reports. Clinical relapse was defined by the Crohn's disease related symptoms or complications, such as intra-abdominal collection or occlusion, or subsequent surgery Postoperative. Statistical analysis was performed using SPSS.25 for Windows.

Results: Eighty patients were included, with a mean age of 35.7 years, and a gender ratio H/F=2,2. Median follow-up was 5 years from surgery. Clinical recurrence-free survival was significantly shorter in patients with ileal lesions whatever their severity was I(1,2,3,4)A(x), compared with patients without ileal lesions I(0)A(x): p<0,001 and not significantly different between patients without anastomotic lesions I(x)A(0) and patients with anastomotic lesions whatever their severity was I(x)A(1,2,3): p=0,2.

However, patients with at least semicircumferential anastomotic ulcerations A(2,3) had more anastomotic occlusive complications than patients classified A0 or A1: A0 VS A2 p=0,01 A0 VS A3 p<0,001 A0 VS A1 p=0,9. The I(x) score, compared with the Rutgeerts and A(x) scores, had the best values in terms of discriminative capacity (Area under the curve= 0,83 VS 0,73 VS 0,61), monotonicity (linearity test $\chi 2$ of 26,77 VS 12,36 VS 3,89), and homogeneity (likelihood ratio $\chi 2$ of 33,91 vs 18,45 VS 5,49).

Conclusion: In contrast to the Rutgeerts and A(x) scores, the I(x) score seems to exhibit superior performance in predicting postoperative recurrence. Therefore, the use of a score describing separately ileal and anastomotic lesions might be more appropriate to define postoperative endoscopic recurrence.

Introduction: Patients with inflammatory bowel disease (IBD) in clinical and endoscopic remission may still experience disease relapse. Therefore, there is an unmet need for reliable predictors of outcomes to enable a personalized therapeutic approach. Recently, a novel histological score has highlighted the pivotal role of neutrophils in predicting disease outcomes in Ulcerative Colitis (UC)[1]. Furthermore, the impairment of the intestinal barrier plays a key role in forecasting disease outcomes in UC and Crohn's disease (CD). Hence, this study aims to assess the predictive role of neutrophils according to their tissue localization and intestinal barrier protein expression in IBD patients.

Aims & Methods: IBD patients in clinical remission who underwent colonoscopy between January 2020 and June 2022 at two tertiary referral centres were enrolled. Patients with a Mayo Endoscopic Score ≤1 for UC and a Simple endoscopic score of ≤6 for CD were included. The histological activity was assessed using the Robarts Histopathology Index, Nancy Histological Index, and PICaSSO Histological Remission Index. Neutrophil localization in the epithelium and lamina propria was carefully evaluated

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. by experienced pathologists. Additionally, the immunohistochemical expression of barrier proteins, such as Claudin-2 and JAM (junctional adhesion molecule)-A, was assessed to evaluate the integrity of the intestinal barrier.

Results: Out of 60 UC and 76 CD patients, 60% were in histological activity. 25.8% of patients developed an adverse outcome within 12 months. Only neutrophils in the epithelium and not in lamina propria could predict adverse outcomes for UC (HR 5.20, *p*=.01) and CD (HR 4.38, *p*=.03) patients in endoscopic remission.

Moreover, epithelial Claudin-2 expression correlated with endoscopic and histological disease activity and predicted outcomes in UC. Combining neutrophils in the epithelium or Claudin-2 expression significantly predicted outcomes in UC patients (HR 3.23, *p*=.035). Similar results were found for JAM-A in CD despite this protein showing less specificity as a barrier predictor of outcome.

	Ulcerative colitis	Crohn's disease
Neutrophils in epithelium		
Study sample	5.20 (1.46 - 18.46; .01)	1.86 (0.72 - 4.81; .20)
Endoscopic remission	2.5 (0.6 - 11.04; .24)	4.38 (1.16 - 16.55; .03)
Endoscopic mild inflammation	Inf (0 - Inf; .999)	0.32 (0.07 - 1.44; .14)
Neutrophils in lamina propria, not epithelium		
Study sample	3.02 (0.85 - 10.72; .09)	1.59 (0.6 - 4.25; .35)
Endoscopic remission	1.75 (0.39 - 7.83; .46)	4.36 (0.94 - 20.21; .06)
Endoscopic mild inflammation	Inf (0 - Inf; .999)	0.32 (0.07 - 1.44; .14)
Claudin-2 expression		
Study sample	2.12 (1.62 - 43.18; .01)	1.28 (0.001 - 1368.4; .94)
Endoscopic remission	2.08 (0.46 - 9.36; .34)	1.45 (0.44 - 4.76; .54)
Endoscopic mild inflammation	1.07 (0.21 - 5.29; .94)	0.27 (0.06 - 1.36; .11)
JAM-A expression		
Study sample	1.20 (0.44 - 3.32; .72)	3.18 (1.22 - 8.30; .02)
Endoscopic remission	1.32 (0.30 - 5.9; .71)	1.98 (0.58 - 6.78; .27)
Endoscopic mild inflammation	1.16 (0.29 - 4.63; .84)	6.88 (1.23 - 38.43; .03)

Conclusion: This multicentre study highlights the potential role of *epithelial* neutrophil localization and Claudin-2 'leaky gut' protein expression as practical clinical tools for predicting outcomes in IBD and potentially guiding patient-tailored therapy.

Introduction: Bowel urgency is one of the symptoms that patients with Crohn's disease (CD) frequently experience and consider most important to control. Bowel urgency often has a substantial negative impact on quality of life. The Urgency Numeric Rating Scale (NRS) is a single-item patient-reported outcome assessing severity of bowel urgency in the previous 24 hours on an 11-point scale (0–10), with higher scores indicating more severe bowel urgency. The Urgency NRS was initially developed to assess the urgency to have a bowel movement in ulcerative colitis due to lack of appropriate existing instruments.

Aims & Methods: This work aimed to evaluate the psychometric properties of the Urgency NRS in CD and to estimate thresholds for meaningful change and remission for bowel urgency. Pooled data from VIVID-1 (NCT03926130), a Phase 3, multicentre, randomised, placebo- and active-controlled study of mirikizumab in adults with moderately to severely active CD were analyzed.

The measurement properties (reliability, validity, and responsiveness) of the Urgency NRS were evaluated using weekly average scores at Weeks 0 (Baseline), 4, 12, and 52, which were calculated by averaging the most recent 7 days in the 12 days prior to the visit.

These analyses used other measures administered in VIVID-1, including the Patient Global Rating of Severity (PGRS), Patient Global Impression of Change (PGIC), Inflammatory Bowel Disease Questionnaire (IBDQ), and Crohn's Disease Activity Index (CDAI). PGRS and PGIC were used as primary anchors to establish the Urgency NRS score thresholds for meaningful change and remission of bowel urgency. Data from VIVID-1 treatment arms were pooled for these analyses.

Results: The analysis population comprised 1065 adults (mean age 36.2 years [standard deviation: 13.0]; 55% male, 71% White). The Urgency NRS weekly average score decreased during the trial (from 6.6 at Baseline to 2.9 at Week 52), indicating a reduction in bowel urgency severity. Test-retest reliability was good for patients who were stable between Baseline and Week 4 based on the PGRS (intraclass correlation coefficient [ICC] 0.86) and the PGIC (ICC 0.78).

At Weeks 12 and 52, the Urgency NRS showed moderate correlations ($0.30 \leq r < 0.70$) with the PGRS, IBDQ Bowel Symptom domain, IBDQ total score, and CDAI score; as expected, correlations with clinical and laboratory assessments were weak ($r < 0.30$), demonstrating discriminant validity. The Urgency NRS could differentiate between groups of participants known to be distinct based on PGRS and IBDQ Bowel Symptom domain scores.

Improvement in the Urgency NRS average score from Baseline to Weeks 12 and 52 was statistically significantly different between most PGRS change groups and PGIC groups, as well as groups based on IBDQ Bowel Symptom domain, IBDQ response and remission, and clinical response/remission by CDAI, indicating that the Urgency NRS was able to detect change. Anchor-based analysis indicated that clinically meaningful improvement could be represented by a 3–5-point reduction in the Urgency NRS score and that an Urgency NRS score of ≤2 could represent bowel urgency remission.

Conclusion: These results support the reliability, validity, responsiveness of the Urgency NRS and provide definitions of clinically meaningful improvement (reduction of 3–5 points in the Urgency NRS score) and remission of bowel urgency (Urgency NRS score of ≤2) in adults with moderately to severely active CD. These findings confirm the Urgency NRS as suitable for assessing treatment benefits in patients with CD during clinical trials.

Contact E-Mail Address: s.schreiber@mucosa.de

Introduction: The Crohn's Disease Activity Index (CDAI) is an 8-item disease activity measure with three patient-reported items that cover stool frequency, presence of abdominal pain, and patient's general well-being. Absolute scores of the Stool Frequency (SF) and Abdominal Pain (AP) items, together referred to as the Patient Reported Outcome (PRO), have been used separately in the VIVID-1 study.

Both PRO items have recall periods of 24 hours; the SF item measures the number of liquid or very soft stools per day and the AP item measures abdominal pain severity on a 4-point scale (0=none, 1=mild, 2=moderate, and 3=severe).

Aims & Methods: This study aimed to evaluate the measurement properties of the SF and AP items and estimate thresholds for remission. Pooled data from VIVID-1 (NCT03926130), a Phase 3, multicentre, randomized, placebo- and active-controlled study of mirikizumab in adults with moderately to severely active Crohn's Disease (CD) were analysed.

The measurement properties (reliability, validity, and responsiveness) of the PRO items were evaluated separately using average weekly scores of the SF and AP items at Weeks 0 (Baseline), 4, 12, and 52. Patient Global Rating of Severity (PGRS) and Patient Global Impression of Change (PGIC) were used as primary anchors to estimate the remission thresholds. Exit interviews were conducted in a subgroup of participants to support the remission thresholds.

Results: Data from 1065 participants (mean age: 36.2 years [standard deviation: 13.0], 55% males, 71% White) were analysed. During the trial, average weekly scores decreased for both items: SF from 5.7 (Baseline) to 1.9 (Week 52) and AP from 2.1 (Baseline) to 0.8 (Week 52). Both PRO items demonstrated moderate to good test-retest reliability for participants who were stable between Baseline and Week 4 based on PGRS (intraclass correlation coefficient [ICC] 0.85 for SF and 0.82 for AP) and PGIC (ICC 0.79 for SF and 0.69 for AP). SF had moderate ($0.30 \leq r < 0.70$) correlations with Inflammatory Bowel Disease Questionnaire (IBDQ) item 1–stool frequency (Baseline and Weeks 12 and 52) as well as with IBDQ total score, IBDQ Bowel Symptoms domain score, and PGRS (Weeks 12 and 52 only). AP had moderate to large correlations ($0.30 \leq r \leq 0.90$) with PGRS, IBDQ total score, IBDQ item 13–abdominal pain, 36-item Short Form Health Survey (SF-36) Bodily Pain domain, and EQ-5D-5L Pain/Discomfort (Baseline and Weeks 12 and 52).

As anticipated, both PRO items had weak correlations ($r < 0.30$) with the Simple Endoscopic Score for Crohn's Disease (SES-CD), demonstrating discriminant validity. The PRO items could differentiate between groups of participants known to be distinct based on PGRS (for SF and AP), IBDQ Bowel Symptom domain score (for SF), and EQ-5D-5L Pain/Discomfort (for AP).

The PRO items were able to detect change, as score changes in both items between Baseline and Weeks 12 and 52 were statistically significantly different between most PGRS change groups and PGIC groups. Anchor-based analyses combined with results from the exit interviews suggested that an SF score of ≤3 and an AP score of ≤1 could represent remission.

Conclusion: These psychometric evaluation results support the reliability, construct-validity, and responsiveness of the PRO items when administered to adults with moderately to severely active CD. A combination of an SF score of ≤3 and an AP score of ≤1 could represent clinical remission by PRO.

PSYCHOMETRIC EVALUATION OF THE FUNCTIONAL ASSESSMENT OF CHRONIC ILLNESS THERAPY–FATIGUE IN ADULTS WITH MODERATE-TO-SEVERE CROHN'S DISEASE

V. Jairath[1], S. Su[2], A. Vadhariya[2], X. Zhou[3], F. Durand[2], L. Stassek[4], A. Kawata[4], C. Clucas[4], M. Regueiro[5]
[1]Western University, Division of Gastroenterology, Department of Medicine, London, Canada, [2]Eli Lilly and Company, Indianapolis, United States of America, [3]Syneos Health, Morrisville, United States of America, [4]Evidera, Bethesda, United States of America, [5]Cleveland Clinic, Department of Gastroenterology, Hepatology and Nutrition, Cleveland, United States of America

Contact E-Mail Address: vjairath@uwo.ca

Introduction: In Crohn's disease (CD), fatigue is a common symptom that affects ~40% of patients [1] and often has a major impact on their quality of life. The Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-Fatigue) is a 13-item patient-reported outcome assessing fatigue over the previous week on a 5-point scale. In the FACIT-Fatigue, scores for all items are summed to give a total score between 0 and 52, with a higher score indicating less fatigue. The psychometric properties of the FACIT-Fatigue have been assessed in multiple chronic illnesses, including CD.

Aims & Methods: The objective of this study was to provide further evidence on the measurement properties of the FACIT-Fatigue and to determine thresholds for meaningful improvement in fatigue for patients with moderately to severely active CD. Pooled data from VIVID-1 (NCT03926130), a Phase 3, multicentre, randomised, placebo- and active-controlled study of mirikizumab in adults with moderately to severely active CD were analysed. The measurement properties (reliability, validity, and responsiveness) of the FACIT-Fatigue were evaluated at Weeks 0 (Baseline), 12, and 52. Other assessments completed in the trial were used for these analyses, including the Patient Global Rating of Severity (PGRS), Patient Global Impression of Change (PGIC), Inflammatory Bowel Disease Questionnaire (IBDQ), Crohn's Disease Activity Index (CDAI), and 36-Item Short Form Health Survey (SF-36). PGRS and PGIC were used as primary anchors to estimate the FACIT-Fatigue total score change that would constitute meaningful improvement.

Results: Analyses included 1065 adults (mean age 36.2 years [standard deviation: 13.0], 55% males, 71% White). The mean FACIT-Fatigue total score improved during the study (Baseline: 31.5; Week 12: 37.1; Week 52: 40.0). The measure demonstrated internal consistency across visits (Cronbach's alpha: 0.92–0.94); correlations between individual items and the total score were moderate ($0.30 \leq r < 0.70$) to large ($r \geq 0.70$). Across visits, the FACIT-Fatigue total score showed moderate to large correlations with the PGRS; IBDQ Bowel Function domain, item 2 (fatigue), and total score; CDAI score; and SF-36 Vitality domain score. However, correlations with clinical measures were weak ($r < 0.30$), demonstrating discriminant validity. The FACIT-Fatigue could differentiate between groups of participants known to be distinct based on the PGRS, IBDQ total score, and IBDQ item 2. The FACIT-Fatigue was able to detect change, as FACIT-Fatigue total score improvements from Baseline to Weeks 12 and 52 were statistically significantly different between most PGRS change groups and PGIC groups, as well as between groups based on IBDQ response/remission, IBDQ item 2, SF-36 Vitality domain, and clinical response/remission by CDAI. Anchor-based analyses suggested that a 6–9-point increase in the FACIT-Fatigue total score could represent meaningful improvement.

Conclusion: These findings expand on previous research supporting the internal consistency, reliability, construct validity, and responsiveness of the FACIT-Fatigue. Analyses suggest an improvement range of 6–9 points for FACIT-Fatigue as clinically meaningful in the VIVID-1 trial population of adults with moderately to severely active CD.

CLINICAL USEFULNESS OF IMMUNE PROFILING FOR DIFFERENTIAL DIAGNOSIS BETWEEN CROHNS DISEASE, INTESTINAL TUBERCULOSIS, AND BEHCETS DISEASE

J.S. Soh[1]
[1]University of Hallym College of Medicine, Department of Internal Medicine, Anyang, South Korea

Contact E-Mail Address: jssoh@hanmail.net

Introduction: It is important to make a differential diagnosis between inflammatory diseases of the bowel with similar clinical and endoscopic features. Misdiagnosis or delayed diagnosis can affect patients' therapeutic outcomes and prognosis. The profiling of immune cells is helpful for accurately diagnosing inflammatory diseases.

Futhermore, evaluating differences of immune marker expression between Crohn's disease (CD), intestinal Behcet's disease (BD), and intestinal tuberculosis (TB) could be useful in differentiating the diseases.

Aims & Methods: This study aimed to compare the expression levels of immune markers between CD, intestinal BD, and intestinal TB and evaluate the usefulness of immune profiling in differential diagnoses using this advanced imaging system. Biopsy specimens were acquired around ulcerations on the terminal ileum or cecum from five patients with each disease.

Panel 1 included multiplexed immunohistochemistry staining for CD8, CD4, Foxp3, CD20, programmed death-1, and granzyme B. CD56, CD68, CD163, CD11c, and HLA-DR were analyzed in panel 2. Cell density was used to compare the expression levels of immune cells.

Results: The expression of immune cells in panel 1 was not different between diseases. Differences in cytotoxic T cells, helper T cells, and regulatory T cells identified by the double-positivity method were also not significant. However, the expression of $CD68^+$ cells in panel 2 was the highest in intestinal BD among bowel diseases (Table 1).

In the co-expression method, the expression levels of M1 macrophages ($CD56^-CD68^+CD163^-HLA\text{-}DR^-$) and dendritic cells ($CD56^-CD68^-CD163^-CD11c^+HLA\text{-}DR^+$) were significantly different ($P = 0.001$, $P = 0.012$, respectively).

	Crohn's disease	Intestinal Behcet's disease	Intestinal tuberculosis	p-value
CD56+, median cells/mm² (range)	199 (63-263)	75 (44-335)	160 (14-602)	0.582
CD68+, median cells/mm² (range)	530 (508-840)	1828 (1648-3366)	1224 (508-1404)	<0.001
CD163+, median cells/mm² (range)	63 (17-228)	154 (89-408)	114 (69-167)	0.165
CD11c+, median cells/mm² (range)	362 (20-1160)	19 (0-616)	304 (36-649)	0.252
HLA-DR+, median cells/mm² (range)	258 (193-451)	152 (3-640)	890 (168-1147)	0.208

Table 1. Comparison of immune cell densities in panel 2 between Crohn's disease, intestinal Behcet's disease, and intestinal tuberculosis.

Conclusion: The expression of immune cells, including M1 macrophages and dendritic cells, was different between CD, intestinal BD, and intestinal TB. Immune profiling can be helpful for differential diagnoses of inflammatory bowel diseases.

USEFULNESS OF NOVEL IMAGE-ENHANCED ENDOSCOPY FOR PREDICTING MAINTENANCE OF CLINICAL REMISSION IN ULCERATIVE COLITIS

Y. Mamiya[1], T. Taida[1], Y. Ozeki[1], Y. Koshibu[1], N. Shu[1], M. Furuya[1], Y. Oyama[1], H. Nakazawa[1], R. Horio[1], S. Takahashi[1], A. Kurosugi[1], M. Sonoda[1], T. Kaneko[1], T. Ishikawa[1], Y. Ohta[1], K. Okimoto[1], T. Matsumura[1], J. Kato[1], N. Kato[1]

Introduction: Clinical remission and mucosal healing have been advocated as treatment goals for patients with ulcerative colitis (UC). Novel molecularly targeted drugs for the treatment of UC have enabled to target not only clinical remission but also endoscopic remission and even histologic remission.

Recently, the usefulness of novel image enhanced endoscopy (IEE) such as texture and color enhancement imaging (TXI) and red dichromatic imaging (RDI) have been reported in endoscopic evaluation of UC. We aimed to verify the usefulness of the novel IEE in prediction of maintenance of clinical remission in UC patients.

Aims & Methods: Patients with UC in clinical remission who underwent colonoscopy with IEE from March 2021 to December 2023 at our hospital were enrolled in this prospective study.

Disease activities in six segments (cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum) were assessed using white-light imaging (WLI), TXI and RDI. Endoscopic evaluation of disease activity using WLI was performed using Mayo endoscopic score (MES) and the Ulcerative Colitis Endoscopic Index of Severity (UCEIS). IEE evaluation was performed using predefined TXI score (0-2: 2 indicates maximum severity) and RDI score (1-4: 4 indicates maximum severity) for UC. MES of ≤1 and UCEIS of ≤1 were defined as endoscopic remission. With IEE, TXI score 0-1 and RDI score 1 were defined as endoscopic remission in accordance with previous reports.

We evaluated the correlation of those scores by Spearman's rank correlation coefficient. Moreover, relationships between endoscopic remission of WLI, TXI and RDI, and maintenance of clinical remission were evaluated by Kaplan-Meier analysis. Relapse was defined as worsening of clinical symptoms that required additional medical therapies for UC.

Results: Total 117 patients with UC were enrolled. Of these, 17 were excluded because adequate images could not be obtained. Therefore, total 100 patients were assessed. The median MES, UCEIS, TXI, and RDI scores were 1 (range 0-3), 1 (range 0-5), 2 (range 1-3) and 2 (range 1-4), respectively. The average follow-up period was 10.1 months, and 8 cases showed clinical relapse during the observation period.

Evaluation of endoscopic images at each colonic site revealed that UCEIS (P<0.001), TXI score (P<0.001), and RDI score (P<0.001) were significantly associated with MES, respectively. In addition, scores at the most inflamed area showed a positive correlation between MES and UCEIS (r=0.91, P<0.001), MES and TXI (r=0.73, P<0.001), and MES and RDI (r=0.77, P<0.001).

In Kaplan-Meier analysis, MES remission (log-rank, P=0.245), UCEIS remission (log-rank, P=0.701), and RDI remission (log-rank, P=0.827) were not significantly associated with subsequent maintenance of clinical remission. On the other hand, TXI remission (log-rank, P=0.045) was significantly associated with subsequent maintenance of clinical remission.

Conclusion: TXI score and RDI score were significantly associated with existing endoscopic score. In particular, TXI remission was significantly associated with subsequent maintenance of clinical remission. Novel IEE may be useful option in prediction of maintenance of remission in UC patients.

Introduction: Malnutrition is a common condition of patients with inflammatory bowel disease (IBD) and could be associated with sarcopenia i.e. a reduced muscle mass and strength. Recent data suggest that the prevalence of sarcopenia is, respectively, 52% and 37% in Crohn's disease (CD) and ulcerative colitis (UC). It is well demonstrated that sarcopenic IBD patients have two to three times higher risk of lost of response to biotechnology drugs than non-sarcopenic patients.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Aims & Methods: Consecutive IBD patients accessing the IBD outpatient service were enrolled. Detailed data regarding the characteristics of MC and CU populations, current therapy and disease activity are reported. Each patient was interviewed about the frequency (none, low, high) and the kind (aerobic or anaerobic) of the physical activity they were practicing.

At the enrolment, nutritional assessments were performed by body mass index (BMI) evaluation according with the World Health Organization recommendations, global subjective assessment by the MUST (Malnutrition Universal Screening Tool) index according with the European Society for Clinical Nutrition and Metabolism and the Global Leadership Initiative on Malnutrition [GLIM]. Moreover, the SARC-F questionnaire, recommended by the scientific consensus EWGSOP 2 to identify individuals at risk for sarcopenia was administrated. A SARC-F value ≥ 4 was significant of sarcopenia. Finally, the quality of life was assessed using the inflammatory bowel disease questionnaire (IBDQ). Univariate and multivariate analysis was conducted between BMI, MUST, SARC-F and IBDQ values and patient characteristics (age, current therapy, disease activity and physical activity).

Results: A total of 321 IBD patients (158 CD and 163 UC), 56.07% male, with a mean age of 44.78 years were enrolled. Sixty-seven patients (20.87%) reported a current smoking habit. A mean BMI of 70.37 kg, was calculated. Regarding malnutrition, 199 patients (61.99%) were considered at low risk (MUST=0), 75 subjects (23.36%) at medium risk (MUST=1), 47 (14.64%) at high risk (MUST ≥2). A SARC-F value ≥4 was evaluated in 50 patients (15.58%). A reduction in quality of life, understood as IBDQ < 209, was found in 45 (14.02%) patients. Females and males presented a significantly different prevalence of sarcopenia (chi2: 9.69; p-value: 0.002). Univariate analysis shows a significant protective role of male sex (OR vs. female sex: 0.33; p-value: 0.018) in the risk of sarcopenia; older subjects had a slightly higher sarcopenic risk (OR: 1.04; p-value <0.001). The risk was associated with corticosteroid therapy (OR 1,03, p-value <0.001), with increasing MUST (OR 1,65, p-value <0.001) and with the IBDQ decreases (OR 2,1; p-value<0.001).

Multivariate analysis confirmed an higher incidence of sarcopenia in female subjects of advanced age with active-stage disease (R^2: 0.88, p-value<0.0001), furthermore female patients with active-stage disease who did not engage in physical activity had a greater impairment in quality of life, regardless of age (R^2: 0.75, p-value<0.0001). Aerobic and anaerobic physical activity played a protective role in the onset of sarcopenia regardless of sex and age (R^2: 0.82, p-value<0.0001).

Conclusion: In our cohort of patients, sarcopenia was present in only 18.94%. Male sex was found to be a protective factor for sarcopenia. Disease status is firmly linked to the risk of sarcopenia. Regular physical activity has been shown to have a protective role for good quality of life and it was related with a lower risk of sarcopenia. This study will continue to expand the cohort taken into account.

TRANSMURAL HEALING ON INTESTINAL ULTRASOUND IS ASSOCIATED WITH IMPROVED LONG TERM OUTCOMES IN ULCERATIVE COLITIS

C.T. Lim[1,2], C. Teichert[1], M. Pruijt[1], F. de Voogd[1], G.R. D'Haens[1], K.B. Gecse[1]

[1]Amsterdam University Medical Centre, Amsterdam, Netherlands, [2]Singapore General Hospital, Singapore, Singapore

Contact E-Mail Address: thomson.lim.c.t@singhealth.com.sg

Introduction: Recently, endoscopic healing (EH) has been recognized as a long term treatment goal for ulcerative colitis (UC)[1]. It has been demonstrated that UC does not often remain limited to the mucosa but affects all layers of the bowel[2]. Intestinal ultrasound (IUS) is a useful tool to assess transmural disease in UC[3].

Aims & Methods: We performed a retrospective study on UC patients in remission and on stable maintenance treatment with EH (endoscopic Mayo score of ≤ 1) who had an IUS performed between 2 weeks before and 6 months after endoscopic evaluation and had clinical follow up data available for at least 6 months. Patients were identified from 4 prospective cohorts (January 1, 2017 up till December 31, 2023). Clinical follow up data were analysed from date of endoscopy till December 31, 2023.

Transmural healing (TH) measured with IUS was defined as bowel wall thickness(BWT) ≤ 3mm and modified Limberg Doppler score of ≤ 1 on all colonic segments except for rectum. Histology data (healing defined as absence of granulocytes) was also obtained.

Primary outcome was occurrence of any UC related event: documented relapse, initiation of corticosteroids, intensification/change of medical therapy, hospitalization and/or surgery. Patients were censored at first event and time to event analyses with Cox regression was used to determine the association between TH, EH, histological healing and UC related event.

Characteristic	Transmural Healing (n=30)	Non Transmural Healing (n=18)	Overall (n=48)	p value
Gender (male, %)	15 (50.0)	8 (44.4)	23 (47.9)	0.71
Duration of disease (years, median, IQR)	8.6 (3.2, 11.7)	7.6 (4.1, 16.7)	7.9 (3.6, 17.1)	0.77
Age at baseline (years, median, IQR)	33 (27, 46)	42 (27, 55)	38 (27, 50)	0.37
C-Reactive Protein (mg/L, median, IQR)	0.6 (0.3, 0.9)	1.3 (0.4, 4.4)	0.7 (0.3, 9.0)	0.22
Number of prior biologics used (%)				
0	12 (40.0)	1 (0)	13 (27.1)	0.09
1	8 (26.7)	9 (50.0)	17 (35.4)	
2	5 (16.7)	5 (27.8)	10 (20.1)	
≥ 3	5 (16.7)	3 (16.7)	8 (16.7)	
Previous anti-TNF use (%)				
Yes	16 (53.3)	14 (77.8)	30 (62.5)	0.09
No	14 (46.7)	4 (22.2)	18 (37.5)	
Current Medications (%)				
5-Aminosalicylate	7 (23.3)	5 (27.8)	12 (25.0)	0.88
Thiopurines / Methotrexate	2 (6.7)	1 (5.6)	3 (6.3)	
Anti-TNF (Infliximab / Adalimumab)	7 (23.3)	4 (22.2)	11 (22.9)

Endoscopic Mayo Score (%)				
0	12 (40.0)	6 (33.3)	18 (37.5)	0.64
1	18 (60.0)	12 (66.7)	30 (62.5)	

Table 1.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: There were 48 patients available for the current analysis. Baseline characteristics are shown in Table 1. The mean duration of follow up was 38.1±13.1 months. Primary outcome occurred in 18/48 patients (37.5%; TH=5, no TH=13). All patients had a clinical relapse as the first UC related event. Subsequently, 4 patients were initiated with corticosteroids, 13 patients had intensification/change of medical therapy and 1 patient had a colectomy. The mean time to event was numerically shorter in patients without TH than in those with TH (67.9±46.4 weeks vs 92.4±61.2 weeks; *p=0.370*)

Univariate Cox regression showed that TH (HR 0.17, 95% CI 0.06-0.48), endoscopic Mayo score of 0 (HR 0.52, 95% 0.18-1.48) and histological healing (n = 31, HR 0.96, 95% CI 0.26-3.59) were associated with absence of UC related event. However, in multivariate analysis adjusting for age, gender, duration of disease and number of previous biologics and anti-TNF exposure, only TH remained a significant factor (*p=0.025*) associated with event-free long term outcome. Similar results were observed in analysis involving BWT ≤ 3mm with modified Limberg Doppler score 0.

Conclusion: TH is an independent predictor of favorable long-term outcome for UC patients with EH. This novel finding is currently undergoing validation in larger cohorts.

Introduction: Precision medicine relies on accurate prediction of treatment response. Anti-integrin αvβ6 autoantibodies serve as a serum diagnostic biomarker for ulcerative colitis (UC) and associated with adverse UC-related outcomes.[1]

Aims & Methods: We aimed to investigate the association between anti-αvβ6 autoantibody titers and treatment outcomes of advanced therapies. This study was conducted as a part of the prospective biobank in two centers in Japan and Israel. Patients with active UC who received advanced therapies between June 2017 and February 2023 were prospectively included and followed up for 1 year.

The primary and secondary outcomes were treatment persistence rate for 1 year and clinical remission rate at week 6 in the anti-αvβ6 autoantibody low-titer versus high-titer groups, respectively. Treatment persistency was defined as continuation without switching to another advanced therapy or UC-related surgery, and clinical remission was defined as a two-item patient-reported outcome of ≤ 1 (rectal bleeding = 0 and stool frequency ≤ 1).

The cumulative treatment persistence rate was analyzed using the log-rank test. Cox proportional hazards models adjusted for confounders were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for treatment persistence.

Week 6 remission rate was presented as numbers (%) and differences were analyzed using the Chi square test. Logistic regression models adjusted for confounders were used to estimate odds ratios (ORs) and 95% CIs for Week 6 remission.

Results: A total of 102 patients were enrolled in the cohort (median age, 41 years; male, 55.9%; median disease duration, 78.5 months; proctitis, 1%, left-sided colitis, 12.7%, extensive colitis, 86.3%; prior use of advanced therapies, 56.9%, median modified Mayo score, 7). The median observation period was 10 months (interquartile range [IQR]: 2-12 months), with treatment discontinuation occurring in 49 (48.0%) patients.

The cumulative treatment persistence rate was significantly lower in the high-titer(>128 U/mL) compared to the low-titer (≤128 U/mL) group (p = 0.03).

Multivariate Cox proportional hazards model analysis indicated that anti-αvβ6 autoantibodies were the sole independent predictor of treatment persistence (HR, 2.03 [95% CI, 1.04-3.95], p = 0.04) (Table).

Clinical remission at Week 6 was achieved more frequently in the low-titer group than in the high-titer group (48.8% versus 18.2%, respectively, p = 0.04). Multivariate logistic regression analysis also showed that anti-αvβ6 autoantibody titer (OR, 3.52 [95% CI 1.08-11.47], p = 0.04) was a significant predictor associated with Week 6 remission, in addition to the modified Mayo score (OR, 0.35 [95% CI 0.14-0.90], p = 0.03).

CRP (per 1mg/dL increase)	1.00 (0.89-1.15)	0.98	1.02 (0.91-1.21)	0.69
Anti-αvβ6 autoantibody titer				
128 U/mL	1.93 (reference)		1.00 (reference)	
>128 U/mL	1.00 (reference)	0.03	1.00 (reference)	0.04

The multivariable Cox proportional hazards analysis included 5 likely confounders: disease duration, disease extent, history of advanced therapies use, modified Mayo score, and CRP.
Abbreviations: CI, confidence interval; CRP, C-reactive protein; HR, hazard ratio.
The modified Mayo score is the sum of the Mayo stool frequency, rectal bleeding, and endoscopic subscores, with a maximum total score of 9. On the modified Mayo scoring system, a score of 4 to 6 indicates moderate ulcerative colitis, and a score of 7 to 9 severe ulcerative colitis.

Table. Predictors of treatment persistence by Cox proportional hazards model analysis.

Conclusion: Anti-αvβ6 autoantibodies are valuable for predicting the outcomes of advanced therapy in active UC.

INADEQUATE VACCINATION RATES AGAINST HEPATITIS B AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN GREECE: A SINGLE-CENTER STUDY

S. Rellou[1], D. Manou[1], S. Efstathiou[1], S. Lamprou[1], A. Pagoni[1], A. Spyrantis[1], T. Sdonas[1], A. Tasovasili[1]
[1]General Oncology Hospital of Kifisia, Gastroenterology Department, Athens, Greece

Contact E-Mail Address: s_r_1235@hotmail.com

Introduction: Although there is a childhood vaccination program against hepatitis B virus (HBV) in Greece, vaccination rates are thought to be suboptimal both in general population and in inflammatory bowel disease (IBD) patients[1,2].

Wide use of new immunosuppressant and biologic therapy could lead to an oppurtunistic infection. As it is recommended by European Crohn's and Colitis Organisation (ECCO) for prevention of HBV infection, patients should be serologically screened at baseline, before and during an immunosuppressive therapy[3] and be appropriately vaccinated. Vaccination is until now the most effective way in order to protect from HBV offering longtime protection. Lower successful immunization rates are seen after induction of immunosuppressant therapy carrying a higher risk of a current HBV infection and complications . There are limited epidemiological data about successful immunization, among Greek patients with inflammatory bowel disease, prior to immunosuppressant therapy initiation[1].

Aims & Methods: The aim was to detect the vaccination rate against HBV among IBD patients who are going to be treated with immunosuppressant therapy. Retrospectively collected data from medical records of IBD patients in a single referral IBD center between 2017 and 2023 were analyzed. Inclusion criteria were IBD patients prior to immunosuppressant therapy initiation with no natural immunity to HBV, absence of hepatitis B surface antigen (HBsAg), absence of isolated hepatitis B core antibody (anti-HBc) and any status of hepatitis B surface antibody (anti-HBs).

Results: In total 126 patients were included in the study with average age 46 years old (+/- 28 years old). 42.86% (54/126) of them were women and 57.14% (72/126) were men. 52.38% (66/126) had been diagnosed with Crohn's disease and 47.61% (60/126) with ulcerative colitis. In total 40,48% (51/126) had positive anti-HBs, because of successful immunization against HBV and 59.52% (75/126) were seronegative.

Conclusion: Our study confirms inadequate immunization results against hepatitis B among IBD patients in Greece. Intensive care should be given in vaccination protocols and serology testing especially in IBD patients that are going to start immunosuppressive agents. Primary care and IBD specialist should be well informed about serology testing and appropriate vaccination against hepatitis B, carefully advise and strongly recommend vaccination in IBD patients.

NEW BLOOD-BASED TEST, 7-ALPHA-HYDROXY-4-CHOLESTEN-3-ONE (7ALPHAC4), FOR BILE ACID MALABSORPTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE OR UNSPECIFIED DIARRHEA

J. Yang[1], D. Alfego[2], K.Y. Chun[3]
[1]Labcorp, Specialty Medicine, Calabasas, United States of America, [2]Labcorp, Center for Excellence in Data Science, Artificial Intelligence and Bioinformatics, Burlington, United States of America, [3]Labcorp, Esoterix Specialty Medicine, Calabasas, United States of America

Contact E-Mail Address: yangj5@labcorp.com
Introduction: Serum 7AlphaC4 (7-alpha-hydroxy-4-cholesten-3-one) is a diagnostic test for bile acid (BA) malabsorption (BAM) or bile acid diarrhea (BAD) and the only available blood-based test for BAM/BAD. Concentrations >48 ng/mL have a high positive predictive value (PPV) of 82% for BAD and high likelihood of responding to BA sequestrants.[1]
In BAM, less BAs re-enter enterohepatic circulation and more BAs spill into the colon increasing motility and secretion. Less reabsorbed BA means less negative feedback and an ensuing increase in hepatic BA synthesis. As BA synthesis increases, blood levels of 7AlphaC4, a BA precursor, also increase.
This 7AlphaC4 test performed on a random blood collection as a surrogate measure of stool BA aims to simplify the investigation and thereby, improve recognition of BAM/BAD which may often be overlooked in IBD and other patients with more than one possible etiology of diarrhea.
Aims & Methods: We assessed the distribution of numeric serum 7AlphaC4 results (in ng/mL) in 712 patient samples using an in-house developed method utilizing protein precipitation followed by liquid chromatography with tandem mass spectrometry. Reference range of this validated assay is 1.8 – 57 as determined using sera of 120 non-disease individuals.
Results: Analysis of 712 patient samples yielded a mean (± standard deviation) 7AlphaC4 of 36.2 ± 50.1 ng/mL (range, undetectable (<0.5) to 549); 37.6% were low at <15 (associated with a NPV of 85%); 21.3% were high at >48. Most 7AlphaC4 was ordered in the general or urgent medical setting (42.8%), by gastroenterologists (27.8%) or infectious disease specialists (9.3%).
Other testing in order of frequency included: tTG IgA or other celiac tests, fecal calprotectin, fecal pancreatic elastase, stool PCR for 22 GI pathogens, fecal fat, *C. difficile* toxin, *Giardia, H.pylori*, *C.* and stool lactoferrin. Most common International Classification of Diseases (ICD) codes were: diarrhea unspecified, noninfectious gastroenteritis and colitis, abdominal distension, unspecified abdominal pain, irritable bowel syndrome with diarrhea (IBS-D), change in bowel habit, other fatigue, gastroesophageal reflux, functional diarrhea.
ICD codes are not known for all samples. However, of 50 patients with the highest 7AlphaC4 levels (>100), at least 20% had CD (ileal resection status unknown). In 86 patients with known diagnoses, those with CD with small intestine involvement had the highest mean 7AlphaC4 of 83.9 ± 77.1 (n=27) compared to 46.1 ± 83.7 in functional diarrhea (n=20), 37.3 ± 58.9 in unspecified diarrhea (n=191), 31.4 ± 22.3 in IBS-D (n=31), and 22.1 ± 10.8 in UC (n=8).

Serum 7AlphaC4 concentration (ng/mL)	Percentage of total patient results	Interpretation
< 15	37.6%	Low; Associated with 85% NPV for BAM/BAD
15 – 48	41.1%	Normal; Does not help rule in/out BAM/ BAD
> 48	21.3%	High; Associated with 82% PPV for BAM/BAD

Table 1. Distribution of All Serum 7AlphaC4 Results

Conclusion: More than half (58.9%) of all 7AlphaC4 results were low (< 15) or high (>48) and as such, potentially diagnostic, carrying a high NPV or high PPV for bile acids contributing to diarrhea. BAM/BAD may account for 30% of all chronic diarrhea cases, thereby, affecting 1-2% of the general population. Disruptions in BA homeostasis and reabsorption occur more frequently in IBD (up to 40%, with or without ileal resection).
We observed that many of the highest 7AlphaC4 levels occurred in Crohn's patients. In summary, 7AlphaC4 is a new blood-based marker that provides quantitative evidence of the contribution of colonic BA toward diarrhea (and hence, a higher likelihood of responding to BA sequestrants), especially in patients with persistent diarrhea of more than one possible etiology.

Contact E-Mail Address: bargasandre2@gmail.com
Introduction: Recent studies have indicated an increased prevalence of steatosis and liver fibrosis(LF), obesity and cardiovascular diseases among inflammatory Bowel disease(IBD) patients. We aimed to characterize these conditions and risk factors associated.
Aims & Methods: Cross-sectional study on patients with IBD. Pregnancy or known cause of chronic liver disease were excluded. All patients underwent transient elastography, clinical and laboratorial assessment. International Physical Activity Questionnaire(IPAQ) classified activity as low, moderate, or high. Presence of steatosis and fibrosis was defined as Controlled Attenuated Parameter(CAP) measurement of >248dB/m and Liver Stiffness Measurement(LSM) >8kPa, respectively. Fibrosis-4 score (FIB4) was also calculated. For cardiovascular risk (CVR), SCORE2 was calculated according to European Society of Cardiology (if >40 years).
Results: 79 consecutive patients were enrolled [53 Crohn's disease (CD), 24 Ulcerative colitis (UC)]. Baseline characteristics and CVR factors are presented in table 1. Median SCORE2 was 4 (IQR3-10) and 5 (IQR2-10),

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(p=0.83), conferring low cardiovascular risk; 36% of CD and 70% of UC patients had liver steatosis (p=0.04) and 11% of CD and 25% of UC had LF (p=0.13). Median LSM and CAP was 4.7, IQR (4-6) kPa vs 4.6, IQR (3.6-8.6) kPa (p=0.86) and 234, IQR (171-284) vs 217, IQR (179-294) dB/m (p=0.86), for CD and UC respectively. We found a moderate correlation between FIB4 and LSM in CD (r=0.66, p<0.001), but not in UC (r=0.37, p=0.37).
Comparison between patients with and without fibrosis in IBD showed significant differences in terms of age (47, IQR [45-66] vs 36, IQR [29-54]), p=0.01); body mass index (BMI) (31.01, [26.54-37.83] vs 24.61, [20.61-28.05], p=0.03), and history of thromboembolic diseases (23%vs 3%,p=0.007). In a multivariate regression, adjusting for clinically relevant variables, only higher BMI showed higher risk of fibrosis (OR 1.25, CI [1.05-1.48],p=0.01).

	CD	UC	p
Male,%	53%	46%	0.57
Age, median,IQR	55, (31-54)	45,(29-56)	0.42
Low IPAQ,%	87%	71%	0.13
Dyslipidemia,%	11%	8%	0.13
Diabetes,%	4%	4%	0.93
Smoker/Previous smoker,%	44%	65%	0.93
BMI, median,IQR	25.5,(21- 29)	26.53,(21-29)	0.93

Conclusion: In our population, IBD patients had a low cardiovascular risk, and 11% of CD and 25% of UC had liver fibrosis. A potential factor linking both conditions is a higher BMI, was independent risk factor for the development of fibrosis.

ASSESSMENT OF INTESTINAL ULTRASOUND IN THE DIAGNOSIS OF POST-OPERATIVE RECURRENCE IN CROHN'S DISEASE

C. Amor Costa[1], C. Suárez Ferrer[1,2], J. Poza Cordón[2,1], J.L. Rueda García[2,1], M. Sanchez-Azofra[2,1], E. Martín-Arranz[2,1], K. Silva[2], C. Amiama Roig[1], I. González Díaz[1], L. Garcia Ramirez[2], M.D. Martín-Arranz[1,2,3]
[1]Hospital La Paz, Gastroenterology and Hepatology, Madrid, Spain, [2]Hospital La Paz Institute for Health Research (IdiPAZ)., Madrid, Spain, [3]School of Medicine. Universidad Autónoma de Madrid, Madrid, Spain

Contact E-Mail Address: carmenamorcc@gmail.com
Introduction: Ileocolonoscopy and Rutgeerts endoscopic score (RS) remains the gold standard to evaluate post-operative recurrence (POR) in Crohn's disease (CD). Intestinal ultrasound (IUS) is proposed as a non-invasive alternative for the diagnosis of POR, with a sensitivity of 89%, specificity of 86% and area under curve (AUC) of 0.93 (1).
Bowel wall thickness (BWT) alone has a high accuracy in the diagnosis of POR and it is proposed that the association of other parameters such as hyperemia, loss of bowel wall stratification, involvement of mesenteric fat (i-fat) or ultrasound scores, increases sensitivity and specificity in the diagnosis of POR (2).
Aims & Methods: The aim of this study is to assess whether IUS parameters and ultrasound scores correlate with endoscopy in the diagnosis of POR. A unicentric retrospective study was performed. There were included patients with CD with both an ileocolonoscopy and intestinal ultrasound performed for the detection of POR, the time between tests was less than 6 months or there was no therapeutic change between tests.
Endoscopic POR was evaluated with Rutgeers score (RS), RS i0 and i1 was considered no POR and RS ≥i2a was POR. The IUS parameters were: BWT, Limberg Score, bowel wall stratification, inflammation of mesenteric fat, Simple US Score, SUS-CD and IBUS-SAS score.
Results: 129 patients were included, baseline characteristics are in Table 1. In 108 patients (83.7%) the time between test was <6 months and in 21 (16.3%) >6 months without therapeutic changes. 38 (29.7%) were classified as endoscopic POR (RS i0 – i1) and 90 (69.8%) as POR: 28 (21.2%) i2a, 17 (13.3%) i2b and 45 (35.1%) severe (RS i3 – i4). With IUS, 42 patients (32.6%) were classified as no POR and 87 (67.4%) as POR. The mean BWT by IUS in patients without endoscopic POR was 2.6 mm (SD +/- 1.2) versus 4.8 (SD +/- 1.6) in patients with RS ≥i2a (p 0.001). BWT ≥3 had a sensitivity of 86.6%, specificity 78.9% and AUC of 0.83 in the diagnosis of POR. Hyperemia (Limberg ≥1) was present in 75 patients (84.3%) with RS ≥i2a versus in 8 patients (21.1%) without endoscopic POR (p 0.001). 21 patients (23.9%) of patients with RS ≥i2a presented loss of bowel wall stratification versus 0 (0%) with i0-i1 (p 0.001). I-fat was present in 16 patients (12.4%), all of them RS ≥i2a (p 0.02).
The mean results of IUS scores were: Simple Us score 5.6 (SD +/- 2.9), SUS-CD 2.1 (SD +/- 1.8) and IBUS-SAS 31.6 (SD +/- 23.3). In patients without endoscopic POR the mean result of Simple US Score was 3.0 (SD +/- 2.0) versus 6.7 (SD +/- 2.4) in RS ≥i2a (p>0.05). The mean result of SUS-CD without POR was 0.5 (SD +/ 1.0) versus 2.8 (SD +/- 1.5) in POR (p>0.05). In IBUS-SAS the mean result in RS i0-i1 was 13.4 (SD +/- 10.8) versus 39.2 (SD +/- 22.9) in RS ≥i2a (p>0.05). Simple US Score showed an AUC of 0.85 in the diagnosis of POR (95% CI 0.78 – 0.92), SUS-CD of 0.87 (95% CI 0.81 – 0.93) and IBUS-SAS of 0.85 (95% CI 0.77 – 0.92).

Variable	n 129
Men (%)	65 (50.4)
Active smoking (%)	32 (25.4)
Montreal classification (%)	
- L1	59 (45.7)
- L2	2 (1.5)
- L3	60 (46.5)
- L4	8 (6.2)
- B1	19 (14.7)
- B2	49 (38.0)
- B3	61 (47.3)
- p	8 (6.2)
Preventive treatment (%)	
- None	35 (27.1)
- Inmunomodulator	39 (30.2)
- Biological therapy	33 (25.6)
- Inmunomodulator + biological	21 (16.3)
C-reactive protein (mg/L) (mean, SD)	16.3 (127.7)
Fecal calprotectin (µg/g) (mean, SD)	192.1 (391.6)
Bowel wall thickness (mm) (mean, SD)	4.1 (1.8)
Limberg score (0-3) (mean, SD)	1.5 (1.2)
Loss of bowel wall stratification (%)	21 (16.5)

Conclusion: In our experience, IUS parameters such as BWT, Limberg score, loss of wall stratification, i-fat and IUS scores (IBUS-SAS, SUS-CD and Simple US Score), have a high accuracy in the diagnosis of POR.

Contact E-Mail Address: sara.massironi@libero.it

Introduction: Intestinal ultrasound (IUS) is increasingly used as a point-of-care tool for patients with ulcerative colitis (UC). The non-invasive monitoring of pediatric patients with UC is crucial in managing disease progression and therapeutic intervention. The Milan Ultrasound criteria (MUC), the Intestinal Bowel Ultrasound Segmental Activity Score (IBUS-SAS), and the Civitelli score are promising tools for evaluating disease activity in real-time, offering a potential alternative to invasive procedures like endoscopy.

Aims & Methods: The study aimed to assess the correlation and efficacy of MUC, IBUS-SAS, and the Civitelli score in evaluating disease activity in pediatric UC patients, using endoscopic findings and histological parameters as comparative benchmarks.

A prospective cohort of 16 pediatric UC patients underwent IUS and colonoscopy to assess disease activity using the MUC, IBUS-SAS, and Civitelli scores in relation to endoscopic findings and histological evaluation using the Nancy Index. Endoscopy and ultrasound examinations were performed within a 7-day interval, without any change in therapy between assessments. The diagnostic accuracy was evaluated through receiver operating characteristic (ROC) analysis, considering endoscopy as the reference standard.

Results: The study population consisted of 16 pediatric patients with UC (average age 12 years, 56% male), presenting a range of disease severities and durations. The area under the curve (AUC) for MUC was 0.615, IBUS-SAS was 0.667, and Civitelli was 0.603, indicating moderate diagnostic accuracy. Although no significant differences were observed in ROC curve comparisons among these scores, IBUS-SAS demonstrated the highest accuracy. Regarding histological parameters, the AUC was 0.500 for MUC, 0.579 for Civitelli, and 0.563 for IBUS-SAS.

Conclusion: Although potentially less effective than in adult populations, both MUC, Civitelli score, and IBUS-SAS provide reasonable diagnostic accuracy in the assessment of pediatric UC, compared to traditional endoscopic and histologic evaluations. IBUS-SAS, in particular, may offer superior sensitivity in pediatric contexts due to its focus on vascularization and wall patterns. These features are particularly significant in pediatric cases where the disease is recent and the wall often is not very thickened, yet highly vascularized.

Introduction: Psychiatric manifestations in individuals with inflammatory bowel disease (IBD) have been the subject of extensive research. Still, uncertainties remain regarding its precise magnitude, its impact on intestinal disease, and the whole burden of psychiatric manifestations.

Aims & Methods: This systematic review aims to synthesize available evidence on the prevalence and impact of psychiatric symptoms, including depression, anxiety, bipolar disorders, and schizophrenia in IBD patients.

A systematic search was conducted in the PubMed/MEDLINE, EMBASE and SCOPUS databases to identify relevant studies published between January 2010 and January 2023. Cross-sectional, case-control, cohort, registry and population studies were selected that addressed the prevalence of depression, anxiety, bipolar disorder, and schizophrenia in people with IBD compared to the general population. A meta-analysis was also conducted to assess the strength of the association. Data extraction and quality assessment were performed.

Results: The search yielded a total of 3209 articles. Although 193 met the inclusion criteria, only 26 studies provided complete data. Overall, the prevalence of psychiatric comorbidities was found to be significantly higher in IBD patients compared to the general population. The analysis revealed a moderate but significant association between IBD and depression, with a calculated pooled odds ratio (OR) of 1.42 (p<.0001).

Also, anxiety disorders emerged as a prevalent comorbidity in IBD with a calculated pooled OR of 1.3 (p<.0001). Evidence for the association between bipolar disorders and IBD was limited but significant, with a pooled OR of 1.64 (p<.0001), despite a substantial heterogeneity (I2=94.01%). Only 3 studies examined the association between schizophrenia and IBD, providing widely heterogeneous results, with an inconclusive OR (0.93, p= 0.73).

Conclusion: This systematic review with meta-analysis highlights that psychiatric comorbidities such as depression, anxiety, and bipolar disorders are more prevalent in IBD than in the general population. Depression and anxiety are particularly prevalent. Bipolar disorder is still an under-researched area in the context of IBD. Data on the association between schizophrenia and IBD is sparse and inconclusive and requires further research.

Given the findings of this systematic review, there is a need for a deeper understanding of these associations and early detection in order to develop tailored mental health interventions for patients with IBD.

INFLAMMATORY BOWEL DISEASE IN REMISSION IS ASSOCIATED WITH MINOR COGNITIVE IMPAIRMENT COMPARED TO HEALTHY CONTROLS

D. Compare[1], C. Sgamato[1], S. Minieri[1], S.A. Marchitto[1], S. Cinque[1], C. Ambrosio[1], F. Cascella[1], A. Rocco[1], G. Nardone[1]

Introduction: Compelling evidence suggests that inflammatory bowel disease (IBD) can affect the brain. IBD can increase the risk of developing mood and behavioural disorders or neurological diseases. However, few studies assessed cognitive function in such patients, yielding inconsistent results.
Aims & Methods: To evaluate minor cognitive impairment in IBD patients compared with age, sex, and education-matched healthy controls (HC). We enrolled adult (18-65 years) IBD patients referred to our tertiary centre. Clinical remission was defined as Harvey-Bradshaw Index <5 for Crohn's disease (CD) and Partial Mayo score <2 for Ulcerative colitis (UC), respectively. Healthy subjects were recruited from friends and relatives of physicians involved in the study. Exclusion criteria were psychiatric or neurologic diseases, language difficulties, sleep disorders, ileostomy or colostomy, severe comorbidities, alcohol abuse, and use of corticosteroid or other medications with known effects on neuropsychological functions in the three months before enrolment. Cognitive function was assessed by using the Montreal Cognitive Assessment (MoCA) test. A MoCA score greater than 26 was considered normal. To rule out the potential impact on cognitive abilities of conditions such as anxiety and depression, we screened patients using the Hospital Anxiety and Depression Scale (HADS) test. A score equal to or greater than 8 on either HADS-D or HADS-A is considered a 'possible case', and above 11 a 'probable' case. Demographic and clinical data were also recorded. The Mann-Whitney rank-sum or t-test and Chi-square or Fisher's exact test were used to compare continuous or categorical variables, respectively.
A univariate analysis was performed to establish whether baseline clinic psychometrics parameters contributed to predicting MoCa score below the lower limit of normal. Multivariate analysis was then performed by logistic regression with the calculation of odds ratio (OR) and a confidence interval (CI) of 95%.
Results: Ninety-four IBD patients [48 CD and 46 UC] and 68 HC were finally considered for statistical analysis. No significant differences in terms of sex (p=0.224), age (p=0.243), and years of schooling (p=0.279) were observed between patients with IBD and HC. A significantly higher percentage of IBD patients had MoCA scores below the lower limit of normal in comparison to HC (57% vs 42%, p=0.037). A similar result was obtained also after excluding patients with probable anxiety and depression as assessed with HADS (42% vs 25%, p=0.025). UC patients had significantly lower mean scores in the memory domain than HC (3.1±1.4 vs 2.5±1.5, p=0.041). Age (p=0.036), years of schooling (p=0.002), and UC (p=0.037) were significantly associated with a MoCA score below the lower limit of normal. At multivariate analysis, age (OR 1.04, 95%CI 1-1.1, p=0.017) and UC (OR 2,2, 95%CI 1.4-5.3, p=0.047) were the only variables that independently predicted a MoCA score below the lower limit of normal.
Conclusion: IBD patients had minor cognitive impairment in a percentage significantly higher than controls as assessed by MoCA. UC patients showed deterioration of the memory domain. Our data support the existence of a gut-brain axis and suggest that colonic rather than small bowel inflammation could be the pathogenetic link for cognitive impairment in IBD. A multidisciplinary approach is required for IBD patients, which should also include cognitive function assessment.

EVALUATION OF THE RESULTS OF A MICROLEARNING PROGRAMME FOR PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN IMPROVING THERAPEUTIC ADHERENCE. THE ADEII PROJECT

L. De Castro Parga[1], V. Hernández Ramírez[1], J. Martínez-Cadilla[1], L. Sanromán Alvarez[1], J.i. Rodriguez Prada[1]
[1]Hospital Alvaro Cunqueiro. Complexo Hospitalario Universitario de Vigo (CHUVI), Gastroenterology, Vigo, Spain

Contact E-Mail Address: maria.luisa.de.castro.parga@sergas.es
Introduction: Information and communication technologies (ICTs) represent a novel approach to chronic disease management. However, their use in Inflammatory Bowel Disease (IBD) is scarce as no specific tools are available. Our aim was to develop a microlearning programme for IBD patients and to evaluate their outcomes with respect to adherence, medication beliefs and perception of the disease.
Aims & Methods: Prospective cohort study in adult IBD patients (18-70 years) who underwent a microlearning programme over 2 months, through 4-minute videos organised into individualised video pathways that were sent via mobile phone using a Telegram bot. All patients received the main pack of 4 videos, consisting of 2 videos with information about their disease (ulcerative colitis or Crohn's disease), 1 video on adherence and 1 video on corticosteroid treatment. We then add a video for each medication used by the patient in the management of their IBD. Before starting the programme and at 6 months, patients completed the BMQ (Beliefs Medicines Questionnaire) and Brief Illness Perception Questionnaire (BIPQ). We checked the medication possession rate (MPR) at these same intervals, considering a MPR ≥80% as adequate adherence.
Results: Between June and October 2022, 1226 videos were sent to 200 IBD patients: 51.5% female (103), Ulcerative colitis 52.5% (105), median age 46.1 (13.2) years (Table 1). The median of videos per patient was 6 (6-7). Attendance to the ADEII programme ranged from 78% to 90%. Baseline non-adherence in this cohort was 29.8% (59 patients), decreasing significantly to 18.1% (36) after the programme (p=0.02). Likewise, in the BMQ scales, we found significant decreases in the median and IQR of the BMQ scores : Medication Abuse: 8 (7-9) vs 8 (6-9) (p=0.001), BMQ-Medication Harm 10 (8 -12) vs 9.5 (7-11) (p=0.002) and BMQ-Treatment Concern 13.5 (11-16) vs 13 (10-16) (p=0.001), with no change in BMQ-Treatment Need. Regarding illness perception, on the post-intervention BIPQ scale there were significant decreases in P8 Negative Emotions 6 (3-8) vs 5 (3-7) (p=0.003) and P5 Identity 6 (4-8) vs 5 (3-7) (p=0.003), as well as a significant increase in P7 Understanding of illness 7 (5-9) vs 8 (7-9) (p=0.003).

HEAD TO HEAD COMPARISON OF A RAPID AND A CONVENTIONAL FECAL CALPROTECTIN KIT AS PREDICTOR OF CLINICAL SCORE IN ULCERATIVE COLITIS AND CROHN'S DISEASE

J. Florholmen[1], E. Lindi[2], S.B. Gaup[2], S. Hegge[2], H. Kitti[2], K.-M. Johnsen[1], S.U. Johansen[1]

[1]Inst Clinical Medicine, Gastroenterology, Tromso, Norway, [2]Sami Klinihkka, Hospital of Finnmark HF, Norway, Internal medicine, Hammerfest, Norway

Contact E-Mail Address: jon.florholmen@unn.no

Introduction: Measurements of fecal (fe) calprotectin as a surrogate biomarker of gastrointestinal inflammation have great clinical impact in the judgement of clinical activity in inflammatory bowel disease. There is no accepted standardization procedure of ELISA-based calprotectin kits, but several commercial kits use of a combined pioneering polyclonal calprotectin antibody (CA) (1) and a monoclonal CA.

Aims & Methods: To evaluate the accuracy of a new rapid fe-calprotectin kit (RFC) including a polyclonal-based CA to predict clinical activity in comparison to a standard commercial (SCFC) kit in patients with ulcerative colitis (UC) and Crohn's disease (CD) with special focus on clinical remission.

Included were 16 UC and 20 CD patients on ongoing treatment from May 2022 to March 2024 (5ASA, azathioprine, biological therapy). The degree of illness was evaluated at regularly visits every three months using the clinical scoring system- Ulcerative Colitits Clinical Score (UCCS), and Harvey-Bradshaw index (HBI). From the same fe-sample RFC analyses were performed at the Sami Klinikkha, Finnmark Hospital and the SCFC analyses at the University Hospital Tromsø, Norway, both with an upper normal level of 50 µg/g.

Statistical evaluation was done by correlation and limits of agreement analysis; cut-off levels were explored by Receiver Operating Characteristic (ROC) analysis against clinically defined remission

Results: The intra-assay variation of the RFC was 5.3% at a level of 133 µg/g.

Mean calprotectin values (µg/g) with 95 % confidential interval (CI) are shown at various degrees of clinical activities during the observation time (remission, slight and mild), Table 1. In general, the RFC measured lower means and CI levels compared to the SCFC. In clinical remission, the upper RFC CI interval were in proximity to the upper normal level, whereas the corresponding SCFC CI levels were almost three times higher than the upper normal level.

A ROC curve was performed for prediction of clinical remission. Both assays had significant area under the curve (AUC) in both UC and CD patients (p<0.0001). The RFC kit predicted endoscopic remission with 100% specificity at cut-off levels 139 µg/g in both UC and CD. The specificity of the SCFC kit was lower applying the same cut-off levels. Increasing the cut-off to 246 µg/g in the SCFC kit (Youden's J index 0.68 in the UC group and 0.49 in the CD group), the specificity increased to 96.3 and 96.4% in the UC and CD group, respectively.

On the other hand, the test sensitivity decreased (71.4% in UC and 52.2% in the CD patient group).

	Remission UC n=27	Slight UC 10	Moderate UC 8	Remission CD 28	Slight CD 27	Moderate CD 10
RFC	60 (mean) 45-69 (CI)	202 170-232	365 161-569	69 54-84	206 175-236	433 283-583
SCFC	104 69-139	325 187-436	677 143-1209	110 82-138	234 183-286	558 314-801

Table 1.

Conclusion: The rapid fe-calprotectin test is an accurate test and predicts remission in UC and CD patients better than a conventional commercial fe-calprotectin kit

Introduction: Bowel Urgency (BU), identified as the sudden need for bowel movements, is increasingly being recognized as an impactful symptom in patients with Ulcerative Colitis (UC), distinct from Stool Frequency (SF) and Rectal Bleeding (RB).

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: We aimed to assess the association of bowel urgency (BU) with Patient-Reported Outcomes (PRO), including stool frequency (SF) and rectal bleeding (RB), along with endoscopic findings in a real-world setting. Additionally, we investigated its impact on disability and quality of life.

A cross-sectional multicenter study, which consecutively enrolled UC patients aged ≥ 18 years, was conducted between February 2023 and October 2023 using data from the 'IBD-Disk: Italian translation and validation study. Demographic, clinical and endoscopic data were collected. Clinical remission was defined as partial Mayo score ≤ 1 and endoscopic activity as MES ≥ 2. All patients completed the following questionnaire for disability IBD-Disk and IBD Questionnaire-32 (IBDQ-32) for quality of life. BU was assessed using the question about regulating defecation in the past 7 days using a 10-point NRS ranging from 0 (absolutely disagree) to 10 (totally agree) from the IBD-Disk. RB was measured from question 22 of IBDQ and SF from question 1 of IBDQ-32, both using a 7-point NRS ranging from 0 (always) to 7 (never).

Results: 209 UC patients with a median age of 37 (IQR 28-52) were enrolled, 111 (53.1%) being female. Overall, 31 (14.8%) had proctitis, 91 (45.5%) had left colitis and 87 (41.6%) had extended/pancolitis. The median pMAYO score was 4 (IQR=2-6), while the median MES was 2 (IQR=1-2). 75% patients (35.9%) reporting BU were more likely to have moderate clinical (pMAYO=5; IQR=3-6) and endoscopic activity of disease (median MES=2; IQR=1-2) compared to those without urgency (p< .0001). Additionally, BU was associated with a higher median rate of hospitalizations in the previous 12 months (Δ=1; p<0.001). Patients with BU reported a higher degree of RB (33.3%) and SF (50,7%) than patients without BU (p< .0001). Noteworthy, individuals with BU had higher median IBD-Disk total score (29; IQR=9-52) and lower scores for IBDQ-32 (168; IQR=138-196) compared to patients without BU [median IBD-Disk=17 (IQR=5-39); median IBDQ-32=181, IQR=158-202), p<0.001]. In the univariate analysis, BU was associated with a higher IBD-Disk total score (OR=1.04, CI=1.02-1.06; p<0.001) and SF (OR=0.59, CI=0.45-0.78; p=0.001), without being associated with RB (p=0.57) and IBD-Q32 total score (p=0.84).

	BU (n=75)	No-BU (n=134)	OR (CI 95%)	p value
pMAYO score, median (IQR)	5 (3-6)	1 (0-3)		p<0.001
pMAYO >1, n (%)	60 (80,0%)	62 (46,3%)	4,6 (2,4-9,0)	p<0.001
MES, median (IQR)	2 (1-2)	1 (1-2)		p<0.001
MES ≥2, n (%)	53 (70,7%)	54 (40,3%)	3,6 (1,9-6,5)	p<0.001
Relapes in prev 12 months, median (IQR)	1 (0-1)	0 (0-1)		p<0.001
RB, n (%)	25 (33,3%)	9 (6,7%)	6,9 (3,0-15,9)	p<0.001
SF, n (%)	38 (50,7%)	12 (8,9%)	10,4 (4,9-22,0)	p<0.001
IBD Disk, median (IQR)	29 (9-52)	17 (5-39)		p<0.001
IBDQ-32, median (IQR)	168 (138-196)	181 (158-202)		p<0.001

Conclusion: BU can be a surrogate marker for UC clinical and endoscopic activity. Our findings suggest that BU is an independent factor from RB and it is associated with disability. Hence, it can be considered as an additional key PRO in UC. However, a systematic standardized approach for BU definition and assessment is strongly awaited to incorporate it as treat-to-target endpoint.

Contact E-Mail Address: joaogoncalves92@gmail.com

Introduction: Capsule panendoscopy is increasingly used in Crohn's disease (CD), particularly in patients with extensive small bowel and colonic involvement. It offers a non-invasive, one-step evaluation of both segments, making it appealing for disease monitoring and treatment response. However, there is a need for validated scoring systems that objectively assess inflammatory activity in both the small bowel and the colon.

Aims & Methods: The aim of this study was to externally validate the Eliakim Score (Elk-S), developed to assess mucosal inflammation in CD by capsule panendoscopy. Patients referred for PillCam™ Crohn's examination at our institution were selected, and procedure data were collected retrospectively to calculate the Elk-S.

Results: A total of 72 patients were included, 62.5% female, with a mean age of 42±15 years. In 52 (72.2%) individuals, the indication for the procedure was suspected CD. Among them, the diagnosis was rejected in 38 cases, while in 14 cases, the diagnosis was established. There was a significant difference in mean Elk-S between the two groups (5.3±1.5 vs. 21.8±5.3, respectively; p<0.001). Capsule panendoscopy was used to evaluate inflammatory activity in 20 (27.8%) patients with CD. Treatment remained unchanged in 10 cases, while therapy was intensified in 10 patients, and there was a significant difference in mean Elk-S between the two groups (2.2±0.5 vs. 17.1±2, respectively; p<0.001). The Elk-S demonstrated an area under the ROC curve of 0.979 for the diagnosis of CD and 0.875 for predicting therapeutic escalation. An Elk-S ≥ 7 (Table 1) had a Sensitivity, Specificity, Negative Predictive Value, and Positive Predictive Value of 100%, 89.5%, 100%, 77.8%, respectively, for the diagnosis of CD. To determine the need for therapeutic intensification in patients with established CD, the same cut-off value showed a Sensitivity, Specificity, Negative Predictive Value, and Positive Predictive Value of 90%, 70%, 87.5%, 75%, respectively.

Elk-S cutoff: ≥7	Sensitivity	Specificity	NPV	PPV
CD Diagnosis	100%	89.5%	100%	77.8%
Treatment intensification	90%	70%	87.5%	75%

Table 1: Performance of the Elk-S for diagnosing CD and predicting therapeutic escalation.

Conclusion: The Elk-S exhibited high accuracy in establishing the diagnosis of CD and was equally useful in predicting the need for therapeutic intensification in cases of established CD. The present study represents the first external validation of the Elk-S, demonstrating its effectiveness for assessing inflammatory activity via capsule panendoscopy of both the small bowel and colon.

Contact E-Mail Address: iacuccim@yahoo.it

Introduction: Clinical trials are ongoing to develop novel therapies for ulcerative colitis (UC), aiming to break the existing therapeutic ceiling. Mirikizumab, a monoclonal antibody targeting the p-19 subunit of IL-23, was evaluated in a phase-II clinical trial for the treatment of moderate-to-severe UC. Identifying predictive variables for response to therapy is still an unmet need and would serve as a valuable asset in clinical trials and clinical practice to guide therapeutic strategies.

Aims & Methods: This post-hoc data analysis aimed to identify variables predicting response to mirikizumab in UC patients from a phase II clinical trial. One-hundred and six randomly selected patients from the induction phase were considered: 26 (24.5%) were assigned to receive mirikizumab 50mg IV Q4W, 37 to 200mg IV Q4W (34.9%), 30 to 600mg IV Q4W (28.3%) and 13 to placebo (12.3%). In the maintenance phase, 44 received 200mg SC Q12W (42.3%), 47 received 200mg SC Q4W (45.2%), and 13 received placebo (12.5%). Patients who did not achieve clinical remission (14, 13.2%) were excluded from the analysis related to the maintenance phase.

A stepwise analysis was conducted, initially using a principal coordinate analysis (PCoA) with permutational multivariate analysis of the variance (PERMANOVA), followed by a univariate analysis (Fisher's or Wilcoxon signed-rank test) to select significant variables (p<.05).

Further, a country-nested, three-visit repeated-measured generalized mixed ordinal logistic regression model (GLM) using significant PCoA variables was conducted. For both models the endpoint was histological remission at weeks 12 and 52, defined as Geboes score <2.

Results: At week 12, histological remission was achieved in 34 patients (32.1%) while at week 52 in 42 patients (39.6%). PCoA, PERMANOVA and univariate analysis considered histological remission to be significantly predicted by faecal calprotectin, endoscopic remission (Mayo 0, UCEIS ≤1) and induction therapy at weeks 12 and 52 (p<.05). Also, at week 52, the 32-IBD Questionnaire (systemic symptoms and social function), Physician Global Assessment, partial and total Mayo scores, and maintenance treatment were significant.

Considering these as explanatory variables for the GLM, we confirmed the following as significant predictors of histological remission: faecal calprotectin <250 µg/g (Odds Ratio 0.26; 95% CI 0.12-0.58; p<0.001), endoscopic remission (OR 0.16; 95% CI 0.04-0.57; p=.005), induction treatment with mirikizumab 200mg IV Q4W (OR 0.09; 95% CI 0.02- 0.45; p=.004), 600 mg IV Q4W (OR 0.09; 95% CI 0.01-0.50; p=.006) and maintenance with 200 mg SC Q4W (OR 0.05; 95% CI 0.01-0.30; p=.001). A more severe Physician Global Assessment predicted histological activity (OR 2.29; 95% CI 1.03- 5.11; p=.043).

Conclusion: Our predictive model identified faecal calprotectin, endoscopic remission, and Physician Global Assessment as predictive factors for response to therapy. Notably, our model identified the most effective therapeutic strategies to achieve histological remission during induction and maintenance phases, showing promising ability to guide therapeutic choices in clinical trials and clinical practice.

Additional investigation utilizing a larger clinical dataset would further enhance the ability of this model to identify variables predictive of response to therapy.

Introduction: Sarcopenia is prevalent in patients with inflammatory bowel disease (IBD) and impacts surgical and therapeutic outcomes; thus, effective diagnostic tools are needed to assess muscle mass and function in IBD population. The ileo-psoas muscle (IP) muscle has already been used in the literature for the assessment of sarcopenia, however, as it is a deep muscle and it needs experienced operators for a proper measurement. Therefore, diaphragm muscle (DM) more superficial and easily assessed, was examined to check its correlation with IP.

Aims & Methods: The aim of this work was to evaluated the correlation of positivity SARC-F score with ultrasound (US) measure of the IP and DM. A total of 50 IBD patients with significant suspected sarcopenia with SARC-F score positive ≥4, were enrolled. IP and DM US were detected in the enrolled patients. The transverse diameter of the right IP was evaluated.

We defined "reliable" the measurements of the IP that fulfilled all of the following criteria: all anatomical boundaries could be clearly identified (superior margin of the iliac crest and lumbar vertebrae); the maximum diameter of the psoas between each of the three measurements did not deviate from the other two by more than 5 mm. Moreover, we calculated the US psoas/height ratio as the average of the psoas diameter divided by the patient's height (mm/m). For DM, an extended space between the axillary line and the hemi clavicular line was used, in the diaphragmatic thickness between the hyperechogenic limiting. Diameters during expiration and during inspiration were assessed, then diaphragmatic expansion was evaluated.

We calculated the diaphragm/height ratio (mm/m) as well. The correlation between IP and DM ratio was researched by using the Pearson correlation test. Age and sex were taken into consideration as confounders in a linear regression model, using the psoas/height ratio and these confounders as independent variables and the diaphragm index as dependent variable.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The mean of the three US IP measured diameters was 30.37 mm, the psoas/height ratio was 17.92 mm/m. The mean maximum inspiration DM diameter was 20.4 mm (± 5 mm), the mean minimum expiration DM diameter was 10.7 mm (± 35 mm). The mean difference between the two diameters was 9.7 mm (± 3,4 mm). The diaphragm/height ratio was 0.59 mm/m (±0.21 mm/m).

A significant correlation was identified between IP and DM ratio, with a Pearson coefficient r = 0.3568 (p-value <0.05). A consistent association was found between the two indices, with diaphragm/height ratio increasing linearly with the psoas/height ratio (OR: 0.018; p-value: 0.008). Multivariate analysis showed that age and sex were not significantly associated with the diaphragm/height ratio (p-value >0.05).

Conclusion: The findings of this study emphasize the potential of muscle US as a reliable diagnostic tool for assessing sarcopenia in IBD patients. IP US is confirmed to correlate with sarcopenia. DM can be used more easily and correlates with IP. This research could take a significant implications for disease management in IBD patients and underscores the importance of further investigations to validate these findings in larger cohorts. This study will continue to expand the cohort under evaluation.

Contact E-Mail Address: Olga.nardone@libero.it

Introduction: Patients with inflammatory bowel disease (IBD) can face various challenges, including sexual dysfunction, which refers to any physical or psychological perturbation of sexual health. This can manifest through symptoms such as reduced libido, erectile dysfunction, discomfort during intercourse, and other psychosocial issues that negatively impact patients' quality of life. However, uncertainties remain about the magnitude of this problem

Aims & Methods: Therefore, we aimed to assess prevalence of sexual dysfunction in adult patients with IBD. We conducted a systematic review and meta-analysis examining this issue. MEDLINE EMBASE, EMBASE Classic (from inception to 30th March 2023) were searched to identify observational studies that reported prevalence of sexual dysfunction in adult patients with IBD based on validated screening instruments (Female Sexual Function Index (FSFI) and International Index of Erectile Function (IIEF) for women and men respectively). Data were extracted from published study reports, and pooled prevalence, odds ratios (OR), and 95% confidence intervals (CIs) were calculated.

Results: Of 1017 citations evaluated, 18 articles fulfilled eligibility criteria, containing 2,694 patients with IBD recruited from 13 different countries. The pooled prevalence of sexual dysfunction in patients with IBD, was 50.6% (95% CI 40.8% to 60.5%; I2=96.3%). The OR for sexual dysfunction in patients with IBD versus healthy controls was 2.94 (95% CI 1.99 to 4.35, I2=73.4%). When we considered UC or CD separately, the pooled prevalence of sexual dysfunction was 64.8% (95% CI 45.1% to 82.1%; I2=88.8%) in patients with UC, and 58.3% (95% CI 36.0% to 79.0%; I2=95.3%) in patients with CD. When we conducted subgroup analyses based on sex, the pooled prevalence of sexual dysfunction was higher in females with IBD compared with males (62.7% versus 34.0%), with a four-times higher odds of sexual dysfunction. Similar trends were observed when analysing CD and UC patients separately by sex, although limited data were available for this subgroup analysis.

Finally, the pooled prevalence of sexual dysfunction was higher in patients with IBD with active disease compared with inactive disease (75.1% vs 34.2%), with a nine-fold higher odds of sexual dysfunction.

Conclusion: We demonstrated a high prevalence of symptoms of sexual dysfunction in patients with IBD, especially in women with CD. Encouraging gastroenterologists to screen for, and treat, these disorders with a holistic approach might improve quality of life of patients with IBD.

Introduction: Endoscopic and histologic remission are key therapeutic targets in Ulcerative Colitis (UC). Recently, intestinal barrier healing has demonstrated superiority in predicting clinical adverse outcomes. It is promising, especially in patients with primary sclerosing cholangitis (PSC) colitis, which has more aggressive disease behaviour and a higher risk of colorectal cancer.[1]

Hence, novel real-time and in-vivo tools for the intestinal barrier are pivotal.

Aims & Methods: This study aimed to assess intestinal barrier healing in UC using ultra-high magnification endocytoscope (ECS) and automated multispectral imaging. Thirty-four UC patients, 68% with PSC, in clinical remission undergoing surveillance colonoscopy, and 3 healthy controls were prospectively enrolled from two tertiary university referral centres. Ileal, ascending and descending colonic mucosa were evaluated with high-definition, virtual chromoendoscopy, and ECS, with biopsies taken from each segment.

Endoscopic remission was defined as MES ≤1, UCEIS≤1, PICaSSO≤3, while histological remission as RHI≤3 without lamina propria or epithelial neutrophils, NHI ≤1 and PHRI=0. A novel ECS score was applied to assess ileal and colonic intestinal barrier (Table 1).

Furthermore, the barrier was deeply characterised through automated multiplex immunofluorescence (inForm® Akoya Biosciences), quantifying tight junctions (TJs). Specifically, the cell density and mean expression of Claudin-2, Occludin and JAM-A were assessed in all intestinal segments.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patients were followed up for a median of twelve months, and adverse outcomes, including flare-ups, hospitalisation, colectomy and changes in medication, were recorded.

ECS Ileum		ECS Colon	
Normal	0	Crypts architecture	
Break		Normal, elongated	1
	1	Irregular	2
		Necrosis	3
Few gaps / drop-out	2	Infiltration of the cell between the crypts	
Multiple gasp / dropout	3	≤ 50%	1
		> 50%	2
Total Score	0 – 3	Distance between crypts	
		Normal (≥ 3 crypts in a VF)	1
		Elongated (< 2 crypts in VF)	1
		Intermediate (2-3 crypts in a VF with infiltrating cells in LP)	2
		Drop-out / necrosis	3
		Visibility of superficial microvessels	
		Not visible	0
		Visible	1
		Total score	3 – 9

Table 1. ECS score for barrier assessment.

Results: The ECS score moderately correlated with endoscopic scores (r=0.48 for MES, r=0.66 for UCEIS and r=0.63 for PICaSSO) and strongly with histological scores (r=0.69 for RHI, r=0.71 for NHI and r=0.84 for PHRI). Seven patients experienced adverse outcomes, with an ECS score <5 in the colon and <3 in the ileum predicting them (HR 2.35; p<0.01 and HR 5.78; p=0.05, respectively). All TJs were less expressed in UC patients than controls, with Claudin-2 and Occludin predominantly expressed in the epithelium and JAM-A mainly in the lamina propria. Notably, Claudin-2 cell density predicted outcomes (3370 vs 1290; p=0.01) and the ECS score in both colon and ileum correlated with Claudin-2 mean expression and cell density (ρ=.15; p=0.02 and ρ=.48, p<0.01, respectively). The combined intestinal barrier assessment by ECS and Claudin-2 cell density and mean expression significantly predicted outcomes in both colon and ileum (log rank test p<0.01).

Conclusion: ECS demonstrated promising ability to assess intestinal barrier in UC, positively correlating with TJ expression. Moreover, the novel barrier assessment through ECS complemented automated multispectral imaging in predicting adverse outcomes. These innovative tools hold promise in clinical practice for assessing barrier healing and guiding therapeutic management in UC and PSC colitis.

Introduction: While patients with Sickle Cell Disease (SCD) often exhibit digestive manifestations, the underlying pathophysiology remains poorly understood. SCD could notably affect the intestinal mucosa through microvascular phenomena. Co-occurrence of SCD and Inflammatory Bowel Diseases (IBD) has been reported in a very limited number of cases.

Our aim was to explore the intersection between SCD and IBD, particularly focusing on the impact of SCD on the natural course of IBD and the safety profile of drugs in this high-risk population.

Aims & Methods: We conducted a multicenter retrospective case-control study involving all adult patients diagnosed with both IBD and concomitant SCD and followed in 3 tertiary university hospitals. Each IBD patient with SCD was matched with up to 4 IBD patients without SCD, based on disease phenotype (UC or CD), sex, date of birth (±3 years), length of disease follow-up (±2 years), and year of diagnosis (±3 years). The primary outcome was a complicated disease course, defined by a composite outcome including intestinal resection, perianal surgery, and/or the need for advanced therapy.

Results: Overall, 125 patients with IBD were studied, including 24 with concomitant SCD and 101 controls. Of the 24 SCD patients, 5 (20.8%) had Crohn's disease (CD), 17 (70.8%) had ulcerative colitis (UC) and 2 (8.3%) had indeterminate colitis. 23/24 (95 %) had colonic involvement. Of note, 8 of 24 (33.3%) SCD patients had concomitant primary sclerosing cholangitis (PSC) compared to 1% of patients in the control group (p<0.001). Survival without a complicated course of the disease was estimated at 58.7 % (IC95[49.6-69.5]) at 5 years and at 38.9% (IC95[29.9-50.4]) at 10 years, for non-SCD patients, and at 63.3% (IC95[45.7-87.6]) and 52.7% (IC95[34.9-79.6]) at 5 and 10 years, respectively, for patients with SCD and IBD (p=0.36, Log-rank test). The survival without the need of advanced therapy was estimated at 66.1% (IC95[57.3-76.2]) at 5 years for non-SCD patient, and at 78.2% (IC95[63-97.2]) in patients with SCD patients (p=0.45). Regarding the safety profile, 26.3% (5/19) of patients with SCD and 13.5 % (14/104) of controls experienced adverse events with advanced therapies (p=0.17, Fisher's exact test). There was one reported vaso-occlusive crisis associated with the use of thiopurines. No death occurred during follow-up.

Conclusion: While patients with SCD and IBD displayed a distinctive phenotype characterized by nearly constant colonic involvement and a high prevalence of associated PSC, the disease natural history of IBD did not differ from that of patients without SCD. Given the notable prevalence of PSC, systematic screening with cholangio-MRI should be considered. Furthermore, no significant safety signal regarding the use of immunomodulator or advanced therapy was raised.

Disclosure: Nothing to disclose.

Introduction: Sexual function is an important determinant of quality of life (QoL) and may be affected in patients with perianal fistulizing Crohn's disease (pCD). However, the literature on this topic is limited in patients with pCD.

Aims & Methods: Aims: This study aimed to evaluate the sexual function, the correlation between sexual function and quality of life and to identify potential risk factors for SD in patients with active pCD in a national prospective multicenter cohort study.

Methods: Patients with active pCD were identified from a prospective multicenter cohort study in 41 Dutch hospitals. Respondents on the sexual function (FSFI [female patients] or IIEF-5 [male patients]) and HR-QoL questionnaires (CAF-QoL scale and sIBDQ) were included in this study. Primary outcome was the prevalence of SD (FSFI<26.55, IIEF-5<22). Correlation for SD with HR-QoL was assessed with Spearman's correlation test. Potential risk factors for SD were identified using multivariable logistic regression.

Results: 214 patients with active pCD were included. Median age of the study cohort at inclusion was 37 years (IQR 30 – 51) and 52% of the patients were female. The median CD duration and median pCD duration comprised 8 years (3 – 17) and 4 years (2 – 8). The median FSFI and the median IIEF-5 scores were 19 (IQR 3.0 – 27) and 19 (IQR 9 – 24). Overall SD was reported by 69% of the patients and was more prevalent in female patients (75%) as compared to male patients (63%) without reaching significance (p=0.07). A significant higher CAF-QoL score (i.e. decreased pCD-related QoL)(median score 54 points vs. 35 points, p<0.01) and significant lower sIBDQ (i.e. decreased IBD-related QoL)(median score 46 points vs. 52 points, p<0.01) were observed in patients with SD. In addition, SD patients reported significantly more depressive symptoms (49% vs. 27%, p<0.01) as compared to patients with no SD. Higher rates of fatigue were reported in patients with SD, but did not reach significance. A weak correlation of SD with the CAF-QoL scale (r=0.25) and sIBDQ (r=-0.24) was observed. Multivariable analysis identified an older age (aOR 1.0; 95% CI 1.0 – 1.1), a longer pCD duration (aOR 0.9; 95% CI 0.8 – 0.9) and a decreased pCD-related QoL)(aOR 1.0; 95% CI 1.0 – 1.1) were independently associated with SD (**Table 1).**

Variable	aOR	95% CI
Female sex	1.7	0.8 - 3.3
Age at baseline*	1.0	1.0 - 1.1
pCD duration*	0.9	0.8 - 0.9
Low educational level	1.7	0.6 - 5.3
Active luminal disease	1.3	0.7 - 2.7
Seton in situ	0.8	0.4 - 1.6
Ostomy in situ	0.9	0.4 - 2.7
Self-reported depressive symptoms	1.2	0.5 - 2.9
Self-reported fatigue	1.1	0.4 - 2.8
CAF-QoL scale*	1.0	1.0 - 1.1
sIBDQ	0.9	0.9 - 1.1

Table 1. Multivariable logistic regression

Abbreviations. aOR = adjusted odds ratio; CI = confidence interval; pCD = perianal fistulizing Crohn's disease;
CAF-QoL= Crohn Anal Fistula - Quality of Life; sIBD = short Inflammatory Bowel Disease Questionnaire

Conclusion: Sexual dysfunction is highly prevalent in both male and female patients with pCD. A weak correlation between HR-QoL and SD was observed. An older age and a decreased pCD-related QoL were identified as risk factors for SD. Reversely, a longer pCD duration was identified as protective factor. Due to the high prevalence, the sexual function should be evaluated routinely by the treating team. When necessary, a referral to an expert may be considered.

Disclosure: Nothing to disclose.

QUALITY OF CARE IN INFLAMMATORY BOWEL DISEASE THROUGH PATIENTS' EYES: VALIDATION OF THE PORTUGUESE VERSION OF IQCARO-QOC QUESTIONNAIRE

S. Ramos Lopes[1], M. Teixeira[1], D. Tomás[1], C. Sequeira[1], C. Teixeira[1], E. Gamito[1], A.L. Alves[1]
[1]Unidade Local de Saúde da Arrábida - Hospital São Bernardo, Gastroenterology Department, Setúbal, Portugal

Contact E-Mail Address: saramarlopes@gmail.com

Introduction: As a chronic disease, patients' perspectives of the quality of care (QoC) provided are increasingly recognized as an essential aspect of inflammatory bowel disease (IBD) management and an essential standard for units that manage patients with IBD[1].

Aims & Methods: Aims:

- Primary: Translation and validation of the Portuguese version of the IQCARO-QoC decalogue[2].
- Secondary: identify factors associated with a perception of better QoC.

Methods: A unicentric cross-sectional study was conducted in an IBD unit in a non-tertiary hospital. All consecutively evaluated IBD patients in the outpatient setting between january and december 2023 were included. Demographic and disease characteristics were collected.

The original version of IQCARO-QoC decalogue was translated and adapted into Portuguese (independent forward and back-translation).

Validity was assessed through correlation between IQCARO-QoC and visual analogue scale (VAS). Fiability was assessed through internal consistency, test-retest and intraclass correlation. Test–retest (4-week repeat) was used for measuring reliability.

Factors associated with QoC were analyzed.

Results: A total of 114 patients were included (51% female; mean age: 44±15years), of whom 63% had Crohn's disease. 69% of patients were receiving biological therapy. Among the patients, 24% were solely in clinical remission and 48% in both clinical and endoscopic remission. 31 patients (27%) perceived their disease to be in remission.

The mean IQCARO score was 9.3±1.9. Construct validity analyses demonstrated moderate-to-strong correlations between the IQCARO-QoC and VAS. The IQCARO-QoC exhibited high internal consistency (Cronbach's $\alpha = 0.703$) and intraclass correlation (intraclass correlation coefficient = 0.622).

In univariate analysis, concerning patients' self-assessment of disease activity, those who considered their disease to be in remission reported higher IQCARO scores (p=0.02). Individuals with higher educational levels tended to perceive higher QoC (p=0.037). Disease duration, previous surgeries, hospitalizations, and number of outpatient appointments did not exhibit a statistically significant impact on QoC perception. Regarding quality of life, as assessed by the SIBDQ[3] with a mean score of 50.7±12.1, a statistically significant positive correlation was observed between QoC and the SIBDQ (r=0.276, p=0.004).

Multivariate analysis revealed that education significantly influenced the perception of QoC provided ($\beta = -0.284$ [-1.490; -0.340], p=0.002).

Relationship between clinical outcomes and IQCARO-QoC	IQCARO-QoC
Treatment (Conventional vs Biological/ Advanced therapies)	p=0.099
Previous intestinal surgery	p=0.296
Hospitalization related to IBD	p=0.346
Clinical remission	p=0.877
Clinical and endoscopic remission	p=0.624
Patient-reported disease activity	p=0.02
Education	p=0.037
Disease duration	r=0.112 (p=0.256)
Quality of life (SIBDQ-PT)	r=0.276 (p=0.004)

Conclusion: The Portuguese version of the IQCARO-QoC is a simple, valid, and reliable tool for assessing the QoC perception among patients with IBD in clinical practice.

Furthermore, these observational data suggest an association between patients' perspectives of QoC and their evaluations of disease activity and quality of life. In our cohort, education emerged as an independent predictor influencing the perception of QoC received.

Introduction: Recurrence of Crohn's disease (CD) after ileocolic resection is common. However, reliable non-invasive monitoring methods are lacking, for instance, the use of faecal calprotectin (FC) has showed inconsistent results in this subgroup of patients.

Aims & Methods: The aim of this study was to evaluate clinical and biochemical factors associated with post-operative endoscopic recurrence in CD patients.

Retrospective single-center study including patients with CD who underwent ileocolonoscopy for CD surveillance, after ileocolic resection. The patients' clinical status was evaluated through Harvey-Bradshaw index (HBI), with clinical remission considered as ≤ 4 points. Biochemical parameters included erythrocyte sedimentation rate (ESR), c-reactive protein (CRP) and FC.

Clinical and biochemical parameters were evaluated in the 6 months prior to ileocolonoscopy. Post-operative endoscopic recurrence was defined as a Rutgeerts score ≥ i2b.

Results: A total of 81 patients and 121 ileocolonoscopies were included. Most patients were female (55.6%), with a mean age of 48±13 years. Regarding the Montreal classification, 37 patients had ileal disease (45.7%) and 44 ileocolonic disease (54.3%); 9 patients had nonstricturing, nonpenetrating disease (11.1%), 35 stricturing (43.2%) and 37 penetrating disease (45.7%). Nineteen patients had perianal disease (23.5%). The mean time between the surgery and the endoscopic evaluation was 135±79 months. Post-operative endoscopic recurrence was observed in 52 ileocolonoscopies (43.0%).

Symptomatic patients (HBI > 4 points) were 11 times more likely to have post-operative endoscopic recurrence (OR 10.686, 95%CI 2.930-38.974, $p<0.001$). Those with post-operative endoscopic recurrence had a significantly higher FC values (median 189 *vs* 69 µg/g, $p<0.001$) and higher ESR

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. values (median 14 *vs* 9 mm, *p*=0.002). In fact, patients with FC values ≥ 150 µg/g and those with ESR values > 12 mm were 4 and 3 times more likely to have post-operative endoscopic recurrence (OR 3.654, 95%CI 1.605-8.316, *p*=0.002 and OR 3.059, 95%CI 1.397-6.696, *p*=0.005, respectively). The presence of post-operative endoscopic recurrence was not associated with CRP values (median 2.9 *vs* 2.9 mg/L, *p*=0.466), and neither with mean time between the surgery and the endoscopic evaluation (mean 126±83 *vs* 142±75 months, *p*=0.263).

Conclusion: The presence of symptoms (HBI > 4 points), FC values ≥ 150 µg/g and ESR values > 12 mm was associated with post-operative endoscopic recurrence in CD. Therefore, the HBI, FC and ESR values can be used to monitor CD patients after ileocolic resection, and prompt endoscopic evaluation should be performed in those with HBI > 4 points, FC values ≥ 150 µg/g and/or ESR values > 12 mm.

ASSESSMENT OF A REMOTE CALPROTECTIN MONITORING TOOL IN IBD: A COMPARATIVE AGREEMENT ANALYSIS OF A CLASSICAL LAB-BASED ASSAY AND A MOBILE PHONE-BASED QUANTITATIVE PATIENT SELF-TEST

H. Solhaug[1], A. Qamar[1], K. Sikorski[1], M. Schartum[1], L. Tommerup[1], E. Moerk[1]
[1]Calpro AS, Lysaker, Norway

Introduction: Several treatment guidelines and published clinical consensus studies recommend using fecal Calprotectin as a monitoring tool for IBD. Available analysis methods range from well-established laboratory analysis methods to more recently developed rapid methods for remote monitoring and point of care.

Since there is no international reference for calprotectin, an established agreement between different assay platforms is needed to use them interchangeably. Ideally the assays from the same manufacturers should measure fecal calprotectin equally, although this is not always the case.

This study compares fecal calprotectin measurements from two different assay platforms from the same manufacturer.

Aims & Methods: 131 fecal samples from IBD patients were measured using CalproLab ELISA ALP (CALP0170) and CalproSmart Self-Test for remote monitoring of IBD. All fecal samples were extracted and analysed in parallel according to the kit-specific instructions given by the manufacturer, requiring individual sample collection and extraction methods for both assays. 64 samples covered the linear range for the assays and were included in the method comparison analysis.

Results: When comparing the two analysis methods, the slope and intercept values of 0,92 and 4,44 respectively suggest that there is no significant difference between the two methods within their common linear range. This includes all relevant clinical cut-off values for the two methods. Furthermore, the relative difference between the two assays ranges from -1,9% to -6,8% at selected calprotectin values.

Calprotectin values [mg/kg]	Relative difference [%]
77	-1,9%
100	-3,2%
200	-5,5%
250	-5,9%
500	-6,8%

Table 1: The relative difference between CalproSmart and CalproLab ELISA at selected calprotectin values.

Conclusion: CalproSmart and CalproLab ELISA measures fecal calprotectin equally and can be used interchangeably.

Disclosure: All authors are employees at Calpro AS. Experiments performed at Calpro R&D lab.

Introduction: Data on using Intestinal Ultrasonography (IUS) for monitoring colonic lesions and treatment response in ulcerative colitis (UC) are still limited and most results are from single-center units usually performed in centers with a special expertise in IUS.

Aims & Methods: Our multicenter study aimed to identify predictive factors and monitor early response after different therapies in UC.

Methods: From July 2022 to Oct. 2023, we conducted a multicenter study at 5 IBD centers. UC pts starting biological therapies or small molecules were included, and underwent colonoscopy (CS), IUS, clinical assessments at baseline and at 12 weeks. All pts received standard of care therapy according to ECCO guidelines.

Exclusion criteria were disease limited to the rectum, active infections, and inability or contraindication to perform CS and/or IUS within the time intervals established by the study. Colonic wall thickening (CWT), vascularization (CWF), Milan Ultrasound Criteria (MUC), Mayo endoscopic score (MES), total/partial Mayo score were evaluated.

Results: Eighty-four UC patients were enrolled and eligible for starting biological therapy or small molecules. Forty-nine out of 84 pts (58.4%) were male, 40 pts (47.6%) had extensive colitis and 44 pts (52.4%) had left colitis, with a disease duration of 20 months (1-336); 53 pts (63%) were steroid-dependent/refractory.

Forty-one pts (48.9%) started anti-TNFs, 14 pts (16.6%) anti-IL12/23 or anti IL 23, 16 pts (19%) vedolizumab, and 13 pts (15.5%) JAKi. After 12 weeks, 39 out of 84 patients (46.4%) had partial Mayo score<2, 31 patients (36.9%) 2-4, 10 patients (11.9%) 5-7, and 4 patients (4.76%) >7.

Forty-three out of 84 patients (51.2%) had MES=0-1, while 41 out of 84 patients (48.8%) had MES=2-3. Fifteen out of 84 patients (17.9%) had ultrasonographic response (defined as CWT<3mm) and 26 out of 84 patients (30.1%) had MUC<6.2 (*1*). Logistic regression was performed to evaluate the relationship between clinical/endoscopic and ultrasonographic

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

characteristics and early IUS response at 3 months. Univariable analysis showed that active smoking ([RR], 1.9; 95% CI, 1.2–3.1, p<0.005), appendectomy ([RR], 2.5; 95% CI, 1.9–3.2, p<0.0001), partial Mayo score <2 ([RR], 2.18; 95% CI, 1.5–3, p<0.001) were associated with higher risk of response at 3 months. Inversely, severe endoscopic lesions (MES 3) (RR, 0.3; 95% CI, 0.2–0.6; p<0.0001), presence of lymph-nodes, mesenteric hypertrophy and vascularization (p<0.001, RR 0.36, 0.28, 0.45 respectively) were associated with a lower risk of response at 3 months. CWT was associated with a lower risk of response at 3 months (RR 0.66, 95% CI, 0.53-0.81, p<0.0001) and every increased mm was associated with a 34% reduction of IUS response. MUC was associated with a lower risk of response at 3 months (RR 0.78, 95% CI, 0.7-0.87) and every increased of one point was associated with a 22% reduction of IUS response.

In the multivariable analysis, CWT and MUC were the only predictive factors associated with IUS response at 3 months (RR 0.70, 0.78 respectively, p<0.04). A CWT<5.5 mm showed a 2.5 risk of treatment response at 3 months.

Conclusion: Our multicenter study demonstrated that IUS allows close monitoring of treatment in UC. MUC, and in particular CWT, are valuable parameters to predict early response in UC.

EVALUATION OF THE IMPACT OF AN IBD NURSE IN AN INFLAMMATORY BOWEL DISEASE CENTER

A. Rachart[1], V. Cluzeau[1], C. Martins[2], X. Hebuterne[1], A. Nicolau[1]
[1]Hospital Archet 2, Nice, Department of Gastroenterology and Clinical Nutrition, Nice, France, [2]APHP, Gastroenterology, Paris, France

Contact E-Mail Address: nicolau.a@chu-nice.fr

Introduction: In some European countries, IBD nurse is not a recognized status. IBD nurses are general care nurses who wants to improve their knowledges and get involved in the « Care and Support » of IBD patients. An increasing number of IBD centers are using the services of IBD nurse. It seems important to evaluate the role and impact of IBD nurse.

Aims & Methods: The aim of this study was to evaluate prospectively the activity and impact of IBD nurse on the management of IBD patients in an IBD center. From March 13th to June 13th, 2023, all patients having interacted with IBD nurse in an expert center, were prospectively recorded. The main points were, the number and characteristics of patients, means and reasons of contact, actions implemented, follow-up and, finally, patient satisfaction assessed using a standardized questionnaire (visual analog scale from 0 to 10).

Results: During three months, 132 patients, 69 women and 63 men (47% Ulcerative Colitis, 52% Crohn's disease and 1% indeterminate colitis), with a median age of 40 years (16 to 87), had contacted the IBD nurse. Contact were made by phone call: n =131 (42%), text messages: n = 25 (8%), e-mail: n = 69 (22%), face-to-face consult: n = 86 (27.5%) and teleconsultion: n = 1 (0.5%).

The reasons for contact were: advices/questions/information: n = 121 (39%), a scheduling/organization appointment issue: n = 60 (19%), care-providing (biological check-up + starting treatment): n = 77 (25%), emergency: n = 22 (7%), request for an appointment/Information with IBD nurse: n = 19 (6%), request for a patient education session (PE): n = 13 (4%).

The 312 contacts had led to 315 actions divided into seven groups:

Action realized	Number of patients (n)	Percentage (%)
Explanation/Reinsurance	166	53%
Implementations or renewing prescription /administrative documents	55	17%
Scheduled visit (doctor, dietician, Nurse, Patient education program, outpatient unit, ...)	40	132%
Nursing care/learning self-care	25	8%
Referral to Patient Education Program	19	6%
Referral to emergency department or another department	7	2%
Patient hospitalization	3	1%

Over this period, IBD nurse was contacted 22 times by 19 patients for a real or perceived emergency. These situations were managed by a multidisciplinary team, and resulted in reinsurance (68%), referral to others medical specialist (18%) or hospitalization (14%).

Overall satisfaction with the IBD nurse intervention has been evaluated at 10/10 for 78% of patients and 9/10 for 11%. To the question: "do you think that the intervention of the IBD nurse improves disease management?": 78.5% agreed at 10/10 and 7% at 9/10. To the question: "do you think contact with the IBD nurse improves access to care: 67.5% agreed at 10/10 and 3.5% at 9/10.

The main patients' advice / reviews to improve care were: to adjust levels of follow-up according to the patient and his/her needs, to strengthen the IBD Nurse coordination team to limited days off, to have explanation sheets and reports of IBD Nurse intervention, to develop more workshops for patients in the Education program.

Conclusion: This pilot study showed the importance of the IBD Nurse activity in an expert center. The patients who benefited from this care were very enthusiastic about it.

Disclosure: This study has been funded by Janssen Pharmaceuticals.

PP0490

METAGENOMIC SEQUENCING IN DE NOVO PEDIATRIC INFLAMMATORY BOWEL DISEASE VERSUS CONTROLS WITH AND WITHOUT GASTROINTESTINAL SYMPTOMS

F. Prins[1], E. Vermeer[2], I.J. Hidding[1], J. Jagt[3], R. Gacesa[1], R.K. Weersma[1], N.KH de Boer[4], T.G. de Meij[5]

Contact E-Mail Address: f.m.prins@umcg.nl

Introduction: Inflammatory bowel disease (IBD), including Crohn's disease (CD), ulcerative colitis (UC), and IBD-unclassified (IBD-U), often manifests in adolescence or young adulthood, with a trend towards decreasing age at presentation. Current diagnostic protocols for pediatric IBD involve an invasive colonoscopy under general anesthesia to differentiate between IBD and other conditions, such as functional abdominal pain and irritable bowel syndrome.

Previous microbiome research indicates significant differences in microbial composition of pediatric IBD patients compared to healthy controls (HC), illustrating its potential as non-invasive biomarker for pediatric IBD,

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

but an IBD-specific microbial signature has not yet been defined(1). This study aims to profile the microbiome in de novo pediatric IBD patients compared to controls with gastrointestinal symptoms (CGI), and HC.

Aims & Methods: We collected baseline fecal samples and clinical data from a cohort of de novo pediatric IBD patients and CGI. Consecutively, we matched all included patients from this cohort to a HC cohort from the Dutch Microbiome Project, based on age and sex. Metagenomic sequencing was performed to obtain data on bacterial species and functional pathway abundances. Diversity, dissimilarity and differential abundance analyses were conducted for bacterial species and pathways across various group comparisons.

Additionally, prediction analysis using Coda4Microbiome was performed to differentiate IBD from HC, IBD from CGI, and to predict treatment outcomes based on both microbial features and clinical features, including disease activity scores and inflammatory markers.

Results: We included 99 de novo IBD patients (66 CD, 27 UC, 6 IBD-U) and 74 CGI, matched to 341 HC. Microbial composition differed significantly across HC, CGI and IBD groups. Alpha-diversity decreased progressively from HC to CGI (p<0.001), further decreasing in IBD patients (p=0.0056). Disease status significantly explained a part of microbiome composition variance (beta-diversity, p=<0.001, R2=0.045), with distinct clustering patterns between HC, CGI and IBD samples. Differential abundance analysis revealed 116 differential abundant species between HC and IBD, and 30 species between CGI and IBD. We observed an increase in *F. prausnitzii* (p=<0.001) in IBD compared to HC. Prediction models accurately distinguished IBD from HC using microbiome features (microbiome: AUC=0.96±0.02, clinical + microbiome: AUC=0.96±0.02) based on high abundance of *G. pamelaeae* and low abundance of *A. communis*, and IBD from other diseases (microbiome: AUC=0.72±0.10, clinical + microbiome: AUC=0.83±0.09), based on high abundance of *E. coli* and low abundance of a *Clostridia* species. Prediction of response to diet-based induction of remission in CD patients using baseline microbiome features yielded an AUC of 0.67±0.13, suggesting a potential effect of the gut microbiome, possibly limited by our non-responder numbers.

Conclusion: This study confirmed previous findings of profound microbiome differences between de novo pediatric IBD patients and HC. Additionally, we observed distinct microbiome compositions between CGI and IBD. Although clinical and biochemical models are often effective in distinguishing IBD from other diseases, our prediction models demonstrated that microbiome features have predictive power as well, including for predicting responses to nutrition-based treatments. Given the non-invasive nature of fecal sample collection, integrating microbiome features into future clinical diagnostics shows promise for improving diagnostic and therapeutic precision.

IS TRANSMURAL HEALING BETTER THAN MUCOSAL HEALING IN PEDIATRIC CROHN'S DISEASE?

G. D'Arcangelo[1], L. Carnevale[1], S. Oliva[1], F. Maccioni[2], G. Russo[1], L. Busato[2], M. Aloi[1]

[1]Sapienza University of Rome, Pediatric Gastroenterology Unit, Rome, Italy, [2]Sapienza University of Rome, Rome, Italy

Contact E-Mail Address: giuliadarcangelo87@gmail.com

Introduction: Data on the long-term benefit of transmural healing (TH) are scarce in children.

Aims & Methods: We investigated the outcomes of pediatric Crohn's disease (CD) patients with TH comparing them to those with mucosal healing (MH) and with "no healing".

We conducted a prospective, single-center, observational study conducted at the Pediatric Gastroenterology Unit of Sapienza University of Rome. Children with an established diagnosis of CD and under biological therapy undergoing an MRE and an ileocolonoscopy within a 3-month interval were consecutively enrolled. TH was defined as the complete healing of both the mucosa at endoscopy and of the bowel layers at the MRE. In the presence of a normal colonoscopy but an active MRE children were deemed as MH. The group "no healing" (NH) included children with an active endoscopy, regardless of the MRE classification. At 6, 12, and 24 months number disease flares, CD-related hospitalization, CD-related surgery, need for step-up treatment, and occurrence of complications were collected.

Results: 93 children were included (mean age 11,2±3,8). Twenty-three (25%) were classified as TH, 27 (29%) as MH and 43 (46%) as NH. The risk of any unfavorable outcome was lower in both TH and MH patients compared to NH (Log Rank p<0.0001 and p=0.002). Children with TH were at lower risk of hospitalization (p=0.02), and complications (p=0.007) compared to those with NH.

No difference was found between MH and NH children for the same outcomes. Both TH and MH children were at lower risk of step-up treatment (p<0.0001 and p=0.0002, respectively) compared to NH. TH and MH patients were comparable for all the outcomes evaluated.

Conclusion: Achieving TH in pediatric CD is associated with better outcomes, although the additional benefit over MH alone does not appear significant. However, the persistence of inflammation is associated with worse outcomes in all patients.

Disclosure: Nothing to disclose.

A COMPREHENSIVE ASSESSMENT OF FECAL INCONTINENCE, SEXUAL FUNCTION, AND QUALITY OF LIFE IN INFLAMMATORY BOWEL DISEASES

J. Vastarella[1], S. Camera[1], A. Di Domenico[1], L. Ruggiero[1], N. Sica[1], M. Angiuoni[1], A. Santonicola[1], P. Iovino[1]

[1]University of Salerno, Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana", Salerno, Italy

Contact E-Mail Address: josephinevastarella@gmail.com

Introduction: Inflammatory bowel diseases (IBD) are chronic systemic conditions that affect patients' lives in various ways. To date, there is a scarce evidence correlating fecal incontinence, sexual dysfunctions, disease activity, and quality of life (QoL) in these patients.

This study aimed to evaluate the impact of fecal incontinence on sexual functions such as erectile and prostatic function in a cohort of IBD patients; and to analyse the relationship among fecal incontinence, sexual function and QoL.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: IBD patients were enrolled from IBD clinic of the Gastroenterology Unit of the University Hospital of Salerno. Demographic characteristics, anthropometric data, and usage of immunosuppressive drugs were collected. Patients underwent a physical examination, and laboratory tests, including C-reactive protein (CRP) and fecal calprotectin (FC). A standardized questionnaire was used to assess gastrointestinal (GI) symptoms such as abdominal pain and fecal incontinence. For the latter, we also used the Wexner score. Crohn's Disease Activity Index (CDAI) and Mayo score as well as FC levels, and endoscopic findings were used to classify IBD patients as in active or in remission phase. Patients with perianal manifestations were excluded. Hormonal values (FSH, LH, Prolactin, 17-betaestradiol, testosterone) were measured. Sexual function was evaluated using the International Index of Erectile Function (IIEF), Male Sexual Health Questionnaire (MSHQ), Ejaculatory Dysfuction (EjD), prostatic dysfunction using the National Institute of Health - Chronic Prostatitis Symptom Index (NIH-CPSI) and International Prostatic Symptoms Score (IPSS). QoL was assessed by FiQol domains (lifestyle, coping behaviour, self-perception and depression, embarrassment).

Results: Eighty-five male IBD patients (47 Crohn's disease [CD] and 38 ulcerative colitis [UC]), were enrolled. Mean age was 43.7 ± 15.9 years; mean BMI was 36.4±25.5 Kg/m^2. Twenty-four CD patients had an active disease and 23 were in remission, while 20 UC patients had an active disease and 18 were in remission. UC patients showed significantly higher fecal incontinence and Wexner scores compared to CD patients (1.0±1.9 vs 0.4±1.2, p=0.05 and 2.84±4.2 vs 2.3±1.1, p=0.01, respectively). Only the Mayo score significantly correlated with Wexner score (Rs=0.578; p<0.001), and fecal incontinence (Rs=0.584; p<0.001).

Sexual function, evaluated by erectile and prostatic scores, nicely correlated each other's (p<0.05 in all cases). However, no association was found between fecal incontinence and all sexual function scores. The FiQol domain self-perception and depression was significantly associated with IIEF (p=0.01).

Conclusion: This study highlighted the prevalence of fecal incontinence is higher in UC than CD patients. However, fecal incontinence did not impact on sexual function, evaluated by erectile and prostatic scores. QoL influenced erectile function.

Disclosure: Nothing to disclose.

Contact E-Mail Address: vergeslaia@gmail.com

Introduction: The terminal ileum stands out as the most frequently affected segment of the gastrointestinal tract in Crohn's disease (CD). However, ileocolonoscopy (IC) may occasionally fail to fully explore this area. Notably, there is a lack of standardized quality criteria for IC in the context of ileal CD. Additionally, assessing inflammation activity only in the terminal ileum may lead to an underestimation of the overall ileal involvement. Capsule endoscopy (CE) offers a complete examination of both the entire terminal ileum and the remaining ileal segment.

Aims & Methods: This study presents the preliminary analysis of a retrospective study conducted at a single center. The primary outcome is the correlation between the total ileal activity, as assessed by CE, and the activity in the terminal ileum, as evaluated by IC.

Furthermore, we explored the correlation between the results of these two examinations specifically concerning the evaluation of the terminal ileum. Patient inclusion criteria permitted a maximum time interval of 3 months between the two examinations.

Activity measurement for CE was graded with the Lewis score of the third segment of the small intestine (Lewis-3S) and the Lewis score of the terminal ileum (Lewis-TI). For IC, the SES-CD index of the terminal ileum was collected.

The study also includes an analysis of the correlation of endoscopic scores with biochemical markers (PCR, fecal calprotectin). Clinical, blood tests, and therapeutic data from medical records were systematically collected.

Results: A total of 18 patients with ileal CD underwent CE and IC. CE revealed terminal ileum activity in 14 out of 18 patients (78%), whereas IC detected activity in only 4 out of 18 patients (22%).

Notably, no significant correlations between CE and IC scores were observed. A moderate to strong correlation was, however, identified between the two CE scores, Lewis-3S and Lewis-TI (ρ 0.72 [0.31-0.94], p=0.001). The median length explored by IC was 15 [15-20] centimeters.

Importantly, no correlation between endoscopic scores and biochemical parameters was observed, and no adverse events were documented.

Correlation SESD terminal ileum and Lewis 3rd segment ρ	0,391 (p>0,05%)
Correlation SESD terminal ileum and Lewis terminal ileum ρ	0,545 (p<0,05%)
Correlation Lewis third tercer segment and Lewis terminal ileum ρ	0,719 (p<0,05)

Table 1: Correlation between analytical data and between the two explorations.

Conclusion: In this preliminary analysis, despite the limited sample size, our findings indicate an underestimation of global ileal activity when measured by IC in comparison to CE examination.

Disclosure: Nothing to disclose.

Introduction: The BELCOMID study recruited immune mediated inflammatory disease (IMID) patients during the COVID19 pandemic. Patients were evaluated before vaccination, after onset of the vaccination campaign and after onset of booster vaccinations.

Clinical data, Nucleocapsid(N-)antibodies and Spike(S-) antibodies were assessed.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: Current subgroup analysis aimed to firstly, explore factors associated with N-/S-antibody response in IMID patients with different COVID19 vaccination status. Five patient groups were identified. G1: no vaccination before the vaccination campaign, G2: complete baseline vaccination, G3: 1 booster, G4: 2 boosters, G5: patients refusing every vaccine even after the booster campaign. We report on influence of IMID treatment and smoking status.

Secondly, we explored influence of SARS-CoV2 infection and vaccination on IMID flare-up.

Results: Demographics of 2165 recruited IMID patients are shown in *Table*.

After baseline vaccination (G2) odds of N-seroconversion were higher in patients treated with combined IMM/TIMT (OR2.52, p=0.023). No other association with N-seroconversion was found.

Mean S-antibody titre increased progressively from G2 to G4. After completed baseline vaccination (G2), odds of S-antibody seroconversion were lower in those treated with TIMT (OR0.28, p=0.0079) particularly rituximab (OR0.0354, p<0.001), IMM (OR0.276, p<0.001), combined IMM/TIMT (OR0.156, p<0.001) and systemic steroids (OR0.183, p<0.001). IMID flare prior to vaccination was associated with lower risk of S-seroconversion (RR0.94, p<0.001). By contrast, mean S-titre was higher for those treated with antiIL23 (mean ratio 2.17, p=0.011) and vedolizumab (mean ratio 1.84, p<0.001) in G2.

After 1 booster (G3), lower odds of S-seroconversion remained with rituximab (OR0.0368, p<0.001), IMM (OR0.222, p=0.0014), combined IMM/TIMT (OR0.15, p<0.001) or systemic steroids (OR0.0637, p<0.001). Vedolizumab was associated with lower odds of being in the lowest S-titer quartile (OR0.206, p<0.001). Odds for S-antibody seroconversion with anti-TNF were higher compared to rituximab both for patients in G2 (OR26.3, p<0.001) and G3 (OR27.5, p<0.001).

Patients who received 2 boosters (G4) all had S-seroconversion and no IMID treatment modality was associated with higher odds of being in the lowest quartile.

After baseline vaccination (G2) smokers had higher risk of being in the lowest S-antibody titer quartile (RR1.45, p=0.0098). This observation persisted after 1 booster (G3)(RR1.42, p=0.0122) but was no longer noticed after 2 boosters (G4).

After start of booster vaccinations, 25.17% of patients had experienced IMID flare-up in the previous months. No significant association between IMID flare-up rate and previous SARS-CoV2 infection was found. There was no increased risk of IMID flare-up with additional booster vaccination. However, patients who received 2 booster vaccines showed a lower RR for IMID flare-up compared to those who only received 1 booster (RR0.70, p=0.0067).

	G1 (N: 2144)	G2 (N: 1532)	G3 (N: 1283)	Group 4 (N: 147)	Group 5 (N: 40)
Mean age (SD)	44.6 (35.5)	46.9 (30.8)	46.6 (32.7)	51.0 (15.7)	39.4 (14.4)
Male/female	1088 (51.0%) /1047 (49.0%)	794 (51.9%) /737 (48.1%)	661 (51.6%) /621 (48.4%)	80 (54.4%) /67 (45.6%)	24 (60.0%) /16 (40%)
Active smoker	369 (17.2%)	261 (17.0%)	201 (15.7%)	24 (16.3%)	12 (30.0%)
TIMT (targeted treatment)	1580 (73.7%)	1232 (80.4%)	1073 (83.6%)	119 (81.0%)	38 (95.0%)
IMM (immunomodulator)	456 (21.3%)	311 (20.3%)	225 (17.5%)	39 (26.5%)	8 (20.0%)
IMM+TIMT combined	263 (12.3%)	197 (12.9%)	152 (11.8%)	24 (16.3%)	8 (20.0%)
Recent systemic steroids	229 (10.7%)	91 (5.94%)	59 (4.60%)	6 (4.08%)	4 (10.0%)

Conclusion: Certain immune-modulating treatment modalities and smoking may blunt serologic COVID19 vaccination responses. However, this is overcome by repeated booster vaccination without increased risk of IMID flare-up.

Disclosure: The BELCOMID study group received research grants from following pharmaceutical companies: Almirall, Roche, Janssen, Pfizer, Eli Lilly, Amgen, Biogen, Mylan, LEO Pharma. These companies had no role in study design, conduct nor reporting of results.

IBD-DISK AS A PREDICTIVE TOOL FOR INSOMNIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

R. Limam[1], N. Elleuch[1], H. Kallel[1], W. Dahmani[1], A. Hammami[1], A. Ben Slama[1], A. Braham Ep Krifa[1], H. Jaziri[1], M. Ksiaa[1]

[1]*Sahloul Gastroenterology Departement, Sousse, Tunisia*

Contact E-Mail Address: limamrihab33@gmail.com

Introduction: The IBD-Disk is a validated 10-question, self-administered visual questionnaire used to assess the inflammatory bowel disease (IBD) related disability. Insomnia is common in IBD, and is often associated with a decline in patients' quality of life. The Insomnia Severity Index (ISI) is a validated tool that assesses the severity of insomnia in individuals.

Aims & Methods: The aim of this study was to evaluate the role of IBD Disk in the predilection of sleep disorders.

We conducted a cross-sectional study over 3 months between April and June 2023. IBD patients responded to the IBD-Disk and ISI questionnaires. Insomnia and severe insomnia were defined by a "Sleep" sub-score > 5 and > 7 respectively. The correlation between IBD-Disk and the ISI was analyzed using Pearson's correlation coefficient.

Results: We enrolled 57 patients with a mean age of 40.37 years [20-69] and a M/F sex ratio of 1.03.

Two-thirds of patients had Crohn's disease (CD). It was ileal in 14 patients (24.6%), ileocolic in 15 (15.8%), and colonic in 9 (26.3%). Ano-perineal involvement was present in 38.2% of cases. Nineteen patients (33.3%) had ulcerative colitis. Severe disease activity was noted in 14 patients (24.6%).

According to the ISI, insomnia was present in 24 patients (42.1%), distributed as follows: Mild insomnia in 19.3% of cases, moderate insomnia in 17.5% and severe insomnia in 1.8%. Insomnia was associated only with disease activity (p=0.003). According to the IBD Disk "Sleep" sub-score, insomnia was present in 29.8% of patients, distributed as follows: Moderate insomnia in 12.3% and severe insomnia in 17.5%.

A significant correlation was noted between the ISI, the IBD-Disk global score and the "Sleep" sub-score (respectively r=0.506 and 0.609, p<0.001).

Conclusion: The IBD Disk is a psychometric tool that predicts the presence and severity of insomnia in IBD patients.

Disclosure: Nothing to disclose.

Introduction: Currently, most IBD clinics are equipped with endoscopic devices with virtual chromoscopy (VC) and autofluorescence imaging (AFI) screening functions.

These functions allow the mucosa and various neoplasms of the gastrointestinal tract to be examined in more detail and allow a presumptive conclusion to be made about the origin and histological nature of the changes detected.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: To determine the potential of virtual chromoscopy (VC) and autofluorescence (AFI) for the assessment of inflammation in ulcerative colitis (UC) and Crohn's disease (CD).

151 patients with IBD (51 with CD, 100 with UC) were examined by ileocolonoscopy using the Olympus CF FH260AZL endoscope system EVIS LUCERA ELITE CLV-290SL with narrow-spectrum function and autofluorescence function with biopsy. Similar examinations were performed on 45 controls without bowel disease.

Results: Minimal UC showed the absence of venules in VC($p<0.05$), as well as green staining with purple foci in AFI ($p<0.05$). Moderate inflammation was characterised by visualisation of submucosal venules ($p<0.001$) and violet staining of the mucosa with green foci, which was significantly higher than this colour with minimal activity ($p<0.001$).

Autofluorescence diffuse purple staining occurred significantly more often in patients with severe inflammation than in those with less severe inflammation, in those in remission and in controls ($p<0.001$), and two types of vascular patterns were absent in VC ($p<0.001$).

In CD, the infiltration phase was characterised by a statistically significant higher frequency ($p = 0.033$ and $p = 0.006$) of the visualisation of two types of green staining in the autofluorescence mode in comparable amounts than other colour options.

In the ulcer-fissure phase of VC, we observed predominantly capillary or venous visualization in the same amount ($p < 0.001$). In the scar phase, the frequency of the different types of staining was comparable to that in the remission phase and to that in the control group. In the VC, both types of vascular patterns were detected with a significantly higher frequency ($p = 0.001$).

Conclusion: Based on the results of our study, VC and AFI are additional methods in diagnosing the degree of activity of IBD and can be used in difficult cases to clarify the severity of inflammation in patients with UC and CD.

THE VALUE OF FAECAL CALPROTECTIN TESTING IN PATIENTS PRESENTING WITH LOWER GASTROINTESTINAL SYMPTOMS; A RETROSPECTIVE PRIMARY CARE STUDY

N. Umar[1], P. Harvey[2], N. Harvey[3], S. Haroon[3], N. Trudgill[4]

[1]Sandwell and West Birmingham Hospitals NHS Trust/University of Birmingham, Gastroenterology, West Bromwich, United Kingdom, [2]The Royal Wolverhampton NHS trust, Gastroenterology, Wolverhampton, United Kingdom, [3]University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom, [4]Sandwell and West Birmingham Hospitals NHS Trust, Gastroenterology, West Bromwich, United Kingdom

Contact E-Mail Address: nosheen.umar@nhs.net

Introduction: Faecal calprotectin (FC) is of value in differentiating Inflammatory Bowel Disease (IBD) from other causes of lower gastrointestinal (GI) symptoms and is recommended in national guidance. This study aims to examine its role and factors associated with faecal calprotectin requesting in primary care.

Aims & Methods: Retrospective open cohort study using Clinical Practice Research Datalink (CPRD Aurum) of adults aged over 18 years with lower GI symptoms between 2015 and 2019. FC requested 30 days before to 3 months after a lower GI symptom record in primary care were included. Logistic regression analysis explored patient level factors associated with FC testing. Referral pathways and outcomes (IBD diagnoses) of patients with and without FC testing were also examined.

Results: Of 741,190 symptomatic patients, only 18,320 (2.5%) had FC requested in primary care: median age 38.3 (IQR 28.9-50.7); 51.4% female. The rate of FC requesting in symptomatic patients increased from 0.02% in 2010 to 4.4% in 2019 ($p=0.001$).

FC value of <50 ug/g and 50-200 ug/g were predominantly seen in patients with abdominal pain (42.1% and 37.9% respectively), while FC > 200 ug/g was predominantly seen in patients with diarrhoea (45.3%). Factors associated with FC requesting included: increasing age (>70 years adjusted Odds Ratio 0.16 (95% CI 0.15-0.18)); female (0.89 (0.86-0.92); Black (0.61(0.56-0.66) or Asian (0.75 (0.70-0.80) ethnicity; obesity (0.89(0.85-0.93); lower socioeconomic status (0.91(0.86-0.98); comorbidity score >2 (0.73(0.68-0.79); current smoking (0.89(0.85-0.92)); change in bowel habit (7.31(6.90-7.75), rectal bleeding (2.04(1.95-2.13) or diarrhoea (2.88(2.78-2.99) compared to abdominal pain; and ex-smokers (1.06(1.03-1.11).

IBD was diagnosed in 21.5% of patients referred with a FC >200 ug/g, but only 2.9% of referred patients with a FC 50-200 ug/g. The only patients with a significant risk of IBD with FC 50-200ug/g were patients with rectal bleeding (8%), with the risk in all other patients only 1.7%. 27.8% patients with a normal FC test result were still referred to secondary care, of which only 0.4% had IBD.

Conclusion: Despite an increase in FC requests in recent years, only 4.4% of patients with relevant lower GI symptoms had an FC requested in primary care as recommended. Despite a negative FC test, a third of patients were still referred to secondary care, with very few diagnosed with IBD . Patients with an FC between 50 ug/g and 200 ug/g without rectal bleeding have a low risk of IBD and can be safety netted in primary care.

Disclosure: Nothing to disclose.

PP0498

CLUSTERING OF PATIENT-REPORTED OUTCOMES IN INFLAMMATORY BOWEL DISEASES – FINDINGS FROM A DANISH POPULATION-BASED INCEPTION COHORT

M. Attauabi[1,2,3], G. Roager Madsen[2,3], F. Bendtsen[2,3,4], J.B. Seidelin[4,1], J. Burisch[2,3,4]

Contact E-Mail Address: mohamed.attauabi.02@regionh.dk

Introduction: Patient-reported outcomes (PROs) are pivotal in assessing treatment efficacy, delivering patient-centered care, and estimating the burden for inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Crohn's disease (CD).

Aims & Methods: We aimed to investigate PROs at IBD diagnosis, including associated factors.

Since May 1st, 2021, all adult and pediatric patients with incident IBD within a catchment area encompassing 20% of the Danish population were enrolled in the prospective population-based Copenhagen IBD Inception Cohort.[1]

Upon diagnosis, all adult patients diagnosed between May 2021 and May 2023 were asked to report PROs including Short inflammatory Bowel Disease Questionnaires (SIBDQ), IBD-Disability Index (IBD-DI), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F). Symptoms were evaluated using Memorial Symptom Assessment Scale, IBD Symptom Inventory, and Mayo Assessment of Functional Gastrointestinal

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Disease. Multivariable logistical analysis adjusting for gender, age, and disease phenotype was conducted (adjusted odds ratio, aOR (95% confidence interval)).

Results: The population consisted of 203 and 116 patients with UC and CD (66% and 58% of the original cohort), respectively, who completed the PROs questionnaires within a median of 1.2 (IQR 0.3–3.0) months from diagnosis. The only baseline difference between participants and non-participants was a higher proportion of females with UC in the former group (60% vs. 44%, p<0.01).

In total, 160 (79%) and 99 (85%, *p*=0.18) patients with UC and CD, respectively, reported moderate to severe affection of at least one PRO, while 44% and 64% (*p*<0.01), respectively, reported moderate to severe affection of at least two PROs.

Specifically, a higher proportion of patients with CD reported moderately to severely impaired quality of life (QoL) (96 (82.8%)) compared to UC (141 (69.5%), p<0.01). Of those, 33 (82.5%) and 41 (56.9%), respectively, reported simultaneously moderate to severe fatigue and disability (p=0.48), while 19 (19.8%) and 27 (19.1%, p=0.90), respectively, reported moderate to severe QoL and fatigue but not disability. In addition, among 71 (35.0%) and 52 (44.8%) with UC and CD, respectively, reporting moderate to severe fatigue (p=0.08), all but three patients with UC had moderate to severe QoL, while 57.6% and 63.5%, respectively, reported moderate to severe disability. Accordingly, FACIT-F correlated strongly with SIBDQ in both UC (Pearson correlation coefficient (PCC) 0.76 (0.70-0.82) and CD (PCC 0.84 (0.78-0.89).

The most frequent symptoms of UC were bloody stool (88%), lack of energy (82%), and abdominal pain (78%), whereas those of CD were lack of energy (86%, *p*=0.36) and abdominal pain (84%, *p*=0.17). These symptoms as well as bowel urgency (46% vs. 43%, *p*=0.60) were equally common in UC and CD, while bloody stool was less frequent in CD (54%, p<0.01). Finally, bowel urgency was linked to moderate to severe disability in UC (aOR=4.01 (1.11;14.51)), but not QoL or fatigue, which was confirmed in sensitivity analysis of proctitis.

Conclusion: Our prospective population-based inception cohort study highlights a considerable burden of UC and CD at the time of diagnosis, with moderate to severe impairment of PROs in most patients. In addition, we observed a clustering of impaired PROs in half of the patients, underscoring the interconnectedness of PRO metrics and symptoms. These findings emphasize the importance of tight monitoring of PROs and symptoms in clinical practice, allowing timely interventions.

Introduction: Diagnosing and assessing Inflammatory Bowel Disease (IBD) requires invasive procedures such as endoscopy and intestinal biopsies. However, reliable and accurate non-invasive tools for assessing and monitoring inflammation in IBD patients are in an exciting phase of early development. Raman spectroscopy (RS), which provides molecular vibrational spectra, can characterise human biofluids and intestinal samples, offering the potential for non-invasive molecular assessment, characterisation and monitoring in IBD.

Aims & Methods: This study aims to explore the potential of RS applied to saliva, blood and intestinal biopsies from IBD patients for molecular characterisation and development of new biomarkers enabling a reliable and accurate non-invasive diagnosis of IBD, phenotyping between Crohn's disease (CD) and Ulcerative Colitis (UC) and predicting mucosal healing (MH). IBD patients undergoing advanced endoscopy, i.e. ultra-high magnification endocytoscopy or probe-based confocal laser endomicroscopy, for disease assessment or surveillance and healthy controls were prospectively enrolled from two university hospitals in Cork, Ireland. Peripheral blood, saliva, and biopsies from the most representative bowel areas were collected. All matching samples were processed through a novel waveguide-enhanced RS technique, enabling sensitive detection of metabolites and other biochemical components.

Additionally, MH from matching biopsies was assessed as RHI≤3 without lamina propria or epithelial neutrophils, NHI ≤1 and PHRI=0. RS data processing was performed using Matlab®. Spectral markers matched for saliva, blood and biopsies and differentiating IBD vs controls, CD vs UC and MH vs active inflammation were identified. A machine learning model based on linear discrimination analysis was used to assess the classification accuracy.

Results: A cohort of 16 IBD patients (median age 39, 11:5 M: F), comprising 9 UC and 7 CD, and 4 healthy controls (median age 43.5, 3:1 M: F) was enrolled, with matching saliva, blood, and biopsies. MH was found in 4 IBD patients. When comparing IBD patients with controls, differences in 3 wavenumbers were observed in all samples, corresponding to decreased tyrosine and lipids signals and increased carotenoids signal in IBD. Similarly, differences in spectral markers were found in CD vs UC, with increased lipids signal in CD and increased signals for carotenoids, nucleic acid, and amide proteins in UC.

Interestingly, 5 matching differences in saliva, plasma and biopsies spectra were found in patients with MH compared to those with active inflammation, including an increase in nucleic acids and amide proteins and a decrease in phosphate, lipids, and carotenoids. The machine learning model showed promising accuracy (above 82%) of RS-aided biofluids analysis in diagnosing IBD and predicting phenotype and MH.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The combination of spectral markers from saliva and plasma, confirmed at tissue level, showed promise in accurately diagnosing IBD and distinguishing CD from UC. Notably, RS non-invasive biomarkers could predict MH with promising accuracy, identifying metabolites involved in IBD-associated inflammation, particularly lipids, carotenoids, and nucleic acids. Therefore, RS holds potential as a monitoring and predictive tool for inflammation and healing in IBD, with intriguing translational implications. Further studies are required to validate these preliminary findings and shed light on molecular mechanisms.

PP0500

THE PREDICTIVE VALUE OF INTESTINAL ULTRASOUND FOR TREATMENT RESPONSE IN IBD: A SYSTEMATIC REVIEW

C. Teichert[1,2], J.M. Vos[3,2], F. de Voogd[1], G.R. D'Haens[1], B. Koot[3], K.B. Gecse[1]

[1]Amsterdam University Medical Center, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands, [2]Amsterdam Gastroenterology Endocrinology Metabolism (AGEM) Amsterdam University Medical Center, Amsterdam, Netherlands, [3]Emma Children's Hospital Amsterdam University Medical Center, Department of Pediatric Gastroenterology and Nutrition, Amsterdam, Netherlands

Contact E-Mail Address: c.teichert@amsterdamumc.nl

Introduction: Selecting the right treatment in the early stages of inflammatory bowel disease (IBD) is essential for preventing disease progression and modifying disease course. Intestinal ultrasound (IUS) is a promising tool in predicting early treatment response. We aimed to systematically review current literature on the predictive value of IUS for treatment response.

Aims & Methods: A literature search was performed on the 24th of October and updated on the 26th of March 2024 using PubMed, Medline, Embase, Cochrane Library and Cinahl. We included articles in paediatric and adult IBD patients where IUS was used for the assessment of treatment. Studies were grouped based on timing of IUS after start of treatment. In acute severe ulcerative colitis (ASUC) timing included within 5 days or between 6-14 days. In ulcerative colitis (UC) or Crohn's disease (CD) baseline, 0-3 weeks, 4-8 weeks, 12-16 weeks and >16 weeks were used.

Additional response assessments included clinical or endoscopic disease activity scores and adverse events (e.g. surgery, hospitalization, treatment escalation).

Results: Out of 1739 unique articles, 27 were included with 17 in CD, 6 in UC and 4 in ASUC.

Baseline IUS parameters were not predictive of treatment response in CD, UC or ASUC.

In CD, most studies investigated response to anti-TNF (n=12), though multiple therapies were evaluated (n=5). For anti-TNF, IUS was predictive of response to therapy at all time points from 2 weeks onward. IUS at week 4 to 8 showed conflicting results in studies using multiple treatments. After 12 weeks, IUS predicted clinical and endoscopic outcomes as well as adverse events in all studies regardless of treatment.

Lastly, an IUS several months after starting treatment predicted clinical response, adverse events and endoscopic response in the follow years.

A variety of medical treatments were included in most UC studies (n=3). IUS within 3 weeks of treatment initiation was able to predict both short- and long-term clinical response in UC. Endoscopic response could be predicted by IUS after 6 weeks. The combination of BWT and colour Doppler signal (CDS) measured at 3 and 9 months of therapy predicted endoscopic activity after 9 and 15 months, respectively.

In ASUC, bowel wall thickness (BWT) significantly differed between responders and non-responders of intravenous steroid treatment when measured 1-3 days after treatment initiation.

	IUS time point	Drug*	Clinical outcomes	Adverse outcomes**	Endoscopic outcomes
CD	<3 weeks	Anti-TNF	Yes		Yes
		MT		No	
	4-8 weeks	Anti-TNF	Yes		Yes
		USTE			Yes
		MT	Yes	Inconclusive	Yes
	12-16 weeks	Anti-TNF			Yes
		USTE			Yes
		MT	Yes	Yes	Yes
	>16 weeks	Anti-TNF		Yes	Yes
		MT	Yes		Yes
ASUC	1-5 days	CS	Yes	Yes	
	6-21 days	CS	Yes	Yes	
UC	<3 weeks	CYTA	Yes		
		MT	Yes		No
	4-8 weeks	MT			Yes
	12-16 weeks	CS			Yes
		MT			Yes
	>16 weeks	CS			Yes

** CS=corticosteroids | MT=multiple treatments |CYTA=cytapheresis | USTE=Ustekinumab*

***Hospitalization, surgery, treatment escalation or no discontinuation of corticosteroids*

Conclusion: IUS performed at 1-3 days, 2 weeks and 6 weeks was predictive of treatment response in ASUC, CD and UC, respectively. Further data is needed to characterize IUS response kinetics of the individual therapies.

PHYSIOLOGIC AND ANATOMIC CHARACTERISTICS OF PELVIC FLOOR DISORDERS IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Livne Margolin[1], R. Yehuda Margalit[1], C. Maradey[1], A. Levartovsky[1], U. Kopylov[1], D. Carter[1]
[1]*Sheba Medical Center, Gastroenterology, Ramat Gan, Israel*

Contact E-Mail Address: Moranlivne@gmail.com

Introduction: With the expansion of treatment options available for inflammatory bowel disease (IBD), the emphasis on refractory functional disorders grows along with new treatment targets, aiming at quality-of-life improvement. Pelvic floor disorders such as fecal incontinence (FI) and obstructive defecation syndrome (ODS) are considered as disabling conditions and are a source of embarrassment and suffering for IBD patients. Reluctance to complain and feeling of incompetence leads to a delay in diagnosis and treatment.

Aims & Methods: Aim: To characterize the etiology and the physiological characteristics of pelvic floor disorders in a cohort of IBD patients as compared with non IBD patients.

Methods: Data was collected from the medical files of IBD patients who went through a workup due to defecation disorder during 2015-2024. All patients completed either an anorectal manometry, trans anal ultrasound (TRUS) or evacuation proctography. Data was compared to that of a control group, that included patients with defecation disorders without IBD, that went through a similar medical workup.

Results: 67 IBD patients were included, 44 patients (66%) with Crohn's disease (CD) and 23 with ulcerative colitis (34%). Perianal involvement was diagnosed in 25% of the CD group. The control group consisted of 140 patients. Gender and age did not differ significantly between the groups. The median number of deliveries in the IBD group was 2.5 (IQR=1) versus 2 births (IQR=1) in the control group (P=0.38). The prevalence of pelvic floor surgery was higher in the control group (36%, VS. 18%, p=0.01).

Pelvic floor dyssynergy was diagnosed in 75% of the patients in the control group compared with 59% of the patients in the IBD group (p=0.03). Rectal hyposensitivity was found in 44% of the patients in the control group compared with 46% of patients in the IBD group (p=0.06), and rectal hypersensitivity was diagnosed in 13% of the patients in the control group versus 33% of the IBD group, p=0.003. (Table 1)

		IBD	Non-IBD	P value
Dyssynergia		34 (59%)	75 (75%)	P=0.03
Anal compliance	normal	12 (25%)	51 (39%)	P=0.07
	low	36 (75%)	79 (61%)	
Balloon explosion		11 (21%)	22 (16%)	P=0.56
	hyposensitive	24 (46%)	58 (44%)	P=0.06
	hypersensitive	17 (33%)	17(13%)	P=0.003
TRUS	Internal sphincter tear	6 (16%)	24 (17%)	0.84
	External sphincter tear	10 (26%)	23 (16%)	0.16
	fistula	4 (11%)	1 (0.7%)	0.0009

Conclusion: Pelvic floor disorders in IBD patients may be associated with higher prevalence of rectal hypersensitivity compared with non-IBD patients. Dyssynergy is common in IBD patients and is associated with FI. Understanding the mechanisms of pelvic floor disorders in IBD patients is essential for choosing the best treatment modalities in this group of.

CPA9-HNE: A NEUTROPHIL-DERIVED FRAGMENT OF CALPROTECTIN MEASURED IN SERUM CAN MONITOR ENDOSCOPIC AND CLINICAL DISEASE ACTIVITY IN ULCERATIVE COLITIS

M. Sorokina Alexdóttir[1], A. Poulsen[2], M. Pehrsson[1], M.A. Karsdal[1], A.-C. Bay-Jensen[1], J. Burisch[3], J.B. Seidelin[4], J.H. Mortensen[1]

Contact E-Mail Address: mara@nordicbio.com

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease (IBD) presenting in remitting ulcerations of the colonic mucosa and submucosa. Mucosal healing is therefore an important treatment target for optimal disease management. While fecal calprotectin is a common biomarker used to monitor mucosal healing in UC, patient compliance is low due to a preference for serological markers over fecal ones.

Aims & Methods: This study aimed at investigating the association of serum calprotectin [CPa9-HNE], a non-invasive neo-epitope biomarker of neutrophil activity, with both clinical and endoscopic disease activity in UC. The cohort included 49 patients with active UC and 50 and healthy controls (HC). Endoscopic and clinical disease activity was assessed using the Ulcerative Colitis Endoscopic Index of Severity (UCEIS) and the full Mayo score. Serum calprotectin [CPa9-HNE] was measured, reflecting a human neutrophil elastase-derived fragment of calprotectin. Spearman's rank correlation was applied. Group differences were evaluated using Kruskal-Wallis with Dunn's test, bonferroni corrected for MCP. Diagnostic and discriminative capabilities were assessed using receiver operating characteristic (ROC) statistics with are under the curve (AUC).

Results: CPa9-HNE was significantly elevated in patients with UC compared to HC (ng/ml [IQR]: 32.4 [29.0–52.3] vs. 26.0 [22.6–29.0], $p<0.0001$) and presented acceptable discriminative capabilities (AUC [95% CI]: 0.77 [0.67–0.87], $p<0.0001$). CPa9-HNE showed a moderate positive correlation to UCEIS and Mayo ($\rho=0.42$; $\rho=0.48$, both $p<0.01$). When patients were stratified according to endoscopic disease activity (UCEIS), CPa9-HNE was significantly elevated in patients with severe disease compared to those with mild disease (ng/ml [IQR]: 55.6 [40.9–66.4] vs. 28.9 [24.6–31.1], $p<0.01$) and could accurately discriminate between the two groups. Similarly, when patients were grouped according to the full Mayo score, CPa9-HNE was significantly elevated in patients with mild vs. severe disease (29.1 [24.3–32.4] vs. 62.9 [55.2–67.5], $p<0.01$) and moderate vs. severe disease (32.0 [29.2–39.2] vs. 62.9 [55.2–67.5], $p<0.01$), and could accurately discriminate between the groups.

Conclusion: CPa9-HNE was elevated in patients with UC compared with healthy subjects. Furthermore, CPa9-HNE accurately discriminated between patients with mild and severe endoscopic disease based on the UCEIS score, as well as between patients with mild, moderate, and severe clinical disease activity according to the full Mayo score. These findings highlight the potential use of CPa9-HNE as a non-invasive tool to monitor both endoscopic and clinical disease activity in UC, with the potential of guiding treatment decisions and better aligning with patient preferences.

ANTI-TNF EXPOSURE IS A RISK FACTOR FOR ENDOSCOPIC ILEAL RECURRENCE IN ILEOSTOMY PATIENTS WITH CROHN'S DISEASE

L. Oldenburg[1], B. Hens[2], M. Hollenberg[1], G.R. D'Haens[1]
[1]Amsterdam University Medical Center, Gastroenterology and Hepatology, Amsterdam, Netherlands, [2]UZ Brussel, Gastroenterology, Jette, Belgium

Introduction: A small but significant proportion of patients with Crohn's disease (CD) will ultimately require a permanent ileostomy. (1-3) The natural history and treatment success in these patients remain unclear and studies on endoscopic recurrence are lacking.

The aim of this study was to investigate the endoscopic recurrence rate, possible risk factors, and treatment outcomes with current biological agents.

Aims & Methods: We performed a retrospective study of CD patients with a permanent ileostomy in a tertiary referral center. Inclusion criteria were CD adults (≥16 years) and the presence of an ileostomy for at least 12 months. Ileal postoperative recurrence was defined as the presence of ulcerations during ileoscopy.

Traditional risk factors historically associated with postoperative recurrence (age at diagnosis ≤16 years, active smoking, penetrating phenotype, and inflammation at resection margin) were evaluated. (4,5) The probability of developing post-operative ileitis was examined by cox regression and Kaplan Meier analysis.

	All patients (N=166)	Endoscopic surveillance (N=115)
Female, n (%)	105 (63.3)	77 (67.0)
Median age at diagnosis, years (IQR)	22.0 (16.8-31.0)	22.0 (16.0-30.0)
Median disease duration at time of surgery, years (IQR)	7.0 (2.0-15.0)	7.0 (2.0-13.0)
Smoking status at time of surgery, n (%)		
Never	89 (53.6)	68 (59.1)
Former	29 (17.5)	26 (22.6)
Current	36 (21.7)	16 (13.9)
Unknown	12 (7.2)	5 (4.3)
Disease location and behaviour at diagnosis, n (%)		
L1, ileal	13 (7.8)	11 (9.6)
L2, colonic	95 (57.2)	67 (58.3)
L3, ileocolonic	42 (25.3)	30 (26.1)
Unknown location	16 (9.6)	7 (6.1)
B1, inflammatory	71 (42.8)	54 (47)

Unknown behaviour	54 (32.5)	34 (29.6)
Perianal disease at time of surgery, n (%)	74 (44.6)	51 (44.3)
Previous intestinal resection, n (%)	86 (51.8)	55 (47.8)
Previous immunomodulator, n (%)	109 (65.7)	79 (68.7)
Previous biological therapy, n (%)	125 (75.3)	88 (76.5)
Previous anti-TNF	102 (61.4)	71 (61.7)
≥2 prior biologicals	32 (19.3)	23 (20)
≥1 traditional risk factor*, n (%)	138 (83.1)	95 (82.6)
Endoscopic recurrence, n (%)		46 (40)
Endoscopic remission after treatment, n (%)		
Infliximab		4/13 (20.8)
Adalimumab		7/13 (53.8)
Vedolizumab		6/8 (75)
Ustekinumab		4/12 (33.3)

Table 1.

**Defined as age at diagnosis ≤16 years, active smoking, penetrating phenotype, history of IBD-surgery and inflammation at resection margin.*

Results: 166 patients were identified (median age 34 years (IQR 24-46), 63% female) (Table 1). Median follow-up after surgery was 5.5 years (IQR 2-14) and 37% had a loop ileostomy without resection. 115/166 (69%) underwent endoscopy during follow-up. Indications for ileoscopy were symptoms of flare (50%), planning for ostomy closure (14%) and other indications (21%). Endoscopic lesions were observed in 40% of patients, with a cumulative risk at 1-, 3- and 5-years of 13%, 27% and 36%, respectively. Controlling for traditional risk factors, patients with preoperative anti-TNF treatment were at higher risk (HR 2.18, 95% CI 1.11-4.28), with 17%, 41%, and 44% recurrence rates at 1, 3, and 5 years respectively (log rank P = 0.01). Other traditional risk factors for postoperative recurrence were not predictive of endoscopic disease recurrence in this cohort. Ileal recurrence was treated with biological therapy, including infliximab, adalimumab, vedolizumab, or ustekinumab. Patients treated with vedolizumab had the highest rate of remission (6/8 patients) and longest treatment persistence (54 months, IQR 19-102.8) (Table 1).

Conclusion: This retrospective study showed that 40% of ileostomy patients developed endoscopic recurrence. Patients with previous anti-TNF exposure were at higher risk of recurrence. Vedolizumab was the most effective treatment, although this finding needs to be confirmed in larger cohorts.

EARLY INTESTINAL ULTRASOUND IN ULCERATIVE COLITIS PATIENTS TREATED WITH FILGOTINIB: PRELIMINARY DATA FROM THE STEER STUDY

M. Pruijt[1], C. Teichert[1], F. de Voogd[1], M. Lowenberg[1], R. Goetgebuer[1], G.R. D'Haens[1], K.B. Gecse[1]
[1]*Amsterdam UMC, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands*

Contact E-Mail Address: m.j.pruijt@amsterdamumc.nl

Introduction: Intestinal ultrasound (IUS), in particular bowel wall thickness (BWT), is accurate in determining endoscopic disease activity in ulcerative colitis (UC). Reduction of BWT six weeks into advanced anti-inflammatory treatment predicted endoscopic response and clinical remission. Filgotinib is a preferential JAK1-inhibitor effective in UC. Currently, there is no data on IUS-kinetics or early prediction of treatment response with filgotinib.

Aims & Methods: In this study, we aimed to identify early IUS predictors of treatment response to filgotinib in patients with moderate to severe UC. This prospective observational study included UC patients with active endoscopic disease (i.e. endoscopic MAYO score (EMS) ≥2) starting with filgotinib. Clinical scores (UCEIS, Lichtiger), biochemical parameters and IUS parameters of the sigmoid were assessed at baseline, after 4 weeks (W4) and at the time of the second endoscopy (between W8 and W23). Endoscopic remission (i.e. EMS=0), endoscopic response (i.e. decrease in EMS ≥1 compared to baseline) and clinical remission (SCCAI ≤2 or Lichtiger score ≤3) were assessed. IUS response (i.e. defined as a reduction in BWT of >25% or >2.0 mm, or >1.0 mm and one colour Doppler signal) was assessed at week 4. All normally distributed data were reported in mean ± standard deviation [SD] and non-normally distributed in median and interquartile range [IQR]. Mann–Whitney U tests were used to compare continuous non-parametric variables, chi square tests for dichotomous variables.

Results: A total of 20 patients were included. 13 patients underwent second endoscopy, 2 refused a follow-up endoscopy and 5 patients were still in follow-up. At baseline, 9 patients (9/20, 45%) had received ≥2 biologicals, 16 patients (16/20, 80%) had previous anti-TNF exposure, and no patients were exposed to other JAK-inhibitors. 8 patients (8/20, 40%) had severe endoscopic disease at baseline (i.e. EMS=3). 5 patients (5/13, 38%) were endoscopic responders at W8-23, and no patient reached endoscopic remission. BWT was significantly lower in the sigmoid colon from W4 onwards for patients reaching endoscopic response (Table 1). Decrease in BWT compared to baseline was statistically greater in endoscopic responders from W4 onwards (Table 1). IUS response was seen at W4 in 6 patients, of which 5 were endoscopic responders (83%, p=0.002). Decrease in BWT from W4 onwards was statistically greater in patients reaching clinical remission at W8-23 (-45% (-55% to -36.6%) vs -9% (-25% to +8%), p=0.014).

Time point	*Endoscopic response (n=5)*	*Endoscopic non-response (n=8)*	*p-value*
Median BWT (IQR) at baseline	4.5 mm (3.2-6.2)	5.1 mm (3.6-6.5)	*p=0.61*
Median BWT (IQR) at W4	1.9 mm (1.8-3.8)	4.7 mm (3.3-5.9)	***p=0.019***
Median BWT (IQR) at W8-23	2.2 mm (1.8-3.7)	5.3 mm (4.3-6.7)	***p=0.008***
Median decrease in BWT (IQR) W4	-42% (-53% to -38%)	-3% (-16% to +9%)	***p=0.003***
Median decrease in BWT (IQR) W8-23	-45% (-51% to -35%)	-10% (-1% to +24%)	***p=0.003***

Conclusion: On IUS, UC patients treated with filgotinib have significantly lower BWT from week 4 onwards compared to baseline, which could predict endoscopic response.

ARTIFICIAL INTELLIGENCE-ASSISTED DIGITAL PATHOLOGY IS COMPARABLE TO EXPERT PATHOLOGISTS AND OUTPERFORMS NON-EXPERTS IN INFLAMMATORY BOWEL DISEASE: A NETWORK META-ANALYSIS

M. Puga-Tejada[1], S. Majumder[1], Y. Maeda[1], I. Zammarchi[1], I. Ditonno[1], G. Santacroce[1], S. Ghosh[1], M. Iacucci[1]
[1]*APC Microbiome Ireland, College of Medicine and Health, University College of Cork, Cork, Ireland*

Contact E-Mail Address: miguel.puga01@hotmail.com

Introduction: Histological diagnosis and assessment of Inflammatory Bowel Disease (IBD) face significant intra- and inter-observer variability, even among expert pathologists (1). Artificial intelligence (AI)- assisted digital pathology models have been developed to address this challenge (2). However, their comparative accuracy with pathologists remains uncertain.

Aims & Methods: This is the first meta-analysis comparing performance metrics among IBD-related AI models and expert and non-expert pathologists. A systematic search identified papers investigating AI-digital pathology in IBD, published from inception to March 2024. Using the online EPPI-reviewer platform duplicates among PubMed and Scopus were automatically excluded. Consequently, four experienced IBD researchers conducted blind manual screening and excluded studies lacking sufficient data. We computed the pooled diagnostic accuracy metrics, including sensitivity or recall, positive predictive value (PPV) or precision, observed agreement or accuracy, F1 score and Matthew's correlation coefficient (MCC). Data were meta-regressed and network meta-analysed using the "meta" and "netmeta" libraries from R v4.0, respectively (R Foundation for Statistical Computing; Vienna, Austria).

Results: Among 223 studies retrieved after the systematic search strategy, only 23 were selected for full-text evaluation, and 12 were included for final analysis (*Table 1*).

The included studies were published between 2022 to 2024. According to the random effect model, pooled sensitivity, PPV, accuracy, F1 score and MCC of AI models were 0.85 (0.81; 0.88; I^2=94.9%), 0.88 (0.85; 0.90; I^2=91.1%), 0.88 (0.85; 0.90; I^2=96.3%), 0.85 (0.82; 0.88; I^2=96.4%), and 0.71 (0.60; 0.82; I^2=100.0%), respectively. Although high heterogeneity was found, accuracy sub-analysis showed no significant difference between CD vs UC (.88 vs.87) or disease diagnosis vs disease assessment (.89 vs .87). Expert pathologists reached the highest pooled accuracy (.91), fol-

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

lowed by AI models (.88) and non-expert pathologists (.82), being significantly different according to the meta-regression (p<.01). Network meta-analysis revealed no significant difference between the performance of AI vs expert pathologists, while AI outperformed non-experts in accuracy (OR 2.68; 95% CI 1.08-.66), F1 score (OR 2.52; 95% CI 1.03-6.16), and MCC (OR 4.53; 95% CI 2.08-9.88).

Studies included		n (%)
Inflammatory Bowel Disease (IBD) phenotype*, n (%)	Ulcerative colitis (UC)	9/12 (75%)
	Crohn's disease (CD)	3/12 (25%)
	Not specified	1/12 (8%)
Aim of the study, n (%)	IBD diagnosis	2 (17%)
	Disease assessment	10 (83%)
Observer, n (%)	Artificial intelligence (AI)	12 (100%)
	Expert pathologist	2 (17%)
	Non-expert pathologist	1 (8%)

Table 1. Studies included in the network meta-analysis.
**Not-mutually exclusive variables.*

Conclusion: AI-assisted digital pathology exhibits promising potential in IBD diagnosis and disease activity assessment, comparable to expert pathologists and superior to non-experts. These findings support the integration of AI models to expedite central reading in clinical trials and hold promise for future application in clinical practice. Nonetheless, standardisation efforts are pivotal to reducing heterogeneity and facilitating widespread AI implementation.

Introduction: Intestinal ultrasound (IUS) is effective for monitoring treatment efficacy in Crohn's disease (CD). Bowel wall thickness (BWT) is used as a surrogate of inflammatory activity. However, the added value of other IUS parameters ((bowel wall flow (BWF), stratification (BWS), lymph node enlargement, mesenteric fat hypertrophy, and complications)) for monitoring and predicting treatment failure during anti-TNFs' maintenance therapy is still poorly defined and was the goal of this study.

Aims & Methods: This was a retrospective cross-sectional study. The study population included patients treated on infliximab or adalimumab maintenance treatment who had undergone an index intestinal ultrasound examination. We examined the added value of various ultrasonographic activity signs, in addition to bowel wall thickness, for their association with subsequent treatment failure. Treatment failure was defined as the need for CD-related surgery, hospitalization, corticosteroid use, dose escalation, and drug discontinuation.

		Treatment Failure			Drug Discontinuation		
Variable		Adjusted Odds Ratio (aOR)	95% CI	P-Value	Adjusted Odds Ratio (aOR)	95% CI	P-Value
BWT	≥3	3.25	1.30-8.12	0.012	2.3	0.94-5.60	0.068
	≥3.5	2.7	1.07-6.78	0.035	1.78	0.73-4.35	0.209
	≥4	2.47	0.93-6.51	0.068	2.68	1.04-6.89	0.042
High BWF		2.93	1.16-7.39	0.023	1.5	0.63-3.59	0.361
Enlarged lymph nodes		1.41	0.32-6.34	0.651	0.68	0.15-3.07	0.62
Mesenteric fat hypertrophy		4.44	1.15-17.07	0.03	5.29	1.61-17.44	0.006
Disturbed BWS		4.64	0.93-23.20	0.062	2.73	0.71-10.44	0.143
IUS Complications		6.04	0.69-52.59	0.104	4.66	0.80-27.05	0.086

Table 1: Sonographic Characteristics Associated with Treatment Failure and Drug Discontinuation.
Abbreviation: BWT - bowel wall thickness; BWF - bowel wall flow; BWS - bowel wall stratification; IUS - intestinal ultrasound.

Results: The study included 103 CD patients treated with anti-TNF therapy (67% adalimumab and 33% infliximab) who underwent an IUS at a median of 10 months (IQR 6-18) after starting therapy. Of 103 patients, 59.2% experienced treatment failure at a median of 5 months (2-12.5) after the index IUS examination. Among the failure group, bowel thickness at preceding index IUS was significantly higher compared with patients without failure (3.9 vs 3mm, respectively, P= 0.007), BWF was higher (49.2% vs.

20506414, 2024, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.12615 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 23.8%, P= 0.009), and mesenteric hypertrophy was more prevalent (20.4% vs 7.1%, P=0.006). Logistic regression identified increased BWT and mesenteric hypertrophy as having a significant association with therapy failure.

A sensitivity analysis with the outcome of therapy discontinuation revealed that mesenteric fat hypertrophy was a significant predictive factor along with increased BWT (Table 1).

Conclusion: Our study highlights the significance of BWT, BWF, and mesenteric fat hypertrophy as key sonographic markers associated with anti-TNF treatment failure in Crohn's disease. Integrating these indicators into scoring systems may enhance predictive accuracy, providing a quantitative tool for evaluating disease severity and treatment response.

Contact E-Mail Address: doctor-gastro@yandex.ru

Introduction: Studies using a variety of diagnostic techniques confirm the importance of the gut microbiota in the pathogenesis of ulcerative colitis (UC), as well as its possible influence on the effectiveness of drug therapy and the prognosis of the disease. In different phases of the UC course, structural and quantitative changes in the gut microbiota suggest its use as a non-invasive diagnostic tool and the tool predicting the achievement of clinical and endoscopic remission of the disease.

Aims & Methods: The objective of the study was to determine the taxonomic diversity of the gut microbiota in patients with UC in various phases of the disease and to identify microorganisms that are predictors of remission. The study included 21 patients (age from 20 to 41 years, 13 men and 8 women) in the relapse phase of UC - left-sided UC with mild to moderate activity (Truelov-Witts scale, Mayo index); and 20 patients (age from 26 to 52 years, 10 men and 10 women) in the phase of clinical endoscopic remission. The gut microbiota was assessed by NGS sequencing of the bacterial 16S ribosomal RNA gene structure using the IlluminaMiSeq platform. After the normality test, we performed statistical analysis using the nonparametric Mann-Whitney test, the analysis is presented by median and quartiles.

Results: We predicted clinical and endoscopic remission of UC using a logistic regression model, including microorganisms, the number of which in absolute values changed more significantly. In cases of achieving clinical and endoscopic remission of the disease, we recorded a statistically significant increase in the levels of Streptococcus, NK4A214_group and Pelomonas and a decrease in Enterococcus and Actinomyces. The developed logistic regression model is statistically significant and statistically reliable using evaluation criteria: chi-square (p = 0.002), Cox & Snell's pseudo R-squared is 0.556, Nagelkerk is 0.741, which allows its use in wide gastroenterological practice to make decisions on modifying the course of drug therapy for UC (Table 1).

Genus	Coefficient	Odds ratio	p
Enterococcus	-117,244	$1{,}2{\cdot}10^{-51}$	0,011
Streptococcus	1,117	3,06	0,045
NK4A214_group	2,335	10,33	0,008
Pelomonas	67,529	$2{,}1{\cdot}10^{29}$	0,011
Actinomyces	-55,947	$5{,}0{\cdot}10^{-25}$	0,008
Constant	-0,528	0,59	0,201

Table 1. Results of modeling the gut microbiotope in patients with UC using logistic regression.

Conclusion: The study results provide a prognostic model for non-invasive diagnosis of achieving UC remission. Predictors of achieving clinical and endoscopic remission of UC are high levels of Streptococcus, NK4A214_group and Pelomonas, as well as a decrease in the number of Enterococcus and Actinomyces.

Introduction: The quality of gastrointestinal endoscopy in inflammatory bowel disease (IBD) patients has been recently identified as a major priority being associated with better outcomes.

Aims & Methods: We aim to assess the adherence of Italian gastroenterologists to current international recommendations on quality performance measures for IBD endoscopy.

From March to July 2023 a total of 178 Italian consultants were invited to participate to an online questionnaire-based survey, which included questions on their demographics, professional characteristics and clinical behaviour as well as structural features of their affiliations. Four clinical domains were analysed: A) the first endoscopy for suspected IBD; B) assessment of endoscopic activity; C) post-operative Crohn's disease; and D) surveillance endoscopy for patients at high risk of colorectal neoplasia. Recommendations from three consensus on quality performance measures for IBD endoscopy (BRIDGE, ECCO, ESGE) were used as reference standards. A p value ≤0.05 was considered statistically significant.

Results: Overall, responders paid low attention to perform ileal biopsies in case of the first colonoscopy for suspected IBD (67% vs standard of care 80%) as well as to the use of the Paris (70%) and mucosal pattern classifications (60%) for lesion characterization of endoscopic visible lesions. Ileal intubation (97%) and colonic biopsies (80%) during the first colonscopy for suspected IBD, adequate tissue samples management (96%), post-operative schedule within 1 year (94%), implementation of surveillance plans (96%) and use of endoscopic index of activity (95%) were highly reported. No significant regional differences were observed, while significantly lower performances were reported for many outcomes by small centers (<100 IBD patients in follow-up and/or no more than 2 physicians for each IBD unit) or physicians spending <50% of their clinical activity for IBD. Young doctors <35 years old had a significantly higher use of modern classifications for lesion characterization (Paris: 89% vs 68%; Kudo:82% vs 56%).

Conclusion: In Italy, the adherence to current standards of care for IBD endoscopy is generally good, with some practices to be improved. There is a need to support the endoscopic activity of small centers and doctors less engaged in IBD.

Disclosure: Nothing to disclose.

SERUM BIOMARKERS OF PROTEOLYTIC TISSUE DESTRUCTION, FORMATION AND MACROPHAGE ACTIVITY CAN DISCERN PATIENTS WITH IBD ACCORDING TO INFLIXIMAB TREATMENT NON-RESPONSE OR RESPONSE

M. Pehrsson[1], E. Aighobahi[1], M. Sorokina Alexdóttir[1], C.S. Steenholdt,[2], T.L. Boye[2], M. Karsdal[1], A.-C. Bay-Jensen[1], M.A. Ainsworth[3], J.H. Mortensen[1]

Introduction: Characterized by chronic inflammation, patients with Inflammatory Bowel Disease (IBD) experience detrimental remodeling of their intestinal extracellular matrix (ECM). Treatment with anti-inflammatory drugs can reduce inflammation, leading to remission and tissue healing. However, adequate monitoring of patients is critical to ensure and maintain treatment response. As potential surrogate markers of ECM remodeling, we investigated blood-based biomarkers of type III and -VII collagen and posttranslational modifications of vimentin in patients with IBD.

Aims & Methods: By quantifying biomarkers of intestinal tissue destruction (C3M), tissue formation of type VII collagen (PRO-C7), and the macrophage activity biomarker, VICM, we aimed to determine the value of these biomarkers for identifying and monitoring response to infliximab (IFX).
160 IBD patients initiating IFX treatment at visit 1 were included, having blood drawn at visits 1, 2, and 3, with treatment response evaluated at visit 3 using the Physicians Global Assessment (PGA) score. The response was defined as a PGA of 0 at Visit 3. Measuring the biomarkers C3M (MMP-9 degraded type III collagen), PRO-C7 (pro-peptide of type VII collagen), and VICM (citrullinated and MMP-degraded vimentin) in the blood, we evaluated their ability to identify responders (n=141) and non-responders (n=19) to IFX induction therapy. The biomarker levels between responders and non-responders were statistically assessed using a stepwise logistical regression model and DeLong et al. receiver operating characteristics.

Results: Using logistical regression, the combination of serum C3M and PRO-C7 measured at visit 1 could discern non-responders and responders with an AUC of 0.717 (p=0.001, sens: 61.1%, and spec: 80.2%). At visit 2, serum VICM provided an AUC of 0.684 (p=0.006, sens: 57.9%, and spec: 78.9%), whereas measuring C3M at visit 3 discerned patients with an AUC of 0.695 (p=0.009, sens: 60.0%, and spec: 74.4%). Finally, we performed a stepwise logistical regression model combining all the biomarkers for a composite score. Measuring PRO-C7 at visit 1, VICM at visit 2, and C3M at visit 3 identified non-responders to IFX treatment with an AUC of 0.797 (p<0.001, sens: 80.0%, and spec: 74.5%).

Conclusion: Quantifying specific fragments of MMP-degraded type III collagen reflecting tissue destruction, the formation of type VII collagen, and the macrophage activity biomarker VICM in patients treated with IFX could, with a moderate to good AUC, identify patients who at visit 3 would be determined a non-responder or responders to IFX treatment based on their PGA. Our data suggest differences in the proteolytic tissue destruction and formation biomarkers, in combination with macrophage activity, can discriminate between responders and non-responders to IFX treatment.

BACTERIAL PROFILE OF THE GUT IN PATIENTS WITH ULCERATIVE COLITIS IN DIFFERENT PHASES OF DISEASE PROGRESSION

A. Zubova[1], G. Tarasova[1]
[1]Rostov State Medical University, Gastroenterology, Rostov-on-Don, Russian Federation

Contact E-Mail Address: doctor-gastro@yandex.ru

Introduction: Numerous studies show that changes in the composition of the gut microbiota constitute an important factor influencing both the development of ulcerative colitis (UC) and the prognosis of the disease, drug metabolism and effectiveness of treatment. The growing global prevalence of UC necessitates continued advances in diagnostics and treatment. Gut microbiota can be considered as a promising dynamic biomarker for non-invasive assessment of the severity of UC and the effectiveness of treatment.

Aims & Methods: The purpose of the research was to study the taxonomic diversity of the gut microbiota in patients with UC at different stages of the disease. The study included 21 patients (ages from 20 to 41, 13 men and 8 women) in the relapse stage of UC - left-sided UC with mild to moderate activity (Truelov-Witts scale, Mayo index); and 20 patients (ages from 26 to 52, 10 men and 10 women) in the stage of clinical endoscopic remission. The study of the coprofiltrate microbiota was carried out by NGS sequencing of the structure of the bacterial 16S ribosomal RNA gene using the Illumina MiSeq platform. Statistical analysis was preceded by testing of the distribution for normality using the Kolmogorov-Smirnov (with Lilliefors significance correction) and Shapiro-Wilk tests. Hypotheses about the distribution corresponding to normal were rejected, and therefore the calculation of descriptive statistics is presented by median and quartiles. Group comparisons were made using the nonparametric Mann-Whitney test.

Results: Statistically significant differences between the relapse and remission groups were identified for 15 genera of microorganisms. In the relapse group, higher levels of Enterococcus, Streptococcus, Granulicatella, Pelomonas, TM7x, Actinomyces, Gemella, Corynebacterium, Bradyrhizobium, and lower levels of NK4A214_group, Pseudoscardovia, Family_XIII_UCG-001, Anaerofilum, Candidatus_Soleaferrea, DNF00809 were found (Table 1).

Genus	Me (Q25%; Q75%)		U Mann-Whitney	p
	Relapse (n=21)	Remission (n=20)		
Enterococcus	0.03 (0.00; 0.26)	0.00 (0.00; 0.00)	24.00	0.012
Streptococcus	1.22 (0.78; 6.27)	0.28 (0.18; 1.15)	25.00	0.035
