Results: Thirty-five patients were enrolled (CD in 65%, Sex ratio 1.4, 14 % with clinically and 57 % with endoscopically active disease, and 23 under SC IFX therapy). The characteristics of both IV and SC IFX groups were comparable, except for drug dose intensification in 90% of those treated with IV IFX group and 5% in the SC IFX cohort ($p < 0.001$). In patient in endoscopic remission, tissue levels were undetectable or very low for both IV and SC IFX therapy. Serum and tissue drug levels were significantly higher in the SC IFX cohort compared with the IV IFX group (22 mg/mL vs 9 mg/mL for serum; $p < 0.001$ and 25 mg/g vs 10 mg/g for tissue; $p = 0.002$, respectively). A moderate correlation was found between serum and tissue drug levels for both IV and SC IFX therapy (Spearman $r = 0.42$; $p = 0.014$ and $r = 0.43$; $p = 0.001$, respectively). Tissue drug levels increased gradually in patients with minimal or moderate endoscopic activity and were lower in those with severe endoscopic activity for both IV and SC IFX groups ($p < 0.001$). Tissue drug levels remained significantly higher in minimal or moderate endoscopically active disease in SC compared with IV route of IFX administration. The two independent factors associated with drug tissue levels > 14 mg/g (median levels) were the SC IFX route (OR: 2.25, 95% CI = [1.19–2.23]; $p = 0.001$) and the serum IFX levels (OR: 1.63, 95% CI = [1.19–2.23]; $p = 0.002$). A serum IFX level greater than 16.1 mg/mL was highly predictive of a tissue drug level > 14 mg/g tissue (Se: 0.94, Spe: 0.94, PPV: 0.94, NPV: 0.94, and Accuracy = 94.3%).

Conclusion: Serum and tissue drug levels are positively correlated in IBD patients under IV and SC maintenance IFX therapy. Interestingly, drug levels were higher both in serum and tissue in patients under SC IFX compared with IV IFX and tissue drug levels gradually increased in minimally to moderately inflamed intestine but were lower or undetectable in more severe inflamed areas.

TREATMENT PATTERNS, CLINICAL CHARACTERISTICS AND ECONOMIC BURDEN OF COMBINED ADVANCED THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A RETROSPECTIVE US DATABASE REVIEW

P.S. Dulai[1], Z. Farhat[2], J. Caloyeras[2], T. Gift[2], R. Ghanbariamin[3], R. Ayyagari[3]

Introduction: Several advanced therapies have been approved for treatment of patients with ulcerative colitis (UC) and Crohn's disease (CD) although efficacy is limited and up to 60% of patients relapse.[1,2] Combining advanced therapies that target different pathways may raise the therapeutic ceiling; however, little is known about real-world utilization of combined advanced therapies.

This study aimed to estimate prevalence, duration, and describe clinical characteristics, healthcare resource utilization (HCRU) and costs versus monotherapy.

Aims & Methods: This retrospective cohort study used the MarketScan Commercial Claims Encounters database (January 1, 2013 to December 31, 2022). Adult patients with UC or CD were included if they had used ≥1 advanced therapy and had ≥6 months of data prior to (baseline period) and after the index date. The index date for combined advanced therapies was defined based on the start of the overlap period, while monotherapy patients were assigned a mock-index date by selecting random patients from the combined advanced therapies cohort and adding their duration on monotherapy to the monotherapy start date of the monotherapy patient.

The study was conducted in two phases: in the initial phase, the frequency of patients with combined advanced therapies across multiple overlap periods was described to establish a clinically relevant and implementable definition of combined advanced therapies; in the second phase, patient characteristics, HRU, and costs were described separately for combined advanced therapies and monotherapy. Baseline characteristics were described during the 6-month baseline period, HRU and costs were described during baseline and follow-up period, for combined advanced therapies and monotherapy cohorts.

Results: Among patients with combined advanced therapies, the most frequent overlap duration was 30–59 days (33.6% in CD, 35.9% in UC), with infliximab + vedolizumab being the most prevalent combination (27.7% in CD, 26.7% in UC). Based on clinical input and sample size considerations, combination therapies were defined as overlapping use of combined advanced therapies for at least 30 days for subsequent analyses.

The prevalence of combined advanced therapies was low, observed in 2.9% of patients with CD and a similar proportion in UC. The most common combinations were ustekinumab + vedolizumab in CD and tofacitinib

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

+ vedolizumab in UC. Most patients discontinued combined advanced therapies within a few months, with significant drops in persistence by six months. Among combinations, ustekinumab + vedolizumab demonstrated the longest persistence, with a median of 3.3 months in CD and 3.7 months in UC. At baseline, the combination cohort exhibited younger age, higher comorbidity burden, greater diagnostic testing, and significantly higher HRU and healthcare costs versus monotherapy cohort. In CD, the combination cohort incurred significantly higher all-cause costs than monotherapy ($124,928 vs $43,239), largely driven by advanced treatment costs ($86,940 vs $32,468) during the 6-month study period. This suggests that combination therapy is used for induction to regain control of disease rather than as a long-term option.

Conclusion: The prevalence of combined advanced therapies is relatively low, with vedolizumab frequently used as part of the combination. Patients on combined advanced therapies had higher disease burden, HCRU and healthcare costs versus monotherapy. Higher initial costs of combination therapy may be offset by achieving long-term disease control with subsequent monotherapy.

Contact E-Mail Address: fernandomagro65@gmail.com

Introduction: Mirikizumab (MIRI) is an anti-IL-23p19 antibody with demonstrated efficacy compared to placebo (PBO) in the treatment of moderately-to-severely active ulcerative colitis (UC) (LUCENT-1: NCT03518086; LUCENT-2: NCT03524092).[1] Prevention of IBD-related surgery and hospitalizations is a goal in disease-modification trials for preventing disease progression.[2] We described the rates of these events in the LUCENT-1 and -2 trials.

Aims & Methods: Patients were randomized to intravenous MIRI 300 mg or PBO every 4 weeks (Q4W) for induction in LUCENT-1. Patients randomized to MIRI induction and achieving clinical response at Week (W)12 were re-randomized 2:1 in LUCENT-2 to subcutaneous MIRI 200 mg Q4W or PBO (MIRI withdrawal) for maintenance (W12-52). Descriptive statistics were used for proportion of patients in LUCENT-1 and -2 who had hospitalization and/or surgery by treatment group and the exposure-adjusted incident rate (IR). For LUCENT-1, hospitalizations in the induction period and surgeries during the induction and 16-week follow-up period were included. For LUCENT-2, all events were from the on-treatment period. Only hospitalizations associated with an adverse event with ≥24-hour stay (for any causes) were recorded.

Results: MIRI-treated patients had significantly lower IR of overall hospitalization, UC-related hospitalization, and overall surgery vs PBO-treated patients in LUCENT-1 (IR ratio MIRI vs PBO: 0.4, 0.1, 0.4, respectively). IR of UC-related surgery was 1.3 per 100 patient-years in MIRI-treated patients vs 2.6 per 100 patient-years in PBO group (Table). Mean time to first surgery or hospitalization from randomization was 30.5 days for PBO and 58.7 days for MIRI. Additional analyses revealed that patients on MIRI who had surgery/hospitalization in LUCENT-1 or -2 tended to have prior biologic failure and longer duration of disease. Similarly, in LUCENT-2, MIRI-treated patients had significantly lower IR of all-cause hospitalization and similar all-cause surgery vs PBO. No UC-related hospitalization and surgery were reported in the MIRI group while 2 UC-related hospitalizations (1.8 per 100 person-years) were reported from PBO.

Hospitalization and Surgery Rates in LUCENT-1 and LUCENT-2

	LUCENT-1							LUCENT-2						
	MIRI 300mg (N=868, PYE=201.0)			PBO (N=294, PYE=65.8)			MIRI vs. PBO	MIRI 200mg (N=365, PYE=267.9)			PBO (N=179, PYE=111.0)			MIRI vs. PBO

BENCHMARKING CORTICOSTEROID USE IN INFLAMMATORY BOWEL DISEASE AGAINST BSG KEY PERFORMANCE INDICATORS AT BARTS HEALTH NHS TRUST

S.A. Neama[1], A. Grobbelaar[2], F. Almukhtar[2], N. Jawad[2]

Contact E-Mail Address: farah.almukhtar@nhs.net

Introduction: The advent of numerous biologic drugs and small molecules has significantly reduced the role of steroids in maintaining remission in inflammatory bowel disease (IBD), particularly in ulcerative colitis and Crohn's disease [1]. The British Society of Gastroenterology (BSG) recommends identifying patients who are steroid-dependent or those who relapse within three months of discontinuing steroids in order to consider escalation of therapy [2].

Additionally, the UK IBD Standards advocate for regular audits of steroid use to ensure adherence to guidelines and to identify instances of steroid misuse or excess [3].

Aims & Methods: This audit aimed to evaluate corticosteroid prescriptions for patients with inflammatory bowel disease (IBD) at Barts Health NHS Trust (Newham University Hospital, Royal London Hospital, Whipps Cross Hospital). The primary goal was to ascertain whether therapy escalation was appropriately considered in prescribing corticosteroids and benchmarked against key performance indicators for inflammatory bowel disease in the UK [1].

All corticosteroid prescriptions issued for IBD treatment were reviewed between September 2023 and September 2024. Data was collected from Electronic Medical Records to identify prior corticosteroid prescriptions within the preceding 12 months and to determine if prescribers had considered the need for therapy escalation.

Results: A total of 368 patients received corticosteroid treatment, including 186 with ulcerative colitis and 182 with Crohn's disease. Prednisolone was the most commonly prescribed corticosteroid for ulcerative colitis (183 out of 186 cases), while budesonide was preferred for Crohn's colitis (115 out of 182 cases). Among these patients, 5 (2.6%) in the ulcerative colitis group and 6 (3.2%) in the Crohn's group met the criteria for escalation, having received 2 or more courses of oral steroids. Notably, none of the Crohn's disease patients had previously received biologic treatment. Of the patients who did not receive escalation therapy, the reasons were not clearly documented for 4 patients. Other missed escalations were attributed to factors such as referrals for the ADDapt trial, missed follow-up appointments, patient decline, or delays in escalating therapy in three instances. Importantly, none of these patients had documented hospital admissions requiring intravenous steroids or experienced surgical complications.

Conclusion: Prescribers exhibited a judicious approach to corticosteroid use, supported by specialised clinics and multidisciplinary meetings focused on steroid-sparing strategies. However, there remains an opportunity for improvement in the appropriate use of second-line steroids, the implementation of annual audits of steroid prescribing practices, and the consideration of the need for escalation. A notable limitation of this audit was the difficulty in obtaining corticosteroid prescription data from primary care or non-specialist hospital services.

Introduction: Vedolizumab (VDZ) is approved for moderate-to-severe inflammatory bowel disease (IBD; ulcerative colitis [UC] & Crohn's disease [CD]).[1,2] While the subcutaneous (SC) formulation of VDZ is effective as maintenance treatment (mTx) in patients (pts) responding to intravenous (IV) VDZ induction treatment (Tx),[1,3] real-world data on Tx patterns of pts switching mTx from VDZ IV to SC or initiating mTx VDZ SC after IV induction are limited.

Aims & Methods: This prospective, non-interventional, multicentre (NCT05384080) study (conducted under the umbrella VARIETY protocol) enrolled adults with UC or CD initiating/undergoing induction with VDZ IV or continuing VDZ IV mTx, with the option to switch to VDZ SC mTx. The primary endpoint was real-world Tx patterns with VDZ, including Tx persistence. Additional endpoints assessed pt characteristics, pt-reported outcomes, and safety (adverse events [AEs]). Data were descriptively analysed.

Results: Overall, 162 enrolled pts (August 2022–June 2023; UC, n=103; CD, n=59) were included in the interim analysis. At enrolment, 127 (78.4%) received VDZ mTx (UC, n=78; CD, n=49) and 35 (21.6%), VDZ induction (UC, n=25; CD, n=10). The mean (SD) age was 38.2 (12.3) yrs, and time since IBD diagnosis was 10.7 (11.1) yrs. Majority of pts were male (96 [59.3%]), currently employed (124 [76.5%]), had never smoked (109 [67.3%]), and reported previous biologic therapy (95 [58.6%]). Demographic and IBD Tx history data were consistent across cohorts. At baseline, in pts with UC, the mean (SD) partial Mayo score was 1.8 (2.7); in pts with CD, the mean (SD) Crohn's Disease Activity Index (CDAI) score was 90.6 (70.1). During the 1-yr study period, 20.0% (n=7; UC, n=2; CD, n=5) of pts in the induction and 51.2% (n=65; UC, n=40; CD, n=25) in the mTx cohort switched to VDZ SC. At week (W) 52, Tx persistence was 40.0% (n=14; UC, n=11; CD, n=3) and 77.2% (n=98; UC, n=61; CD, n=37) in the induction and mTx cohorts, respectively, and highest overall in mTx pts who switched to VDZ SC (86.2%; n=56; Table).

The most common reason for Tx discontinuation was investigator decision (64.7%; n=33). For VDZ IV and SC, the mean (SD) number of doses per pt was 10.5 (7.6) and 23.8 (15.0), respectively. The median time from VDZ Tx initiation to SC Tx was 383 days (induction: 98 days; mTx: 434 days). In the induction cohort, the mean (SD) Work Productivity & Activity Impairment (WPAI) scores improved from 32.7 (24.1) at baseline (n=21) to 21.5 (31.2) at W52 (n=11), and the Short IBD Questionnaire (SIBDQ) scores improved from 44.1 (10.0) at baseline (n=34) to 51.0 (12.9) at W52 (n=15). In the mTx cohort, WPAI and SIBDQ results remained consistent over time. Fifty-three AEs were reported, including 4 serious AEs (malignancy, IBD flare requiring hospitalization, abdominal abscess, and unconsciousness). One AE of special interest (hypersensitivity reaction) was considered VDZ-related.

Tx persistence at W52	Total	IV only	SC only	IV-SC	IV-SC-IV
Overall	112/162 (69.1%)	53/86 (61.6%)	13/18 (72.2%)	59/72 (81.9%)	2/3 (66.7%)
Induction cohort[a]	14/35 (40.0%)	11/28 (39.3%)	-	3/7 (42.9%)	-
Maintenance cohort[b]	98/127 (77.2%)	42/58 (72.4%)	13/18 (72.2%)	56/65 (86.2%)	2/3 (66.7%)
UC cohort	72/103 (69.9%)	36/58 (62.1%)	8/12 (66.7%)	36/42 (85.7%)	1/2 (50.0%)
CD cohort	40/59 (67.8%)	17/28 (60.7%)	5/6 (83.3%)	23/30 (76.7%)	0 (0.0%)

Data are presented as n/N (%). [a]Induction cohort includes pts who started the study with VDZ induction Tx. [b]Maintenance cohort includes pts who started the study with VDZ maintenance Tx.
IV-SC are pts who started with VDZ IV and switched to SC during the study. IV-SC-IV are pts who switched from IV to SC and then back to IV. SC only are pts who received only VDZ SC during maintenance (with IV induction).
IV, intravenous; CD, Crohn's disease; SC, subcutaneous; Tx, treatment; UC, ulcerative colitis; VDZ, vedolizumab; W, week.

Conclusion: In this Polish real-world study, high Tx persistence was reported, especially in pts who switched to VDZ SC. No new safety signals were noted. Overall, the results were consistent with those from other VARIETY cohorts,[4] although lower persistence was observed during induction. The small size of the induction cohort was a limitation of this study.

EFFICACY AND SAFETY OF MIRIKIZUMAB AS INDUCTION THERAPY FOR CHINESE PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: A SUBGROUP ANALYSIS OF THE PHASE 3 LUCENT-1 STUDY

Z. Ran[1,2], J. Shen[3], Y. Chen[4], J. Luo[5], Y. Wang[6], X. Ding[7], H. Fang[8], D. Tang[9], C. Qian[9], J. Yu[9]

Introduction: Mirikizumab is an anti-IL-23p19 monoclonal antibody, a key mediator in the pathogenesis of inflammatory bowel diseases. We evaluated the induction efficacy and safety of mirikizumab in the LUCENT-1 (NCT03518086) Chinese subpopulation.

Aims & Methods: In this Phase 3, multi-center, randomized, parallel-arm, double-blind, placebo-controlled trial, conventional-failed or biologic/tofacitinib-failed Chinese adult patients (N=184) with moderately to severely active ulcerative colitis (UC, Modified Mayo Score 4-9, endoscopic subscore ≧2) were randomized in a 3:1 ratio to 300 mg mirikizumab (intravenous) or placebo every 4 weeks for 12 weeks. Randomization was stratified by biologic/tofacitinib failure status, baseline corticosteroid use and baseline disease activity (Modified Mayo Score). The primary objective was to test the hypothesis that mirikizumab was superior to placebo in inducing clinical remission at Week 12 (W12). Key secondary endpoints included alternate clinical remission, clinical response, clinical response in biologic-failed patients, symptomatic remission, endoscopic remission, histologic-endoscopic mucosal and bowel-movement urgency improvement. Analyses in Chinese subpopulation were descriptive. Missing data was imputed as non-responders for the categorical endpoints. Bowel urgency change from baseline data was reported based on Mixed Model Repeated Measured.

Results: Baseline characteristics were balanced across groups. A greater proportion of mirikizumab-treated patients achieved clinical remission (18.6% vs. 7.0%; Δ=11.5 [95%CI: 1.7, 21.3]) and alternate clinical remission at W12 (21.4% vs. 7.0%; Δ=14.3 [95%CI: 4.4, 24.2]). Mirikizumab also improved key secondary endpoints at W12. The frequencies of treatment-emergent adverse events were similar between groups (mirikizumab [60.0%] vs. placebo [62.8%]). There were fewer serious adverse events (10 [7.1%] vs. 7 [16.3%]) and discontinuations due to adverse events (2 [1.4%] vs. 3 [7.0%]) in mirikizumab-treated patients compared to placebo. There was 1 adenocarcinoma of colon (mirikizumab group) and no deaths during the treatment period.

	Placebo IV N=43	Miri 300 mg IV N=140
Clinical Remission at Week 12, n (%)	3 (7.0)	26 (18.6)
Common risk difference vs placebo		11.5
Alternate Clinical Remission at Week 12, n (%)	3 (7.0)	30 (21.4)
Common risk difference vs placebo		14.3
Clinical Response at Week 12, n (%)	13 (30.2)	76 (54.3)
Common risk difference vs placebo	3 (13.0)	23.2
Clinical Response (biologic-failed) at Week 12, n (%)		32 (45.1)
Common risk difference vs placebo		32.0
Endoscopic remission at Week 12, n (%)	5 (11.6)	44 (31.4)
Common risk difference vs placebo		19.0
HEMI at Week 12, n (%)	2 (4.7)	24 (17.1)
Common risk difference vs placebo		12.6
Symptomatic remission at Week 4, n (%)	5 (11.6)	15 (10.7)
Common risk difference vs placebo		-1.6
Symptomatic remission at Week 12, n (%)	8 (18.6)	49 (35.0)
Common risk difference vs placebo		16.2
Urgency Numeric Rating Scale (NRS), LSM (SE)	-1.6 (0.4)	-2.0 (0.2)
LSM difference vs placebo		-0.39

CI = confidence interval; IV = intravenous; LSM = least squares mean; Miri = mirikizumab; SE = standard error.
Modified Intent-to-Treat population. Number of biologic-failed patients in placebo and Miri groups were 23 and 71, separately.
Clinical remission: Stool frequency (SF) subscore = 0 or 1 with a ≥1-point decrease from baseline, and Rectal bleeding (RB) subscore = 0, and Endoscopic subscore (ES) = 0 or 1 (excluding friability)
Alternate clinical remission: SF subscore = 0 or 1, RB subscore = 0, and ES = 0 or 1 (excluding friability)
Clinical response: decrease in the modified Mayo score of ≥2 points and ≥30% decrease from baseline, and decrease of ≥1 point in the RB subscore from baseline or an RB score of 0 or 1
Clinical response (bio-failed): clinical response in patients who had previously failed biologic or tofacitinib therapy
Endoscopic remission: ES = 0 or 1 (excluding friability)
HEMI (histologic-endoscopic mucosal improvement): Histologic improvement, defined using Geboes scoring system with neutrophil infiltration in <5% of crypts, no crypt destruction, and no erosions, ulcerations, or granulation tissue; and endoscopic remission
Symptomatic remission: SF = 0, or SF = 1 with a ≥1-point decrease from baseline and RB = 0
Urgency NRS (numeric rating scale) Δ baseline: least square mean change in urgency NRS from baseline
Mixed Model for Repeated Measures (MMRM) was used to compare the treatment groups for bowel movement urgency improvement; for all other endpoints, the Cochran-Mantel-Haenszel (CMH) test with missing data imputed as nonresponse, was used to compare the treatment groups while adjusting for the stratification factors. All analyses in Chinese subpopulation were for descriptive purpose, and multiplicity adjustment was not applied.

Table 1: Primary and key secondary outcomes of LUCENT-1 in Chinese population.

Conclusion: Efficacy and safety profiles were consistent with LUCENT-1 overall population, supporting benefits of mirikizumab treatment in the Chinese UC patients.

Disclosure: Nothing to disclose.

Introduction: Sex-based differences have shown to impact ulcerative colitis (UC) treatment outcomes and need to be considered when managing therapy strategies for patients with UC. Etrasimod is an oral, once-daily (QD), selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator for the treatment of moderately to severely active UC.

Aims & Methods: This pre-defined subgroup analysis reports on efficacy and safety outcomes in male and female patients receiving etrasimod 2 mg QD or placebo in the phase 3 ELEVATE UC 52 (NCT03945188) and ELEVATE UC 12 (NCT03996369) trials. Key efficacy endpoints were assessed in patients with a baseline modified Mayo score 5–9 at Week 12 (data pooled from both trials) and Week 52 (ELEVATE UC 52 only). Safety was assessed in the pooled ELEVATE UC 52 and ELEVATE UC 12 safety population.

Results: In the pooled population, a total of 269 male and 227 female patients received etrasimod; 150 and 97, respectively, received placebo. Significantly more male and female patients receiving etrasimod vs placebo achieved clinical remission (Week 12 – male: percentage difference for etrasimod vs placebo [Δ] 10.7, female: Δ 19.7; Week 52 – male: Δ 21.5, female: Δ 29.1; all $p < 0.01$), symptomatic remission (Week 12 – male: Δ 21.4, female: Δ 20.6; Week 52 – male: Δ 26.4, female: Δ 22.5; all $p < 0.01$), endoscopic improvement (Week 12 – male: Δ 12.7, female: Δ 21.2; Week 52 – male: Δ 21.9, female: Δ 32.5; all $p < 0.01$) and endoscopic improvement-histologic remission (Week 12 – male: Δ 9.9, female: Δ 16.7; Week 52 – male: Δ 14.1, female: Δ 24.1; all $p < 0.01$; Table). Similar findings were seen for corticosteroid-free and sustained clinical remission (Table). Similar proportions of treatment-emergent adverse events (TEAEs; 56.8% and 64.6%), serious TEAEs (4.9% and 5.0%) and TEAEs leading to discontinuations (3.8% and 5.8%) were reported in male and female patients receiving etrasimod and were comparable to those receiving placebo.

Conclusion: Similar findings in male and female patients support the use of etrasimod in both to achieve symptomatic, endoscopic and histologic outcomes.

Introduction: Identifying patient populations and factors associated with long-term treatment response can enable personalised management strategies in ulcerative colitis (UC). Etrasimod is an oral, once-daily, selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator for the treatment of moderately to severely active UC.

Aims & Methods: Our aim was to identify patient subgroups with distinct response trajectories based on changes in combined rectal bleeding subscore (RBS) and stool frequency subscore (SFS) over time. In this post hoc analysis of etrasimod-treated patients from the ELEVATE UC 52 trial, PRO2 (SFS+RBS) was assessed to identify unique disease response trajectories, with further evaluation of the Week 52 achievement of primary and secondary endpoints. Additionally, a composite of objective and subjective disease activity measures, previously used in trajectory modelling, was assessed as comprehensive disease control (CDC). CDC was defined as meeting all the following criteria by Week 52: complete treatment (up to Week 50), clinical remission, RBS and SFS =0, endoscopic subscore =0/1, complete Mayo score ≤2, histological remission (Geboes score <2 or Robarts Histopathology Index <3), and C-reactive protein and/or faecal calprotectin within normal range. Longitudinal k-means was used to analyse PRO2 disease activity data as individual time-series connected datasets. Response-trajectory groups (TGs) were related to maintenance outcomes and baseline clinical characteristics. We evaluated the clinical relevance of grouping patients this way by assessing the proportions achieving key endpoints and their association with baseline demographics.

Results: Among the cohort of 283 etrasimod-treated UC patients, five TGs were identified (Table). 57% of the super-responders who achieved CDC were clustered in TGs C and E, characterised by rapid response and sustained clinical remission (TG C: 34/51 patients, TG E: 25/44 patients). Baseline characteristics of these patients included lower baseline disease activity, as measured by histology and Mayo score components. In TGs B and D, clinical remission was achieved by 31.7% and 34%, respectively, with clinical response achievement of 48.3% (29/60) and 53.2% (25/47). In TG E, symptomatic improvement according to PRO2 continued beyond Week 12.

Cluster	Clinical remission, n (%)	Clinical response, n (%)	Symptomatic remission, n (%)	Symptomatic response, n (%)	Endoscopic improvement, n (%)	EIHR, n (%)	CDC, n (%)
C (N=51)	34 (66.7)	44 (86.3)	45 (88.2)	45 (88.2)	34 (66.7)	26 (51.0)	17 (33.3)
E (N=44)	25 (56.8)	37 (84.1)	34 (77.3)	38 (86.4)	29 (65.9)	18 (40.9)	7 (15.9)
D (N=47)	16 (34.0)	25 (53.2)	22 (46.8)	27 (57.4)	17 (36.2)	12 (25.5)	6 (12.8)
B (N=60)	19 (31.7)	29 (48.3)	25 (41.7)	33 (55.0)	26 (43.3)	19 (31.7)	12 (20.0)
A (N=81)	0	8 (9.9)	1 (1.2)	9 (11.1)	7 (8.6)	4 (4.9)	0

Clusters (A–E) are presented in descending order according to the highest proportion of patients with clinical remission at Week 52.
CDC, comprehensive disease control; EIHR, endoscopic improvement-histologic remission; N, number of patients in each patient cluster; n, number of patients achieving each endpoint; UC, ulcerative colitis.

Table. Number of patients achieving efficacy endpoints at Week 52 in the ELEVATE UC 52 trial, by patient clusters.

Conclusion: Trajectory modelling allows the identification of distinct phenotypic subgroups among UC patients responding to a targeted therapy, highlighting heterogeneity often masked when analysed as a single population or clinical trial. Notably, a subset of etrasimod patients demonstrated super-fast and fast response dynamics, associated with higher rates of clinical remission and CDC. This may provide an important utility for therapeutic choice and patient management under therapy. Further studies across different modes of action are ongoing to validate these results and identify similarities and differences across patient populations and treatment effects.

Introduction: When conventional ulcerative colitis (UC) therapy fails to achieve or maintain remission, advanced UC therapies should be considered to improve patient outcomes. The responder re-randomisation trial (efficacy reported at the end of the maintenance phase for patients who achieved induction clinical response) is a common design used in UC drug development. Etrasimod is an oral, once-daily (QD), selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator for the treatment of moderately to severely active UC. The etrasimod ELEVATE UC 52 trial utilised a treat-through design, where efficacy at the end of the maintenance phase was reported for the total baseline population.

Aims & Methods: This post hoc analysis evaluated the efficacy of etrasimod vs placebo at Week 52 among biologic/Janus kinase inhibitor (bio/JAKi)-naïve patients with moderately to severely active UC who achieved clinical response at Week 12. ELEVATE UC 52 (NCT03945188) comprised a 12-week induction phase followed by a 40-week maintenance phase with a treat-through design. Patients were randomised 2:1 to receive etrasimod 2 mg or placebo QD. Week 12 clinical response was defined as a ≥2-point and ≥30% decrease from baseline in modified Mayo score (MMS), and a ≥1-point decrease or absolute value ≤1 in rectal bleeding subscore.

Efficacy outcomes evaluated in Week 12 bio/JAKi-naïve responders (baseline MMS 5–9) were the achievement of clinical remission, clinical response, symptomatic remission, endoscopic improvement, endoscopic improvement-histologic remission and corticosteroid-free clinical remission at Week 52.

Results: Among bio/JAKi-naïve patients, Week 12 clinical response was achieved by 132/194 (68.0%) receiving etrasimod and 35/93 (37.6%) receiving placebo. Among Week 12 responders, significantly greater proportions receiving etrasimod vs placebo achieved clinical remission (51.5% vs 17.1%; $p<0.001$) and all secondary endpoints at Week 52 (all $p<0.05$; Table).

	Placebo QD (N=35)	Etrasimod 2 mg QD (N=132)	Adjusted % difference (95% CI) [p value]
Clinical remission, n (%)[a]	6 (17.1)	68 (51.5)	34.6 (19.41, 49.83) [p<0.001]
Clinical response, n (%)[b]	19 (54.3)	99 (75.0)	20.5 (2.50, 38.53) [p=0.026]
Symptomatic remission, n (%)[c]	16 (45.7)	93 (70.5)	24.4 (6.07, 42.63) [p=0.009]
Endoscopic improvement, n (%)[d]	8 (22.9)	75 (56.8)	34.4 (17.83, 50.99) [p<0.001]
EIHR, n (%)[e]	7 (20.0)	53 (40.2)	20.6 (4.55, 36.58) [p=0.012]
CS-free clinical remission, n (%)[f]	6 (17.1)	68 (51.5)	34.6 (19.41, 49.83) [p<0.001]

p<0.05 are highlighted in bold.
Treatment comparisons within each subgroup (adjusted percentage difference and 95% CI) and 2-sided p values were obtained using the Cochran–Mantel–Haenszel method, adjusting to reported randomisation stratification of baseline CS use and baseline disease activity (MMS of 4–6 or 7–9). Missing response was considered as nonresponse.
[a]Clinical remission was defined as an SFS=0 (or =1 with a ≥1-point decrease from baseline), RBS=0, and ES ≤1 (excluding friability).
[b]Clinical response was defined as a ≥2-point and ≥30% decrease from baseline in MMS and a ≥1-point decrease from baseline in RBS or an absolute RBS ≤1.
[c]Symptomatic remission was defined as an SFS=0 (or =1 with a ≥1-point decrease from baseline) and an RBS=0.
[d]Endoscopic improvement defined as an ES of ≤1.
[e]EIHR was defined as an ES ≤1 with histological remission (Geboes Index score <2.0).
[f]CS-free clinical remission was defined as the proportion of patients with clinical remission at Week 52 who had not been receiving CS for ≥12 weeks immediately prior to Week 52.
bio, biologic; CI, confidence interval; CS, corticosteroid; EIHR, endoscopic improvement-histologic remission; ES, endoscopic subscore; JAKi, Janus kinase inhibitor; MMS, modified Mayo score; QD, once daily; RBS, rectal bleeding subscore; SFS, stool frequency subscore.

Table. Efficacy endpoints at Week 52 among bio/JAKi-naïve patients who met clinical response criteria at Week 12 (baseline MMS 5–9).

Conclusion: Etrasimod demonstrated significant efficacy over placebo in all Week 52 efficacy outcomes in bio/JAKi-naïve induction treatment responders. These findings help contextualize data from the ELEVATE UC clinical programme for patients receiving their first advanced UC therapy within a treat-through trial design.

UNDERSTANDING BENEFIT-RISK TRADE-OFF DIFFERENCES BETWEEN ADVANCED THERAPY NAÏVE AND EXPERIENCED PATIENTS TO INFORM SHARED DECISION MAKING IN ULCERATIVE COLITIS: A DISCRETE CHOICE EXPERIMENT IN THE UNITED STATES AND EUROPE

Introduction: Prior experience with advanced therapy (AT) may influence the benefit-risk trade-offs ulcerative colitis (UC) patients are willing to make when choosing treatment. It is important to understand differences between AT naïve and experienced patients to inform shared decision making.

Aims & Methods: We aimed to compare preferences for AT and willingness to make benefit-risk trade-offs among AT naïve and AT experienced patients with moderate-to-severe UC. An online discrete choice experiment (DCE) survey was administered to patients with self-reported moderate-to-severe UC in the US, UK, France, Germany, Italy and Spain. Patients chose between hypothetical AT profiles with varying levels of six treatment attributes: time until symptom improvement, probability of remission at one year, probability of corticosteroid (CS)-free remission at one year, annual risk of serious infection, five-year risk of cancer and annual risk of major adverse cardiovascular event (MACE).
We used random parameters logit models stratified by AT naïve vs experienced to estimate the relative attribute importance (RAI: 0–100%). For the RAI, remission attributes were combined. Risk tolerance measures included the maximum acceptable risk (MAR) for each risk independently and the simultaneous MAR threshold for the three risks together that respondents would accept for a 10 percentage-point increase in probability of remission at one year.

Results: 557 patients (49.6% AT naïve; 50.4% AT experienced) completed the survey. ATnaïve patients ranked combined remission and CS-free remission at one year (RAI=36.0%) and five-year cancer risk (RAI=35.3%) as most important, whereas AT experienced patients ranked combined remission (RAI=43.1%) as most important over cancer risk (RAI=28.8%; Table).
The MAR of five-year cancer risk in exchange for a 10 percentage-point increase in probability of remission at one year was higher for AT experienced patients than AT naïve patients (2.9% vs 1.8%). The MARs for the other two risk attributes were close to or above the maximum level tested in the DCE.
When cancer and MACE attributes were considered jointly in exchange for a 10 percentage-point increase in probability of remission at one year, no difference in risk tolerance was observed between AT experienced and naïve patients when serious infection was >1%.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 	Attributes tested in the DCE[a]				
	Time until symptom improvement	Combined probability of remission and CS-free remission at one year	Annual risk of serious infection	Five-year risk of cancer	Annual risk of MACE
RAI,[b] % (95% CI)[c]					
Advanced therapy naïve	9.7 (6.6, 12.9)	36.0 (32.9, 39.0)	9.4 (7.0, 11.9)	35.3 (32.8, 37.9)	9.5 (7.1, 12.0)
Advanced therapy experienced	11.4 (9.5, 14.0)	43.1 (40.6, 45.4)	6.3 (4.4, 8.3)	28.8 (26.7, 30.7)	10.4 (8.4, 12.2)

[a]Treatment attributes and corresponding levels included in the DCE: time until symptom improvement (2 weeks, 4 weeks, 8 weeks, 12 weeks), probability of remission at one year (20%, 35%, 45%), probability of CS-free remission at one year (5.0%, 15%, 20%, 30%, 35%, 40%, 45%), five-year risk of cancer (1.0%, 4.0%, 7.0%), annual risk of MACE (0.1%, 0.3%, 0.5%) and annual risk of serious infection (1.0%, 3.0%, 5.0%). We combined the probability of remission at one year and the probability of CS-free remission at one year into one attribute at the analysis stage for the RAI.

[b]RAI is calculated as the difference in preference weights between the most preferred and least preferred level divided by the sum of the differences across all attributes; estimates sum to 100%.

[c]95% CIs that do not include zero indicate a statistically significant relative importance of an attribute. All attributes were statistically significantly important when selecting an advanced therapy.

CI, confidence interval; CS, corticosteroid; DCE, discrete choice experiment; MACE, major adverse cardiovascular event; N, number of patients; RAI, relative attribute importance; UC, ulcerative colitis.

Table. Relative importance of attributes influencing advanced UC therapy choice in patients who are advanced therapy naïve (N=276) and advanced therapy experienced (N=281).

Conclusion: On average, combined remission at one year and five-year risk of cancer had similarly strong influence on treatment choice for AT naïve patients, while AT experienced patients prioritised combined remission followed by five-year risk of cancer. The difference between AT experienced and naïve patients' willingness to accept five-year risk of cancer for an increase in probability of one-year remission reduced as the other risks increased. For shared decision making, clinicians should consider discussing the holistic risk profile with prioritisation of remission and malignancy throughout the lines of therapy.

Introduction: Guselkumab (GUS) is a dual-acting IL-23p19 subunit inhibitor that potently neutralizes IL-23 and binds to CD64, a receptor on cells that produce IL-23.[1]
In the Phase 3 QUASAR maintenance study (NCT04033445), both the GUS 100mg every 8 weeks (q8w) and 200mg q4w subcutaneous (SC) maintenance dose regimens were efficacious.[2]
Here, we evaluated efficacy of these dose regimens in clinically relevant subgroups of participants (pts) with and without extensive ulcerative colitis (UC) disease or high inflammatory burden.

Aims & Methods: Clinical responders after 12 weeks of GUS intravenous (IV) induction were randomized 1:1:1 to GUS 100mg SC q8w, GUS 200mg SC q4w or placebo (PBO) (GUS withdrawal) at start of the maintenance study (M-0). Efficacy endpoints were analyzed at Week (W)44 in the primary analysis population of pts randomized and treated in the maintenance study who had a modified Mayo score of 5-9 at induction baseline (I-0).
Subgroup analyses were conducted by (1) extent of UC disease (limited to left side of colon vs extensive) based on screening endoscopy and/or medical history at I-0 and (2) inflammatory burden based on serum C-reactive protein (CRP) levels (≤3 vs >3mg/L) at M-0.

Results: Of 568 pts in the primary analysis population, 257 (45.2%) had extensive UC disease at I-0 and 182 (32.0%) had serum CRP >3mg/L at M-0. Proportions of pts achieving W44 clinical and histologic-endoscopic efficacy endpoints were greater with both GUS dose regimens vs PBO across subgroups (Table).
For pts with extensive UC disease, the proportion of pts achieving clinical remission at W44 was numerically greater with GUS 200mg q4w (62.7%) relative to GUS 100mg q8w (49.4%) (PBO, 11.6%). For those with elevated CRP (>3mg/L) at M-0, clinical remission at W44 was achieved by 48.2% of GUS 200mg q4w vs 30.2% of GUS 100mg q8w pts (PBO, 14.3%).
Proportions of pts achieving endoscopic improvement, histo-endoscopic improvement, endoscopic remission, and maintenance of clinical remission were also greater with GUS 200mg q4w in these subgroups. Among pts with disease limited to the left side of the colon or CRP ≤3mg/L at M-0, proportions of pts achieving these efficacy endpoints were similar with GUS 100mg q8w and GUS 200mg q4w.

Endoscopic remission	22.1%	31.2%	25.2%	8.4%	39.2%‡	44.6%‡	18.1%	40.0%‡	34.3%†	9.5%	23.8%*	32.1%†

Includes pts with modified Mayo score of 5-9 at induction baseline who achieved clinical response to GUS induction and were re-randomized at maintenance study entry.
*P<0.05, †P<0.01, ‡P<0.001 vs PBO (nominal P values), based on the Cochran-Mantel Haenszel test stratified by clinical remission status at maintenance baseline and induction treatment, except for maintenance of clinical remission where P values were based on Fisher's exact test.
[a]Denominator includes only pts with clinical remission at maintenance baseline.
Clinical remission is defined as a stool frequency subscore of 0 or 1 and not increased from induction baseline, a rectal bleeding subscore of 0, and an endoscopy subscore of 0 or 1 with no friability. Maintenance of clinical remission is defined as clinical remission at W44 among pts in clinical remission at maintenance baseline. Endoscopic improvement is defined as an endoscopy subscore of 0 or 1 with no friability. HEMI is defined as achieving a combination of histologic improvement and endoscopic improvement. Endoscopic remission is defined as an endoscopy subscore of 0.
Pts who had an ostomy or colectomy, dose adjustment, prohibited change in UC medication, or who discontinued study agent due to lack of efficacy or an AE of worsening of UC prior to W44 were considered not to have achieved the efficacy endpoints. For pts who discontinued study agent due to COVID-19 related reasons (excluding COVID-19 infection) or regional crisis in Russia and Ukraine prior to W44, the observed values were used if available. Pts who discontinued study agent for other reasons prior to W44 were considered not to have achieved the endpoint. Nonresponder imputation for missing data: pts who were missing 1 or more of the components pertaining to an endpoint at W44 were considered not to have achieved the endpoint. Pts who had an unevaluable biopsy were considered not to have achieved histologic endpoints.
AE=Adverse event; CRP=C-reactive protein; GUS=Guselkumab; HEMI=Histologic-endoscopic mucosal improvement; I-0=Induction study baseline; M-0=Start of the maintenance study; PBO=Placebo; pts=Participants; Q4W=Every 4 weeks; Q8W=Every 8 weeks; SC=Subcutaneous; UC=Ulcerative colitis; W=Week.

Table. Key efficacy endpoints at maintenance W44 in subgroups of pts from QUASAR defined by extent of UC disease (limited to left side of colon vs extensive) at I-0 and inflammatory burden (serum CRP ≤3 vs >3mg/L) at M-0.

Conclusion: For pts with moderately to severely active UC with extensive disease or high inflammatory burden, greater efficacy rates were observed with GUS 200mg SC q4w compared with GUS 100mg SC q8w.

PP0493

COMPARATIVE ANALYSIS OF HEALTHCARE RESOURCE UTILISATION AND DIRECT COSTS IN CROHN'S DISEASE FROM US CLAIMS: EARLY VS LATE BIOLOGIC INITIATION

A.M. Parian[1], D. Fisher[2], A.J.M. Brnabic[2], N. Bires[2], D. Tinsley[2], Z. Kadziola[2], W.M.M. Chan[2]
[1]Johns Hopkins Medicine, Baltimore, United States of America, [2]Eli Lilly and Company, Indianapolis, United States of America

Contact E-Mail Address: chan_wai_man_maria@lilly.com

Introduction: While early intervention with biologics improves clinical response in Crohn's disease (CD), the optimal timing to reduce healthcare resource utilisation (HCRU) and direct costs remains unclear. This study examined the impact of biologic initiation on HCRU and direct costs over 5 years in adults recently diagnosed with CD in the US.

Aims & Methods: Adults with >2 non-ancillary outpatient claims (30 days apart) or 1 inpatient claim for CD (ICD-10: K50.x) from 1/1/2015 to 7/31/2024 were identified using Optum® Clinformatics® Data Mart. Patients with CD who started biologic treatment within 2 years of diagnosis (index date) and had continuous enrollment for 1 year pre- and 5 years post-index were stratified into early (<12 months) or late (>12-24 months) initiators. Due to skewed distributions, CD-related and non-CD-related costs at 5-year post-index were analysed using gamma log. Poisson or negative binomial (with zero-inflated models in some cases) were used to model HCRU. All models were adjusted for demographic and clinical characteristics at biologic initiation.

Results: Early initiators (EI) were significantly younger (mean[SD] age: 43.2[16.9] vs 48.0[16.6] years, p<0.001), predominantly male (50.6% vs 44.5%), had significantly higher commercial insurance (84.5% vs 77.2%,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

p=0.004) than late initiators (LI), and had similar Deyo Charlson comorbidity index scores (mean[SD]: 0.7[1.2] vs 0.7[1.3]). EI had significantly lower total mean medical costs ($63,761 vs $66,282), significantly lower IBD-related mean medical and pharmacy costs ($1074 vs $1494), as well as significantly lower mean pharmacy costs to treat depression ($28 vs $346), and anxiety ($38 vs $79) than LI (Table).

Additionally, EI had fewer emergency visits (1.5 vs 1.6), fewer all-cause (4.2 vs 4.9 days), and CD-related hospitalisations days (3.9 vs 4.7 days) than LI. Other HCRUs and costs were similar between the two groups.

	Early initiator (EI) (N=1273)	Late initiator (LI) (N=290)	Adjusted P-value
Costs in US Dollars			
Medical and pharmacy costs	$290,491 (239,398)	$298,162 (246,492)	0.794
Medical costs	$63,761 (128,352)	$66,282 (97,089)	0.0497
Anxiety/depression outpatient costs	$11,492 (48,843)	$12,203 (41,583)	0.763
Non-IBD pharmacy costs	$225,657 (194,145)	$230,385 (210,412)	0.711
Opioid pharmacy costs	$170 (1697)	$189 (1285)	0.825
Anti-depression pharmacy costs	$28 (393)	$346 (4746)	<.001
Anti-anxiety medication costs	$38 (476)	$79 (690)	0.007
CD-related medical and pharmacy costs	$108,293 (116,124)	$100,574 (112,197)	0.070
CD-related medical costs	$42,451 (70,935)	$45,547 (74,554)	0.159
IBD-related medical and pharmacy costs	$1,074 (5,567)	$1,494 (6,971)	0.046
HCRU			
Number of emergency department visits	1.5 (4.1)	1.6 (4.0)	0.004
Number of outpatient visits	56.6 (49.8)	60.1 (53.6)	0.402
Number of CD outpatient visits	23.7 (19.2)	24.1 (19.9)	0.357
Number of CD-related emergency department visits	0.7 (2.3)	0.8 (2.3)	0.071
Number of CD-related hospitalisations	0.6 (1.2)	0.7 (1.4)	0.886
Number of IBD-related diagnostic procedures	0.8 (1.0)	0.9 (1.0)	0.398
Number of CD-related management procedures	0.1 (0.3)	0.1 (0.3)	0.417
Patients having pharmacy claim, n (%)	1240 (97.4%)	277 (95.5%)	0.289
Patients having IBD-related pharmacy, n (%)	184 (14.5%)	33 (11.4%)	0.163
Patients having Extraintestinal manifestation, n (%)	58 (4.6%)	17 (5.9%)	0.458
Days of hospitalisation	4.2 (10.4)	4.9 (12.3)	0.013
Days of CD-related hospitalisations	3.9 (9.5)	4.7(12.2)	<.001
Length of hospitalisation in days	2.0 (3.8)	2.1 (4.5)	0.102

Data are presented as mean (SD=standard deviation) unless otherwise specified.
CD, Crohn's disease; IBD, inflammatory bowel disease

Conclusion: Early initiators of biologics had lower HCRU and reduced non-CD medication pharmacy costs at 5 years post-index compared to starting biologics after a year, potentially leading to overall cost savings and improving patient health outcomes.

Introduction: Real-world data on the speed of onset of ustekinumab (UST) in patients with ulcerative colitis (UC) are limited. Current information regarding early response in these patients comes from the UNIFI trial.

Aims & Methods: The primary outcome of this study was to evaluate the response to UST in patients with moderate-to-severe UC by assessing PRO2 at 14 days after the first intravenous dose (6mg/kg).

Methods: A multicenter, prospective observational study was designed in patients ≥18 years old with moderate-to-severe UC (partial Mayo score ≥6) who initiated UST 6mg/kg between June 2023 and September 2024. Patients received a diary to record the stool frecuency and rectal bleeding during first 14 days after first dose of induction. The proportion of patients achieving the combined outcome of rectal bleeding score = 0 and stool frequency score ≤ 1 (PRO-2: patient-reported outcome 2 remission) was assessed. FC was measured at baseline and at day 7 and 14. Health-Related Quality of Life was evaluated using the disease-specific shortened Spanish version of the IBDQ (SIBDQ-9) at baseline and at 4 weeks. Patients with previous panproctocolectomy with ileostomy or pouch and those who had received cyclosporine within one month prior to starting UST were excluded. Descriptive statistics are presented as frequencies with percentages for categorical variables.

Results: A total of 54 patients were included across 14 hospitals in Spain. Of these, 29 (53.7%) were men, with a mean age of 54 (± SD 16.1) years. Thirty (55.6%) patients had pancolitis, 20 (37%) had left-sided colitis, and 4 (7.4%) had proctitis. Five (9.3%) patients were bio-naïve, 32 (59.3%) had previously received one biological therapy, 10 (18.5%) had received two, and 7 (13%) had received three biologics prior to starting UST. By day 14, 26% of patients had achieved clinical remission. No significant differences

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. in clinical remission were observed based on disease extent (p = 0.11) or the number of prior biologics (p = 0.39). By day 7, 12/31 (38.7%) patients with baseline bloody stools had achieved a rectal bleeding score = 0. A reduction in FC >50% was observed in 14/48 (29%) patients by day 7 and in 20/47 (43%) patients by day 14. The SIBDQ9 average score was 54.9 (± SD 6.2) at baseline and 61.3 (± SD 7.4) at week 4.

Conclusion: One-quarter of patients with moderate-to-severe UC achieved clinical remission by day 14 following the first induction dose of UST. Nearly 40% of patients achieved a rectal bleeding score = 0 (PRO2) by day 7. A reduction in FC >50% was observed in 43% of patients by day 14.

Introduction: Mesalazine suppositories are recommended in guidelines for the induction and maintenance of remission in patients with ulcerative proctitis (UP). Nevertheless, nonadherence can be frequent and the recommended dose of mesalazine suppositories in maintenance treatment remains unknown.

Aims & Methods: The aim of this study was to determine the frequency of non-adherence to mesalazine suppositories, evaluate potential factors for nonadherence and the impact on quality of life and number of relapses in patients with UP.

Methods: A multicenter, prospective observational study was designed in patients ≥18 years old with UP under maintenance treatment with mesalazine suppositories (Claversal© 500 mg, Pentasa© 1g or Salofalk©1g). We evaluated adherence, socio-demographic data and complications associated with poor adherence at 6 and 12 months. Adherence was assessed by tracking pharmacy refills (medication possession ratio, MPR). We defined good adherence as MPR ≥80% over 12 months. Health-Related Quality of Life (HRQoL) was evaluated using the disease-specific shortened Spanish version of the IBDQ (SIBDQ-9). Relapse was defined as partial Mayo ≥2; biological remission as a partial Mayo score <2 and fecal calprotectin ≤150. Multivariate analysis allowed us to determine the risk factors for non-adherence to mesalazine suppositories.

Results: A total of 188 patients with mean age 51 were consecutively included across 14 Spanish hospitals (Table 1). Of these, mean MPR was 76% and 56% presented MPR ≥80%. Mean age was higher among patients with MPR ≥80% (p=0.045). A total of 125 (71,4%) patients were in biological remission, 31 patients (16%) had a relapse and 3 (1.6%) patients were hospitalized during the follow-up. The use of corticosteroids during the follow-up (OR=4.25, p=0.041) were associated with better adherence. There were no differences between the different brands and doses of suppositories analyzed. Low adherence was not related with increased number of flares (p=0.927), hospitalizations (p=0.225) or decreased quality of life (p = 0.353) over the 12 months of follow-up

Conclusion: Almost half of patients with UP on maintenance treatment with mesalazine suppositories have low adherence. The use of oral corticosteroids during the follow-up may increase adherence, but poor adherence to mesalazine suppositories was not related with risk of relapse, hospitalizations or worst quality of life.

Introduction: Biologic therapy remains a key treatment modality in the management of ulcerative colitis (UC) and Crohn's disease (CD). However, prospective observational studies assessing its longitudinal impact on health-related quality of life (HRQoL) in these patients are lacking.

Aims & Methods: This study aimed to compare HRQoL scores at one-year follow-up between patients who received biologic therapy within the first year after diagnosis and those who did not. A secondary objective was to evaluate the same association at three-year follow-up.

Adults (≥18 years) were recruited from the Inflammatory Bowel Disease in South-Eastern Norway III (IBSEN III) cohort, a prospective, population-based study of newly diagnosed, unselected patients with UC and CD.

HRQoL was measured using the disease-specific Inflammatory Bowel Disease Questionnaire (IBDQ) and the generic Short Form-36 (SF-36) at diagnosis, as well as at one- and three-year follow-ups. For the SF-36, we analysed the General Health domain, as well as Physical Component Summary (PCS) and Mental Component Summary (MCS) scores.

Generalised linear mixed models for repeated measures were used to estimate associations between biologic therapy and HRQoL scores over time. For UC, models were adjusted for age, sex, education, civil status, work status, Montreal disease extent, disease severity at diagnosis, and Simple Clinical Colitis Activity Index (SCCAI) scores. For CD, we adjusted for demographics, Montreal disease location and behaviour, and Harvey-Bradshaw Index (HBI) scores. HRQoL scores at diagnosis were included as covariates.

Results: A total of 1278 patients were included (UC: 857 [67.1%], CD: 421 [32.9%]). Patients who completed HRQoL questionnaires were significantly older and more often female than non-responders. No other demographic or disease-related significant differences between responders and non-responders were found. Therefore, the study population was considered representative of the broader cohort. During the first year, 121/857 (14.1%) patients with UC and 165/421 (39.2%) patients with CD received biologic therapy.

Patients with UC who received biologic therapy reported significantly lower IBDQ scores at one-year follow-up compared to those who did not, even after adjusting for demographics, disease activity, and IBDQ scores at diagnosis (estimated mean IBDQ score with biologics: 170.6, without biologics: 182.5; p=0.04). Similarly, SF-36 scores were significantly lower at one-year follow-up among patients with UC who received biologics compared to those without: General Health (57.0 vs. 63.3), PCS (43.4 vs. 46.9), MCS (43.4 vs. 46.0) (all p<0.05). No significant associations were found between biologic therapy during the first year and HRQoL scores at three-year follow-up for patients with UC.

Among patients with Crohn's disease, no statistically significant associations were found between biologic therapy in the first year and HRQoL scores at either of the follow-ups.

Conclusion: In newly diagnosed patients with UC, biologic therapy initiated within the first year was independently associated with significantly lower HRQoL scores at one-year follow-up, but not at three-year follow-up. In CD, biologic therapy was not associated with significant changes in HRQoL at either of the follow-ups.

PERIODONTITIS (PO) - A COMMON COMPLICATION OF CHRONIC INFLAMMATORY BOWEL DISEASE A SYMPTOM-ORIENTATED SCORE FOR RECORDING PO REQUIRING TREATMENT

M. Gund[1], M. Hannig[1], S. Rupf[1], W. Kreisel[2]

[1]Saarland University Medical Centre, Homburg, Germany, Clinic of Operative Dentistry, Periodontology and Preventive Dentistry, Homburg, Germany, [2]University of Freiburg, Faculty of Medicine, Medical Centre, Department of Medicine II, Gastroenterology, Hepatology, Endocrinology and Infectious Diseases, Freiburg, Freiburg, Germany

Contact E-Mail Address: madline.gund@uks.eu

Introduction: A disturbed intestinal mucosal barrier is crucial in the pathogenesis of chronic inflammatory bowel disease (IBD). A higher susceptibility of patients with IBD to periodontitis (PO) is consistent with a similar pathogenesis. However, PO is often neglected in IBD patients, because their therapy is focussed on the intestinal symptoms.

Aims & Methods: A symptom-orientated score should be developed, which results from the information in a questionnaire that patients answer. A threshold value should indicate PO requiring treatment. A PO score is calculated on the basis of the questionnaire and compared with an objective grading of PO (determined by a clinical assessment). Grade 0 = no PO, grade 1 = mild PO (not requiring treatment), grade 2 = moderate PO, grade 3 or 4 = severe PO. Data was collected from 146 control subjects without IBD, 76 patients with Crohn's disease (CD) and 42 patients with ulcerative colitis (UC).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The table shows the distribution of clinical PO grades in the 3 groups (No IBD, CD, CU) in absolute numbers and per cent as well as the respective mean PO score. The data of the control group were used for the evaluation of the questionnaire. There was a good correlation between the objective degree of PO and the PO score determined from the patients' statements. The ROC analysis showed that a PO score of 6.75 resulted in a sensitivity of 72.4% and a specificity of 64% for the detection of PO stage ≥ 2. For the detection of a PO stage ≥ 3, a PO score of 7.75 results in a sensitivity of 73.2% and a specificity of 64%. The AUROC was 0.746 and 0.742, respectively. There were no cases with grade 0 or 1 PO in the CD group or UC group, i.e. all had at least moderate/moderate PO. The high prevalence of severe PO, even in people without IBD, can be explained by the fact that most of these people were recruited in a specialised periodontology clinic. Accordingly, the mean PO score is relatively high here.

	Clinical grade of PO	Number	Percent	Mean PO score
Persons without IBD	0	23	15.8	9.1
	1	2	1.4	
	2	36	24.7	
	3	64	43.8	
	4	31	14.4	
	total	146	100	
UC	2	12	28.5	8.7
	3	29	69.0	
	4	1	2.4	
	total	42	100	
CD	2	23	30.3	9.7
	3	46	60.5	
	4	7	9.2	
	total	76	100	

Conclusion: Our data confirm a high prevalence of higher grade PO requiring treatment in patients with IBD. A higher PO score (from 6.75) can predict with high probability PO requiring treatment, which is often overlooked or neglected in IBD patients. These patients can therefore be referred for integrated therapy.

Introduction: Mesenchymal stem cells (MSCs) exhibit immunomodulatory properties through Treg induction[1], yet their clinical efficacy varies across gastrointestinal immune disorders[2].

This study integrates systematic evidence from 79 MSC-GVHD trials with preclinical IBD models to identify critical determinants of MSC therapeutic success.

Aims & Methods:

• Clinical Analysis: Meta-analysis of 79 trials (4,710 patients) evaluating MSC efficacy in GVHD, stratified by MSC source (bone marrow vs. umbilical cord), dosing, and disease severity.

• Preclinical Validation: DSS-induced murine colitis treated with human umbilical cord-derived MSCs (hUCB-MSCs; 2×10^6 cells/IP, n=8/group). Outcomes included histopathology, Treg quantification (flow cytometry), and IDO/PGE2 mechanisms (qPCR/ELISA).

Results:

1. GVHD Clinical Data:
   - Umbilical cord MSCs showed superior 1-year survival vs. bone marrow sources (76% vs. 47%, p=0.016) in steroid-refractory GVHD.
   - Pediatric patients exhibited 71.2% response rate with early MSC intervention (<48h post-diagnosis).
2. IBD Preclinical Findings:
   - hUCB-MSCs reduced colitis activity index by 67% (p=0.003) and increased colonic Foxp3+ Tregs 3.2-fold vs. controls (p=0.017).
   - IFN-γ priming enhanced hUCB-MSC immunosuppression via IDO↑ (4.8-fold, p=0.008) and PGE2↑ (2.1-fold, p=0.03).

Conclusion: MSCs demonstrate disease-specific therapeutic hierarchies: Umbilical cord-derived cells optimized for acute GVHD and IBD through Treg/IDO/PGE2 axis activation. Timing (early intervention) and inflammatory priming (IFN-γ) are critical modulators. These insights warrant phase II trials of IFN-γ-primed UCMSCs for immune-mediated gastroenterological diseases.

Introduction: Despite the growing number of biological therapies available for ulcerative colitis (UC), data on how best to sequence these agents in clinical practice are still scarce. Vedolizumab (VDZ) is an α4β7 integrin antibody used to treat moderate-to-severe ulcerative colitis (UC).

Aims & Methods: We aimed to assess the real-life long-term effectiveness and safety of VDZ as a first- or second-line biological therapy and identify predictors of efficacy in a large cohort of patients with refractory or difficult-to-treat UC. This was a multicenter, retrospective observational cohort study including patients with moderately-to-severely active UC who received VDZ for at least 12 weeks.

Primary endpoints were clinical remission (partial Mayo score ≤ 2), endoscopic remission (endoscopic Mayo subscore of 1 or 0), and steroid-free clinical remission at week 52.

Secondary endpoints included clinical response at weeks 12, 26, and 52; endoscopic response at week 52; primary and secondary loss of response; drug discontinuation; need for dose optimization; adverse events (AEs); need for hospitalization; and colectomy. Clinical predictors of VDZ treatment success were evaluated.

Univariable and multivariable analyses as well as Kaplan–Meier analyses of treatment persistence were performed.

Results: We included 206 UC patients (mean age 44.9 ± 16.2 years, 56.8% female, 56% pancolitis, 76.8% biologic-naïve, and 22.7% with previous anti-TNF failure). Clinical remission was observed in 69.2% of biologic-naïve patients and 63.8% of anti-TNF failure patients at week 52. Steroid-free clinical remission was achieved in 70.3% and 58.8% of biologic-naïve and anti-TNF failure patients, respectively. Endoscopic remission at one year was achieved in 48.9% and 42.9% of biologic-naïve and anti-TNF failure patients, respectively. Biochemical remission at one year was achieved in 77.8% and 73.9% of biologic-naïve and anti-TNF failure patients, respectively. Primary and secondary loss of response occurred in 7.5% and 13.8% of biologic-naïve patients and in 18.2% and 21.3% of anti-TNF failure patients, respectively. Treatment persistence was higher among biologic-naïve UC patients (84.9% vs. 72.3%, p = 0.048). Three patients (1.4%) required colectomy, and 14 patients (6.8%) needed hospitalization while on VDZ treatment. Clinical response at week 12 (p = 0.001) and biologic-naïve status (p = 0.006) were predictors of better VDZ response, whereas BMI > 30 kg/m² (p = 0.04) and serum albumin ≤ 3.5 g/dL (p = 0.03) were predictors of poorer response.

Conclusion: In this real-world study of patients with severe UC, VDZ demonstrated effectiveness in inducing clinical remission and endoscopic improvement, even in cases of previous anti-TNF failure, with a favorable safety profile. Biologic-naïve status and early clinical response were associated with higher likelihood of one-year clinical and endoscopic remission.

COMPARATIVE EFFICACY OF GUSELKUMAB VS. RISANKIZUMAB IN INDUCTION PHASE FOR MODERATE TO SEVERE CROHN'S DISEASE: AN ANCHORED MAIC ANALYSIS

S. van Sanden[1], M. Trevisan[2], A. Strobl[3], D. Wirth[4]
[1]J&J Innovative Medicine, EMEA Strategy & Operations HEMAR, Beerse, Belgium, [2]J&J Innovative Medicine, EMEA Strategy & Operations HEMAR, Zug, Switzerland, [3]J&J Innovative Medicine, HEMAR, Neuss, Germany, [4]J&J Innovative Medicine, EMEA Strategy & Operations HEMAR, Neuss, Germany

Contact E-Mail Address: dwirth2@its.jnj.com

Introduction: The need for effective therapies in moderate to severe Crohn's disease (CD) drives the comparative evaluation of biologic treatments. The current work uses an anchored Matching-Adjusted Indirect Comparison (MAIC) to assess the efficacy of guselkumab (GUS) relative to risankizumab (RZB) during the treatment induction phase. This MAIC is using data from five phase 3 placebo-controlled blinded clinical trials (GRAVITI, GALAXI 2, GALAXI 3, ADVANCE, MOTIVATE).

Aims & Methods: Adult patients with moderate to severe CD, as defined in GRAVITI, GALAXI 2/3, ADVANCE and MOTIVATE trials were included. An anchored MAIC was utilized, leveraging placebo as common comparator and following guidance from the National Institute for Health Care Excellence in UK. The analysis aligned pooled individual patient data for GUS with published data for RZB by matching exclusion criteria and patient baseline characteristics that could be treatment effect modifiers (eg Age, Sex, BMI, CDAI, disease location or prior biologic treatment failure).

During induction, patients received GUS 200 mg intravenous or 400 mg subcutaneous at weeks 0, 4, and 8 or RZB 600 mg intravenous at weeks 0, 4, and 8. The endpoints of interest were symptomatic endpoints such as clinical remission, PRO-2 remission, clinical response, abdominal pain and stool frequency remission, as well as endoscopic response at week 12, which marks the end of the induction period.

Results: After matching, baseline characteristics were balanced between the GUS and RZB cohorts. In a mixed population of bio-naïve and bio-experienced patients, GUS demonstrated statistically significant results in comparison to RZB for PRO-2 remission, clinical response and abdominal pain remission (Table 1).

Clinical remission showed a trend in favor of GUS, endoscopic response and stool frequence remission were comparable to RZB. In patients with biologic treatment failure versus the MOTIVATE trial, results had been

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

generally more in favor of GUS, while maintaining positive outcomes seen across mixed populations (ADVANCE & MOTIVATE). Results were also mostly consistent whether analyzing pooled GUS data or individual trials, eg from GRAVITI, against RZB.

Endpoint	RE measure	Mixed population (ADVANCE & MOTIVATE)		Bio-failure population (MOTIVATE)	
		BC	SA	BC	SA
Clinical response	OR [95%CI]	1.78* [1.06; 2.99]	1.42 [0.76; 2.64]	1.71 [0.82; 3.57]	1.23 [0.49; 3.04]
Endoscopic response	OR [95%CI]	1.05 [0.56; 1.97]	1.05 [0.53; 2.09]	1.57 [0.59; 4.18]	1.56 [0.49; 5.01]
Clinical remission	OR [95%CI]	1.51 [0.84; 2.70]	1.22 [0.60; 2.46]	1.52 [0.65; 3.51]	1.08 [0.39; 3.01]
PRO-2 remission	OR [95%CI]	1.96* [1.13; 3.38]	1.85* [1.03; 3.33]	2.89* [1.29; 6.49]	2.97* [1.11; 7.94]
AP score remission	OR [95%CI]	1.68 [1.00; 2.82]	1.37 [0.75; 2.52]	2.02 [0.97; 4.20]	1.68 [0.69; 4.09]
SF score remission	OR [95%CI]	0.99 [0.62; 1.59]	0.93 [0.55; 1.58]	1.14 [0.59; 2.19]	1.04 [0.48; 2.26]

Table 1: Results of GUS from pooled GRAVITI, GALAXI 2/3 vs. RZB for induction period at week 12.

Footnotes: clinical response= ≥100-point reduction from baseline in CDAI OR CDAI <150; endoscopic response= ≥50% improvement from baseline in SES-CD OR SES-CD ≤2; clinical remission= CDAI <150; PRO-2 remission=AP mean daily score at or below 1 [AP≤1] AND SF mean daily score at or below 3 [SF≤3], and no worsening of AP or SF from baseline; AP score remission=Abdominal Pain mean daily score at or below 1 [AP≤1]; SF score remission= number of liquid or very soft stools mean daily score at or below 3 [SF≤3];

*BC=baseline risk-adjusted; SA=sensitivity analysis; *p<0,05.*

Conclusion: The anchored MAIC analysis demonstrates comparable to even superior efficacy of guselkumab over risankizumab in inducing symptomatic improvements in Crohn's disease patients. It also suggests that subcutaneous induction seems to be preferential over iv induction.

IMPACT OF HLA-DQA1*05 GENOTYPE IN IMMUNOGENICITY AND RESPONSE TO TREATMENT WITH TUMOUR NECROSIS FACTOR-ALPHA ANTAGONISTS IN INFLAMMATORY BOWEL DISEASE PATIENTS

A. Gutiérrez-Casbas[1], V. Moreno-Torres[2], C. Mira[2], A. García-Trueba[2], R. Muñoz Pérez[2], O. Belen Galipienso[2], B. Herreros[2], L. Madero[2]

Contact E-Mail Address: gutierrez_anacas@gva.es

Introduction: Carrying the HLA-DQA1*05 gene has been linked to a higher risk of developing immunogenicity in patients with inflammatory bowel disease (IBD) who are treated with tumor necrosis factor-alpha inhibitors (antiTNF). However, studies have shown inconsistent evidence regarding its connection to a loss of response (LOR) or adverse events in patients with IBD.

Aims & Methods: Aims: To determine the impact of carriage of HLADQA1*05 allele on effectiveness, drug persistence and safety in patients diagnosed with IBD who had received antiTNF.

Methods: Retrospective, single-center cohort study including IBD patients who had received antiTNF therapy. The HLA-DQA1*05 allele was determined from a saliva sample (kit OGD-600 de DNA Genotek Oragene) and DNA extraction with the Maxwell® RSC-Stabilized Saliva DNA kits. We evaluate drug persistence, withdrawal of antiTNF, primary non-response and secondary loss of response, through antiTNF levels, development of antiTNF antibodies and adverse events in patients distributed by HLA-DQA1*05 allele presence.

Results: A total of 170 patients were included, 51% male, mean age 46.2 ± 14.6, 120 (70.6%) diagnosed with Crohn's disease. The mean disease duration was 189.6 ± 99.8 months. Fifty patients (29.4%) had extraintestinal manifestations and 30% comorbidities. HLA-DQA1*05 was positive in 74/167 (44%) patients. One hundred twenty-seven patients (75%) received infliximab (IFX) and 43/170 (25%) adalimumab. AntiTNF was the first advanced therapy in 161/179 (95%) of the cohort. Seventy-five out of 170 patients (44%) received an intensified antiTFN regimen, as well as 80/170 (47%) were treated with combotherapy with immunosuppressants. AntiTNF was withdrawn in 88/170 (52%) patients during follow-up, and the rate of adverse events that led to discontinuation of the drug was 17.6% (30/170).

When we compared the rate of primary non-response (12.2 vs. 7.5%. p=0.3) and secondary loss of response (48% vs. 44%, p=0.5), withdrawal of antiTNF therapy (48 vs. 54%, p=0.5), duration of antiTNF therapy, (85.3 ± 69.1 months vs. 90.3 ± 76.4, p=0.3), need of intensified regimen (47% vs. 42%, p=0.4),use of combotherapy (46% vs. 49%, p=0.6) and antiFNF levels (2.6 ± 2.3 vs. 2.9 vs. 2.9, p=0.3) we did not find significant differences between patients by HLA-DQA1*05 status (presence vs absence). On the other hand, the rate of infusion reactions (8.1% vs. 11.8%, p=0.4), development of anti-TNF antibodies (9.5 vs. 10.8, p=0.7) , overall (14.9 vs. 19.4, rate of adverse events (14.9 vs. 24.7, p=0.5) or adverse events that led to drug withdrawal (14.9 vs 19.4, p=0.4) were also similar among patients regardless HLA-DQA1*05 carriage.

Conclusion: In our real-life cohort of IBD patients treated with antiTNF, being an HLA-DQA1*05 carrier did not act as a predictor of effectiveness (primary non-response or secondary loss of response), immugenicity or need of intensified regimen. The safety of anti-TNF treatment has also not been influenced by the variant.

Disclosure: Nothing to disclose.

CLINICAL EFFECTIVENESS OF VEDOLIZUMAB IN CHINESE PATIENTS WITH ULCERATIVE COLITIS: FINAL RESULTS FROM THE VALUE, A MULTICENTER PROSPECTIVE STUDY

X. Zuo[1], Y. Chen[2], Y. Li[3], L. Gu[4], F. Zhou[4], M. Chen[5]
[1]Qilu Hospital of Shandong University, Jinan, China, [2]Integrated Clinical Microecology Center, Shenzhen Hospital, Southern Medical University, Shenzhen, China, [3]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China, [4]Takeda Pharmaceutical Company, Shanghai, China, [5]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Contact E-Mail Address: lifei.gu@takeda.com

Introduction: Vedolizumab (VDZ), a monoclonal antibody therapy approved for moderate-to-severe ulcerative colitis (UC) and Crohn's disease (CD) in China in 2020[1] has a unique, gut-selective, anti-lymphocyte trafficking (GSALT) mechanism of action.[2] However, there is limited data on VDZ's real-world effectiveness and safety in Chinese IBD patients.[3] Interim results from the VALUE study that enrolled patients with UC have been published [3,4] and final results are reported here.

Aims & Methods: VALUE (NCT04872491), a multicenter, single-arm, prospective, observational study evaluated the safety and effectiveness of VDZ in adult Chinese patients with IBD (N = 500) over 72 weeks. Clinical response, clinical remission, and endoscopic remission were assessed at Weeks 14, 30, and 54. Partial Mayo and Mayo endoscopic subscores at baseline and Weeks 14, 30, and 54 were calculated. Clinical response was defined as ≥2-point reduction in Partial Mayo Clinic score and ≥25% decrease from baseline score accompanied with ≥1-point decrease in the rectal bleeding or absolute rectal bleeding subscore ≤1. Clinical remission was defined as Partial Mayo Clinic score ≤2 with no subscore >1, endoscopic remission as Mayo endoscopic subscore ≤1, and complete endoscopic remission as Mayo endoscopic subscore 0. Safety results and CD patients' data are presented in separate VALUE abstracts (IDs: AS-UEG-2025-01329 and AS-UEG-2025-01324).

Results: Among 409 UC patients enrolled in the final analysis, 91.9% (376/409) were included in the effectiveness analysis set. Mean age (±standard deviation [SD]) of patients was 46.3 (±15.1) years, and 59.4% (n=243) were male. At baseline, 30.8% (126/409) of patients had moderate UC, and 29.8% (122/409) had severe UC. The median duration of UC was 2.5 years, concomitant steroids were prescribed in 18.9% (71/376). Mean (±SD) partial Mayo score was 5.1 (2.1) at baseline, which declined to 1.7 (1.7), 1.5 (1.7) and 1.3 (1.5) by Weeks 14, 30 and 54, respectively, post-VDZ treatment. Patients achieving clinical response, clinical remission, endoscopic remission, and complete endoscopic remission were 76.9% (220/286), 71.1% (207/291), 63.6% (35/55), and 21.8% (12/55) at Week 14; 78.1% (193/247), 76.3% (190/249), 63.6% (28/44), and 27.3% (12/44) at Week 30; and 80.3% (155/193), 83.3% (165/198), 71.4% (20/28), and 50.0% (14/28) at Week 54, respectively. Patients with moderate and severe UC; biologic naïve patients and patients with prior exposure to biologics at baseline also achieved clinical response, clinical remission, and endoscopic remission (Table).

	Moderate UC			Severe UC		
	Clinical response	Clinical remission	Endoscopic remission	Clinical response	Clinical remission	Endoscopic remission
Week 14	89.8 (79/88)	65.9 (58/88)	57.1 (12/21)	90.0 (72/80)	63.8 (51/80)	56.3 (9/16)
Week 30	87.7 (64/73)	69.9 (51/73)	30.8 (4/13)	91.2 (62/68)	66.2 (45/68)	90.9 (10/11)
Week 54	92.2 (59/64)	81.3 (52/64)	62.5 (5/8)	88.5 (46/52)	73.1 (38/52)	60.0 (3/5)
	Biologic-exposed UC: 10.9% (41/376)			Biologic-naïve UC: 89.1% (335/376)		
Week 14	69.0 (20/29)	66.7 (20/30)	16.7 (1/6)	77.8 (200/257)	71.7 (187/261)	69.4 (34/49)
Week 30	74.2 (23/31)	71.0 (22/31)	83.3 (5/6)	78.7 (170/216)	77.1 (168/218)	60.5 (23/38)
Week 54	60.0 (15/25)	81.5 (22/27)	83.3 (5/6)	83.3 (140/168)	83.6 (143/171)	68.2 (15/22)

Data are presented as % (n/N).
N, number of patients having clinical response/remission/endoscopic remission data.
n, number of patients achieving clinical response/remission and endoscopic remission data.

Compared with baseline, mean (±SD) reduction of C-reactive protein (mg/L) at Weeks 14, 30, and 54 were 7.8 (20.2), 6.5 (22.2), and 3.4 (24.8), respectively; mean (±SD) reduction of fecal calprotectin (mu g/g) was 42.7 (150.7) at Week 14 and 212.6 (480.1) at Week 30. The proportion of patients achieving clinical remission without steroid use by Week 14 was 37.7% (23/61), which increased to 60.6% (20/33) by Week 54.

Conclusion: This study indicated that VDZ demonstrated a good effectiveness profile in Chinese UC patients in the real-world setting.

PHARMACOLOGICAL AND DIETARY INTERVENTIONS FOR THE MANAGEMENT OF UPPER GASTROINTESTINAL CROHN'S DISEASE: A SYSTEMATIC REVIEW

M.P. Chatto[1,2], D. Alaskar[1], Y. Yuan[1], V. Jairath[3], R. Sedano[1]

Introduction: Upper GI involvement in Crohn's disease (CD) is thought to occur in 13% to 15% of cases. However, despite expansion of the therapeutic armamentarium for CD over the last 30 years, there continues to be minimal data on optimal therapeutic strategies for upper GI CD. This knowledge gap presents major clinical challenges in managing this subset of patients.

Aims & Methods: We conducted an extensive systematic review using multiple databases investigating pharmacological or dietary interventions for patients with upper GI CD. We included fully published, English-language studies that compared at least two active interventions with a placebo from 1990 to 2025. Due to the lack of a standardized definition for "upper GI" CD, we included studies that reported data on CD affecting the esophagus to the jejunum. We excluded studies that included <10 upper GI CD patients, reported data for "small bowel CD" in general or limited to ileal CD, or did not report data separately for upper GI CD. There is no age limitation.

Results: Among 1206 citations, 14 observational studies (11 retrospective, 3 prospective) and 1 post hoc of an RCT met our inclusion criteria, amounting to 487 patients with UGI CD. Majority of patients had concomitant ileocolonic involvement. Five studies with 137 patients had esophageal CD. Follow-up ranged from 1 to 28 years. Interventions and reported outcomes varied. Steroids (mainly prednisone) and anti-TNF, either alone or in combination, showed the highest rates of success for clinical improvement, endoscopic healing and histologic remission for upper GI CD compared to other therapies. Other therapies used, alone or in combination, were EEN, PPI, H2RA, immunomodulators (azathioprine, 6-mercap-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. topurine), 5-ASA, anti-integrins, and anti-IL 12/23, showing moderate to minimal improvement in clinical or endoscopic response and remission. (Table)

Author, year	UGI Subset population	Study design, duration of follow-up	Interventions Studied	Outcomes measured	Key Numeric Results	Authors' Main Interpretations
D'Haens et.al [DIVERGENCE 1]. (2023)	17 adults, jejununal	RCT, 24 weeks	Filgotinib, Placebo	MARiAseg remission at 24 weeks	Non-significant. (MARiAseg mean): 0/3 PBO (6.6); 0/8 FIL 100mg (6.3); 2/6 FIL 200mg (6.8)	Filgontinib did not result in statistically significant differences vs. PBO to achieve MARiAseg remission in jejunum in 24 weeks.
D'Haens et.al. (1994)	14 adults, esophageal	Retrospective observational, 12 years	„Usual therapy": Steroids ± 5-ASA +/- Abx, immunomodulator ± acid suppression, no uniform prospective regimen	Endoscopic healing, flares/ relapse at follow-up	Significant. 69% (9/13) 64.3% (9/14) with partial or complete healing after short course steroids; 21% (3/14) had persistent disease or repeated flares.	Esophageal CD responds to steroids in ~70%.
Miehsler et.al. (2001)	32 adults, UGI	Retrospective observational, 34 mos.	4 arms: PPI, 5-ASA, steroid, AZA	CDAI, UGI symptoms score, CRP	Significant. Antisecretory drugs: UGI Symptoms score 2.5 (1-5) to 1 (0-3) P=0.039 Prednisolone: CDAI from 272 (151-451) to 100 (22-309) P= 0.03 AZA: CDAI 94 (39–426) to 57 (0–203) P=0.04; CRP 2.3 mg/dl (0.5–8.2) to 0.7 mg/dl (0.5–2.2) P=0.02	UGI Symptoms responded to antisecretory drugs. CDAI decreased with Prednisolone, AZA. CRP decreased with AZA.
Juillerat et.al. (2013)	7 adults, UGI	Retrospective observational, 2 years	Natralizumab	Clinical response (HBI), completion of 1 year of treatment	Nonsignificant. 1/7 responded; 2/7 did not respond	Only 1/7 responded to natralizumab; (no further comment or elaboration/subgroup analysis for UGI made for this study)
Olbjorn et.al. (2014)	16 pediatric, UGI	Prospective cohort, 2 years	IFX	Endoscopic, clinical remission maintained at 1-2 years	Significant. IFX treated: from 11 with UGI CD-specific lesions at diagnosis to 2 at ff-up (61% to 12%); non IFX treated: 5/18 at dx to 2/15 at ff-up (31% to 15%) Significant. No numeric value - patients were treated with various combinations, in this case series	IFX resulted in a significant decrease in UGI CD-specific lesions at ff-up 1-2 years after dx. Response was sustained at 2 years for all responders.
De Felice et.al. (2015)	24 adults, esophageal	Retrospective observational, 1 year	Alone or combination: 5-ASA, prednisone, AZA, oral budesonide , IFX, CZP, PPI	Clinical and endoscopic response at 1 year		Inflammatory esophageal CD responded to prednisone, topical budesonide, or biologics. Stricturing esophageal CD was successfully treated with combination of biologic therapy, immunomodulators, and serial dilations with/without steroid injections. Aggressive medical therapy with biologics for fistulizing esophageal CD, was not universally effective.
Lambin et al. (2020)	60 adults, UGI strictures	Retrospective observational, 5 years	Immunomodulator (AZA, MTX), anti-TNF, anti-TNF + immunomodulator, none, UST	Surgery free-survival at 1 and 5 years	Significant. Anti-TNF alone: multivariate OR 0.2, univariate OR 0.4; 70% efficacy at 6.5mos; anti-TNF + immunomodulators: multivariate OR 0.2 univariate OR 0.2; 61% efficacy at 23.5mos; UST + immunomodulator: 67% efficacy at 10.5mos UST alone: 50% efficacy, Immunomodulator alone: 50% improvement in 35mos.	Anti-TNF therapy alone or in association with an immunosuppressant reduces risk of surgery in UGI CD strictures.
Wauters, et.al. (2017)	69 pediatric, UGI	Prospective observational cohort, 5 years	No control groups: corticosteroids (pred, budesonide), EEN, immunomodulators (AZA, 6-MP, MTX), anti-TNF (IFX, ADA)	Clinical response and remission	Nonsignificant. No difference in time to or duration of sustained remission for anti-TNF exposed and non-anti-TNF P=0.60	No significant difference in time to or duration of sustained remission for anti-TNF exposed and non-anti-TNF P=0.60
Huang et.al. (2025)	39 adults, jejunum	Retrospective observational cohort, 1 year	IFX, UST, Vedolizumab	Endoscopic healing at 1 year	Significant. After 1 year: Jejunal endoscopic healing (EH): IFX 8/15 (53.3%), UST 3/15 (23.1%), Vedo 1/11 (9.1%); Endoscopic response (ER): IFX 8/15 (53.3%), UST 7/13 (53.8%), Vedo 2/11 (18.2%); Ulcer healing: IFX 8/15 (53.3%), UST 5/13 (38.5%), Vedo 1/11 (9.1%)	IFX had strongest response compared to either UST or Vedolizumab for endoscopic healing, endoscopic response and ulcer healing in jejunum. Primary outcome at 1 year for all 3 biologics in jejunum: 30.8% Endoscopic healing (EH), 43.6% achieved endoscopic response (ER), 35.9% had ulcer healing (UH)
Vale Rodrigues et.al. (2020)	40 adults, esophageal	Retrospective observational	PPI, corticosteroids, 5-ASA, anti-TNF, thioprurines, EEN	Clinical and endoscopic remission	Significant. 37/40 (92.5%) tx w/ PPI; 33/40 (82.5%) treated w/ >1 drug; 33/40 (82.5%) with 1st line therapy had complete resolution in 7mos.	Clinical and endoscopic remission was achieved in more than 80% of the patients, majority with PPI.
Yamamoto et.al. (2009)	54 adults, gastroduodenal CD	Retrospective observational, 12 years	Medical therapy in 31/54: corticosteroids, 5-ASA, AZA, PPI alone or combination	Clinical response	Nonsignificant. 14/31 (45%) responded to medical tx; 19/31 required surgery, 12 did not require surgery	Medical therapy not effective for UGI CD, although corticosteroids most widely used.
Tang et.al. (2024)	54 pediatric, UGI	Retrospective observational, 6 weeks and at 1 year	EEN	Endoscopic healing	Significant. Upper GI location (OR 0.25, 95% CI 0.11–0.55, P = 0.001) associated with segmental mucosal healing (MH) at EEN completion. EEN had 35% MH for small bowel.	UGI segment in pediatric CD was associated with segmental mucosal healing following EEN therapy. Lewis score significantly improved following EEN treatment, the MH rate was only 35%, and lesions in the small bowel were more likely to worsen after EEN therapy despite anti-TNF maintenance therapy
Lui et.al. (2017)	39 adults, esophageal	Retrospective observational, 4 years	anti-TNF, anti-integrin, anti-IL12/23, combination	Clinical response/remission, endoscopic response/ remission	Significant. anti-TNF resulted in greater clinical (P=0.02) & endoscopic (p<0.01) response and clinical remission (P=0.01) but not endoscopic remission (P=0.85); anti-integrin poorer endoscopic response when tx w/ other biologics (P<0.03) & not assoc. with significant clinical response; anti-IL12/23 compared w/ other biologics assoc. w/ poorer clinical (P<0.01) and endoscopic response (P=0.03); no sig diff bet'n anti-integrin and IL12/23 clin response (P=0.13), clin remission (P=0.34), endoscopic response (P>0.99) and endoscopic remission (P>0.99).	The timing of biologic initiation in patients in this study was not significantly associated with improved clinical or endoscopic outcomes. Treatment with anti-TNF therapy, when given as first-line treatment associated with better clinical and endoscopic outcomes when compared to other second- or third-line biologic therapies.
Annunziata et.al. (2012)	19 adults, UGI	Prospective cohort, 12 weeks	Group A: PPI + anti-TNF (IFX, ADA) + 5-asa, AZA, 6MP; Group B: PPI + 5-ASA, AZA, 6MP	Endoscopic healing at 12 weeks	Significant. 100% of symptomatic patients improved. Group A: Mucosal healing in 8/11 (72.7%), endoscopic healing in 7/8; Group B: 1/8 (12.5%) mucosal healing (P=0.001) Significant. Steroids 9/18 improvement, AZA 2/8, 6-MP 2/3, PPI 2/5	Mucosal healing achieved in 70% of PPI plus anti-TNF and only in 12.5% of PPI plus other treatments group First line therapy with steroids, 5-ASA, H2RA, PPI resulted to improvement in 50% of patients
Anton et.al. (2001)	20 adults, esophageal	Retrospective observational, 1mo - 28 years	5-ASA, H2RA, PPI, Steroids, immunomodulator	Clinical, endoscopic improvement		

Table.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Conclusion: Our comprehensive literature search of comparative studies highlights an almost void of evidence to inform therapeutic strategies in upper GI CD. Steroids and anti-TNF showed the best outcomes, but only from small observational, uncontrolled studies. Data for biologics and advanced therapies remain limited highlighting a large unmet need.

Introduction: Existing treatments aim to induce and maintain remission in Ulcerative Colitis (UC); however, 30–55% of patients remain refractory during the induction phase, highlighting an unmet need for novel therapeutic options(1). Phosphodiesterase-4 (PDE4) is a cyclic adenosine monophosphate (cAMP)-specific enzyme expressed by immune and inflammatory cells. Abnormal expression of PDE4 and dysregulated signal transduction have been reported in colonic biopsies from patients with UC (2,3). Orismilast is an oral, B/D-selective PDE4 inhibitor with a modified-release formulation.

Aims & Methods: This study (the UCORIS study) was a phase 2a, open-label, single-arm exploratory clinical study assessing the efficacy and safety of orismilast in patients with moderate to severe UC. Patients with UC currently on stable 5-ASA treatment and experiencing moderate-severe disease activity (defined as a Mayo endoscopic sub score of 2 or 3) were eligible for inclusion. Orismilast was administered twice daily for 12 weeks, with investigators allowed to individualize the dose based on body weight, treatment response and side effects. Responding patients could extend treatment to a total duration of 52 weeks.

A last-observation-carried-forward (LOCF) approach was applied to early discontinuers when com-paring to those who completed treatment. No hypothesis testing was performed due to the small sample size. The primary endpoint was clinical remission at week 12, defined as a total Mayo score of 2 or lower, with no individual sub score exceeding 1.

Results: 10 patients were included in the study. Six participants discontinued the study prematurely - three due to lack of efficacy and three due to adverse events. Clinical remission at week 12 was achieved by one patient, who continued orismilast for 50 weeks, maintaining endoscopic remission.

In the completed trial group, mean Total Mayo Score decreased from 9.75 to 5.25 (Δ– 4.50, [95% CI: -4.17;13.17], p=0.20), and Partial Mayo Score from 7.25 to 3.75 (Δ –3.5, [95% CI: -2.66;9.66], p=0.17). In the early determination group, Partial Mayo Score declined from 5.83 to 4.17 (Δ–1.66, [95% CI: -2.46;5.79], p=0.35); follow-up Total Mayo Scores were unavailable. Faecal calprotectin levels showed modest reductions in both groups.

A total of 75 adverse events (AEs) were recorded. Of these, 48 were mild (68%), consistent with previous findings(4). The most common ADRs were nausea (15% of AEs; 8 patients (80%)), abdominal pain (12%; 5 patients (50%)), dizziness (5%; 2 patients (20%)), and headache (4%; 2 patients (20%)). Three serious AEs occurred in one patient but did not result in discontinuation. None of the serious AEs were considered related to orismilast. The overall safety profile aligned with known effects of PDE4 inhibitors(4–6), although the frequency of nausea was higher, potentially reflecting overlap with underlying disease symptoms.

Conclusion: Orismilast demonstrated reductions in both Total and Partial Mayo scores among patients who completed the trial, and a reduction in Partial Mayo score among those who discontinued early. Although only one patient, who completed the full 12-week regimen, achieved both clinical and endoscopic response, three out of ten patients achieved remission based on Partial Mayo score, faecal calprotectin, and SCCAI. Adverse drug reactions were common; although none were severe, nausea had a notable impact on daily life. Effective management of this adverse event may be essential to improving tolerability and supporting the therapeutic potential of orismilast in the treatment of ulcerative colitis.

THE SAFETY OF VEDOLIZUMAB IN THE MANAGEMENT OF CHINESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE: FINDINGS FROM THE VALUE, MULTICENTER, PROSPECTIVE, OBSERVATIONAL STUDY

L. Li[1], H. Zhang[2], C. Liu[3], X. Sun[4], X. Qian[5], F. Zhou[5], M. Chen[1]
[1]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China, [2]Guangdong Provincial Hospital of Traditional Chinese Medicine, Guangzhou, China, [3]Affiliated Hospital of Binzhou Medical College, Binzhou, China, [4]Heilongjiang Provincial Hospital, Harbin, China, [5]Takeda Pharmaceutical Company, Shanghai, China

Contact E-Mail Address: xiaoyu.qian@takeda.com

Introduction: Vedolizumab (VDZ) is a monoclonal antibody therapy approved in China in 2020 for the treatment of patients with inflammatory bowel disease (IBD; Crohn's disease [CD] and ulcerative colitis [UC])[2] who were intolerant to conventional therapies.[1] VDZ has a unique, gut-selective, anti-lymphocyte trafficking (GSALT) mechanism of action.[3] However, data on the efficacy and safety of VDZ in Chinese patients with IBD in the real-world setting are limited.[4] This study evaluated the safety of VDZ in adult patients with IBD.

Aims & Methods: VALUE (NCT04872491) was a multicenter, single-arm, prospective, observational study to evaluate the safety of VDZ in adult Chinese patients with IBD (N=500) over a maximum observation period of 72 weeks. Incidence of adverse events (AEs), serious AEs (SAEs), treatment-related adverse drug reactions (ADRs), and AEs of special interest (AESIs) was evaluated. This was the final analysis of the VALUE study conducted in patients with IBD.

Results: A total of 500 patients (UC: n=409; CD: n=91) received VDZ 300 mg. Mean (±standard deviation) age of patients was 44.3 (±15.2) years, and 61.4% (n=307) were male. The mean duration for VDZ exposure was 414 days (UC: 416 days; CD:407 days). A total of 500 patients developed 674 AEs (Table), and the most frequent AEs were infections and infestations (I&I; UC: 115 [28.1%]; CD: 24 [26.4%]), followed by gastrointestinal disorders (GIDS; UC: 87 [21.3%]; CD: 18 [19.8%]). Incidence rates of AEs (/ patient-years) were 1.2 and 1.0 in patients with UC and CD, respectively. Overall, 13 (3.2%) patients with UC and 10 (11.0%) with CD had AEs leading to study discontinuation. SAEs were observed in 78 patients with UC and 18 with CD (Table). A total of 19 AESIs were reported by patients with UC and 9 AESIs by those with CD, with the most common AESIs being I&I (UC: 13 [3.2%]; CD: 4 [4.4%]) and malignancy (UC: 3 [0.7%], CD: 2 [2.2%]). The most common I&I disorders reported by patients with UC and CD were *Clostridium difficile*infection (4 [1.0%]) and pneumonia (1 [1.1%]), respectively. Overall, 17 (4.2%) patients with UC and 7 (7.7%) with CD had at least 1 AESI. A total of 91 and 15 treatment-related ADRs were observed in patients with UC and CD, respectively; I&I were the most frequently documented ADRs to VDZ treatment (Table). A total of 10 (UC: 5 [1.2%]; CD: 5 [5.5%]) patients treated under concomitant IBD advanced therapy (CIBDAT) experienced a total of 16 AEs (UC: 9; CD: 7), with the most common AEs being I&I (UC: 1 [20.0%]; CD: 2 [40.0%]) and GIDS (UC: 3 [60.0%]; CD: 1 [20.0%]) with CIBDAT. No deaths were reported during the study.

	UC	CD
All reported AEs (n)	569	105
Mild/Moderate AEs, n (%)	379 (66.6)/140 (24.6)	73 (69.5)/18 (17.1)
Severe AEs, n (%)	50 (8.8)	14 (13.3)
SAEs (n)	78	18
Mild/Moderate, n (%)	8 (10.3)/31 (39.7)	1 (5.6)/4 (22.2)
Severe, n (%)	39 (50.0)	13 (72.2)
Treatment-related ADRs (n)	91	15
I&I, n (%, 95%CI)	16 (3.9, 2.3-6.3)	2 (2.2, 0.3-7.7)
GIDS, n (%, 95%CI)	16 (3.9, 2.3-6.3)	1 (1.1, 0.03-6.0)

Conclusion: The VALUE study indicated that VDZ was well tolerated in Chinese patients with IBD, with no new safety concerns.

LONG-TERM PERSISTENCE OF USTEKINUMAB TREATMENT IN PATIENTS WITH MODERATE-TO-SEVERE CROHN'S DISEASE

G.J. Mantzaris[1]
[1]White Cross Hospital-The Athens Clinic, Dept. of Gastroenterology, Athens, Greece

Contact E-Mail Address: gjmantzaris@gmail.com

Introduction: Ustekinumab (UST) is efficacious in inducing and maintaining remission in patients with Crohn's disease (CD). Treatment persistence up to 5 years has been documented in open-label extension of pivotal RCTs of UST (1). In a prospective, real-world (RW) nation-wide study (REASSURE) 73% of 169 bio-naive (BN) and bio-experienced (BE) patients were still in the study after 2 years of treatment with UST (2).

Aims & Methods: In this prospective, single-centre study we aimed to assess the long-term persistence of UST treatment in consecutive BN and BE CD patients who were treated in RW setting with UST in approved dosing regimens for induction and remission maintenance.

Consecutive BN and BE CD patients with active moderate to severe luminal CD with or without perianal involvement, aged 18-80 years who received UST induction (6mg/kg iv) and maintenance (90mg sc q8 weeks) and achieved clinical and biomarker response or remission without concomitant steroids at 6 months after initiation of UST were included in a long-term observational study.

Study end-point was treatment discontinuation for whatever reason. Patients were followed every 4 months with clinical examination, recording of the Harvey-Bradshaw Index (HBI) and laboratory tests [including regular CRP and occasional Fecal Calprotectin (FC)]. Ileocolonoscopy was performed at 6 months after initiation of treatment and then every 2 years. Clinical response and remission were defined as a drop in HBI ≤2 and <5 from initiation of treatment, respectively. Biomarker remission was defined as a CRP level ≤0.5mg/dL and FC ≤200 μg/g. Endoscopic remission was defined as a SES-CD score of ≤3 and a Rutgeert's score of ≤1 for patients with inflammatory CD and for patients in post operative setting, respectively. In this abstract we report the results on the persistence of UST-treatment based on clinical and biomarker data.

Results: Between 1/6/2017 and 31/12/2024, 64 patients were evaluated and 52 patients who fulfilled the entry criteria were enrolled in the study. Patient demographic, clinical, biomarker and endoscopic data is shown in table 1. Of these 52 patients, 42 (80.7%) patients were still maintained in clinical, biomarker and endoscopic remission [HBI 2.3 (1-4), mean (range),

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

CRP<0.5 mg/dL and FC <200µg/ml)] on UST 90 mg sc every 8 weeks for >2 [n=10 (24%),3 [n=5 (12%)], 4 [n=5 (12%)], 5 [n=6 (14%)] και ≥ 6 [n=16 (38%)] years after inclusion in the study, respectively. Treatment escalation was not performed and neither serious adverse events nor serious infections were reported in any of these patients during the study period. Ten patients (19.3%), two BN and 8 BE stopped therapy. Cessation of treatment was slightly statistically higher in BE than PN patients (p<0.05). Five of 10 patients stopped treatment because of post-operative endoscopic recurrence (Rutgeert's score ≥i2) at 2,2,2.5, 2.9 and 3.2 years, respectively and 2 patients because of a flare of colitis at 4 and 6.5 years, respectively after inclusion in the study. Another 3 patients stopped therapy because of active axonal spondyloarthropathy 2.3 years (n=1) and two patients because they were diagnosed with pancreatic cancer and a T1-colorectal cancer (patient was on the 3nd biologic agent after a 20-year course of colitis) after 7 years in the study, respectively.

Conclusion: This prospective, open label, single-center RW study confirms the long-term treatment persistence of UST with an acceptable safety profile.

SUSTAINED IMPROVEMENT IN PATIENT-REPORTED OUTCOMES WITH LONG-TERM UPADACITINIB THERAPY IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: 4-YEAR RESULTS FROM THE U-ACTIVATE LONG-TERM EXTENSION STUDY

Introduction: Ulcerative colitis (UC) is associated with debilitating symptoms that impair the quality of life (QoL) of patients; restoration of QoL is an important long-term treatment goal.[1]

Upadacitinib (UPA), an oral, reversible Janus kinase inhibitor approved for the treatment of UC, improves health-related QoL (HRQoL) and patient-reported outcomes (PROs) with 1 year (yr) of maintenance therapy.[2-4] This post hoc analysis of the U-ACTIVATE long-term extension (LTE) study evaluated the long-term efficacy of UPA in sustaining PROs and HRQoL outcomes in patients who had received up to a total of 4 years (yrs) of UPA maintenance therapy.

Aims & Methods: This analysis included patients who completed 1 yr (52 weeks [wks]) in the U-ACHIEVE maintenance study and received UPA15 mg once-daily (QD) (UPA15) or UPA 30 mg QD (UPA30) maintenance treatment in the U-ACTIVATE LTE study. Patients receiving UPA15 or UPA30 who achieved clinical remission per Adapted Mayo score at maintenance wk 52 continued their double-blind treatment upon entering the LTE study. Nonremitters receiving UPA15 were escalated to UPA30, those receiving UPA30 continued UPA30, and those assigned to PBO were escalated to UPA15, all in a blinded manner. The UPA UC program was not designed to compare UPA15 and UPA30 doses.

Efficacy was assessed at LTE wks 0, 96, and 144 (data cutoff date: 30 June 2024) and included the percentage of patients who achieved absence of abdominal pain, absence of bowel urgency, Inflammatory Bowel Disease Questionnaire (IBDQ) response, IBDQ remission, and a meaningful within-person change (MWPC) in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue; Short-Form Health Survey-36 version 2 Mental Component Score (SF-36v2 MCS), and SF-36v2 Physical Component Score (PCS).

Data were reported using as-observed (AO) and modified nonresponder imputation (mNRI) methods (shown in Table). Safety was reported previously.[2]

Results: This analysis included 369 patients treated with UPA15 or UPA30 at wk 0 of LTE trial. In the AO analysis, patients treated with UPA15 or UPA30 achieved sustained improvements from LTE wk 0 to wk 144 in PROs and HRQoL assessments (Table), including the absence of abdominal pain, absence of bowel urgency, IBDQ response, IBDQ remission; and achieved MWPC in FACIT-Fatigue, SF-36v2 PCS, and SF-36v2 MCS.

Similar results were observed for all endpoints with the more conservative mNRI analysis (Table).

Week 144				

AO, as-observed; CI, confidence interval; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy - Fatigue; IBDQ, inflammatory bowel disease questionnaire; MCS, mental component score; mNRI, modified nonresponder imputation; MWPC, meaningful within-person change; LTE, long-term extension; PCS, physical component score; QD, once-daily; SF-36v2, Short-Form Health Survey-36 version 2; UC, ulcerative colitis; UPA, upadacitinib; wk, week.

Week 0 refers to LTE week 0 (week 52 of the maintenance study). Efficacy analysis includes patients who received UPA15 or UPA30 in cohort 2 of U-ACTIVATE LTE who were UPA 45 mg 8-wk induction responders and were enrolled from cohort 1 of the 52-week maintenance period of the U-ACHIEVE maintenance study.

[a]95% CI for response rate is the synthetic result based on Student's t-distribution from PROC MIANALYZE procedure if there were missing data due to intercurrent events or is based on the normal approximation to the binomial distribution if there are no missing data due to intercurrent events.

[b]AO analysis did not impute values for missing evaluations. AO will include all values collected in the study until the first dose change or enrolment into the dose optimization substudy.

[c]mNRI considered patients as nonresponders on or after study drug dose escalation, or usage of UC-related rescue medication; missing data due to other reasons were imputed using multiple imputation.

[d]Quantified as the percentage of patients who achieved the absence of symptom.

[e]Increase in IBDQ score ≥ 16 points from baseline of induction.

[f]IBDQ total score ≥ 170.

[g]Increase in FACIT-F score ≥ 5 points from baseline of induction.

[h]Increase in SF-36v2 PCS/MCS ≥ 4.1 points from baseline of induction.

Table. PROs and HRQoL Efficacy Analysis From the U-ACTIVATE Long-Term Extension Study.

Conclusion: Patients with UC who responded to induction therapy and received long-term UPA maintenance therapy showed a sustained absence of symptoms and improvements in HRQoL, suggesting that UPA maintains long-term improvements in patient-reported outcomes.

MANAGEMENT AND OUTCOMES IN OLDER PATIENTS WHO PRESENT WITH ACUTE SEVERE ULCERATIVE COLITIS

S. Nario[1], M.Y. Wu[1], C. Tung[1], C. John Kiely[1]
[1]Royal North Shore Hospital, Department of Gastroenterology, St Leonards, Australia

Contact E-Mail Address: steffnario@gmail.com

Introduction: Older adults with ulcerative colitis (UC) have greater morbidity than younger adults, yet there is paucity of data on the management and outcomes of those who present with acute severe ulcerative colitis (ASUC) in this patient population.

This study aims to investigate differences in the management and outcomes between older and younger patients hospitalised with ASUC.

Aims & Methods: We conducted a retrospective study on all ASUC presentations to a Quaternary Sydney hospital over a 10-year period. A modified True-love Witts' Criteria was used to identify ASUC as ≥6 bloody bowel motions daily and presence of at least one systemic feature, including heart rate >90 bpm, temperature >37.8°C, haemoglobin <105 g/L, and C-reactive protein (CRP) ≥30 mg/L. Older patients who presented with ASUC was defined as those ≥65 years old at time of presentation.

Data collected on management included rates of rescue therapy, colectomy and TPN requirement. Data collected on outcomes included hospital length of stay and rates of ICU admission, 30- and 90-day readmission, and 30- and 90-day mortality.

Results: A total of 172 presentations met criteria for ASUC. Of these presentations, 148 patients (86.1%) were <65 years old and 24 patients (13.9%) were ≥65 years old. Median age at presentation in older adults was 73.6 years old and in younger adults was 32.0 years old. Older adults had similar rates of need for rescue therapy (37.5% vs 35.1%, p=0.08), colectomy (12.5% vs 9.5%, p=0,64) and TPN (12.5% vs 10.1%, p=0.73), as their younger counterparts.

Older adults (n=6, 25.0%) had significantly higher rates of ICU admission (p<0.01) compared to those <65 years old (n=3, 2.0%). Older adults also had significantly higher 30- and 90-day mortality rates (n=3, p<0.01). There was no mortality observed in adults <65 years old.

There was no significant difference in 30- and 90-day readmission rates between older adults and those <65 years old at time of ASUC presentation. Table 1 compares management and outcomes in adults <65 years old and ≥65 years old who presented with ASUC.

	Age <65 (n=148)	Age ≥ 65 (n=24)	p-value
Received rescue therapy (n, %)	52 (35.1)	9 (37.5)	0.08
Underwent colectomy (n, %)	14 (9.5)	3 (12.5)	0.64
Required TPN (n, %)	15 (10.1)	3 (12.5)	0.73
Required ICU admission (n, %)	3 (2.0)	6 (25.0)	<0.01
30-day readmission (n, %)	22 (14.9)	6 (25.0)	0.21
90-day readmission (n, %)	30 (20.3)	8 (33.3)	0.15
30-day mortality (n, %)	0 (0.0)	3 (12.5)	<0.01
90-day mortality (n, %)	0 (0.0)	3 (12.5)	<0.01
Mean length of stay (days)	10.3	14.0	0.12

Table 1. Comparison of management and outcomes in adults <65 years old and ≥65 years old who presented with ASUC.

Conclusion: Despite similar rates of need for rescue therapy and colectomy, older patients who present with ASUC are more likely to have poorer outcomes, with increased requirement of ICU admission and higher mortality rates compared to patients <65 years old. The higher morbidity and mortality observed in our study in older adults who present with ASUC highlights the need for further research to optimise care pathways and improve outcomes in this patient population.

Disclosure: Nothing to disclose.

Contact E-Mail Address: massimoc.fantini@unica.it

Introduction: Clinical remission of symptoms and endoscopic disease activity were the primary endpoints of two phase-3 studies (LUCENT-1 and -2; NCT03518086 and NCT03524092) in patients with moderately-to-severely active ulcerative colitis (UC) treated with the anti-IL23p19 monoclonal antibody, mirikizumab (miri)(1). This outcome was reached in 24.2% and 49.9% of miri-treated patients at week (W) 12 and 52, respectively.

In clinical practice, access to endoscopic evaluation can be limited. Measurement of faecal calprotectin (FCP) can be a surrogate biomarker for endoscopic disease activity and therapy response in patients with UC(2). Combined symptom and FCP remission may serve as a surrogate for clinical and endoscopic remission in real-world clinical practice.

Aims & Methods: This post-hoc analysis evaluates the proportion of patients in LUCENT-1/-2 who achieved combined symptom and biomarker remission.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patients in LUCENT-1 (N=1162) were randomised to receive either 300mg miri (n=868) or placebo (PBO; n=294) intravenously (IV) every 4W (Q4W) for 12W. In LUCENT-2, patients from LUCENT-1 with no clinical response to miri at W12 (N=272) received an extended induction therapy of 300mg miri IV Q4W for 12W (W24 of continuous treatment), while miri-responders (N=544) were randomised to either subcutaneous (SC) 200mg miri (n=365) or PBO (n=179), Q4W for 40W (W52 of continuous treatment).

At W4, W12, W24, and W52, patient symptoms and FCP levels were reported as combined endpoints of symptomatic response or remission (defined in Table 1), with FCP remission (FCP ≤250µg/g). The Cochran-Mantel-Haenszel test compared the treatment groups a) miri and PBO at W4 and W12 from LUCENT-1, and b) miri and PBO at W52 from LUCENT-1 miri-responders. The risk difference and its associated confidence intervals and p-values were reported in Table 1. Non-responder imputation was used for binary variables, while modified baseline observation carried forward was used for continuous variables.

Results: At W4 and W12, 14.2% and 33.2% of the miri group compared to 8.5% and 18.7% of PBO (p=0.0113 and <0.0001, respectively) achieved the combined symptomatic response and biomarker remission endpoint, while 7.3% and 23.7% of the miri group compared to 3.7% and 11.2% of PBO (p=0.0282 and <0.0001, respectively) achieved the combined remission endpoints. At W52, 54.3% of the miri group compared to 27.4% of PBO (p=<0.0001) achieved the combined symptomatic response and biomarker remission endpoint, while 48.5% of the miri group compared to 21.8% of PBO (p=<0.0001) achieved the combined remission endpoints. At W12 and W24, 2.9% and 23.5% of the extended induction group achieved combined symptomatic response and biomarker remission endpoints, respectively, while 1.1% and 13.2% achieved the combined remission endpoints.

Week	Dose	Symptomatic response[a] and FCP ≤250 µg/g, n (%)	Common risk difference (CI)[b]	P-Value	Symptomatic remission[c] and FCP ≤250 µg/g, n (%)	Common risk difference (CI)[b]	P-Value
Week 4	Miri, N=868	123 (14.2)	5.7 (1.7, 9.6)	0.0113	63 (7.3)	3.7 (0.9, 6.4)	0.0282
	PBO, N =294	25 (8.5)			11 (3.7)		
Week 12	Miri, N=868	288 (33.2)	14.8 (9.4, 20.2)	<0.0001	206 (23.7)	12.7 (8.1, 17.3)	<0.0001
	PBO, N =294	55 (18.7)			33 (11.2)		
Week 52	Miri, N=365	198 (54.3)	25.4 (17.3, 33.6)	<0.0001	177 (48.5)	25.0 (17.3, 32.6)	<0.0001
	PBO, N=179	49 (27.4)			39 (21.8)		

[a]Defined as ≥30% decrease from baseline of the sum of stool frequency (SF) and rectal bleeding (RB) subscores

[b]Common risk difference is the percentage difference between miri and PBO adjusted for the baseline factors a) prior biologic or tofacitinib failure (yes/no), b) baseline corticosteroid use (yes/no), c) baseline disease activity (Modified mayo score: [1-6] or [7-9]), and d) region (North America/Europe/Other).

[c]Defined as SF = 0, or SF = 1 with ≥1 point decrease from baseline and RB = 0

Table 1: Proportion of patients with Ulcerative Colitis who achieved combined symptomatic and biomarker endpoints in LUCENT-1/-2 studies.

Conclusion: In moderate-severe UC, patients treated with miri demonstrated improved efficacy compared to PBO in combined symptomatic and biomarker response and remission endpoints. Additionally, the data from this post-hoc analysis is consistent with the clinical remission data from LUCENT studies, indicating that this is a suitable endpoint measure in real-world practice.

Introduction: Mirikizumab, a p19-directed interleukin-23 monoclonal antibody, is efficacious in inducing clinical response at Week(W) 12 and maintaining clinical remission through W52 in patients with moderately-to-severely active Crohn's disease (CD) as shown in the phase 3 treat-through trial VIVID-1 (NCT03926130).[1]

Here, we present analysis of maintenance outcomes through W52 for Patient-Reported Outcome (PRO) clinical responders and nonresponders at W12.

Aims & Methods: The analysis set includes patients randomized to mirikizumab at baseline, who did or did not achieve PRO clinical response at W12 after intravenous (IV) induction treatment (900 mg mirikizumab IV every 4 weeks [Q4W]) before entering subcutaneous (SC) maintenance treatment (300 mg mirikizumab SC Q4W).

Descriptive statistics are used to summarize the data, applying nonresponder imputation for missing binary endpoints. As a treat-through study, no rerandomization was applied.

Results: From a total of 551 patients who entered SC maintenance treatment, baseline characteristics of age, duration of CD, and baseline Crohn's Disease Activity Index (CDAI) were similar between W12 PRO responders (n=402, 73.0%) and W12 PRO nonresponders (n=149, 27.0%). PRO responders at W12 had a higher objective inflammatory burden at baseline (faecal calprotectin, c-reactive protein, and Simple Endoscopic Score-CD), whereas concomitant or prior medication usage was similar between the groups. For W12 PRO responders, SC mirikizumab treatment from W12 to W52 resulted in an increase in CDAI clinical remission from 52.2% to 65.4%, PRO clinical remission from 53.2% to 65.4%, and endoscopic response from 35.1% to 54.7%, respectively (Table 1).

		PRO Nonresponders at W12 (N=149)	PRO Responders at W12 (N=402)
CDAI clinical remission, n (%)[a]	W12	8 (5.4%)	210 (52.2%)
	W16	16 (10.7%)	208 (51.7%)
	W20	28 (18.8%)	243 (60.4%)
	W24	35 (23.5%)	242 (60.2%)
	W52	50 (33.6%)	263 (65.4%)
Endoscopic response, n (%)[a]	W12	45 (30.2%)	141 (35.1%)
	W52	60 (40.3%)	220 (54.7%)

[a]Percentage of response is calculated by n/Nx*100%.
CDAI, Clinical Disease Activity Index; PRO, patient-reported outcome

Table 1.

Among W12 PRO nonresponders, PRO response was achieved by 39.6% at W16, 45.6% at W20, 44.3% at W24, and 56.4% at W52 with continued mirikizumab SC treatment, while CDAI clinical remission and PRO clinical remission were achieved by 33.6% and 31.5% at W52, respectively. Endoscopic response increased from 30.2% at W12 to 40.3% at W52 among W12 PRO nonresponders (Table 1).

Conclusion: Subcutaneous mirikizumab maintenance treatment over 40 weeks leads to incremental and sustained improvements in rates of clinical and endoscopic response regardless of PRO clinical response status after induction. A substantial proportion of clinical nonresponders at W12 improved early during maintenance treatment suggesting continued treatment with mirikizumab can be beneficial and lead to long-term response.

Introduction: G protein-coupled receptor (GPCR) is the largest single family for modern drug discovery. They involve in a wide range of important cellular and physiological functions, including sight, taste, smell, growth, behavior, mood, immune regulation and many others. In the human body, there are more than 830 different GPCRs have been discovered. About 30-40% of the marketed drugs are targeting this big family.

The mas-related G protein coupled receptor 2 (MRGPRX2), which belongs to the class A GPCR, is expressed in sensory neurons, mast cells and in keratinocytes. MRGPRX2 has been detected in adipose tissue, esophagus, urinary bladder, colon and lungs with the highest levels found in skin.

Clinical analysis indicated that the over-expression level of MRGPRX2 was extremely high in the inflammatory bowel disease (IBD) patient colons, which made it as an ideal target to treat IBD.

Here we applied artificial intelligence to design first-in-class dual functional MRGPRX2 modulator. The DSS-induced IBD model in monkey indicated that our drug candidate exhibits excellent efficacy at low dose against IBD.

Aims & Methods: Develope next generation IBD drug molecules.

Here we used artificial intelligence to design first-in-class dual functional MRGPRX2 modulator. We first built the 3D model of MRGPRX2 receptor in the inactive state in computer. The AI-based high throughput virtual screening against 10 billion virtual compounds was performed to obtain hit compounds. Lead optimization, in vivo study and safety valuation were followed as well.

Finally, we performed IND-enabling and submitted profiles to FDA for IND approval.

Results: We established a severe DSS-induced monkey model wtih DAI score at 12. In this experiment, our drug candidate could resolve most inflammation at low dose 1mg/kg (DAI=5), whereas the tissue at 3mg/kg (DAI=3) was comparable with normal group under enteroscope.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this work, we sucessfully designed dual functional drug candidates against MRGPRX2 receptor to treat IBD via AI, which was confirmed by the DSS-induced monkey model.

Introduction: Faecal urgency (FU) is a frequently encountered yet frequently underappreciated symptom experienced by many individuals suffering from inflammatory bowel disease (IBD)[1,2]. In cases of ulcerative colitis, the presence of FU is relatively easy to comprehend, as inflammation typically involves the rectum and left-sided colon, which are closely linked to urgency symptoms. However, in patients diagnosed with Crohn's disease (CD), where lesions are more commonly found in more proximal areas of the gastrointestinal tract — such as the ileum or the right colon while the distal regions like the left colon and rectum often remain unaffected, the emergence of FU becomes more difficult to explain.

Aims & Methods: The objective of this study was to evaluate and compare the prevalence and intensity of FU in CD patients with proximal versus distal involvement, using the splenic flexure as the dividing point. The study also aimed to explore associations between FU and markers of disease activity, work-related productivity, quality of life (QoL), and psychological symptoms such as anxiety and depression.

A cross-sectional study was carried out at a tertiary care centre, involving a sample of CD patients who completed a comprehensive survey between July and September 2024. FU severity was measured on a numeric rating scale ranging from 0 to 10, with scores of 0 or 1 indicating absence of FU[3]. Participants also completed the Work Productivity and Activity Impairment Questionnaire (WPAI-GH), the Short Inflammatory Bowel Disease Questionnaire (SIBDQ), and the Hospital Anxiety and Depression Scale (HADS). Data analysis was conducted using SPSS Statistics software, version 26®.

Results: A total of 158 patients were included in the study, with a mean age of 42.1 ± 1.3 years; 88 individuals (55.7%) were female. Among the participants, 109 (69.0%) reported experiencing faecal urgency (FU). Proximal disease was present in 97 patients (61.4%), while 61 patients (38.6%) had distal involvement. Of those, 69 individuals (71.1%) with proximal disease and 40 (65.6%) with distal disease reported FU. However, distal involvement was not significantly associated with the presence of FU symptoms (OR = 0.77; 95% CI [0.39–1.54]; p = 0.46), nor with symptom severity, even in the subset of patients with documented rectal involvement (n = 24; 39.3%).

No significant correlation was found between the presence or severity of FU and markers of disease activity, including faecal calprotectin, C-reactive protein, endoscopy, histology, abdominal ultrasound or clinical indices. In contrast, the severity of FU showed a weak but statistically significant positive correlation with elevated anxiety symptoms (ρ = 0.32; p = <0.001) and depressive symptoms (ρ = 0.31; p = <0.001). Only FU, not anxiety or depression, showed to be associated with overall work productivity loss (β = 2.48 [0.55-4.40]; p = <0.001). Higher scores of FU, anxiety and depression were all associated with poorer QoL (β1 = -1.09 [-1.50--0.68]; β2 = -0.61 [-1.00--0.23]; β3 = -1.32 [-1.71--0.92]; p = <0.001).

Conclusion: In this study, the occurrence of FU in CD was not associated with the location of disease involvement or markers of disease activity. Instead, FU showed a stronger relationship with psychological factors, specifically symptoms of anxiety and depression. These findings suggest that managing FU may require therapeutic strategies beyond conventional immunomodulatory treatments[4].

Contact E-Mail Address: robert.tosse@charite.de

Introduction: Advanced biological therapies have improved outcomes of patients diagnosed with Inflammatory Bowel Diseases (IBD) such as Ulcerative colitis (UC) and Crohn's disease (CD). However, nonresponse or loss of response remains a significant challenge. Primary sclerosing cholangitis (PSC) is associated with IBDs, but the impact of concurrent PSC on response to IBD therapy is not well explored.

Aims & Methods: This study compared therapy response to IBD treatment with Infliximab, Vedolizumab and Ustekinumab in patients diagnosed with PSC and IBD (PSC/IBD group) versus patients diagnosed with IBD only (control group). Therefore, we identified 46 patients in the PSC/IBD group and 180 in the control group treated with Infliximab, Vedolizumab and/or Ustekinumab at our IBD outpatient clinic at Charité – Universitätsmedizin Berlin. Propensity score matching was employed to match the groups with a ratio of 1:1 based on age, sex, BMI, smoking status, Charlson Comorbidity Index (CCI), IBD subtype, duration of IBD, age at IBD diagnosis and Montreal-Classification (tolerance = 0.2).

The primary outcome was clinical therapy response within 20 weeks, defined as remission (partial Mayo Score (pMS) ≤ 1/Harvey-Bradshaw-Index (HBI) < 5) or partial response (decrease of pMS ≥ 2/HBI > 3). Group differences were compared using Fisher's Exact test.

Secondary outcomes included time to loss of response, mucosal healing (defined as no or mild inflammation e.g. Mayo Endoscopic Score 0 or 1) and decreased levels of C-reactive Protein (CRP) < 5mg/l and faecal calprotectin (FC) < 50 mg/g. Only patients achieving clinical remission or partial response were included in the secondary analyses.

Variables	IFX-PSC (n=19)	IFX-control (n=20)	VDZ-PSC (n=28)	VDZ-control (n=22)	UST-PSC (n=21)	UST-control (n=26)
IBD-subtype UC (%)	11 (57.9%)	16 (80.0%)	24 (85.7%)	20 (90.9%)	14 (66.7%)	16 (61.5%)
Primary Outcome						
clinical remission (%)	13 (68.4%)	14 (70.0%)	19 (67.9%)	18 (81.8%)	8 (38.1%)	18 (69.2%)
clinical partial response (%)	2 (10.5%)	1 (5.0%)	4 (14.3%)	1 (4.6%)	1 (4.8%)	2 (7.7%)
p-values (Fisher's Exact test)	p = 1.000		p = 0.521		p = 0.044	
Secondary outcomes (only patients with clinical remission or clinical partial response included)						
Time to loss of response (Mean ± SD)	13 ± 11 months	16 ± 9 months	25 ± 18 months	32 ± 21 months	13 ± 4 months	12 ± 9 months
Mucosal healing (%)	4 (50.0%)	7 (87.5%)	9 (45.0%)	11 (84.6%)	1 (20.0%)	9 (75.0%)
Decreased levels of CRP and FC (%)	10 (76.9%)	13 (86.7%)	8 (47.1%)	16 (88.9%)	2 (40.0%)	14 (77.8%)

Table 1. Comparison of therapy response to IBD treatment with Infliximab, Vedolizumab and Ustekinumab between PSC/IBD group and control group.

Results: After matching, 46 patients per group were analysed, with a total of 136 treatments administered. The cohort demographics and disease characteristics were balanced between PSC/IBD group and control group with all p-values > 0,05 (mean age: 39.7 ± 12.4 vs. 39.9 ± 13.9 years; male sex: 31 (67.4%) vs. 24 (52.2%); mean BMI: 23.1 ± 3.9 vs. 23.8 ± 4.8 kg/m2; smokers: 9 (20.0%) vs. 13 (31.7%); mean CCI 0.6 ± 1.1 vs. 0.5 ± 1.0). In both groups 34 (73.9%) patients having an UC diagnosis and 12 (26.1%) a CD diagnosis.

While clinical response rates did not significantly differ between groups in patients receiving Infliximab or Vedolizumab, in patients treated with Ustekinumab clinical remission and partial response rates were significantly lower in the PSC/IBD group (p=0.04, Table 1).

The time to loss of response was not different between groups for any of the therapies. Mucosal healing rates were lower in the PSC/IBD group compared to controls as well as decreased levels of CRP and FC across all therapies (Table 1).

Conclusion: Infliximab and Vedolizumab appear equally efficient for achieving clinical response in IBD patients with and without PSC, while the efficacy of Ustekinumab is significantly lower in IBD patients with PSC. Future prospective data is needed to strengthen our knowledge of treatment outcomes in this population.

Disclosure: Nothing to disclose.

JAK INHIBITORS EXHIBIT SUPERIOR CLINICAL EFFICACY COMPARED TO ANTI-IL-23 BIOLOGICS IN REFRACTORY ULCERATIVE COLITIS

M. Manti[1], N. Kamperidis[1], A. Toskas[1], R. Misra[1], J. Nightingale[1], N. Arebi[1]
[1]St Mark's National Bowel Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: mantmagda@gmail.com

Introduction: Biologic therapies play a pivotal role in the management of ulcerative colitis (UC). Anti-TNFα agents are recommended as first-line biologics according to ECCO guidelines; however, JAK inhibitors have recently emerged as a viable alternative (1).

Vedolizumab has also demonstrated effectiveness when introduced early in the disease course with a greater 52-week treatment persistence and reduced hospitalisation rates compared to anti-TNFα agents as second-line therapy (2). The AGA guidelines (3) now favour biologics such as anti-IL-23 and JAK inhibitors over Vedolizumab or S1P receptor modulators in patients previously exposed to anti-TNFα agents.

Notably, Guselkumab is not yet approved for UC treatment in the UK. The latest ECCO guidelines (1) do not address the role of biologics in third-line or subsequent treatment settings, and there remains a lack of clear clinical guidance.

Aims & Methods: This study aimed to retrospectively evaluate the effectiveness of *third-line* biologic therapies in adult patients with UC over a 12-month period. Clinical response was assessed using the Simple Clinical Colitis Activity Index (SCCAI), Partial Mayo Score, and Physician Global Assessment, while biochemical and endoscopic responses were measured at 3, 6, and 12 months post-induction. Biochemical markers included faecal calprotectin and CRP levels. Endoscopic response was assessed using the Ulcerative Colitis Endoscopic Index of Severity (UCEIS). Colectomy rates were also recorded. Patients treated at a UK tertiary care centre were included up to March 2025. Statistical analyses were conducted using SPSS.

Results: A total of 24 patients were included in the analysis, with 13 receiving anti-IL-23 therapy and 11 treated with JAK inhibitors. Within the anti-IL-23 group, 5 patients received Mirikizumab and 8 Ustekinumab; Risankizumab was not used in this cohort. In the JAK group, 3 patients were treated with Upadacitinib, 4 with Filgotinib, and 4 with Tofacitinib. A statistically significant reduction in SCCAI scores at 6 months was

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. observed in the JAK groups compared to anti-IL-23 (7.64 ± 3.61 vs 4.90 ± 1.97, p = 0.047). However, biochemical response, assessed by faecal calprotectin reduction, did not reach statistical significance at either 3 or 6 months (p = 1.000 and p = 0.314, respectively). Endoscopic response, measured by changes in UCEIS at 12 months, also showed no significant difference between groups (p = 0.668). Subgroup analysis within the anti-IL-23 cohort revealed no significant difference in SCCAI reduction between Ustekinumab and Mirikizumab at 3 months.

Similarly, while Upadacitinib was associated with the *greatest SCCAI reduction among the JAK inhibitors at 3 months*, the difference among the three agents was not statistically significant (p = 0.106). Subtotal colectomy was performed in one patient in the Mirikizumab group following completion of induction therapy, and in two additional patients within three months of initiating the same agent (Table 1).

Biologic	Patients (N)	Colectomy(N)	Drug persistence
Mirikizumab	5	3	3/5
Ustekinumab	8	1	5/8
Upadacitinib	3	0	3/3
Filgotinib	4	0	3/4
Tofacitinib	4	0	4/4

Table 1. Patients' characteristics regarding clinical, biochemical and surgical outcomes within 12 months.

Conclusion: JAK inhibitors showed an improvement in SCCAI at 6 months compared to anti-IL-23 agents. No significant differences were found in biochemical or endoscopic response.

A REAL-WORLD DATA ANALYSIS OF OZANIMOD IN FDA ADVERSE EVENT REPORTING SYSTEM (FAERS) DATABASE

Q. Tang[1], X. Zhong[1]
[1]Department of Gastroenterology, the Affiliated Hospital of Southwest Medical University, Luzhou, China

Contact E-Mail Address: 1925792724@qq.com

Introduction: Ozanimod received approval in the United States in March 2020 for the treatment of relapsing multiple sclerosis, Crohn's disease, and ulcerative colitis. However, there is limited information available on the adverse drug reactions (ADRs) associated with its use. The main objective of this study was to explore the safety of Ozanimod after its market launch.

Aims & Methods: We gathered data from the United States Food and Drug Administration Adverse Event Reporting System (FAERS) database. Following data standardization, an array of signal quantification techniques, such as ROR, PRR, EBGM, and IC, were employed for analysis.

Results: We extracted 7,118,789 reports from the FAERS database, of which 5,587 reports identified Ozanimod as the primary suspected (PS) drug. Adverse reactions attributed to Osimertinib manifested across 27 organ systems, encompassing a total of 77 preferred terms meeting the criteria of all four algorithms simultaneously. Notably, we observed some common adverse drug event (ADE) signals, such as fatigue, headache, and dizziness, which were not documented in the official drug label.

Furthermore, we identified less common but notably potent ADE signals, including abnormal lymphocyte count, abnormal magnetic resonance imaging of the head, and traumatic fracture. The majority of adverse events occurred within the initial 30 days following the initiation of Ozanimod treatment.

Conclusion: Ozanimod presents the potential for diverse adverse reactions alongside its therapeutic benefits. Hence, in clinical practice, prompt detection of adverse drug reactions and the implementation of timely and effective preventive measures are essential.

DIFFERENTIAL SEGMENTAL HEALING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

S. Gopal[1], K. M Shah[1], S. Shenoy[1], A. Shetty[1], B. Tantry[1]
[1]KMC Hospital MAHE University, Gastroenterology, Mangaluru, India

Contact E-Mail Address: sandeep.gopal@manipal.edu

Introduction: Inflammatory Bowel Disease (IBD) presents with distinct patterns of inflammation in Crohn's Disease (CD) and Ulcerative Colitis (UC). Ileal and Colonic CD differ in their clinical presentation, gut microbiota, cytokine profile and the response to treatment. A therapeutic approach based on the segment of intestine involved may show improved outcomes and less toxicity . Whether segment of intestine involved affects outcomes is not completely clear.

Aims & Methods: Our study aimed to determine the influence of the segment of intestine involved on mucosal healing, clinical improvement, health-related quality of life (HRQoL), and endoscopic remission in patients with UC and CD.

In this observational study conducted from March 2023 to August 2024, 50 patients each of CD and UC were evaluated. Disease activity was assessed using CDAI and SES-CD scores for CD, and True Love Witts, PRO2, and UCEIS scores for UC. Patients received medical therapy including mesalamine, steroids, immunosuppressants, or biologicals. Follow-up assessments were performed after 6 to 9 months, assessing clinical remission, endoscopic response, segmental healing, and health related quality of life.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Clinical remission was achieved in 88% of CD and 52% of UC patients. Endoscopic response was observed in 64% of CD and 62% of UC patients, while endoscopic remission was achieved in 34% of CD and 32% of UC patients. Health-related quality of life targets were achieved in 68% of CD and 54% of UC patients. In CD patients, segmental involvement was as follows : terminal ileum (74%), right colon (74%), transverse colon (38%), left colon (72%), and rectum (50%). The baseline mean SES-CD scores were terminal ileum (5.05±2.73), right colon (5.29±2.92), transverse colon (5.1±2.83), left colon (5.52±3.09), and rectum (4.96±2.87).

Complete mucosal healing rates varied across segments: transverse colon (68.4%), terminal ileum (59.4%), left colon (58.3%), right colon (56.7%), and rectum (48.0%). Improvement in mean SES-CD was highest in the transverse colon (3.47) and lowest in the rectum (2.48). In UC patients,-gut involvement was as follows: terminal ileum (6%), right colon (36%), transverse colon (52%), left colon (90%), and rectum (90%). UC patients demonstrated a clear proximal-to-distal gradient in complete mucosal healing rates: terminal ileum (100%), right colon (72.2%), transverse colon (61.5%), left colon (26.6%), and rectum (15.5%). Improvement in mean UCEIS was 2 in terminal ileum, 4.15 in right colon, 3.23 in transverse colon, 2.22 in left colon, and 2.07 in rectum.

Conclusion: Segmental healing patterns differ significantly between UC and CD. In CD, the transverse colon showed the highest remission rates, while UC demonstrated a clear proximal-to-distal gradient. Component analysis of individual endoscopic parameters revealed differential improvements in vascular pattern, bleeding, and ulcer scores across segments. Left colon healing was the most important determinant of HRQoL improvement in both UC and CD. These findings suggest that an individualized approach based on segment of intestine involved in IBD may provide valuable insights for treatment optimization and improvement of patient-reported outcomes.

Introduction: Mirikizumab (miri), a humanized IgG4 monoclonal antibody that selectively binds to interleukin-23 subunit p19, is approved for the treatment of moderately to severely active ulcerative colitis and Crohn's disease. In ulcerative colitis, maintenance treatment with 200 mg miri given as two 1-mL subcutaneous (SC) injections every 4 weeks was efficacious and safe in the phase 3 maintenance LUCENT-2 and long-term extension LUCENT-3 trials. As SC injections can be associated with pain/discomfort and thus poor patient experience, an investigational 2-mL single injection delivering the same miri dose has been developed.

Aims & Methods: This phase 1 study (NCT06475729) aimed to assess the pharmacokinetic (PK) bioequivalence and safety of miri solution administered as one 2-ml injection compared with the commercially available two 1-ml injections. Healthy participants were stratified into weight categories (<75 kg, 75–85 kg, and >85 kg) and randomized (1:1) to receive one dose of 200 mg of SC citrate-free miri as either one (200 mg/2 mL) or two injections (each of 100 mg/1 mL) delivered by an autoinjector. Participants were sub-randomized (1:1:1) by injection site (arm, thigh, and abdomen). Blood samples were collected at pre-defined intervals up to 10 weeks post-dosing. The primary endpoint was PK, assessed by the maximum observed concentration (C_{max}), area under the concentration–time curve (AUC) from time zero to infinity ($AUC_{0-\infty}$), and AUC from time zero to the last timepoint with measurable concentration (AUC_{0-t}). PK parameters were estimated using non-compartmental analysis. The secondary endpoint was safety, assessed by the incidence of treatment-emergent adverse events (TEAEs) and serious adverse events (SAEs) among participants exposed to miri. Evaluating the impact of injection site location on PK was an exploratory endpoint.

Results: A total of 244 participants (mean age: 42.4 years; 55.3% female) received one 200 mg/2 ml injection and 240 (mean age: 42.7 years; 53.3% male) received two 100 mg/1 ml injections. Baseline characteristics were similar in both groups. The three primary PK parameters all fell within the bioequivalence range (geometric least-squares mean [GM] ratio: 0.800–1.250; see table).

	2 × 1-ml SC injections (100 mg/ml) citrate-free miri	1 × 2-ml SC injection (100 mg/ml) citrate-free miri	GM ratio (90% confidence interval)
C_{max}, µg/mL, GM	12.8 (n=238)	13.3 (n=243)	1.039 (0.9853, 1.0956)
$AUC_{0-\infty}$, µg × day/mL, GM	221 (n=238)	223 (n=243)	1.011 (0.9564, 1.0685)
AUC_{0-t}, µg × day/mL, GM	216 (n=238)	218 (n=241)	1.011 (0.9568, 1.0678)

Results were generally consistent across injection site locations with no significant differences between them. TEAEs were reported in 48 participants with one injection (19.7%) and 55 with two injections (22.9%). Most

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

TEAEs were mild (62/74 events with one injection [83.8%] vs 85/100 with two injections [85.0%]). Injection-site reactions occurred in 5/244 [2.0%] of participants with one injection and 4/240 [1.7%] with two injections. No SAEs were reported in either group.

Conclusion: Miri 200 mg administered as one 2-ml SC injection was bioequivalent to two 1-ml injections, and most TEAEs were mild. In clinical practice, reducing the number of injections may improve patient experience and treatment adherence.

Introduction: Janus kinase inhibitors (JAKi), including tofacitinib (TOFA, a pan-JAK inhibitor) and filgotinib (FILGO, a selective JAK1 inhibitor), represent an emerging class of orally administered agents for moderate-to-severe ulcerative colitis (UC). Comparative real-world data on their effectiveness and safety are limited.

Aims & Methods: We conducted a multicenter, real-world, propensity score-weighted cohort study using data from the Sicilian Network for Inflammatory Bowel Diseases (SN-IBD). All adult UC patients treated with TOFA or FILGO with ≥16 weeks of follow-up were included. The primary outcomes were steroid-free clinical remission and clinical response at weeks 8 and 24. Treatment persistence and adverse events were also assessed. Inverse Probability of Treatment Weighting (IPTW) was applied to adjust for baseline differences.

Results: A total of 263 patients were included (TOFA: n=171; FILGO: n=92). At week 8, steroid-free clinical remission was achieved in 53.2% of patients treated with TOFA and 43.4% of those treated with FILGO (IPTW-adjusted OR: 1.51; 95% CI: 0.88–2.61; p=0.14). Clinical response at 8 weeks was reported in 75.4% of TOFA-treated patients versus 69.6% in the FILGO group (IPTW-adjusted OR: 1.34; 95% CI: 0.73–2.46; p=0.34). At week 24, steroid-free clinical remission was observed in 58.8% of the TOFA group and 44.9% of the FILGO group (IPTW-adjusted OR: 1.37; 95% CI: 0.76–2.49; p=0.30). Clinical response rates at 24 weeks were 63.6% for TOFA and 59.0% for FILGO (IPTW-adjusted OR: 1.13; 95% CI: 0.62–2.08; p=0.69). IPTW-adjusted Kaplan–Meier and Cox proportional hazards analyses showed no statistically significant difference in the likelihood of treatment discontinuation (log-rank p=0.294; IPTW-adjusted HR for TOFA: 0.78; 95% CI: 0.49–1.25; p=0.30). Adverse event rates were 12.7 and 5.4 per 100 person-years for TOFA and FILGO, respectively, with no significant difference (p=0.152).

Conclusion: In this real-world, IPTW-based study, TOFA and FILGO were well tolerated and demonstrated comparable and high effectiveness and treatment persistence in patients with moderate-to-severe UC, supporting their use as viable oral options in routine clinical practice.

OUTCOMES IN ACUTE SEVERE ULCERATIVE COLITIS PATIENTS WHO RECEIVED SHORT COURSE INTRAVENOUS STEROIDS AND EARLY RESCUE THERAPY

M.Y. Wu[1], C. Tung[1], C. John Kiely[1], S. Nario[1]
[1]Royal North Shore Hospital, Department of Gastroenterology, St Leonards, Australia

Contact E-Mail Address: steffnario@gmail.com

Introduction: The mainstay first-line treatment of acute severe ulcerative colitis (ASUC) is high dose steroids. One-third of ASUC patients are steroid refractory and will require rescue therapy, either with cyclosporine (CYC) or infliximab (IFX) to reduce the risk of colectomy. It is recommended that patients are assessed on day 3 of steroid therapy to stratify risk of colectomy and therefore guide need of rescue therapy. It is generally understood that prolonged exposure to high dose steroids carries risk of infection, poor wound healing and mood disturbances. However, the optimum duration of intravenous steroids that mitigates risk and improves patient outcomes has not been well-established. Similarly, early rescue therapy in steroid refractory ASUC is also recommended. Delayed rescue therapy initiation may predict a longer hospital length of stay (LOS), but there is limited literature that assesses the effect of delayed rescue therapy on other patient outcomes.

Aims & Methods: All ASUC presentations to a Quaternary Sydney hospital over a 10-year period were included. A modified True-love Witts' Criteria was used to identify ASUC as ≥6 bloody bowel motions daily and presence of at least one systemic feature, including heart rate >90 bpm, temperature >37.8°C, haemoglobin <105 g/L, and C-reactive protein (CRP) ≥30 mg/L. IV hydrocortisone was given at a dose of 100 mg four times daily. Short course IV steroids was defined as ≤5 days and prolonged course of IV steroids was defined as >5 days. Rescue therapy used were either Cyclosporine (CYC), Infliximab (IFX) or JAK inhibitors (Upadacitinib or Tofacitinib). Early and delayed rescue therapy was defined as rescue therapy given within ≤5 days and at >5 days, respectively.

Results: A total of 172 presentations met criteria for ASUC. Of these presentations, 69.7% (n=120) received ≤5 days of IV steroid therapy, whilst 30.2% (n=52) received >5 days. A total of 34.9% (n=60) of patients required rescue therapy. Of those requiring rescue therapy, CYC was used in 26.3% (n=15), IFX was used in 73.7% (n=42) and JAK inhibitors in 5% (n=3). The mean time to rescue therapy was 5.67 days. Rescue therapy was given in ≤5 days for 53.3% (n=32) and >5 days in 46.7% (n=28) of presentations. The mean days on IV steroids in those who required rescue therapy was 6.95 days compared to 4.03 days in those who did not (p<0.01). Table 1 compares outcomes in those who received short and prolonged courses of IV steroids. Table 2 compares outcomes in those who received early and delayed rescue therapy.

	IV steroids ≤5 days (n=120)	IV steroids >5 days (n=52)	p-value	Rescue therapy ≤5 days (n=32)	Rescue therapy >5 days (n=28)	p-value
Days on IV steroids	N/A	N/A	N/A	5.3	8.6	<0.01
Received Rescue Therapy	25	35	<0.01	N/A	N/A	N/A
Underwent Colectomy	9	8	0.31	2	5	0.16
Received TPN	5	12	<0.01	2	8	0.02
Required ICU admission	3	5	0.11	0	2	0.48
30-day Readmission	22	6	0.08	6	3	0.38
90-day Readmission	13	9	0.61	5	4	0.88
30-day Mortality	1	2	0.27	0	2	0.48
90-day Mortality	0	0	N/A	0	0	N/A

Table 1. Comparison of outcomes in patients who received short and prolonged courses of IV steroids, and early and delayed rescue therapy.

Conclusion: Patients who received shorter courses of IV steroids and early rescue therapy were less likely to receive total parenteral nutrition (TPN) but no impact was seen on other clinical outcomes. Patients requiring rescue therapy were on IV steroids for a longer period of time compared to those who did not.

However, giving early rescue therapy significantly reduces the amount of time on IV steroids and overall length of stay. Further research is required to assess whether this may significantly reduce the risk of steroid side-effects and hospital-associated infections.

Disclosure: Nothing to disclose.

PP0520

HOME-MONITORING OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE ON SUBCUTANEOUS VEDOLIZUMAB – A 2 YEARS OBSERVATIONAL STUDY

M. Al-Sheikh[1], Z. Thomsen[1], D.V. Ankersen[1], M. Bennedsen[1], G. Letnar[2], P. Weimers[1], C.T. Peters-Lehm[1], J. Burisch[3], P. Munkholm[1]
[1]Copenhagen University Hospital, Department of Gastroenterology, North Zealand, Denmark, [2]Omicron ApS, Søborg, Denmark, [3]Hvidovre University Hospital, Gastrounit, Medical Section, Hvidovre, Denmark

Contact E-Mail Address: marwa.ss86@gmail.com

Introduction: Multiple studies have evaluated the efficacy and safety of subcutaneous vedolizumab in inflammatory bowel diseases (IBDs). Combined with home-monitoring, subcutaneous vedolizumab has the potential to promote effective and personalized management, enables self-administration and optimize use of medical resources.

Our study aimed to assess the impact of home monitoring based on patient reported outcomes (PROs) and home test fecal calprotectin in patients with IBD treated with subcutaneous vedolizumab.

Aims & Methods: This was an observational study of 43 IBD patients diagnosed with Ulcerative colitis (UC) or Crohn's Disease (CD) at North Zealand Hospital in Denmark (NOH). Patients were switched from intravenous to subcutaneous vedolizumab in 2020-2022 and followed for two years via home-monitoring web app IBD Constant Care (CC).

Data retrieved from www.ibd.constant-care.com included clinical disease activity scores (Simple Clinical Colitis Activity Index (SCCAI) for UC and Harvey-Bradshaw Index (HBI) for CD), medicine adherence score (MARS), quality of life (QoL), disability (WEB-DI), Fatigue (FACIT-F), and fecal calprotectin levels (using a home testing kit, Calpro smart APP subsequently results transferred to patients file in EPIC). Data including patient descriptions, drug frequency (Q) in weeks, adverse events (AE), severe AE, IBD-related hospital admissions, surgeries and death were obtained from patient journals (EPIC system).

Results: After the exclusion of two patients (one for not starting SC vedolizumab and shifting from IV vedolizumab to another biologic due to primary non-response, and another for lacking a recorded date of consent), forty-one patients, CD (n=21) and UC (n=20) were switched from intravenous to subcutaneous vedolizumab. Treatment was evaluated at baseline, after one and two years.

Our study found high adherence to PROs submissions in CC, with only 10% of patients with UC failing to complete them after the two-year period. Only 21 (51%) patients were maintained on subcutaneous vedolizumab after 2 years with tendency to shortened treatment interval compared to baseline and year 1. The proportion of patients achieving remission and low disease activity after 2 years were 70% in UC and 77.8% in CD. 94,1% (n=16) of patients reported improved QoL after 2 years. The most frequent

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

adverse event was reaction at injection site and was reported by 16 (39%) patients, upon which 11 (69%) patients stopped the treatment. 4 (10%) patients undergone IBD-related surgery.

Conclusion: Home monitoring using CC has the potential to transform IBD care by delivering continuous, long-term data on patient reported outcomes. Subcutaneous vedolizumab as maintenance treatment in active, moderate to severe IBD proved to be feasible to monitor by telemedicine and effective for both UC and CD in terms of improving disease activity and quality of life with high rate of adherence to medication. However, local adverse events could lead to treatment discontinuation.

OPTIMIZING THE CLINICAL POTENTIAL OF A NOVEL PH SENSITIVE ANALGESIC IN A PRECLINICAL COLITIS MODEL

N. Parkar[1], N.N. Jiménez-Vargas[1], L. Blazevic[1], C. Stein[2], S. Vanner[1]
[1]Queen's University, Gastrointestinal Diseases Research Unit, Kingston, Canada, [2]Charité-Universitätsmedizin Berlin, Berlin, Germany

Introduction: Improved pain management is an identified top five priority for the treatment of patients suffering from inflammatory bowel disease. Although conventional opioids and NSAIDs can provide pain relief, their side effects pose serious health risks. We developed a unique pH-sensitive analgesic, NFEPP, that is only active at sites of injury/inflammation without affecting healthy tissues, e.g. brain and gut. Preclinical studies using parenteral routes (s.c. or i.v.) demonstrate that NFEPP exhibits potency comparable to fentanyl, but without the risks of addiction or severe side effects like respiratory depression. The duration of action of NFEPP is ~2 hrs., which would require continuous infusion or frequent applications to treat a painful disorder. To broaden the potential clinical applications, strategies are needed to increase its half-life and to understand its efficacy compared to conventional treatments.

Aims & Methods: To examine the therapeutic index (TI) of NFEPP and determine if a high index could be exploited to extend its duration of action, and to compare the analgesic efficacy of NFEPP with a standard NSAID, diclofenac.

Acute colitis was induced in C57BL/6 mice by administering 2.5% dextran sulfate sodium(DSS) in drinking water for five days. Following s.c. injections of vehicle, NFEPP, fentanyl or diclofenac, visceromotor responses (VMRs) to colorectal distension were measured using telemetric transmitters inserted in the abdominal wall muscles. To assess cardiorespiratory side effects, mice were monitored via pulse oximetry.

Results: NFEPP (0.4 mg s.c.) and fentanyl (0.4 mg s.c.) exhibited similar analgesic effects on VMR but fentanyl markedly inhibited oxygen saturation (~10%; $p<0.05$), causing hypoxia. NFEPP at 50X's this analgesic dose (20mg/kg s.c.) had no effect on oxygen saturation, suggesting a very high TI.

We therefore examined whether the duration of action of NFEPP could be extended into the range of other oral analgesics by increasing the dose (doubling the dose increases T1/2 by ~<1, 1st order kinetics). NFEPP 0.4 mg/kg s.c. was tested at 2 hrs. and1.6 mg/kg s.c. at 6 hrs. NFEPP (1.6 mg/kg s.c.) caused a 37.8% ($p<0.05$) reduction in VMR responses after 6 hrs., similar to the effect of NFEPP 0.4 mg/kg at 2 hrs. (36.8% reduction in VMR; $p<0.01$). Comparator studies of the efficacy of NFEPP (0.8 mg/kg s.c.; ~EC75 dose) and diclofenac (30 mg/kg s.c., ~EC100 dose) demonstrated a 54.2% ($p<0.001$) and 49.7% ($p<0.01$) reduction in VMR, respectively.

Conclusion: NFEPP has a very high TI compared to fentanyl, and this property could potentially be exploited to increase its half-life in oral and/or patch formulations by increasing the dose without risk of respiratory depression. NFEPP has similar or greater analgesic efficacy compared to NSAIDs and could potentially be an alternative for some clinical indications.

THERAPEUTIC EFFICACY OF ISM012-042 (ISM5411) IN T CELL TRANSFER-INDUCED COLITIS IN MICE

Q. Han[1], Y. Fu[1], C. Feng[1], H. Li[1], M. Zhang[1], F. Ren[1], A. Zhavoronkov[1,2], C. Satler[3]

Introduction: Inflammatory Bowel Disease (IBD) is driven by dysregulated mucosal immune responses, involving innate lymphoid cells, innate immune cells (e.g., macrophages, neutrophils, dendritic cells), and adaptive immune components like Th17 and Th1 cells, which secrete pro-inflammatory cytokines. Current treatments, such as corticosteroids, 5-aminosalicylates, and anti-TNF-α antibodies, are limited by frequent relapses and side effects, including opportunistic infections. Previously, we demonstrated that ISM012-042, an oral gut-restricted small molecule, significantly alleviated symptoms in animal models of acute colitis, including TNBS- and Oxazolone-induced colitis mouse model [1].

Here, we investigate the efficacy of ISM012-042 in a chronic T cell transfer-induced colitis model, aiming to develop safer and more effective IBD therapies.

Aims & Methods: This study assessed the therapeutic and preventive effects of ISM012-042 and anti-TNF-α in a T cell transfer-induced colitis model mimicking chronic Crohn's disease. Female CB17 mice (8 weeks old) were randomly assigned into seven groups. One control group received 5×10^5 CD4+CD45RB^{low} T cells intraperitoneally. The other six groups received 5×10^5 CD4+CD45RB^{high} T cells intraperitoneally to induce colitis and were treated with vehicle, ISM012-042 (10 or 30 mpk, PO, QD), anti-TNF-α (25 mpk, IP, Q3D), or combinations, administered either preventively (days 0–42) or therapeutically (days 21–42). Disease severity was monitored via body weight, Disease Activity Index (DAI) scores, colon length, weight, and density. Cytokine levels (IL-6, IFN-γ, TNF-α, IL-17A) in intestinal mucosa

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

collected at day 42 were quantified using a CBA kit, and Swiss-rolled colon histopathology was evaluated with H&E and Masson staining. Flow cytometry analyzed T cell subsets in mesenteric lymph nodes.

Results: Groups receiving ISM012-042 (10 or 30 mpk, PO, QD) or anti-TNF-α (25 mpk, IP, Q3D) showed significantly reduced body weight loss, lower DAI scores, and decreased colon density compared to the vehicle group. Colon lengths were longer, and weights were lower, with reduced local inflammatory cytokines (IL-6, IFN-γ and TNF-α). Histological analysis revealed less crypt damage and inflammatory cell infiltration, with reduced fibrosis in Masson staining. Therapeutic Dosing (Days 21–42): ISM012-042 (30 mpk, PO, QD) and its combination with anti-TNF-α also reduced DAI scores, colon density, and cytokines (IL-6, IFN-γ, TNF-α, IL-17A). ISM012-042 (30 mpk, PO, QD) also showed decreased GATA3$^+$, T-bet$^+$, and IL-17A$^+$ T cell subsets.

Conclusion: ISM012-042, administered preventively or therapeutically, alone or with anti-TNF-α, effectively mitigated chronic T cell transfer-induced colitis by preserving colon integrity, and suppressing pro-inflammatory T cell subsets and cytokines, suggesting its potential as a versatile IBD therapy.

Introduction: Mirikizumab (miri), a humanized IgG4-variant monoclonal antibody that specifically binds to subunit p19 of interleukin-23, showed efficacy in phase (Ph)3 induction (LUCENT-1) and maintenance (LUCENT-2) studies involving patients with ulcerative colitis.[1]

Here we report the efficacy and safety of the Ph3 LUCENT-2 study, a double-blind, randomized withdrawal maintenance study, in Chinese subpopulation who responded to miri induction therapy from LUCENT-1.

Aims & Methods: Miri clinical responders after 12-week induction therapy (54.3%)were re-randomized in a 2:1 ratio to receive blinded miri 200 mg or placebo (PBO) subcutaneously (SC) every four weeks (Q4W) for 40 weeks (Chinese primary efficacy population N=80). Randomization was stratified by biologic agent/tofacitinib failed status, induction remission status and baseline corticosteroid (CS) use.

The primary objective was to test the hypothesis that Miri was superior to PBO in achieving clinical remission at Week 40. Key secondary endpoints included alternate clinical remission, CS-free remission, endoscopic remission, histologic-endoscopic mucosal remission (HEMR), improvement in bowel urgency, bowel urgency remission, and maintenance of clinical remission. Analyses in Chinese subpopulation were descriptive.

Results: Baseline demographic and disease characteristics were generally balanced across the two treatment groups, including the proportion of baseline CS/ immunomodulator use, biologic agent/tofacitinib failure status and pancolitis.

A greater proportion of patients treated with miri achieved clinical remission at Week 40 (miri 50.0%, PBO 12.5%; Δ=40.4 [95% confidence interval (CI) 22.5, 58.4]). Miri also improved key secondary endpoints at Week 40 including proportion of patients who achieved alternate clinical remission (miri 55.4%, PBO 12.5%; Δ=45.4 [95%CI 27.3, 63.4]), and who achieved CS-free remission, clinical remission, bowel urgency remission and HEMR compared to PBO.

The frequencies of treatment-emergent adverse events were similar between groups in Chinese patients. There were fewer serious adverse events and discontinuations due to adverse events in miri patients compared to PBO. No deaths were reported in Chinese subpopulation during this study.

Conclusion: In Chinese patients who responded to miri induction therapy, miri's maintenance treatment provided positive efficacy and safety profiles consistent with LUCENT-2 overall population, supporting benefits of miri treatment in the Chinese ulcerative colitis patients.

	Placebo SC N=24	Miri 200 mg SC N=56
Clinical Remission[b], n (%) Common risk difference vs placebo	3 (12.5)	28 (50.0) 40.4
Alternate Clinical Remission [c], n (%) Common risk difference vs placebo	3 (12.5)	31 (55.4) 45.4
Corticosteroid-free Clinical Remission[d], n (%) Common risk difference vs placebo	2 (8.3)	26 (46.4) 40.2
Endoscopic Remission[e], n (%) Common risk difference vs placebo	4 (16.7)	33 (58.9) 45
HEMR[f], n (%) Common risk difference vs placebo	2 (8.3)	24 (42.9) 35.6
Bowel Urgency Improvement from BL[g], LSM (SE) LSM difference vs placebo (SE)	-2.23 (0.47)	-4.52 (0.33) -2.29 (0.53)
Bowel Urgency Remission[h], n/N (%) Common risk difference vs placebo	1/24 (4.2)	23/52 (44.2) 41.4
Maintenance of Clinical Remission[i], n/N (%) Common risk difference vs placebo	0/8 (0)	11/18 (61.1) 60.6

Modified Intent-to-Treat population. BL = baseline (Week 0 of LUCENT-1 induction study); LSM = least squares mean; miri = mirikizumab; SC = subcutaneous; SE = standard error.
[a]Miri induction responders: Patients who had clinical response to miri at Week 12 of LUCENT-1 (decrease in the modified Mayo score of ≥2 points and ≥30% decrease from baseline (BL); and decrease of ≥1 point in the Rectal Bleeding (RB) subscore from BL or a RB score of 0 or 1) after receiving 300mg IV miri every 4 weeks for 12 weeks.
[b]Clinical Remission: Stool Frequency (SF) = 0, or SF = 1 with a ≥1-point decrease from BL; RB = 0; Endoscopic Subscore (ES) = 0 or 1 (excluding friability).
[c]Alternate Clinical Remission: SF subscore = 0, or SF = 1, and RB subscore = 0, and ES = 0 or 1 (excluding friability).
[d]Corticosteroid-free Clinical Remission: Clinical remission at Week 40; Symptomatic remission at Week 28; No corticosteroid use for ≥12 weeks prior to Week 40.
[e]Endoscopic Remission: ES = 0 or 1 (excluding friability).
[f]HEMR (Histologic-endoscopic mucosal remission): Histologic remission with absence of mucosal neutrophils, defined using the Geboes scoring system with subscores of 0 for grades: 2b (lamina propria neutrophils); 3 (neutrophils in epithelium); 4 (crypt destruction); 5 (erosion or ulceration), and Endoscopic Remission.
[g]Bowel Urgency Improvement: Change from induction baseline in the Urgency Numeric Rating Scale (NRS). The Urgency NRS is a patient-reported measure of the severity for the urgency (sudden or immediate need) to have a bowel movement in the past 24 hours using an 11-point NRS ranging from 0 (no urgency) to 10 (worst possible urgency).
[h]Bowel Urgency Remission: Urgency NRS = 0 or 1 among patients induced into clinical response with miri in LUCENT-1 and had Urgency NRS ≥3 at induction baseline.
[i]Maintenance of Clinical Remission: Clinical remission at Week 40 among patients induced into clinical remission with miri in LUCENT-1.

Table 1: Primary and key secondary endpoints of LUCENT-2 at Week 40 in Chinese population (Miri Induction Responders[a]).

Contact E-Mail Address: l.derijks@mmc.nl

Introduction: An increasing number of patients in clinical practice are transitioning from intravenous (IV) to subcutaneous (SC) dosing of infliximab. In this simulation study, we evaluated hypothetical dosing scenarios for both (normal to obese) adults and children switching from steady-state IV to SC infliximab, as well as those initiating SC infliximab therapy.

Aims & Methods: By combining two previous published infliximab models (1,2) we were able to simulate both IV and SC dosing in adults and children. Various dosing regimens were simulated using a large virtual population. In each scenario, the distribution of trough concentrations and area under the plasma concentration time curve (AUC) was calculated.

Results: Peak levels were higher after IV dosing compared to SC dosing, while trough levels were higher after SC dosing leading to more stable infliximab levels over time. Overall exposure remained largely similar when switching from a standard IV to SC dosing regimen. Patients with a high body mass index and those on high-frequency IV dosing regimens of infliximab demonstrated reduced exposure when transitioned to the fixed SC dose. Paediatric patients exhibited higher exposure on the fixed SC dose. Simulation of SC induction schemes demonstrated early achievement of steady state plasma levels.

Conclusion: Infliximab exposure (AUC) remains largely similar when transitioning from standard IV to SC dosing. Current dosing regimens may not be optimal for morbidly obese patients, paediatric patients and patients on high-frequency infliximab regimens. These findings provide a foundation for future clinical research to refine SC infliximab dosing in these populations.

Introduction: Acute severe ulcerative colitis (ASUC) is a life-threatening complication of ulcerative colitis, requiring hospitalization and potentially surgery. Initial treatment relies on intravenous corticosteroids, but non-responders require rescue therapies such as infliximab or cyclosporine. Janus kinase inhibitors (JAKi), including upadacitinib, and tofacitinib, rapidly modulate immune response and have shown promise in managing ASUC, based on small-scale studies.

Aims & Methods: This single-center retrospective study evaluated the efficacy of JAK inhibitors, upadacitinib and tofacitinib, as a rescue therapy in patients with ASUC not responding to intravenous corticosteroids and/or infliximab who were hospitalized during the period from May 2023 to October 2024. Upadacitinib was administered at a dose of 45 or 60mg/day during hospitalization, with the higher dose reduced to 45mg/day upon discharge. Tofacitinib was administered at 30 mg/day during hospitalization, with the dose reduced to 20mg/day upon discharge.
Patient outcome was assessed by partial Mayo score, endoscopic Mayo score (eMayo), and laboratory markers (CRP, hemoglobin, albumin, and fecal calprotectin).

Results: The cohort included 15 patients with ASUC who received JAKi as rescue therapy (8 males, 10 with extensive colitis; 73.3% with prior failure of infliximab): 13 upadacitinib (45mg and 60mg daily in 4 and 9 patients, respectively) and 2 tofacitinib. All patients had failed on intravenous corticosteroids, and one also failed on infliximab as a rescue therapy. All but one patient responded to JAKi and were discharged. One patient with no response underwent a colectomy. Endoscopy was performed at a median time of 8 weeks, with 57 % of patients achieving endoscopic remission (eMayo ≤ 1). During a median follow-up of 26 weeks after initiation of JAKi, 9 patients continued the treatment, 8 on upadacitinib and 1 on tofacitinib. One patient required colectomy, four were switched to another biologic, and one patient (a 76-year-old woman) died of pneumonia one month after starting therapy with JAKi. Within the first 3 months after hospital discharge, no further patients underwent a colectomy.

Conclusion: JAK inhibitors seem to be an effective rescue therapy for ASUC in patients who have already failed infliximab treatment. However, caution is needed in elderly patients.

Disclosure: Nothing to disclose.

EXPLORING BIOMARKERS OF CORTICOSTEROID THERAPY FOR MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS

T. Nishimoto[1], A. Tatsuguchi[1], R. Inoue[1], H. Machida[1], Y. Shimazu[1], J. Omori[1], N. Akimoto[1], S. Tanaka[1], S. Fujimori[1], M. Atsukawa[1]
[1]Nippon Medical School, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: tachan@nms.ac.jp

Introduction: Corticosteroids are a common treatment for patients with moderate to severe active ulcerative colitis (UC), but their effects can vary among individuals, including resistance, response, and dependence. While patient responses to corticosteroid therapy are generally swift, clinical remission may not be immediate for some. This suggests that corticosteroid treatment should be continued for a period of time to differentiate between corticosteroid-resistant and corticosteroid-sensitive patients with moderate to severe disease activity.

Consequently, identifying factors that can predict whether steroid use should be maintained or if a switch to a different treatment is necessary is an important consideration.

Aims & Methods: We compared the clinical characteristics of steroid responders and non-responders in patients with UC and retrospectively evaluated for biomarkers that could predict the efficacy of corticosteroid therapy prior to treatment in patients with moderate to severe active UC. Additionally, we compared the changes in various parameters before and after corticosteroid administration between steroid responders and non-responders. We enrolled 102 UC patients from Nippon Medical School Hospital who had a history of corticosteroid treatment prior to June 2024. The patients were divided into two groups: steroid responders and steroid non-responders. Their clinical characteristics were determined based on medical records.

Results: A total 102 UC patients with moderate to severe disease activity were included in this study. The clinical characteristics at baseline were as follows: the median age, 43 years (average 44.76± 17.79); with 61 males and 41 females. The most common distribution of disease type was total colitis (65%), followed by left-sided colitis (32%), and proctitis (2%). 42.6% of patients had severe disease activity. After remission induction therapy, 16% of patients were steroid non-responders, while 84% were steroid responders. The average Mayo Endoscopic Score was significantly lower, and eosinophil counts were higher in the steroid responder group compared to the steroid non-responder group (P=0.023, 0.016).

We also compared changes in various parameters at baseline and 4 weeks after steroid treatment between the two groups. After 4 weeks, inflammation markers including CRP and platelet counts decreased significantly in both groups. Hemoglobin and albumin levels increased significantly, and eosinophil counts decreased in the steroid responder group, but these changes were not observed in the steroid non-responder group.

Histological examination revealed no significant difference in the number of eosinophils infiltrating the colorectal mucosa on biopsy before steroid therapy between the two groups. However, 4 weeks after treatment, the number of infiltrating eosinophils was significantly decreased in the steroid responder group (P<0.001, Wilcoxon signed-rank test), while no change was observed in the steroid non-responder group.

Conclusion: Eosinophil count in the blood could serve as a potential biomarker for steroid responsiveness prior to administration. Additionally, steroid use decreases inflammatory markers such as CRP and platelet count, regardless of patient response.

However, eosinophil counts were reduced only in the responder group, suggesting that changes in eosinophil count may also be a predictor of efficacy in the long term.

Disclosure: Nothing to disclose.

PP0527

EFFECTIVENESS AND SAFETY OF TOFACITINIB: ONE-YEAR RESULTS FROM THE FRENCH PROSPECTIVE STUDY TOFAST

M. Fumery[1], Y. Bouhnik[2], P. Faure[3], A. Bouzidi[4], Y. Brault[5], L. Peyrin-Biroulet[6], D. Laharie[7]

Contact E-Mail Address: mathurinf@hotmail.fr

Introduction: Tofacitinib (TOFA) is an oral Janus kinase Inhibitor for the treatment of ulcerative colitis (UC). We aimed to prospectively assess the real-world effectiveness and safety of TOFA in patients with moderate-to-severe UC, using a stringent criteria for clinical benefit.

Aims & Methods: TOFAST study is a prospective, multicenter, observational study including patients initiating TOFA from 39 French centers (Dec 2020 – Jun 2023). This interim analysis reports one-year effectiveness and safety. The primary endpoint was clinical benefit at one-year, defined as PRO-2 remission [rectal bleeding subscore (RBS) of 0 and stool frequency subscore (SFS) of ≤1], regardless of TOFA discontinuation.

Patients with colectomy, death, treatment with another biologic/JAKi/immunosuppressant or corticosteroids (CS) in the last 3 months were considered non-responders. Secondary endpoints included clinical remission, clinical response, change in daily PRO-2 scores during the first 14 days, the median time to relief, and safety.

Clinical remission was defined as Partial Mayo Score (PMS) ≤2 with no subscore >1, clinical response as a decrease in PMS ≥ 3 points and ≥30% from inclusion with a concomitant decrease in RBS ≥ 1 point (absolute subscore of 0 or 1). Patient's symptomatic relief was reported as the time in days from initiation of TOFA to improvement of their symptoms. Missing data were imputed as non-responders.

Results: 150 and 146 patients were included in the safety and effectiveness analysis, respectively, with a median exposure duration of 7.4 [Q1; Q3: 2.9; 12.0] months. In the effectiveness population, mean (± SD) age was 36.9 ±13.6 years, median disease duration was 6.0 years [Q1; Q3: 2.6; 11.2], 47.2% of patients had pancolitis, and the mean total Mayo Score was 7.8 ±2.3. 94.5% of patients had previously received at least one TNF-inhibitor, 62.3% vedolizumab and 32.2% ustekinumab. 27.4% of patients received at least 3 biologics. All patients initiated TOFA at 10 mg *b.i.d*, in combination with 5-ASA and CS for 19.9% and 33.6% of patients, respectively.

At one-year clinical benefit was achieved by 38/146 (26.0%) patients, and 66/146 (45.2%) of patients were still treated with TOFA. 30.1% and 30.8% of patients achieved clinical remission and clinical response, respectively. For the 94 (64.4%) patients who reported symptomatic improvement the median time to relief was 7 days [Q1; Q3: 4.0; 14.0]. Among the 102 patients who completed their daily PRO-2 subscores during the first 14 days, 36 (35.3%) and 55 (53.9%) normalized their SFS and RBS, respectively by day 14.

89.3% of patients reported at least one adverse event (AE) and 23.3% reported at least one serious AE. Twenty-two (14.7%) infections, 3 cases of herpes zoster, 2 cases of cancers (one non-invasive low-grade urothelial carcinoma and one colon adenocarcinoma) as well as one death (considered not related to the treatment) were reported. No major cardiovascular or venous thromboembolic event were observed.

Conclusion: In this large prospective real-world cohort of refractory UC patients, one-year clinical benefit was achieved in 26% using a stringent

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. PROOF OF CONCEPT IN VITRO STUDY OF THE ADSORPTION CAPACITY OF THE ENTEROSORBENT ENTEROSGEL FOR CYTOKINES AND ENZYMES RELEVANT TO ULCERATIVE COLITIS

S. Kaur-Paneser[1], L. Hanna[2], N. Powell[2], E.V. Carrington[1,3]
[1]Imperial College London, Translational Colorectal Research Laboratory, Department of Surgery and Cancer, London, United Kingdom, [2]Imperial College London, Department of Metabolism, Digestion and Reproduction, London, United Kingdom, [3]Imperial College Healthcare NHS Trust, Department of Colorectal Surgery, London, United Kingdom

Contact E-Mail Address: ssp121@ic.ac.uk

Introduction: Approximately 50% of patients with Ulcerative Colitis (UC) suffer from daily symptoms of faecal urgency, significantly impacting their quality of life[1]. Treatment in quiescent disease is challenging and the first line treatment, loperamide, is often used with caution due to the side effect of constipation.

Enterosorbents such as Enterosgel provide a potential alternative treatment. Enterosgel is thought to work through the adsorption of small molecules in the gastrointestinal (GI) tract, with minimal or no systemic absorption and metabolism[2], without causing constipation. Enterosgel has shown clinical effectiveness in reducing urgency in patients with diarrhoea predominant irritable bowel syndrome (IBS-D), suggesting potential therapeutic value in patients with UC[3], however the mechanism by which this may occur is unknown.

Aims & Methods: This study aimed to evaluate the in vitro adsorption capacity of Enterosgel for three key inflammatory mediators implicated in UC pathogenesis (IL-1β, MMP9 and TNF-α) to explore its potential as a therapeutic option in this patient group.

Three experimental paradigms were performed by diluting recombinant cytokines and enzymes in water-based Enterosgel solutions. After incubation, gel-free supernatants were harvested to analyse residual levels of metabolite via ELISA to identify the quantity of adsorption by Enterosgel. Conditions were conducted with different:

1. Incubation times (15,30,60,120 min)
2. Metabolite concentrations (5 concentrations ranging from 0 - 3000pg/mL)
3. Gel concentrations (0.056, 0.1125, 0.225g/mL)

A total of 78 samples were analysed including blank wells and charcoal as a positive control. Supernatants were subsequently harvested and prepared for ELISA. Assays were performed in duplicate and concentrations were interpolated from linear standard curves.

Results: Enterosgel demonstrated measurable concentration-dependent adsorption of IL-1β, MMP9 and TNF-α with higher analyte input concentrations resulting in greater absolute adsorption. However for TNF-α adsorption saturated at 1000pg/mL, indicating that Enterosgel may not fully adsorb analytes at levels simulating extreme luminal inflammation. Charcoal consistently resulted in lower residual concentrations, although this did not reach statistical significance on permutation testing ($p = 0.14$). In time dependent analysis, Enterosgel induced a rapid initial reduction in cytokine levels within 15 minutes, (IL-1β: 98.7%, MMP9: 99.4%, TNF-α: 95.8% adsorbed) with a plateau by 120 minutes (IL-1β: r^2=0.74, MMP9: r^2=0.64, TNF-α: r^2=0.45).

In contrast, charcoal demonstrated a near-linear monotonic decline with a slightly greater concentration adsorbed by 120 minutes (IL-1β: 99.9% *vs*. 99.8%; MMP9: 99.9% *vs*. 99.1%; TNF-α: 97.2 *vs*. 96.3%). Increasing gel concentrations improved adsorption efficiency; however, at the highest gel concentration small amounts of residual cytokines remained (IL-1β: 0.25%, MMP9: 0.28%, TNF-α: 3.5%). Doubling of gel concentration led to an average 30% decrease in residual cytokines.

Conclusion: Our findings suggest that Enterosgel demonstrates excellent adsorption of three key pro-inflammatory cytokines relevant to UC, with the greatest reduction at 1 hour and the highest gel concentration—though less than that achieved by charcoal. Evidence of saturation at high analyte levels suggests a limit to Enterosgel's binding capacity under conditions simulating severe inflammation. These results highlight Enterosgel's clinical potential, however further validation with biological replicates and clinical studies assessing urgency in treated UC is required.

Introduction: The Montreal classification reflects the varying phenotypes of Crohn's including location and behaviour, however the majority of trials to date, despite including Montreal classification in baseline characteristics, do not report treatment efficacy by disease location. Ileal disease is associated with a higher risk of progression to stricturing and penetrating complications.

Aims & Methods: To perform a systematic review summarising the evidence for different biologic and advanced therapies available for small bowel Crohn's disease in adult patients.

Systematic search of MEDLINE and EMBASE was conducted. Articles were then screened, duplicates removed. Inclusion criteria included trials with efficacy outcomes stratified via disease location.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The primary outcome was drug efficacy, measured via endoscopic response, healing, clinical remission or improvement of MRI severity scores.

Results: A total of 868 publications were screened and assessed for eligibility following database screening and removal of duplicates. 12 studies were included with 746 patients, with a total median follow up of 52 weeks(range 14-165). All studies were included in qualitative analysis; Infliximab (6 trials n=404) Adalimumab (4 trials n=204), Vedolizumab (2 trials n=50), Ustekinumab (1 trial n=28), Filgotinib (1 trial n=60).

Of the 6 infliximab studies (n=404), 3 reported on endoscopic response (ER) and 2 endoscopic healing (EH) via double balloon enteroscopy, 2 reported on clinical outcomes only and 1 reported on improvements in MRI outcomes, as detailed in the below table. Median follow up was 52 weeks.

First author	Year	N	Design	Drug	Outcome	Follow up
Huang	2025	110	R			
		64		IFX	EH 29.6% (19/64) ER 42.2% (27/64)	52 weeks
		28		UST	UH 35.9% (23/64) EH 10.7%(3/28)	
		18		VEDO	ER 28.6% (8/28) UH 17.9% (5/28) EH 5.5% (1/18) ER 11.1% (2/18) UH 11.1% (2/18)	
Wei	2024	111	R	IFX	ER 42.3% (47/111) MH 29.7% (33/111)	32 months
Han	2021	91	R	IFX	DR(CR+MH) 47.2% (42/91)	14 weeks
Chen	2021	79	R	IFX	CR 46.8% (37/79)	38 months
Zorzi	2012	44 34 (I) 28 (M)	O	IFX – Induction (I) Maintenance(M)	CR 74% (20/28)	54 weeks
Van Assche	2013	15	P	IFX	MRI improvement 40% (6/15)	26 weeks

IFX=Infliximab, ADA=Adalimumab, VEDO=Vedolizumab, EH= Endoscopic healing(defined as a modified SES-CD <3 or 0 if jejunal/proximal ileum), ER=Endoscopic Response(defined as a reduction of SES-CD by more than 50% at both segmental and complete level), UH=Ulcer Healing (defined as no inflammation, ulcers or erosions), MH=mucosal healing(SES-CD=0), DR=Deep Remission, CR=Clinical Remission.

There were 4 trials for adalimumab (n=204), 2 trial outcomes reported on EH(53.3%) and ER on capsule (42%). Two trials focused on clinical response rates; 64-66%[iii][iv]. Median follow up was 52 weeks (range 24-154).

Ustekinumab data (n=28) was available from Huang et al who reported EH in 10.7%(3/28), ER in 28.6% (8/28) and UH rates of 17.9% (5/28).

Two retrospective studies reported on Vedolizumab outcomes(n=50); reporting on EH 5.5% (1/18), ER 11.1% (2/18), UH 11.1% (2/18) [v] and another study (n=36) reported on CT and MRI outcomes for ileal Crohn's reporting a 22% (7/32) imaging response based on EMBARK scoring[vi]. Both studies had 52 week follow up.

One RCT involving two doses of Filgotinib reported rates of clinical remission (based on CDAI<150 at week 24) of 25% in both groups[vii] and secondary outcomes of MRI remission (based on MaRIAseg<7) in 6.3%(2/32) of 100mg arm and 8%(2/25) of the 200mg arm.

Conclusion: Robust retrospective data exists for small bowel mucosal healing with anti-TNF therapy. Data is lacking for vedolizumab, ustekinemab and newer smaller molecule therapies. Dedicated clinical trials are needed to specifically investigate the effectiveness of therapies in isolated ileal Crohn's disease patients to optimise their management.

Introduction: Primary thromboprophylaxis is used in the post-partum and the post-surgical period. 2014 *Canadian Association of Gastroenterology* guidelines and a 2021 *Nature Reviews* consensus recommend outpatient thromboprophylaxis only for those ambulatory inflammatory bowel disease (IBD) patients at high risk of thromboembolic events.

Aims & Methods: We aimed to analyse our inpatient burden and our rate of post-discharge thromboembolic (TEEs) in those with primary and secondary diagnoses pertaining to IBD. We also aimed to identify associated risk factors.

Our hospital inpatient and radiology databases were queried for discharges with primary and secondary diagnoses pertaining to IBD and scans pertaining to TEEs respectively.

Results: 1,601 discharges pertaining to 954 individual patients were identified over the 13-years ended 2024. 54% (n=870) were female. Median age was 44 (IQR:32-59). 58% (n=932) pertained to Crohn's disease.

Investigations for TEEs were performed during 117 admissions (7.3%). 10 patients had inpatient TEEs (0.6%). Age ≥ 50 years was significantly associated with inpatient TEE (Odds ratio [OR]: 1.89; 95% confidence intervals [CI]: 1.13-3.16; p=0.01). Male gender (OR: 0.92; 95% CI: 0.59-1.44; p=0.72), ulcerative colitis subtype (OR: 1.51; 95% CI: 0.95-2.41; p=0.08) and inpatient surgical intervention (OR: 1.39; 95% CIs: 0.89-2.17; p=0.15) were not significant associated factors.

63 discharges (3.9%) had imaging querying TEEs performed within 180 days. Six patients (0.4%) had TEEs within this time frame. No significant associations were identified for age ≥50 years (OR: 1.16; 95% CIs: 0.68-1.99; p=0.59), male gender (OR: 0.84; 95% CIs: 0.48-2.17; p=1.47, p=0.55),

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ulcerative colitis subtype (OR: 1.12; 95% CIs: 0.65-1.91; p=0.68), inpatient surgical intervention (OR: 1.37; 95% CIs: 0.79-2.35; p=0.26) or prior VTE (OR not calculable) in relation to post-discharge TEEs.

Conclusion: Our incidences of inpatient and post-discharge TEEs were low over 13-years. In agreement with international guidelines, we recommend against the need for routine primary prophylaxis in the post-discharge ambulatory period.

Introduction: Risankizumab, a selective interleukin-23 (IL-23) inhibitor, has emerged as a promising therapeutic option for Crohn's disease (CD). This study aimed to evaluate the real-life efficacy and safety of risankizumab in patients with CD, based on data from the Apulian Network for Inflammatory Bowel Disease (AN-IBD).

Aims & Methods: This multicenter, observational study included all consecutive CD patients initiating risankizumab therapy from its availability within the AN-IBD network. Clinical, biochemical, and ultrasound data were collected retrospectively at baseline (T0) and at the end of induction (week 12, T1).

Results: A total of 81 patients were enrolled. The mean age was 43 years, and 58% were male. Most patients (over 85%) were bio-exposed, with prior failure of at least one biologic. Ileocolonic involvement (L3 by Montreal classification) was the most common disease location, 60% of patients exhibited stricturing behavior (B2), 20% non-stricturing non penetrating pattern (B1) and 20% penetrating phenotype (B3).

At week 12 (T1), 21.6% of patients achieved the clinical response (≥3-point HBI reduction), and 19.6% the clinical remission (HBI <5). 71 out of 81 patients achieved steroid free remission (87,65%).

Inflammatory biomarkers improved significantly: mean CRP value decreased from 3.55 mg/L (T0) to 1.12 mg/L (T1); mean ESR value from 6.55 mm/h to 2.09 mm/h, respectively; mean fecal calprotectin from 57.2 µg/g to 0.81 µg/g.

Ultrasound (BUSS score) identified lower scores at T1 in responders vs. non-responders. Median BUSS scores were T0 (0.6 vs 3.4), T1 (0.5 vs 3.5), with statistically significant differences at T0 (p=0.032), T1 (p=0.031), suggesting a predictive role for early ultrasound response.

Regarding safety, one patient discontinued due to gait impairment, one for a cutaneous desquamative reaction, and another following a severe cutaneous reaction post-induction. Four additional patients discontinued due to lack of response, including one who developed a perianal fistula. No infections were reported.

Conclusion: These preliminary real-world data support the efficacy of risankizumab in inducing clinical response in CD, with a low rate of primary failure. Ultrasound response may have predictive value. No new safety signals were identified.

Disclosure: Nothing to disclose.

Introduction: Guselkumab (GUS) is a dual-acting IL-23p19 subunit inhibitor that potently neutralises interleukin 23 (IL-23) and binds to CD64, a receptor on cells that produce IL-23[1]. GUS was effective and safe as intravenous (IV) induction and subcutaneous (SC) maintenance therapy in patients with moderately to severely active ulcerative colitis (UC) (QUASAR)[2]. Week 12 (WK12) results from the ASTRO phase 3 study demonstrated the efficacy of SC induction therapy with guselkumab in UC[3]. Molecular changes occurring from induction baseline WK0 to WK12 evaluated in patients from the ASTRO study are presented here.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: At baseline, 418 patients with moderately to severely active UC were randomized 2:1 to receive GUS 400mg SC induction or placebo (PBO). Molecular analysis of the randomized population was performed comparing induction WK12 to baseline. Transcriptional profiling of colonic biopsies from 339 patients was performed with bulk RNA sequencing. A comparative analysis was also performed with biopsy samples previously analyzed from 593 patients from the QUASAR Phase 3 induction study. Genes and gene co-expression modules (derived from UC single cell RNA sequencing data) were evaluated for differential expression.
Correlation between Geboes scores and transcriptional gene module changes were evaluated in colonic biopsies from 413 patients. Molecular changes were assessed in the context of clinical remission and combined histologic and endoscopic mucosal improvement (HEMI) at WK12. Serum IL-22 proteomic profiling of 355 patients was conducted using a high-sensitivity IL-22 assay and change in protein abundance was assessed.
Results: GUS 400mg SC induction demonstrated significant downregulation of inflammatory transcriptional modules in colon tissue at WK12, representing Th17, IFNG signaling, inflamed epithelium, plasma cell, neutrophil and inflammatory fibroblast biology, and upregulation of healthy epithelium-related gene modules including goblet cells and healthy epithelium (all false discovery rate [FDR]<0.05). Response to GUS SC induction demonstrated significant correlation with changes observed in transcriptional gene modules with GUS 200mg IV induction in QUASAR (r=0.98, p<0.0001). Patients who achieved clinical remission at WK12 demonstrated the most robust changes in gene module expression from baseline (p<0.0001), nearing non-IBD control levels, compared to non-remitters. Similar results were obtained for GUS treated patients who achieved HEMI at WK12. Subgroup analyses defined by prior BIO/JAKi/S1Pi treatment history demonstrated similar magnitude of changes in both treatment-naïve and -resistant groups (R=0.93, p<0.0001). Serum IL-22 was significantly decreased at WK12 (p <0.05) with GUS SC induction, similar to IL-22 changes observed with GUS IV induction. Similar changes were also observed for tissue IL-22 gene expression (p<0.05) nearing non-IBD control levels at WK12. Patients who achieved clinical remission at WK12 demonstrated a robust decrease in Geboes total scores (p<0.05) compared to non-remitters.
Conclusion: Mechanistic observations confirm that GUS SC and GUS IV induction treatment show significant correlation, supporting the efficacy of both routes of administration in UC. Results from molecular analysis of the ASTRO study corroborate efficacy results observed for GUS SC induction in UC. These data demonstrate that GUS SC induction reduced inflammatory biology towards a normal state while upregulating genes associated with healthy epithelium in patients who achieved clinical remission or HEMI at WK12.

Introduction: Histologic (histo) evaluation is an evolving treatment endpoint in Crohn's disease (CD). VIVID-1 evaluated systematically obtained biopsies from 5 intestinal segments demonstrating that histo readouts were impacted upon treatment with mirikizumab (MIRI). This may help differentiate efficacy between CD drugs.[1]

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Aims & Methods: VIVID-2, the long-term extension study of VIVID-1, examines histo and combined endoscopic (endo)-histo endpoints at Week (W)104. These data are presented, as is the impact of 1-year (yr) histo response (H-res) and histo remission (H-rem) on endoscopic and clinical outcomes after 2 yrs of treatment with MIRI.

In VIVID-1, the MIRI group received induction with 900 mg intravenously (IV) at W0, 4, and 8, then 300 mg subcutaneously (SC) every 4W. W52 patients (pts) in endo response (E-res) (≥50% reduction from baseline in Simple Endoscopic Score for CD) continued the same MIRI SC dosing in VIVID-2. Endo non-responders received reinduction with MIRI IV at the start of VIVID-2 followed by SC dosing (IV-SC) as described. Two specimens from each of 5 intestinal segments (1 ileal, 4 colonic) were obtained from the edge of ulcers, or the most inflamed mucosa from randomized pts at screening, W12, W52 (VIVID-1), and W104 (W52 of VIVID-2). H-res was defined as the absence of epithelial neutrophils and epithelial damage, erosions, and ulceration or ≥50% decrease in either the active Robarts Histopathology Index or the active Global Histology Activity Score. H-rem was defined as absence of mucosal neutrophils, no epithelial damage, and no erosions and ulcers. The criteria for H-res and H-rem had to be met in all 5 segments.

Results: Among pts in E-res at W52 of VIVID-1, 81.2% of pts maintained H-res and 57.5% maintained H-rem after an additional 52 weeks of MIRI SC treatment (Table 1A). In the same group of pts in E-res, 70.8% of pts maintained combined endo-histo response. Interestingly, 25.6% of pts who were in H-Res, but not in E-res at W52 of VIVID-1 maintained H-res and gained E-res during the 2nd year of MIRI treatment (IV-SC). Furthermore, when analyzing the impact of histo endpoints at W52 of VIVID-1 to longer term outcomes in the overall population treated with MIRI (SC-SC and IV-SC), both H-res and H-rem were significantly associated with E-res (p<0.001) and endo-remission (p<0.001) at W104 while associations with Crohn's Disease Activity Index remission (p=0.313 and p=0.771, respectively) and bowel urgency remission (p=0.122 and p=0.517, respectively) were not identified (Table 1B).

A. Outcomes at Week 52 of VIVID-1 (NRI)

	Endoscopic Responders MIRI SC/ MIRI SC		Endoscopic Non-Responders MIRI SC/ MIRI IV-SC	
Outcomes at VIVID-2 Week 52 (Week 104 of MIRI treatment)	OC	NRI	OC	NRI
Maintenance of H-Res[a], %(n/N)	92.1 N=178	81.2 N=202	65.8 N=79	57.8 N=90
Maintenance of H-Rem[b], % (n/N)	67.6 N=102	57.5 N=120	48.0 N=25	38.7 N=31

B. Impact of Histologic Response/remission at Week 52 (VIVID-1) on Week 104 (VIVID-2) in MIRI-treated participants (MIRI SC-SC & MIRI IV-SC) (mNRI)

	Week 52 Histologic Response			Week 52 Histologic Remission		
Outcomes at VIVID-2 Week 52 (Week 104 of MIRI treatment)	Yes	No	P Value[c]	Yes	No	P Value[c]
Endoscopic Response, n/N (%)	67.3 N=272	41.6 N=99	<0.001	75.5 N=133	52.3 N=238	<.0001
Endoscopic Remission, n/N (%)	43.2 N=272	20.2 N=99	<0.001	54.5 N=133	27.5 N=238	<.0001
Clinical Remission by CDAI, n/N (%)	75.7 N=272	68.4 N=99	0.313	74.7 N=133	73.2 N=238	0.771
Bowel Urgency Remission, n/N (%)	53.3 N=256	42.3 N=92	0.122	50.2 N=125	50.9 N=233	0.517

CDAI=Crohn's Disease Activity Index; IV=intravenous; MIRI=mirikizumab; mNRI=modified non-responder imputation for missing values; N=number of participants with non-missing values; NRI=non-responder imputation for missing values; OC=observed category; SC=subcutaneous

[a]Among pts in H-res at week 52 in VIVID-1

[b]Among pts in H-rem at week 52 in VIVID-1

[c]P-values are from Cochran-Mantel-Haenszel test adjusted by biologic-failed status (yes/no), baseline SES-CD total score (<12, >=12), either baseline SF >=7 and/or baseline AP >=2.5 (yes or unknown/no)

Table 1.

Conclusion: In VIVID-2, achievement of histologic response and remission after one year of miri treatment was strongly associated with longer term endoscopic outcomes. High rates of histologic and combined endo-histo endpoints were maintained after 2 years of miri treatment.

Introduction: Inflammatory Bowel Diseases (IBD) can lead to various complications, with Acute Severe Colitis (ASC) being among the most critical. ASC is a medical and surgical emergency that poses a significant risk to life, necessitating prompt and effective diagnosis and management. The first-line treatment typically involves intravenous corticosteroids. However, some cases are resistant to corticosteroids and require second-line medical therapy or immediate surgical intervention.

Aims & Methods: The objective was to identify factors associated with the failure of first-line medical treatment in patients with ASC. A retrospective descriptive and analytical study was conducted over ten years (January 2014 to March 2024) in the gastroenterology department of Charles Nicolle Hospital. The study included patients with IBD complicated by ASC, defined by the Truelove and Witts criteria and a Lichtiger score greater than 10.Patients with bacterial superinfection were not included.

Results: Forty-five patients over 18 years old were included, with a mean age of 37.87 years (range: 18–74 years). There was a slight female predominance (53%), with a male-to-female ratio of 0.87. In 31% of cases, ASC was the initial presentation of the disease. Endoscopic signs of severity at admission were observed in 49% of patients. All patients received intravenous corticosteroid therapy with hydrocortisone hemisuccinate as the first-line treatment. The response rate to first-line treatment was 64.5%. Second-line medical therapy was administered to 24.4% of patients, consisting of cyclosporine in 11.1% and infliximab in 13.3%. Five patients (11.1%) underwent subtotal colectomy due to corticosteroid failure.

In univariate analysis, factors associated with corticosteroid failure included male gender (p=0.011), absence of extraintestinal manifestations (p=0.017), higher average number of stools on the first day (p=0.013), Lichtiger score >10 on the third (p=0.011) and fifth day (p<0.001), hemoglobin levels >11 g/dL on the first day (p<0.001), >10 g/dL on the third day (p=0.009), >9 g/dL on the seventh day (p=0.013), white blood cell count >10,000/mm^3 on the first day (p=0.008), >12,000/mm^3 on the third (p=0.001) and seventh day (p=0.004), C-reactive protein (CRP) level >30 mg/L on the seventh day (p=0.005), and persistent endoscopic signs of severity after three to five days of corticosteroid therapy (p=0.001).

Multivariate Analysis showed that only the presence of severe endoscopic signs on follow-up endoscopy after three to five days of corticosteroid therapy was predictive of corticosteroid failure (Odds Ratio = 42.2; p=0.028).

Conclusion: Acute Severe Colitis is a potentially life-threatening complication. The presence of severe endoscopic signs after five days of corticosteroid therapy should prompt the initiation of second-line therapy. Understanding the predictive factors for corticosteroid failure is essential for individualized management to improve both immediate and long-term outcomes.

Introduction: Inflammatory bowel diseases (IBD), including Crohn's disease and ulcerative colitis, are chronic conditions with alternating phases of flare-ups and remission. Due to the persistent and often severe course of these diseases, effective treatment significantly improves patients' daily activities and overall functioning. [1] Given the uncertain prognosis and the frequent disease progression despite pharmacotherapy, it is important to explore additional interventions that could support traditional treatments. While physical activity may provide both anti-inflammatory and functional benefits in IBD, data on its efficacy and safety during disease exacerbation remain scarce. [2] This pilot study is the first real-world investigation into the effects of a supervised physical exercise training in patients hospitalized due to IBD flare.

Aims & Methods: This study aimed to evaluate the effects of an individualized, moderate-intensity, supervised physical exercise training on exercise tolerance, inflammation, and fatigue resistance in patients hospitalized due to IBD flare, and to explore baseline factors associated with greater benefit from the intervention. Patients were randomly assigned to an intervention group, receiving individual cycloergometer training during hospitalization, or to a control group without exercise. Both groups were well balanced at baseline, with no significant differences in demographic, clinical, or laboratory parameters. At both admission and discharge, all patients underwent standardized graded exercise tests to establish their exercise tolerance based on the lactate threshold and heart rate/power output response. Furthermore laboratory assessments, and the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) questionnaire were conducted.

Results: A total of 22 patients were included in the study, with 13 patients in the intervention group and 9 patients in the control group. Although FACIT-F scores improved in both groups, the intervention group demonstrated a significantly greater improvement (median change –39 points; IQR –49 to –11; p = 0.014) compared to the control group (median change –25 points; IQR –52 to –6; p = 0.30). Baseline FACIT-F scores were significantly correlated with changes in heart rate response response during exercise: patients with greater baseline fatigue and poorer functional status experienced greater improvement in exercise tolerance (r = –0.62, p = 0.028). Platelet counts remained more stable in the intervention group (median change +10 ×10^3/µl; IQR –65 to +45) compared to a significant increase in the control group (median +74 ×10^3/µl; IQR +44.5 to +101.75; p = 0.046). In the intervention group, greater reductions in calprotectin were strongly correlated with more favorable heart rate responses during a graded exercise test (r = –0.92, p = 0.009).

Conclusion: Supervised training program during hospitalization for IBD flare was associated with improved fatigue resistance and more favorable inflammatory responses. Patients with worse baseline functioning obtained greater benefit in exercise tolerance. These findings support the feasibility and potential therapeutic role of individualized physical activity in acute IBD care and highlight the need for further investigation in real-world settings.

Introduction: Advances in therapeutic drug monitoring (TDM) have significantly improved the understanding of the relationship between anti-TNF-alpha drug concentrations and disease activity in patients with Crohn's disease (CD). Early dose optimization of adalimumab (ADAL) and higher serum trough concentrations are associated with increased clinical, biochemical, and endoscopic remission in CD[1,2,3,4].

This study aimed to evaluate whether early dose optimization of ADAL to a trough level >15 µg/mL improves clinical and biochemical remission rates at 12 weeks compared to standard dosing.

Aims & Methods: This study aimed to evaluate whether early dose optimization of ADAL to a trough level >15 µg/mL improves clinical and biochemical remission rates at 12 weeks compared to standard dosing. This was a randomized, multicenter, open-label trial evaluating TDM-guided ADAL dose optimization versus standard dosing in biologic-naïve and experienced patients with active CD. In the dose optimization arm , after standard induction doses at Weeks 0 (160 mg) and 2 (80 mg), patients with trough levels ≤15 µg/mL at week 4 received an additional 80 mg at Week 6 followed by 40 mg every week. Patients in the optimization arm who had trough levels >15 µg/mL at week 4 and all patients in the standard care arm remained on 40 mg every 2 weeks. The primary endpoint was a composite of clinical and biochemical remission at Week 12, defined as Harvey-Bradshaw Index (HBI) <5 and C-reactive protein (CRP) <5 mg/L or fecal calprotectin (FCal) <250 µg/g.

Results: A total of 77 patients were enrolled in the trial (39 in optimization arm vs 38 in standard care arm). At week 4, 15/39 patients in the intervention arm were eligible for dose optimization, with twelve going on to receive the accelerated regimen. At week 12, 6/12 (50%) of the optimized patients achieved an ADAL trough level >15 µg/mL. A numerically higher proportion of patients in the dose optimization arm achieved the primary endpoint compared to the standard care arm, however this difference was not statistically significant (17 (43.6%) vs 12 (31.6%), p = 0.394). In total, eleven patients in the optimization arm (28.2%) and seven patients in the standard care arm (18.4%) achieved an ADAL trough >15 µg/mL, with mean trough levels being numerically higher in the optimization group (18.1 vs 12.8 µg/mL, p = 0.160). ROC analysis of the predictive value of Week 12 trough levels on the primary outcome determined an optimal threshold level of 18.2 µg/mL (AUC 0.68, sensitivity 88.9%, specificity 39.3%).

When analyzing the entire cohort, patients who achieved an ADAL trough >15 µg/mL (whether they were dose-optimized or not) at Weeks 8 or 12 were significantly more likely to achieve combined clinical and biochemical remission (19/27 patients (70.4%) vs 10/50 patients (20.0%), p < 0.001). Taken separately, both clinical and biochemical remission occurred more frequently in patients who achieved an ADAL trough >15 µg/mL (*clinical*: 22/27 (81.5%) vs 16/50 (32.0%), p <0.001; *biochemical:* 22/27 (81.5%) vs 14/50 (28.0%), p < 0.001). No difference in adverse effects was observed between trial arms. The major limitation of the trial was the small sample size and patient withdrawal due to the COVID 19 pandemic.

Conclusion: Although proactive dose optimization did not significantly increase remission rates compared to standard dosing, achieving an ADAL trough level >15 µg/mL at Week 8 or 12 was strongly associated with higher remission rates. These findings support early TDM-driven dose escalation and suggest that maintaining ADAL >15 µg/mL is a key target for achieving biochemical remission.

Introduction: Thioguanine (TG) has recently been rediscovered as an immunosuppressive agent in the treatment of inflammatory bowel disease (IBD). This prodrug is directly converted into its active metabolites, 6-thioguanine nucleotides (6-TGNs), targeting the inhibition of RAC1 GTPase in inflammatory conditions, disrupting key cellular signaling pathways necessary for T-cell activation and survival, thereby contributing to

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

its immunosuppressive action. In IBD, TG is used fixed dose and may benefit from model-informed precision dosing (MIPD) to optimize treatment efficacy and minimize toxicity. However, a population pharmacokinetic (PopPK) model to do so is lacking.

Aims & Methods: The aim was to develop a PopPK model for TG in IBD patients, enhancing the understanding of TG's pharmacokinetics and supporting the implementation of model-informed precision dosing (MIPD). We employed a dataset comprising 131 6-TGN trough concentrations from 28 IBD patients treated with TG. The data were analyzed using nonlinear mixed-effects modeling (NONMEM) to estimate pharmacokinetic parameters and explore the influence of covariates such as weight and 5-ASA use on drug disposition. Model fit-for-purpose was evaluated through computation of the model's forecasting performance.

Results: The developed PopPK model was a one-compartment model with first-order absorption. A one-compartment TG model was stable, and able to estimate PK parameters with good precision (RSE 11-15%) with weight and 5-ASA use significantly affected TG clearance. Forecasting performance was also adequate with an rRMSE of 24.1% and practically no systematic bias (MPE 0.2%).

Conclusion: This study presents the first PopPK model of thioguanine for IBD, offering a novel tool for MIPD in clinical settings. Future studies should explore additional covariates such as TPMT genotype and drug interactions to further refine dosing recommendations for diverse patient populations.

COMPARING INFLAMMATORY MARKERS IN THE FIRST 18 MONTHS OF TREATMENT BETWEEN PRIMARY RESPONDERS AND NON-RESPONDERS TO ANTI-TNF THERAPY

O.Z. Gercek[1], C. Alatas Alkim[1], H. Alkim[1], I. Sen[1]

Contact E-Mail Address: oykuzeynepgercek@gmail.com

Introduction: Biologic therapies, particularly anti-TNF agents, are key in managing inflammatory diseases. However, response to treatment varies, necessitating biomarkers to distinguish early responders from non-responders.

This study investigates early longitudinal changes in key inflammatory markers to compare trajectories between primary responders and non-responders over 18 months.

Aims & Methods: A total of 180 anti-TNF naïve patients were included. Patients were categorized into primary remission and primary non-remission groups based on clinical evaluation during follow-up. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), albumin, and hemoglobin levels were measured at baseline, and at 3, 6, 12, and 18 months. Intragroup temporal comparisons were analyzed using paired sample t-tests; intergroup comparisons were assessed via variance analysis.

Results: Across all time points, the responder group consistently demonstrated lower ESR and CRP levels and higher albumin levels compared to non-responders. In the responder group, ESR showed a significant decrease from baseline to 3 months, with stabilization thereafter. A similar pattern was observed in the non-responder group, though levels remained higher. Albumin levels increased significantly in both groups until 6 months and remained stable afterward, with consistently higher levels in responders. CRP levels dropped significantly from baseline to 6 months in both groups, then plateaued. Hemoglobin levels increased slightly only in the responder group at 3 months, with no significant changes in other intervals or in the non-responder group.

Conclusion: Inflammatory markers demonstrated distinct patterns between responders and non-responders to anti-TNF treatment within the first 18 months. Early changes in ESR, CRP, and albumin may help predict long-term response, supporting their role as potential monitoring tools in clinical decision-making.

Introduction: Mirikizumab has been approved for the treatment of moderate-to-severe Ulcerative Colitis (UC). It is a humanized IgG4 monoclonal antibody that binds to the p19 subunit of IL-23, selectively inhibiting the interaction with the IL-23 receptor. Due to the limited real-world data on its effectiveness currently available, this study aims to assess the short-term effectiveness and safety of mirikizumab induction treatment in a real-life Italian cohort of UC patients.

Aims & Methods: From November 2024 to April 2025, all consecutive UC patients treated with mirikizumab across five Italian centers from Latium net were retrospectively enrolled. Only patients who had completed at least two doses of the induction phase of mirikizumab, with a follow-up of at least 8 weeks, were included in the final analysis. Clinical characteristics, disease activity scores, steroid usage, and adverse effects were collected.

The primary endpoint was steroid-free clinical remission, defined as a Clinical Modified Mayo score (MMS) < 2, with absolute Rectal Bleeding (RB) subscore=0 and absence of concomitant steroid therapy at 8-12 weeks.

Secondary endpoints included clinical remission (MMS<2, RB subscore=0), clinical response (≥2 point decrease in Clinical Modified Mayo score or MMS<2, RB subscore=0), biochemical remission (CRP ≤ 5 mg/L), and occurrence of adverse events at 8-12 weeks.

Results: A total of 61 patients were enrolled. The male-to-female ratio was 32:29, with a mean age of 48.7 years (range 19–77). The mean disease duration was 11.4 years (range 0–39). Four patients (6.5%) were biolog-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ic-naïve, while 35 out of 61 (57.4%) had been treated with at least two prior biologic therapies. Sixteen patients were receiving concomitant steroid therapy at baseline.
Extraintestinal manifestations were reported in a subset of patients, including psoriasis in 8.2% (5), peripheral arthropathy in 13.1% (8), and axial arthropathy in 4.9% (3).
40 patients completed the 8-12 week follow-up period, and 7 completed the 20-week follow-up period. Of these, 4 (10%) received mirikizumab as a first-line therapy; 26 (65%) of them had previously been treated with antiTNFα agents and 14 (35%) had received ustekinumab as previous line of therapy.
Interestingly, a prolonged induction regimen was chosen for 25 out of 40 (62.5%) patients completing the 12-week induction therapy.
Specifically, in 4 of these cases, this decision was driven by a history of a "difficult to treat" disease instead of the lack of clinical or biochemical response. The steroid-free clinical remission rate at weeks 8-12 was 55.0% (22/40). The percentage of patients receiving concomitant steroid therapy decreased from 47.5% (19/40) at baseline to 25% (10/40) at weeks 8–12.
Clinical remission and clinical response rates at weeks 8-12 were 65% (26/40) and 82.5% (33/40), respectively.
Nineteen out of 40 (47.5%) patients presented a high C-reactive protein (CRP) at baseline, while ten out of 40 (25%) patients presented a positive CRP at 8-12 weeks. None of the patients discontinued mirikizumab within the 12-week follow-up period, and no adverse events or disease complications were observed during that period.
Conclusion: In a large cohort of refractory UC patients with multiple prior drug failures, including frequent failures with Ustekinumab and infliximab, nearly 55% achieved steroid-free clinical remission following mirikizumab induction. The safety profile of mirikizumab was consistent with existing literature.
Disclosure: Nothing to disclose.

SEVERE ACUTE COLITIS AND OPPORTUNISTIC INFECTIONS: IMPACT OF CO-PATHOGENS (CMV, *CLOSTRIDIOIDES DIFFICILE*) ON THERAPEUTIC RESPONSE

C. Louati[1], E. Belhaj Mabrouk[1], M. Asma[1], S. Ayadi[1], A.T. Allala[2], N. Trad[1], L. Mouelhi[1], Y. Said[1], R. Debbeche[1]
[1]Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia, [2]Mohamed taher Maamouri hospital, Gastroenterology Department, Nabeul, Tunisia

Contact E-Mail Address: Cyrinelouati94@live.fr
Introduction: Severe acute colitis (SAC) <represents a critical complication of inflammatory bowel disease (IBD), requiring prompt and appropriate management. Opportunistic infections, particularly those caused by cytomegalovirus (CMV) and *Clostridioides difficile* (C. difficile), can significantly influence clinical outcomes and therapeutic responses, especially in immunocompromized individuals.
This study aims to evaluate the incidence of these opportunistic infections in patients with SAC complicating IBD and to analyze their impact on clinical progression and treatment efficacy.
Aims & Methods: A retrospective study was conducted involving patients admitted for SAC, diagnosed based on Truelove and Witts criteria and a Lichtiger score exceeding 10. Initial assessments included CMV polymerase chain reaction (PCR) testing on colonic biopsies and/or blood samples, detection of C. difficile toxins A/B in stool specimens, and standard microbiological evaluations. Clinical, biological, and therapeutic response data were systematically collected.
Results: Fifty-five patients over the age of 18 were included, with a mean age of 42.36 years (range: 18–74) and a slight female predominance (55%). In 34% of cases, SAC was the initial manifestation of IBD. All patients met the Truelove and Witts criteria and had a Lichtiger score >10 upon admission. Endoscopic signs of severity were observed in 40% of patients.
Intravenous corticosteroid therapy using hydrocortisone hemisuccinate was administered as the first-line treatment for all patients, yielding a 60% response rate.
CMV co-infection was identified in 4 patients, all of whom were refractory to intravenous corticosteroids and subsequently received ganciclovir. Two patients responded favorably to second-line therapy with cyclosporine, while the remaining two did not respond to infliximab and required subtotal colectomy.
C. difficile co-infection was detected in 6 patients, treated with intravenous metronidazole and oral vancomycin. Among these, 3 patients did not respond to first-line medical therapy; one acheved clinical improvement with cyclosporine, whereas two required emergency subtotal colectomy due to the development of toxic megacolon.
Bivariate analysis revealed a statistically significant association between CMV co-infection and corticosteroid treatment failure (p=0.009). No significant association was found between C. difficile co-infection and first-line treatment failure in SAC.
Conclusion: Opportunistic infections, particularly CMV, are linked to unfavorable therapeutic responses in patients with SAC. Early detection of these co-pathogens is crucial for promptly adjusting treatment strategies, including the consideration of second-line therapies or surgical interventions.
These findings underscore the importance of systematic screening for opportunistic infections in SAC patients to optimize management and improve clinical outcomes.
Disclosure: The authors report no conflicts of interest.

USE OF BIOLOGIC THERAPIES IN PATIENTS WITH ASYMPTOMATIC ISOLATED TERMINAL (CROHN'S) ILEITIS AT SCREENING COLONOSCOPY

A. Mpountouridis[1], B. Mollagioussoufoglou[1], K. Soufleris[1], S. Kallinikidis[1], M. Stafylidou[1], E. Chatzopoulos[1], D. Tzilves[1]
[1]Theageneio Anticancer Hospital of Thessaloniki, Gastroenterology Department, Thessaloniki, Greece

Contact E-Mail Address: a.mpountouridis@gmail.com
Introduction: Incidental inflammation of the terminal ileum is not uncommon in individuals who are submitted to screening colonoscopy. It is mostly mild and considered to have a benign course without the need for immunosuppressive therapy used for moderate Crohn's disease. In the light of recent literature highlighting the effectiveness of early treatment of Crohn's Disease we sought to determine the natural course of asymptomatic terminal ileitis in our pool of individuals who underwent screening (ileo)colonoscopy, and in particular which patients ended up being treated with biologics in real life , as well as any baseline factors.
Aims & Methods: We included individuals from the endoscopic database with asymptomatic terminal (Crohn's) ileitis in the last 5 years: we only included those with recorded endoscopic images available for endoscopic assessment with the SES-CD score and biopsies compatible with Inflammatory Bowel Disease (IBD) without a history of significant NSAID consumption. We recorded baseline characteristics (age, gender, smoking status, IBD family history, extra-intestinal autoimmunity), endoscopic severity, degree of histologic inflammation and biomarkers of inflammation (C-RP, Fecal Calprotectin).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Finally we went through the Greek Prescription Database to find out the ones that were prescribed with biologics, steroids or had IBD-related surgery or hospitalization. We used point-biserial correlation, Pearson correlation, chi-square test to establish any variable correlations.

Results: We included 46 individuals : 28 women, 18 men with a median age of 55.8 years and a median follow up of 46.8 months. Nine of them were smokers (19.5%) and 10 (21.7%) had elevated C-RP (>0.5 mg/dL) and/or Fecal Calprotectin (>250 μg/mg). Steroids were used in 11 patients (23.9%) and only 1 had IBD-related surgery. Patients that received biologic therapy at some time-point amounted to 15 (32.6%): 9 with adalimumab (60%), 5 with ustekinumab (33.3%) and 1 patient received upadacitinib (concomitant rheumatoid arthritis). No factor other than an initial SES-CD score > 4 displayed statistically significant correlation with the future use of biologic therapy (p-bc=0,4214, p=0,0032). Interestingly enough most of the patients to eventually receive biologic therapy showed some kind of endoscopically visible ileocecal valve inflammation.

Conclusion: In this carefully selected but with a real life follow up group of patients with incidental asymptomatic terminal (Crohn's) ileitis a rather surprising one third of patients was eventually treated with biologic therapy during a median period of a 4-year follow up. Only baseline endoscopic severity (SES CD score >4) predicted the use of biologic therapy (mostly adalimumab or ustekinumab). All those patients had moderate disease and uneventful disease course. We need more studies to determine the (endoscopic?) threshold for biologic therapy or the right non-invasive tool (intestinal ultrasound?) to monitor these individuals in order to prevent over (or under)treatment.

Introduction: Mirikizumab is an interleukin (IL)-23 inhibitor approved for the treatment of ulcerative colitis (UC); however, real-world data are limited.

Aims & Methods: The Dutch Initiative on Crohn and Colitis (ICC) Registry is a prospective multicentre study collecting real-world data on advanced therapeutic agents in inflammatory bowel disease (IBD). Patients included in the current study had a confirmed diagnosis of UC and received at least one intravenous induction dose of mirkizumab before the 28th of February 2025. Patients who did not use at least two therapies with different mechanisms of action (i.e. difficult-to-treat UC) or with colectomy were excluded. The primary endpoint was clinical remission at week (W) 12, defined as Simple Clinical Colitis Activity Index (SCCAI) ≤ 2. Secondary outcomes at W12 included corticosteroid-free (CSF) clinical remission (i.e. clinical remission without the use of systemic corticosteroids on the day of the visit), biochemical remission (faecal calprotectin (FC) level ≤ 250μg/g) and endoscopic remission (Mayo endoscopic subscore = 0). In addition, drug survival and adverse events were assessed.

Results: In total, 22 patients were included; 13 (59.1%) were male. Most patients (n = 12; 54.5%) were diagnosed with pancolitis. Patients had a median disease duration of 9.5 years (IQR 18.0). Twelve patients (54.5%) had used at least four different advanced therapies; 19 (86.4%) patients have previously used ustekinumab (IL-12/23 inhibitor). At treatment initiation, all patients showed active disease, either clinically, biochemically or endoscopically. Median SCCAI was 7.0 (IQR 6); median FC was 1696.5μg/g (IQR 2079). As the study is still ongoing, data at W12 were available for 19 (86.4%) patients. Clinical data were available for 14 patients; 35.7% (5/14) of them were in clinical remission. These five patients were also in CSF clinical remission. Similar rates were observed between ustekinumab-experienced and ustekinumab-naïve patients, although the naïve subgroup was rather small (3/14). Biochemical data were available for 12 patients; median FC was 1434.5μg/g (IQR 824). Only one (8.3%) patient was in biochemical remission at W12; this patient was ustekinumab-naïve. Another patient, with only endoscopic data, was in endoscopic remission. Two patients discontinued mirikizumab before W12: one patient stopped mirikizumab after the intravenous injection because of fever; the other patient showed no response. Four other patients discontinued mirikizumab after

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

W12; none of them were in clinical or biochemical remission at W12. Reasons for treatment discontinuation were primary non-response (5/6) and adverse event (1/6). Four adverse events were reported in four patients: nausea and skin problems, both classified as possibly related to the treatment, a gastrointestinal infection requiring antibiotics and fever during the infusion.

Conclusion: We found that 7/16 patients with difficult-to-treat UC were in either clinical, biochemical or endoscopic remission at W12. Moreover, all patients in clinical remission at W12 were not using other medications. Mirikizumab was well tolerated, although the follow-up period was relatively short. The ICC Registry is ongoing, and results with higher patient numbers with longer exposure to mirikizumab will be analysed to further characterise the real-world effectiveness and safety for patients with difficult-to-treat UC.

Introduction: The subcutaneous (SC) formulation of infliximab offers a patient-centered alternative to the intravenous (IV) route, with the potential to improve treatment adherence, quality of life, and reduce the burden of care in patients with inflammatory bowel disease.

Aims & Methods: Aim of our study was to evaluate the clinical impact, safety, and patients' outcomes associated with the switch from IV to SC infliximab in routine care. This was a single-center observational study incorporating both prospective and retrospective data collection. Patients with confirmed diagnosis of Crohn's disease (CD) or ulcerative colitis (UC) who received at least two infusions of IV infliximab and subsequently transitioned to SC infliximab 120 mg every other week were eligible for inclusion.

The primary endpoint was the impact of switching from IV to SC infliximab on patients' quality of life and work productivity measured through the SF-36 and WPAI-GH questionnaires administered at baseline and at week 52. Secondary endpoints included safety profile and clinical effectiveness, defined as clinical remission or improvement at weeks 8, 24 and 52 following the switch to SC infliximab.

Results: A total of 109 adult patients (72 UC (66,1%), 64 male (58.7%)) were enrolled. Median age was 41.6 ± 12.2 years. The switch from IV to SC infliximab was associated with an improvement in work productivity in both UC and CD at week 52 in terms of absenteeism ($p = 0.04$; $\eta^2 = 0.18$; 95% CI: 0.03–1.00 in CD and $p < 0.001$; $\eta^2 = 0.25$ in UC) and productivity loss ($p < 0.001$; $\eta^2 = 0.47$; 95% CI: 0.34–1.00 in CD and $p < 0.001$; $\eta^2 = 0.30$ in UC) . No significant differences were found in activity impairment, presenteeism, or across SF-36 domains in either CD or UC cohorts (all $p > 0.05$). Transitioning from IV to SC infliximab did not affect patients' perceived quality of life as assessed by physical, mental, or social functioning scores. At week 52, 51 out of 55 (93%) patients with UC and 20 out of 27 (74%) patients with CD were in clinical remission. Switching from IV to SC infliximab was significantly associated with achievement of clinical remission over time in UC ($\chi^2 = 8.83$, $p = 0.03$ with Cramér's V = 0.16). In patients with CD, switching from IV to SC infliximab did not show a statistically significant association with the achievement or maintenance of clinical remission at months 12 ($\chi^2 = 1.02$, $p = 0.80$ with Cramér's V = 0.00; 95% CI: 0.00–0.13). The switch was well tolerated with no new safety issues. In total, 6 patients experienced mild adverse events (erythema in the injection site in 3 patients, urinary tract infection in 1 patient, allergic reaction in 1 patient, and skin rash in 1 patient), leading to treatment discontinuation in 3 cases. No patient suffered from severe adverse events.

Conclusion: Switching from IV to SC infliximab is associated with significant improvements in work productivity at week 52 in both UC and CD. No new safety issues were found. These findings support the SC formulation of infliximab as a safe and effective option in the management of inflammatory bowel disease.

Introduction: Secondary loss of response to Infliximab(IFX) occurs in approximately half of patients with Inflammatory Bowel Disease(IBD), due to drug levels falling below the therapeutic range. This study evaluated IFX levels and related clinical and laboratory parameters and their impact on clinical outcomes.

Aims & Methods: Pre-infusion drug levels, associated laboratory data, and clinical parameters were evaluated in IBD patients receiving maintenance doses of IFX(5–15 mg/kg every 4–8 weeks) between Nov2021-Apr2025. Drug levels were measured using a bedside kit capable of quantitatively detecting values between 0.4–20µg/mL.

Results: A total of 1,059 single pre-infusion measurements from 455 patients and consecutive dual measurements at weeks 4 and 8 from 64 patients were evaluated. In the single and double measurement groups, 75.4% and 84.4% of patients had Crohn's disease(CD), respectively. The most commonly used doses were 5 mg/8 weeks and 10 mg/4 weeks(Table 1) Drug levels were below 5 µg/mL in 33% of the measurements. Antibody positivity was present in 47.5% of 120 available measurements ranging from 0.4-20 µg/mL, showing no significant correlation with drug levels or immunomodulatory(IM) use (p=0.62 and p=0.61).

However, for all positive antibody measurements drug levels were ≤ 3.5 µg/mL. CRP differed significantly across drug level groups, whereas albumin did not(Table 1). A weak negative correlation was found between IFX levels and CRP(r = -0.13, p = 0.001), with no correlation for albumin(p=0.54). In UC patients, the correlation between CRP and IFX levels was slightly stronger(r= -0.280, p=0.004).

No significant associations were found between IM use and IFX levels >5 µg/mL(p=0.55), >10 µg/mL(p= 0.93), or >20µg/mL(p = 0.87). Abdominal pain was more common in patients with IFX levels <5 µg/mL (p=0.032) and <10 µg/mL (p=0.044). Smoking status was not associated with achieving IFX levels >5 µg/mL(p=0.57), >10 µg/mL (p=0.89), and >20 µg/mL (p=0.633). Among CD patients, those with IFX levels >5 µg/mL had significantly lower CDAI scores (p = 0.039), and lower daily stool frequency (p=0.002).Regression analysis showed that higher BMI (p=0.045), lower CRP(p < 0.001), higher IFX dose(p < 0.001), and CD diagnosis(p =0.014) to be independently associated with achieving IFX levels >5 µg/mL. These factors also predicted levels >10 µg/mL and >20 µg/mL, except for BMI at the >20 µg/mL threshold. In the dual measurement group, the median CRP levels at weeks 4 and 8 were 2.1(5.1) and 2.5(6.3), respectively (p = 0.108). Among patients with IFX >20 µg/mL at week 4, 75% maintained levels >5 µg/mL at week 8, whereas this rate was 64% for those with levels >10 µg/mL. Only 59.6% of those with >5 µg/mL at week 4 retained >5 µg/mL at week 8(all p <0.001). Week 4 IFX levels was 7.3 times higher than at week 8 for cases within measurable range.

Parameter	>5 µg/ml	>10 µg/ml	>20 µg/ml	Patient Demographics	
Disease (All / CD / UC %)	67 / 69.8 / 56.5	51 / 53 / 43	25 / 25.4 / 21.8	Sex M / F %	56 / 44
p (CD vs UC)	<0.001	0.012	0.29	Age at Diagnosis	29 (19)
CRP # median(IQR)	2.6 (5.2) ; 4.9 (11.1)	2.5 (5.2); 4.1 (9.3)	2.1 (3.9); 3.6 (7.2)	Age at Measurement	38 (21)
p*(CRP)	<0.001	<0.001	<0.001	Duration of IFX Treatment	20 (25)
Dose Groups (%)	5mg/8w: 46 5mg/4w: 84 10mg/8w: 64 10mg/4w: 81 15mg/4w: 70	5mg/8w:28 5mg/4w:75 10mg/8w:38.7 10mg/4w: 71 15mg/4w: 56	5mg/8w: 4 5mg/4w: 43 10mg/8w:15.3 10mg/4w: 42 15mg/4w: 34		
p (Dose)	<0.001	<0.001	<0.001		
Week 4 (%) / Week 8 (%)	89 / 53.1	83 / 31.3	62.5 / 9.4		

* >5 vs <5; >10 vs <10 ; >20 vs <20
>5 and <5; >10 and <10 ; >20 and <20 respectively

Conclusion: One-third of patients demonstrated sub-therapeutic drug levels, which were associated with elevated CRP levels and worse clinical outcomes. Notably, the 5mg/4 weeks group exhibited higher drug concentrations compared to the 10mg/8 weeks group, suggesting that increased infusion frequency may contribute to achieving higher levels.

Moreover, maintaining sufficient drug levels at week 8 requires substantially higher levels at week 4. Measurement of anti-TNF antibodies may not be fruitful if drug level is > 3.5µg/mL. These findings support the drug monitoring and personalized dosing to reduce the risk of loss of response and improve outcomes.

Introduction: Ustekinumab, an IL-12/23 inhibitor, is a well-established treatment for inducing and maintaining remission in moderate-to-severe Crohn's disease (CD) and ulcerative colitis (UC). However, some patients may exhibit a suboptimal response or secondary loss of response, neces-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. sitating dose intensification to 90 mg every 4 weeks. Real-world data on optimal management for patients with suboptimal initial response remain limited (1,2).

Aims & Methods: We aimed to assess the efficacy and safety of intensified ustekinumab dosing (90 mgQ4 weeks) in a multicenter cohort of patients with CD or UC who exhibited an initial suboptimal response, with increased inflammatory burden, to the standard ustekinumab regimen. We retrospectively analyzed data from 55 patients (33 female; median age, 51 years) with Crohn's disease (CD; n=36, 65.5%) or ulcerative colitis (UC; n=19, 34.5%) who underwent ustekinumab dose intensification (90 mg every 4 weeks) due to persistent clinical, biochemical (mean fecal calprotectin >300 µg/g), and endoscopic activity (mean SES-CD score: 10; Mayo score: 2/3) despite standard dosing.

All patients, were either bio-naïve or experienced, followed up for up to 12 months. Collected data included demographics, Montreal classification, treatment and surgical history, and pre-/post-intensification clinical, biochemical (CRP, fecal calprotectin), and endoscopic scores (SES-CD, Rutgeerts, Mayo).

For comparisons, the t-test was used for normally distributed variables, the non-parametric Mann–Whitney U test for non-normally distributed variables, and the chi-square test for categorical variables. A p-value <0.05 was considered statistically significant (Table).

	Response	No response	P-value
CD/UC	21/9	15/10	
Age, mean (SD)	55 (16)	47 (16)	
Perianal, n(%)	4	5	
Previous surgery	2 /26	9 /10	0.006
Biologic naïve CD, n(%)	12/21	3/15	0.023
Biologic naïve UC, n (%)	2/9 (22%)	3/10 (30%)	
Baseline SES-CD	10	10	
Baseline Mayo score 2/3 , n (%)	8/9 (88.8%)	7/10 (70%)	
ΔFcalpro, mean (SD)	-282 (377)	-2 (383)	0.009

Table: Patients' characteristics on ustekinumab intensification.

Results: Among CD patients, 58% had colonic disease (L2/L3), 22% upper GI involvement, 24% IBD-related surgery, and 25% perianal disease, although inactive at baseline. In UC cohort, 79% had left-sided colitis (E2). At 12-months, 21/36 CD patients (58.3%) maintained ustekinumab therapy, demonstrating biochemical, and endoscopic responses, with a mean reduction in the Simple Endoscopic Score for CD (SES-CD) of 6 points. Endoscopic remission—defined as SES-CD ≤3 or Rutgeerts score ≤i2a—was achieved in 62% of these responders.

Prior exposure to biologics and history of CD-related surgery were significantly associated with non-response (p = 0.02 and 0.006 respectively). 9/19 (47.3%) of the UC patients remained on treatment, with a Mayo score 1. A significant improvement in fecal calprotectin (ΔFCAL: −282 µg/g vs. −2 µg/g; p=0.009) was also observed among responders with CD and UC.

Early escalation (<12 months) or late escalation (> 12 months) did not significantly affect the response in CD/UC patients. No serious adverse events were reported during follow-up.

Conclusion: Dose intensification of ustekinumab in patients with persistently active CD and UC on the standard dose proved beneficial for nearly half of the patients over a 12-month period. Prior exposure to biologics and history of CD-related surgery were associated with less favorable outcomes. No safety concerns were identified

Introduction: Whether using Immunomodulators (IMM) as immunosuppressors (ISS), biologics or JAK inhibitors (JAKi) after a diagnosis of cancer in Inflammatory Bowel Disease (IBD) patients (pts) may increase the risk of new or recurrent cancer is undefined.

Aims & Methods: Primary aim: to assess the frequency of new/recurrent cancer in IBD pts treated with IMM after a diagnosis of cancer. Secondary aims: to evaluate in the same population the cancer-related mortality and risk factors for recurrence or new malignancy. In a retrospective multicentre Italian study, clinical records of all IBD pts treated with IMM after a diagnosis of cancer were reviewed.

Inclusion criteria: 1) Diagnosis of Crohn's Disease(CD) or Ulcerative Colitis(UC); 2)History of cancer; 3)Clinical outcome after cancer ≥6 months (mos).

Exclusion criteria: 1)IMM used for ≤3 mos or ≤3 administrations; 2)missing data. Data expressed as median[range], differences assessed with Student t-test and X-square test, univariate analysis performed to search for risk factors for new or recurrent malignancy.

Results: Study population included 122 IBD pts (84 CD, 38 UC) treated with IMM after cancer (Female 58 [47.5%]; age: 59.5[26-89] yrs). Index cancer was: genitourinary in 18(14.8%), non-melanoma skin cancer (NMSC) in 17(13.9%), breast in 15(12.3%), melanoma in 14(11.4%), thyroid in 13(10.6%), colon (CRC) in 11(9.0%), hematopoietic in 9(7.4%), prostate in 8(6.6%), neuro-endocrine in 4 (3.3%), head-neck, liver and endometrial in in 3(2.5%), other in 3(2.5%), lung in 1(0.8%). ISS used after cancer (duration: 29[4-200] mos) included: thiopurines in 10(37%), methotrexate in 14(51.9%), others in 3(11.1%) pts.

Biologics or JAKi used after cancer (duration: 24[3-180] mos) included: Anti-TNF in 36(32.4%), VDZ in 60(53.6%), UST in 45(40.2%), JAKi in 9 (7.3%) and others in 6(5.4%) pts.The median time interval between cancer and IMM use was 27[0-312] and 48[1-432] mos, respectively. In a median follow up of 8[1-45] yrs after index cancer, 12 (9.8%) IBD patients developed new or recurrent malignancy after IMM use. There were 4 recurrent neoplasms

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. (2 prostatic, 2 thyroid) and 7 new malignancy (7 NMSC,1 salivary gland carcinoma, 2 melanoma and 1 CRC). No cancer-related death occurred. No differences were observed in terms of IBD phenotype and IMM treatments between patients with vs without new/recurrent malignancy. At univariate analysis, when considering age at malignancy, smoking habits, gender, IMM treatment and duration before and after index cancer and treatment for malignancy, no predictive factors for new/recurrent malignancy were observed.

Conclusion: A low frequency of new or recurrent cancer was observed using IMM after cancer in IBD. No risk factors for new/recurrent malignancy were observed.

Introduction: The treatment of Crohn's disease remains a complex challenge, with approximately 20% of patients not responding to conventional therapies. Among the available options, biologic therapies particularly tumor necrosis factor (TNF) inhibitors play a key role.

This study aims to describe the epidemiological, clinical, and therapeutic characteristics of patients with Crohn's disease treated with anti-TNF agents, and to compare their efficacy.

Aims & Methods: This is a retrospective, descriptive, comparative, and analytical single-center study conducted in a gastroenterology department over a 20-year period (2004–2024). It included patients with Crohn's disease treated with anti-TNF biologics. Data were collected from patient medical records and follow-up consultations. We analyzed epidemiological, clinical, paraclinical, therapeutic, and disease progression parameters, and compared the efficacy of infliximab and adalimumab.

Results: Out of 1,200 patients followed for Crohn's disease, 20.3% (244) received anti-TNF therapy (adalimumab or infliximab). The mean age at diagnosis was 33.5 ± 14.3 years, with a male-to-female ratio of 1.3. Smoking was reported in 16.9% (40) of cases. The median diagnostic delay was 1 year [0–3], and the median disease duration was 4 years [1–9]. Extraintestinal manifestations were found in 37.4% (91) of patients.

According to the Montreal classification, ileocolonic (L3) involvement was most common (49.6%), followed by colonic (L2, 24%), ileal (L1, 18.2%), and upper GI tract involvement (L4, 8.3%). The inflammatory phenotype was observed in 46.7%, stricturing in 27.7%, fistulizing in 17.8%, and both stricturing and fistulizing in 7.9% of patients. Perianal disease was associated in 45.9% (111) of cases.

Regarding baseline laboratory parameters: hemoglobin ≤10 g/dL was found in 35.3% (48), white blood cell count <8000/µL in 64.7% (88), platelet count >150,000/µL in 97.7% (125), CRP >6 mg/L in 83.4% (121), and albumin <30 g/L in 31.5% (40) of patients.

Therapeutically, 55% (134) of patients had undergone surgery. Corticosteroids were used in 56.6% (137) before initiating anti-TNF therapy, and 66.4% (166) received combination therapy. The overall remission rate at 54 weeks was 74.6% (179). Infliximab was prescribed in 74.9% (182) and adalimumab in 25.1% (61) of cases, with comparable efficacy: 76.3% (45) remission with adalimumab versus 74% (134) with infliximab (p = 0.732), showing no statistically significant difference.

Conclusion: Anti-TNF therapies currently play a major role in the management of moderate to severe Crohn's disease. In our study, both infliximab and adalimumab showed satisfactory clinical, biological, and endoscopic responses at 54 weeks, with no statistically significant difference

Introduction: Guselkumab (GUS) is a selective dual-acting IL-23p19 subunit inhibitor that potently blocks IL-23 and binds to CD64, a receptor on cells that produce IL-23[1].

GUS demonstrated short- and long-term efficacy with intravenous (IV) and subcutaneous (SC) induction dosing followed by SC maintenance treatment in patients (pts) with moderately to severely active Crohn's disease (CD) in the GALAXI and GRAVITI Ph3 trials.[2,3]

Previous analyses showed similar changes in serum inflammatory proteins following GUS SC or IV induction dosing.[4]

Here, we present a comparison of the tissue molecular effects of GUS SC and GUS IV induction treatment in CD.

Aims & Methods: Serum IL-22 was measured in a subset of participants using a high-sensitivity assay and changes in protein abundance were assessed at WK0 and WK12 following GUS 400 mg SC q4w induction (n=202) compared with placebo (PBO) (n=86) or; GUS 200 mg IV q4w induction (n=50) compared with PBO (n=50), and in independent healthy control sera (n=30).

Transcriptional profiling of ileum and rectum segments was performed using samples from 277 GRAVITI patients randomized to PBO or GUS 400mg SC q4w, and from a subset of GALAXI patients (n=259) randomized to PBO or GUS 200mg IV q4w obtained at baseline (BL) and WK12. Gene co-expression modules were evaluated for differential expression in the bulk RNA-seq dataset in ileum and rectum segments, and in patients stratified by prior history of inadequate response or intolerance to biologics. Tissue treatment effect analysis was performed using inflamed samples (defined as bMIS[5] >0) from segments with SES-CD >0 at baseline.

Results: In serum, GUS SC (-0.93 logFC, p<0.05) and GUS IV (-1.10 logFC, p<0.05) showed similar WK12 decreases in the serum IL-22 levels, and is consistent with reductions in IFNγ, IL-17A, CRP and fecal calprotectin levels (p<0.05)[4] previously reported. In tissue, changes in gene modules

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

at WK12 observed with GUS 400mg SC q4w induction were significantly correlated with those observed with GUS 200mg IV q4w induction (R=0.97, p<0.05 in ileum and R=0.93, p<0.05 in rectum). Similar pharmacodynamic and molecular treatment effects were observed in patients stratified by previous biologic exposure. In both ileum and rectum, GUS SC induction reduced key cellular and inflammatory transcriptional modules at WK12 including plasma cell, inflammatory epithelial, neutrophil, and IL-23/Th17 biology (FDR<0.05), consistent with molecular analyses of GUS IV induction in GALAXI Ph3 studies.[6] Similar changes were observed for tissue IFNγ, IL-17A, and IL-22 gene expression with levels approaching those of the non-IBD controls at WK12.

Conclusion: GUS reduced serum levels of IL-22 protein at WK12 relative to baseline with both SC and IV induction. Following GUS SC induction, transcriptional changes observed at WK12 in GRAVITI were highly correlated with those observed with GUS IV induction from GALAXI Ph3 in ileum and rectum segments. GUS SC and IV induction regimens demonstrate similar molecular effects. These data are consistent with previously reported results demonstrating comparable efficacy between GUS SC and IV induction regimen and support the flexibility these options provide to both patients and healthcare professionals.

DO CLINICAL OUTCOMES IN ACUTE SEVERE ULCERATIVE COLITIS DIFFER BETWEEN PRESENTATIONS OF NEW DIAGNOSIS COMPARED TO ESTABLISHED DIAGNOSIS?

C. Tung[1], M.Y. Wu[1], C. John Kiely[1], S. Nario[1]
[1]Royal North Shore Hospital, Department of Gastroenterology, St Leonards, Australia

Contact E-Mail Address: steffnario@gmail.com

Introduction: Acute severe ulcerative colitis (ASUC) develops in approximately 15-25% of patients diagnosed with ulcerative colitis (UC), with 10-20% of ASUC presentations occurring as a first presentation of new UC diagnosis.[1] Increased disease severity at diagnosis is associated with worse clinical outcomes, including higher rates of relapse and colectomy.[2] Comparative data on ASUC outcomes between those with newly diagnosed UC and established UC remains limited.

This study aims to assess outcomes between patients with new and established UC diagnosis presenting with ASUC.

Aims & Methods: A retrospective review included all ASUC presentations to a quaternary hospital over a 10-year period based on modified Truelove and Witts' criteria. ASUC presentations were grouped into new or existing diagnoses of UC. Data was collected on number of days on IV steroids, rates of rescue therapy, referral to colorectal surgery, rates of colectomy and total parenteral nutrition (TPN) requirement. Outcomes measured included rates of intensive care unit (ICU) admission, 30- and 90-day readmission, 30- and 90-day mortality, and mean hospital length of stay (LOS).

Results: A total of 172 ASUC presentations were included with 17% (n=29) presenting as new UC diagnosis, and 83% (n=143) as existing UC diagnosis. Those with new UC diagnosis had significantly lower rates of rescue therapy use compared to those with established UC diagnoses (14% vs 39%, p=0.01). The new UC diagnosis group trended towards lower rates of TPN use (p=0.07), referral to colorectal surgery (p=0.09), rate of colectomy (p=0.31) and days on intravenous steroids (p=0.53) but did not reach statistical significance (Figure 1).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

There were no significant differences in outcomes including rates of ICU admission (p=0.65), readmission at 30 days (p=0.78) and 90 days (p=0.80), mortality (p=1.0) or LOS (p=0.86).

Conclusion: Patients presenting with ASUC with a new diagnosis of UC required significantly lower rates of rescue therapy compared to those with existing diagnosis. However, our study did not find a significant difference in outcomes between patients with new and existing UC diagnoses at time of ASUC presentation, in contrast to current literature. Further studies are required to compare long-term outcomes between new and established UC diagnoses presenting with ASUC.

COST-EFFECTIVENESS ANALYSIS OF ETRASIMOD COMPARED WITH BIOLOGIC THERAPIES FOR PATIENTS WITH MODERATE-TO-SEVERE ACTIVE ULCERATIVE COLITIS EXPERIENCED TO PREVIOUS ADVANCED THERAPIES IN SPAIN

I. Rodríguez-Lago[1], J.F. Muñoz Nuñez[2], A.J. Lucendo[3], A. De Lossada Juste[4], A. Cabez[4], A. de la Cuadra-Grande[5], I. Oyagüez[5], E. Monte-Boquet[6]

Contact E-Mail Address: Alfonso.deLossada@pfizer.com

Introduction: Etrasimod (2 mg/day, oral) is a novel alternative for moderate-to-severe active ulcerative colitis (UC), which has proved to be effective in ELEVATE UC12 and UC52 trials[1,2].

Aims & Methods: This cost-effectiveness analysis compared etrasimod vs. most frequently used biologics in Spain[3], for patients with moderate-to-severe active UC experienced to advanced therapies (AT), from the perspective of the Spanish national health system.

A hybrid model simulated the induction (decision tree) and maintenance (Markov model, 8-week cycles during lifetime) phases treatment to estimate costs (€, 2025) and quality-adjusted life years (QALYs), both yearly discounted (3%). All model inputs derived from scientific literature and were validated by national experts. The patients' characteristics proceeded from etrasimod trials[1,2]. Rates of efficacy, safety, and loss of response of etrasimod, adalimumab, ustekinumab, intravenous (IV) vedolizumab and subcutaneous (SC) vedolizumab were obtained from a Bayesian network meta-analysis[4,5].

After loss of response, a loop of subsequent AT in perpetuity was applied. Total costs included drugs acquisition (authorized posology and dose intensifications when required, both based on the European Public Assessment Reports [EPARs])[6,7], IV administration (€77.16)[8], adverse events (€5,964.49 per serious infection)[8] and management of UC (cost): active UC (€4,471)[9,10], response without remission (€1,801)[9,10], remission (€762)[9,10], surgery (€4,448)[9], post-surgery without complications (€1,101)[9,10] and with complications (€6,428)[9,10]. The annual surgery rate in UC was 0.34%[10] (urgent: 38.2%; elective: 61.8%)[11], early and late complications occurred in 18.4%[12] and 46% (for 6.5 years)[13].

Utility values were 0.78 for active UC[1,2], 0.82 for response without remission[1,2], 0.89 for remission[1,2], 0.74 for surgery[14], 0.90 for post-surgery without complications[14] and 0.71 with complications[14].

Concomitant treatment with azathioprine (35% patients, biologics only), mercaptopurine (15% patients, biologics only), mesalazine (40% patients), prednisone (20% patients) and beclomethasone (10% patients) were considered[7,15].

In addition to age and sex-specific mortality in Spain[16], the excess mortality associated with colectomy was considered (relative risk: 1.3)[17]. A probabilistic sensitivity analysis (PSA) tested the results' robustness.

Results: Etrasimod yielded more QALYs compared to each biologic and produced cost-savings in all pairwise comparisons except for IV vedolizumab (Table 1).

Thus, etrasimod was cost-effective compared to IV vedolizumab (€16,212/QALY), and dominant compared with all remaining biologics. PSA revealed that etrasimod was dominant compared to each biologic (average of Monte Carlo simulations). Under a willingness to pay threshold of €27,000/QALY[18], etrasimod was cost-effective in a minimum of 58.5% simulations (vs. IV vedolizumab) and a maximum of 99.9% (vs. adalimumab), varying between pairwise comparisons of etrasimod vs. biologic.

	Etrasimod	Adalimumab	Adalimumab (biosimilar)	Ustekinumab	Vedolizumab (IV)	Vedolizumab (SC)
QALYs / Total costs [€]	18.407 / €596,254	18.394 / €613,994	18,394 / €610,273	18.388 / €632,484	18.240 / €593,559	18.236 / €619,896
Δ QALYs / Δ Costs [€] (Etrasimod vs. comparator)	–	+0.013 / -€17,740	+0.013 / -€14,019	+0.018 / -€36,230	+0.166 / +€2,695	+0.171 / -€23,642
ICER [€/QALY] (Etrasimod vs. comparator)	–	Etrasimod dominant [A]	Etrasimod dominant [A]	Etrasimod dominant [A]	€16,212 [B]	Etrasimod dominant [A]
PSA mean Δ QALYs / Δ Costs [€] (Etrasimod vs. comparator)		+0.061 / -€23,675	+0.061 / -€17,493	+0.075 / -€48,952	+0.154 / -€22,292	+0.140 / -€70,902
PSA mean ICER [€/QALY] (Etrasimod vs. comparator)	–	Etrasimod dominant [A]	Etrasimod dominant [A]	Etrasimod dominant [A]	Etrasimod dominant [A]	Etrasimod dominant [A]
Proportion of simulations cost-effective (WTP = €27,000/QALY)[18] (Etrasimod vs. comparator)	–	96.7%	88.9%	99.9%	58.5%	88.9%

AT: Advanced Therapy; ICER: Incremental Cost-Effectiveness Ratio; IV: Intravenous; PSA: Probabilistic Sensitivity Analysis; QALY: Quality-Adjusted Life Year; SC: Subcutaneous; WTP: Willingness-To-Pay; UC: Ulcerative Colitis.

[A] Etrasimod represents a dominant alternative (yields more QALYs and cost-savings).

[B] Etrasimod represents a cost-effective alternative when considering a WTP threshold of €27,000/QALY[18].

Table 1. Results of the cost-effectiveness analysis in AT-experienced patients with moderate-to-severe active UC.

Conclusion: Etrasimod represents a cost-effective alternative for AT-experienced patients with moderate-to-severe active UC compared with biologics available in Spain.

EXPLORING THE CHARACTERISTICS OF ULCERATIVE COLITIS (UC) PATIENTS WITH MAYO ENDOSCOPIC SUBSCORE (MES) > 1 WHO HAVE BEEN TREATED WITH NON-TNF BIOLOGICS AND TARGETED ORAL THERAPIES

M. Thoo[1], A. Beckley[2], P. Robinson[2], E. Baynton[2], A. Baskett[2]
[1]Ipsos, Kuala Lumpur, Malaysia, [2]Ipsos, London, United Kingdom

Contact E-Mail Address: amanda.baskett@ipsos.com

Introduction: The Mayo Endoscopic Subscore (MES) is widely used in clinical trials and daily practice to assess disease activity and response to treatment in UC.

Aims & Methods: The objective of this study was to identify any nuances in patients with MES > 1 treated with non-TNF biologics and targeted oral therapies. The Ipsos UC Therapy Monitor, a multi-centre online medical chart review study of patients with UC, was conducted between July and September 2024 among gastroenterologists practicing across hospital and private practices in the UK, France, Germany, Italy, and Spain.
Physicians were screened for practice duration and patient volume. Charts of patients prescribed advanced therapy were included in the analysis.

Results: 205 sampled physicians collectively reported 820 UC patients. Of the reported patients with MES > 1, 62 were treated with non-TNF biologics and 62 were treated with novel oral therapies. Among the patients treated with non-TNF biologics, a higher proportion were female vs those receiving oral therapy (48% vs 31%); they were also older in age (mean years: 43 vs 38).
The patients treated with non-TNF biologics had a higher prevalence of comorbidities, including depression/anxiety (24% vs 19%), cardiovascular disease (8% vs 0%), and dyslipidemia/hyperlipidemia/hypercholesterolemia (11% vs 7%), compared to those treated with novel oral therapy.
Mean CRP levels were higher in the oral therapy group (10.2 mg/L vs 9.1 mg/L), while mean Mayo scores were slightly lower (4.7 vs 5.2). Fecal calprotectin levels were elevated in patients treated with non-TNF biologics vs oral therapy group (441 µg/g vs 503 µg/g).
When analysing reasons for prescribing selected advanced therapy between the two patient groups, a greater proportion of patients treated with non-TNF biologics had safety reasons specified more frequently by the sampled physicians.

% reported UC patients - cited reasons	Patients treated with non-TNF biologics	Patients treated with novel oral therapies
Low incidence of side effects	53%	13%
Good safety profile	61%	16%
Rapid symptomatic profile	19%	60%

Table 1: % of reported UC patients receiving advanced therapy for specific cited reasons.

Conclusion: This study highlights key differences in patient characteristics and treatment considerations among UC patients with MES > 1 treated with non-TNF biologics compared to those treated with targeted oral therapies. Patients on non-TNF biologics tend to be older, more often female, and have a higher prevalence of comorbidities. Physicians prescribing non-TNF biologics prioritize safety, while those prescribing oral therapies focus on rapid symptom control.
These findings highlight the importance of considering patient characteristics and treatment goals when selecting advanced therapies for UC patients with MES > 1. Further investigation using comparator cohort is warranted.

EXAMINING THE CHARACTERISTICS OF ULCERATIVE COLITIS (UC) PATIENTS WHO HAVE BEEN INITIATED WITH ADVANCED THERAPY (AT) WITHIN 12 MONTHS OF DIAGNOSIS

M. Thoo[1], A. Beckley[2], P. Robinson[2], A. Baskett[2]
[1]Ipsos, Kuala Lumpur, Malaysia, [2]Ipsos, London, United Kingdom

Contact E-Mail Address: amanda.baskett@ipsos.com

Introduction: Recent studies suggest that the early use of advanced therapies in the treatment of CD and UC may lead to better patient outcomes and potentially slow disease progression.

Aims & Methods: The objective of this study was to examine the differences in UC patient characteristics between those who initiated advanced therapy within 12 months of diagnosis versus those who started after 12 months. A multi-centre online medical chart review study of patients with UC was conducted between Jul – Sep 2024 among UK, FR, DE, IT & ES gastroenterologists practicing across hospital and private practices.
Physicians were screened for practice duration and patient volume. Charts of patients prescribed with advanced therapy were included in the analysis.

Results: 205 sampled physicians collectively reported 820 UC patients. Of the reported patients, 451 were diagnosed and initiated their first advanced therapy within 12 months (Early AT treated), while 369 patients started their first advanced therapy after 12 months (Delay AT treated).
Early AT treated patients were younger vs delay AT treated (mean ages 38 vs 42 years old). Looking at reported UC patient employment status, early AT treated patients are less likely to be in full time employment (56% vs 63%) vs delay AT treated patients. They are more likely to be diagnosed with severe disease (38% vs 24%)
Mean UC disease activity MAYO score were higher in the early AT treated patients vs delay AT treated (3.2 vs 2.6). Mean CRP and Fecal calprotectin levels were also higher in the early AT treated patients (CRP: 7.1 mg/L vs 4.7 mg/L) and (Fecal calprotectin: 244.4 vs 220.6)

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

When analyzing reasons for prescribing selected advanced therapy between the two patient groups, a greater proportion of early AT treated patients had the following reasons specified more frequently by the sampled physicians, vs delay AT treated patients.

% reported UC patients - cited reasons	Early AT treated patients	Delay AT treated patients
Rapid symptomatic control	42%	36%
Biomarker normalisation (fecal calprotectin/ CRP)	31%	24%
To avoid surgery	30%	24%

Table 1: % of reported UC patients receiving advanced therapy for specific cited reasons.

Conclusion: Comparisons in this study cohort highlight UC patients who started advanced therapy within 12 months of diagnosis were characterized by younger age, more severe disease at diagnosis and experienced higher inflammatory markers compared to those delay initiating advanced therapy patients. These findings suggest early AT treated patients indicate a more severe and complicated disease burden, potentially benefitting from earlier intervention with advanced therapies. Further investigation using comparator cohort is warranted.

A SINGLE CENTRE COMPARISON OF DISEASE CHARACTERISTICS AND TREATMENT OUTCOMES BETWEEN BIOLOGIC NAÏVE AND EXPERIENCED PATIENTS WITH SEVERE ULCERATIVE COLITIS (UC)

V. Philip[1], Y. Fahmay[1], T. Magar[1], N. Magar[1], J. Vincent[1], S. Kharel[1], I.M Bell[1], P. Blaker[1], B. Baburajan[1]
[1]Maidstone and Tunbridge Wells NHS Trust, IBD Unit, Royal Tunbridge Wells, United Kingdom

Contact E-Mail Address: varun.philip@nhs.net

Introduction: Hospitalised patients with UC are likely to be on biologics or small molecule therapy (BST). The diversity of treatment options may contribute to delays in identifying medically refractory disease. Additionally, there may be scope for earlier introduction of advanced therapies.

Aims & Methods: We aimed to compare outcomes between patients previously treated with biologics to those who were BST naive. We conducted a retrospective analysis of patients aged >18 years, admitted between December 2022 and August 2023, with left-sided or extensive colitis. Inclusion criteria were intravenous steroid treatment, length of stay >72 hours, elevated CRP, and stool frequency >4/day. Proctitis and infectious colitis were excluded.

Results: Thirty-eight patients met inclusion criteria: 13 (34%) were BST experienced and 25 (66%) naïve. Of the latter, 10 (40%) were admitted within the first year of diagnosis, and 16 (64%) required rescue therapy. Additionally, left-sided colitis was more prevalent in the BST naïve group (p=0.005). There was one death in this cohort; a patient who suffered post-operative complications of stroke and sepsis after colectomy.The BST group comprised of 4 patients on infliximab (31%), 4 on vedolizumab (31%), 3 on adalimumab (23%), 1 on ustekinumab (8%), and 1 on tofacitinib (8%). Of these, 8 (62%) were on first-line agents, 3 (23%) on second-line, 1 on third-line, and 1 on a fourth-line agent at admission. Gastrointestinal infections were not over represented in this group (n=0). Surgery rates were significantly higher in the BST exposed group: 4 (31%) underwent surgery within a month of admission, compared to 1 (4%) in the BST naïve group (p=0.02). There was a greater proportion of patients on second or third-line BST v/s first line (3 of 4 patients) among the surgical group but serum CRP, albumin, Oxford criteria and UCEIS did not seem to predict risk of surgery.

Demographics	BST naive number (n)	BST naive percentage (%)	BST exposed number (n)	BST exposed percentage (%)	P value
Left sided colitis	22	88%	6	46%	0.005
Pancolitis	3	12%	7	54%	
<1 year from diagnosis to admission	10	40%	2	15%	0.121
>1 year from diagnosis to admission	15	60%	11	85%	
Stool frequency 4-6	5	20%	0	0%	
Stool frequency >6	20	80%	13	100%	
CRP <30	11	44%	8	62%	0.305
CRP >30	14	56%	5	38%	
Surgery within 1 month	1	4%	4	31%	0.021

Conclusion: Our data suggests effective protocolised management of severe UC. Patients receive timely rescue therapy, and colectomy rates are consistent with best practice. On the other hand, the high proportion of BST naive patients admitted with severe symptoms within the first year of presentation could indicate scope for earlier introduction of outpatient BST. The preponderance of lower risk factors such as left sided disease and lower CRP levels in this group could support a shift in emphasis from first line parenteral biologics and its inherent pharmacy logistical limitations to oral small molecule therapy for earlier remission rates. The number of BST experienced patients on anti TNF (50%) may indicate potential for earlier out of class switch to newer small molecule drugs. The relative insensitivity of high-risk features such as CRP and UCEIS among the BST experienced patients highlights the need for specialist management of medically refractory disease. The higher prevalence of limited colitis in the BST naive may indicate a bias towards later introduction of advanced therapies as an outpatient. A larger data set will provide useful insights into the care of this increasingly prevalent cohort of UC patients.

Disclosure: Nothing to disclose.

HIGH RATES OF ORAL 5-AMINOSALICYLIC ACID CO-PRESCRIPTION WITH ADVANCED THERAPY IN PATIENTS WITH ULCERATIVE COLITIS

Z.C. Xu[1], M. Al-Banaa1[1], E. Tan[1], B. Onibon[1], S. Salman[1], T. Levar[1], M. Garg[1,2], S. Kashkooli[1], R. Little[1]
[1]Northern Health, Melbourne, Australia, [2]University of Melbourne, Department of Medicine, Melbourne, Australia

Contact E-Mail Address: mayur.garg@nh.org.au

Introduction: 5-aminosalicylates (5-ASA) are the first-line treatment for inducing and maintaining remission in patients with mild to moderate ulcerative colitis (UC), with over 90% of patients receiving 5-ASA within a year of diagnosis and 60–87% continuing long-term therapy[1].

However, 5-ASAs appear to provide no incremental benefit once advanced therapy is initiated and withdrawal is safe and not associated with increased adverse events[1-3].

Moreover, the cost of 5-ASA therapy can be significant. Reducing unnecessary 5-ASA use could help lower the overall healthcare costs associated with inflammatory bowel disease[4].

Aims & Methods: Retrospective observational study of all consecutive adult patients with UC receiving advanced therapy from a single tertiary IBD centre. Data collection included patient and disease characteristics, 5-ASA and advanced therapy type, dose and duration and objective disease activity (most recent intestinal ultrasound, faecal calprotectin [FCP],

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

endoscopy within 12 months). Biochemical remission was defined as FCP <150µg/g, sonographic remission as normal bowel wall thickness and no hyperaemia and endoscopic remission as Mayo endoscopic subscore of 0 or 1.

Results: 230 patients were included (42% female, median age 40 years, median disease duration 96 months). Concurrent oral 5-ASA therapy was used in 116 patients (50%) for a median duration of 42 months (IQR 11–59), including 19 overlapping months with the most recent advanced therapy. The majority (89%) remained on maximal induction doses and annual average costs were estimated at $3469.73 per patient. Concurrent oral 5-ASA and advanced therapy use was associated with higher topical 5-ASA use (p = 0.002) and shorter duration on current advanced therapy (p = 0.03) compared to those on an advanced therapy alone. Almost two-thirds of patients remaining on 5-ASAs were in biochemical and/or sonographic remission and a third were in endoscopic remission. 5-ASA co-prescription rates varied according to advanced therapy type but no significant differences in clinical, biochemical, endoscopic or histologic activity were observed between groups (Table 1).

Characteristic	Advanced Therapy (n = 114)	Advanced therapy + 5-ASA (n = 116)	p value
Age, median (IQR)	40 (27–53)	39 (30–55)	0.20
Duration of current advanced therapy (months)	20 (11–42)	18 (8–30)	0.03
Advanced therapy type			
Infliximab IV	16 (14.0%)	25 (21.6%)	0.17
Infliximab SC	16 (14.0%)	5 (4.3%)	0.011
Adalimumab	2 (1.7%)	0 (0%)	0.24
Golimumab	1 (0.8%)	2 (1.7%)	>0.99
Vedolizumab IV	38 (33.3%)	37 (31.9%)	>0.99
Vedolizumab SC	8 (7.0%)	8 (6.9%)	>0.99
Upadacitinib	17 (14.9%)	17 (14.7%)	>0.99
Ustekinumab	12 (10.5%)	12 (10.3%)	>0.99
Tofacitinib	3 (2.6%)	8 (6.9%)	0.21
Ozanimod	0 (0%)	1 (0.8%)	>0.99
Estrasimod	0 (0%)	1 (0.8%)	>0.99
Infliximab + Stelara	1 (0.8%)	0 (0%)	>0.99
Topical 5-ASA use	12 (10.5%)	31 (26.7%)	0.002
Clinical remission	97 (85.1%)	87 (75.0%)	0.06
FCP < 150 µg/g	75 (65.8%)	78 (67.2%)	0.88
IUS remission	19/24 (79.2%)	22/35 (62.9%)	0.25
Endoscopic remission	51 (44.7%)	38 (33.0%)	0.07
Histological remission	51 (44.7%)	41 (35.6%)	0.17

Table 1. Patient, disease and medication characteristics according to 5-ASA co-prescription with advanced therapies. Values presented as median (IQR) or number (%), unless specified.

Conclusion: Co-prescription of 5-ASAs and advanced therapies is common despite high rates of objective remission. Identifying patients suitable for 5-ASA withdrawal may allow substantial reductions in healthcare expenditure.

DOES THE CURRENT THERAPEUTIC PARADIGM CHANGE THE OUTCOME IN PATIENTS AT THE FIRST EPISODE OF ACUTE SEVERE ULCERATIVE COLITIS REFRACTORY TO CORTICOSTEROIDS?

P. Lages Martins[1], M. Francisco[1], R. Matos Prata[1], S. Mendez Santos[1], V. Pavão Borges[1], J. Saiote[1], D.F.B. Carvalho[1], J. Ramos[1]

[1]Unidade Local de Saúde São José, Gastroenterology, Lisbon, Portugal

Contact E-Mail Address: pb.lages.martins@gmail.com

Introduction: Acute severe ulcerative colitis (ASUC) is a potentially life-threatening emergency that requires timely management. Intravenous corticosteroids are the first line therapy, but around 30% of patients fail to respond. Rescue therapy is effective in reducing short-term colectomy rates but its impact on disease course in the medium/long-term is not well characterized.

Aims & Methods: We aimed to assess if non-response to corticoids (and subsequent need for rescue therapy) in patients admitted with a first episode of ASUC is associated with worse disease-related outcomes in the long-term.

We conducted a retrospective study of all patients admitted with ASUC in the Gastroenterology department of a Portuguese tertiary center between 2018-2024. ASUC diagnosis was established according to Truelove and Witts' criteria. Response to intravenous corticoids was defined as discharge without need for rescue therapy and/or colectomy. Patients with a previous admission for ASUC before the study period were excluded.

Patient files were reviewed and demographic, clinical, laboratory and endoscopic data was collected regarding the admission for ASUC and subsequent follow-up. Considered disease-related outcomes were need for switch of maintenance therapy, need for readmission and need for colectomy. Subanalyses were performed according to response to corticoid therapy. Statistical analysis was done using Stata version 12.1.

Results: A total of 35 patients hospitalized with a first episode of ASUC were included, 51.4% (n=18) male, median age at admission was 38 years [IQR 27-51]. Roughly half the patients had pancolitis at diagnosis (51.4%, n=18). Median disease duration was 9 months [IQR 0-26] and 22.9% (n=8) had previous exposure to biologic therapy. In 34.3% (n=12), ASUC was the initial presentation of UC. Median follow-up was 30 months [IQR 12-51].

Response to corticosteroid therapy was observed in 57.1% (20/35). All the steroid-refractory patients (15/35, 42,9%) responded to rescue therapy (Infliximab n=11; Tacrolimus n=3; Tofacitinib n=1) and avoided colectomy during the hospitalization.

Baseline characteristics were identical between steroid-responsive and steroid-refractory patients, except for a lower median age in corticoid refractory patients (29 years vs 48 years, p=0.02).

Survival analysis was performed and no differences between steroid-responsive and steroid-refractory patients were observed in need for switch of maintenance therapy [during first year (p=0,28) and during complete follow-up (p=0,54)] , need for readmission [during first year (p=0,55) and during complete follow-up (p=0,54)] or need for colectomy [during first year (p=0,09) and during complete follow-up (p=0,79)].

Conclusion: In our cohort of patients with a first episode of ASUC, with the current therapeutic paradigm, patients with steroid refractoriness had similar outcomes as corticosteroid responders. These results suggest that effective and timely therapy can change the natural history of ASUC.

TARGETED DELIVERY OF RNA-BASED THERAPEUTICS TO THE GUT TO MODULATE THE JAK-STAT PATHWAY IN CROHN'S DISEASE

Introduction: Crohn's disease (CD) is a human immune-mediated inflammatory disease (IMID) of unknown etiology that affects the gastrointestinal (GI) tract. CD is now a global health issue due to its lifelong nature and significant burden on patients and public health [1].
Phase III clinical trials have shown that treatment with oral Janus Kinase (JAK) inhibitors can alleviate disease in patients with CD. However, the United States (US) Food and Drug Administration (FDA) has issued warnings about side effects for this class of oral drugs which target JAKs systemically in the human body. Therefore, new targeted delivery approaches are needed to block JAK activity selectively in the GI tract. The JAK1/2-STAT1 intracellular signaling pathway is activated by the Th1 cytokine IFN-γ alone or in synergy with another Th1 cytokine, TNF-α, and SOSC1 is an endogenous negative regulator of JAK1/2. This pathway activates the expression of inflammatory genes in multiple cell types typically associated with active or inflamed CD [2].
RNA interference (RNAi) mediated gene silencing using small interfering RNA (siRNA) targeting JAK1/2-STAT1 and SOCS1 overexpression using exogenous SOCS1 mRNA are promising methods to reduce the JAK-STAT pathway activation.
Aims & Methods: The GENEGUT project aims to develop oral RNA-based therapies for ileal CD. In this study, we have developed new approaches to deliver siRNAs targeting JAK1, JAK2, and STAT1 into relevant cell models, including human intestinal epithelial cell (IEC) lines. Epithelial cell models that replicate the inflammatory microenvironment in CD were used by exposing IECs to inflammatory cytokines IFN- γ/TNF- α, leading to increased cytokine production and cell death.
Results: Selected siRNAs effectively blocked JAK1, JAK2 and STAT1 expression and activity, preventing the downstream activation of inflammatory and cell death pathways. SOCS1 overexpression also suppressed JAK1/2-STAT1 pathway activation and enhanced cell survival.
Conclusion: Ongoing work is focused on optimizing the delivery of siRNA and mRNA into differentiated epithelial monolayers, co-cultures and patient-derived organoids to advance translational applications.

Introduction: Filgotinib (FIL) is an oral, once-daily Janus kinase 1 preferential inhibitor approved for the treatment of adults with moderately to severely active ulcerative colitis (UC), based on the results of the phase 2b/3 SELECTION trial[1]; however, real-world data are limited.
Aims & Methods: Here, we report baseline (BL) characteristics of enrolled patients with UC and early effectiveness and safety data for those who reached week 10 (W10) of FIL treatment in GALOCEAN (NCT05817942), an ongoing, European, multi-site, prospective, observational study to investigate the real-world effectiveness and safety of FIL. Data collected up to 15 Jan 2025 were included. BL characteristics were reported for the full analysis set and effectiveness outcomes were reported for the response

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

evaluable set (RES). At W10, mean changes from BL (CFBs) in the partial Mayo Clinic Score (pMCS) and the 2-item patient-reported outcome (PRO2) score, and the proportions of patients in pMCS or PRO2 remission were assessed. Mean CFBs and the proportion of patients reaching the minimal clinically important difference at W10 in patient-reported outcomes (Short Inflammatory Bowel Disease Questionnaire, Urgency Numeric Rating Scale and Functional Assessment of Chronic Illness Therapy-Fatigue scores) were also calculated. Safety was assessed by documenting adverse events.

Results: As of 15 Jan 2025, 353 patients starting FIL ≤200mg were enrolled and had BL data available (female: 48.7%; age, median [min–max]: 36.0 [18–86] years; time since UC diagnosis, median [min–max]: 6.3 [0–35] years). The mean (SD) duration of follow-up was 23.9 (17.2) weeks. At BL, pMCS-defined UC severity rates were inactive (pMCS 0–1; 5.8% [n=20]), or mildly (pMCS 2–4; 28.3% [n=97]), moderately (pMCS 5–6; 35.9% [n=123]) or severely (pMCS 7–9; 30% [n=103]) active; 10 patients did not have BL pMCS. Most patients had left-sided colitis (38.2% [n=135]) or pancolitis (39.4% [n=139]). Overall, 21.2% (n=75) of patients were naive to conventional therapies (excluding corticosteroids [CS]), and 26.9% (n=95), 27.8% (n=98) or 45.3% (n=160) had previously received 0, 1 or ≥2 advanced therapies, respectively. At BL, FIL was used without concomitant therapy in 55.8% (n=197) of patients; CS were used as concomitant therapy by 26.3% (n=93) of patients. The most reported cardiovascular risk factor was current or former smoker (31.7% [n=112]). Overall, 75.9% (n=268) of patients had post-BL effectiveness data (RES). At W10, patients had improved clinical symptoms and health-related quality of life (HRQoL) vs BL (Table). A total of 123 (34.8%) patients discontinued FIL, mostly due to lack of effectiveness. No new safety signals were observed.

Conclusion: In this interim analysis of GALOCEAN, patients with UC had improved clinical outcomes (vs BL in symptoms and HRQoL) at W10 of FIL treatment in real-world clinical practice. FIL was generally well tolerated. This is consistent with previous data.[2–4] GALOCEAN is ongoing, and results with higher patient numbers with longer exposure to FIL will be analysed to further characterize the real-world effectiveness and safety of FIL for UC.

Data are reported for patients with available data. Analysis sets are defined as follows: the RES comprised patients who had BL and valid effectiveness data for ≥1 time point after FIL initiation, and the FAS comprised all patients with available BL data.

[a]Definitions of remission were as follows: pMCS remission (RB ≤1, SF ≤1, PGA ≤1, pMCS ≤1); PRO2 remission (SF=0, RB=0).

[b]Definitions of MCIDs were as follows: SIBDQ MCID (increase from BL ≥9); Urgency NRS MCID (decrease from BL ≥3); FACIT-Fatigue MCID (increase from BL ≥4).

BL, baseline; CFB, change from baseline; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; FIL, filgotinib; MCID, minimal clinically important difference; NRS, Numeric Rating Scale; PGA, Patient Global Assessment; pMCS, partial Mayo Clinic Score; PRO2, 2-item patient-reported outcome; RB, rectal bleeding subscore; RES, response evaluable set; SD, standard deviation; SF, stool frequency subscore; SIBDQ, Short Inflammatory Bowel Disease Questionnaire; W10, week 10.

Table. Effectiveness outcomes at BL and W10 after FIL initiation in the RES.

Introduction: Tofacitinib (TFB) is a JAK 1/3 inhibitor small molecule drug used in ulcerative colitis (UC). Prognostic markers of treatment response are lacking, however 39-54% of patients experience loss of response. Multidrug resistance protein (MDR) activity, and differences in hepatic metabolism via cytochrome P450 (CYP) isoenzymes may be associated with decreased intracellular bioavailability, while clinical factors can predict treatment response.
Aims & Methods: Our study aimed to analyse the predictive value of MDR activity, CYP genotype, and cytokine pattern beside clinical factors in a multidisciplinary approach. In this prospective cohort study adult UC patients were enrolled when introducing TFB treatment and followed until week 12. At baseline, blood samples were obtained to measure the activity of three ABC drug transporters (MDR1, MRP1, and BCRP) in leukocytes via immunocytochemistry and flow cytometry. Patients' tofacitinib-metabolizing capacity was characterized by CYP2C19, CYP3A5 and CYP3A4 genotypes. Clinical parameters were registered, while colonoscopy examinations were performed at baseline and at week 12. Mucosal sampling was also performed to measure mucosal cytokine levels (TNF-α, IL-6, IL-1b, IFN-γ, IL-4, IL-17A, PAI-1) via multiplex ELISA methods. Week 12 clinical and endoscopic remission/response, histological remission and treatment persistence were used as outcomes. We performed multivariable logistic regression models on these specific outcomes and data was handled with intention-to-treat analysis.
Results: In total, we included 63 patients (male/female ratio 24/39; mean age 38.7±11.7 years; mean Mayo score 8.9±2.4) in our study. In total, 7 patients (9.2%) achieved histological remission, while 20 patients (26.7%) achieved endoscopic remission, and 27 patients (42.9%) endoscopic response. Clinical remission was observed in 21 patients (33.3%), while clinical response was achieved by 30 patients (47.6%). In total, 34 patients (54.0%) were in corticosteroid-free clinical remission at week 12, and higher baseline pMayo score decreased (OR=0.64 [95% CI: 0.43 – 0.94]), while albumin increased (OR=1.33 [95% CI: 1.01 – 1.76]) the chance of achieving the outcome (AUC = 0.93).
We found that one-year treatment persistence was strongly influenced by week 12 endoscopic remission (β=3.79 [95% CI: 1.21 – 6.37]), but not by histological remission (β=1.58 [95% CI: -0.74 – 3.89]). Higher baseline $CD8^+$ MDR1 activity decreased the chance of clinical response (OR=0.91; p=0.048), while higher $CD8^+$ MRP1 decreased week 12 treatment persistence (p=0.04, r=0.32). CYP3A5 1/3 genotype increased the histological remission rates (OR=13.9 [95% CI: 1.04-186.2]). The levels of mucosal IL-6 (18.51 vs 25.72 pg/mg, p=0.049), IL-4 (94.41 vs 168.8 pg/mg, p=0.037) and PAI-1 (921 vs 1483 pg/mg, p=0.01) were significantly lower in the clinical/endoscopic responders at the baseline.
Conclusion: Based on our prospective cohort study, short-term histological remission is still a hard-to-reach endpoint in moderate-to-severe UC on TOFA. Measurement of baseline $CD8^+$ MRP1 and $CD8^+$ MDR1 activity, and mucosal levels of IL-1β, IL-6, IL-4, and PAI-1, and CYP3A5 genotype may help to increase treatment success.
Disclosure: Nothing to disclose.

Introduction: Biologic agents have emerged as the most important therapeutic weapon in the treatment of Crohn's disease, but there are few data in the literature comparing the efficacy and safety between different molecules. The aim of this study is to describe the population of patients who received different molecules as first-line therapy and their persistence on first-line therapy.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: 622 patients from 6 Gastroenterology departments from Bucharest, Iasi and Cluj treated between 2006 and 2024 were included in the study. 75 (14%) were excluded because they received only Mesalazine. 535 were included in the final analysis. The main outcomes were: clinical response at 12 weeks of treatment (complete response = clinical remission, partial response= decrease of CDAI ≥ 25% of the initial value without remission or primary non-response), persistence on therapy and serious adverse events leading to therapy discontinuation.

Results: The main characteristics of the studied patients are shown in the table 1. There are significant differences between the 3 groups of patients: regarding age, extension of the disease, disease phenotype, proportion of individuals with perianal fistulas, clinical severity of the disease, proportion of operated patients. Median therapy duration was 48 months (3÷330). 45% of patients received Adalimumab, 40% were treated with Infliximab, and in 13% Ustekinumab was given. The 3 biologics studied (Adalimumab/Infliximab/Ustekinumab) had a similar rate of complete response 80%, the non-response rate was also similar: 6.5% but persistence on therapy at 2 years was better for Ustekinumab (64%) compared to Adalimumab and Infliximab (45%) (p=0.03). Serious adverse events leading to therapy discontinuation were more frequent in those treated with Infliximab (10%) compared to Adalimumab (3%) and Ustekinumab (6%) (p=NS).

	Total	UST group	IFX group	ADA group	p-value for comparison between UST/IFX/ADA
N (%)	535 (100)	68 (12.6)	216 (40.1)	242 (44.9)	
Median age (min-max)	33 (11-69)	43 (20-57)	32 (11-61)	33 (13-69)	<0.001

Extension (L1/L2/L3) N(%)	L1 : 154 (28.6) L2: 154 (28.6) L3: 227 (42.1)	L1: 30 (44.1) L2: 14 (20.6) L3: 24 (35.3)	L1: 34 (15.7) L2: 86 (39.8) L3: 96 (44.4)	L1: 88 (36.4) L2: 54 (22.3) L3: 100 (41.3)	0.001
Behaviour (B1/B2/B3/p) N(%)	B1: 283 (52.9) B2: 164 (30.4) B3: 88(16.4) p: 114 (21.3)	B1: 54 (79.4) B2: 12 (17.6) B3: 0 p: 0	B1: 102 (47.2) B2: 54 (25) B3: 64 (29.6) p: 80(37)	B1: 122 (50.4) B2: 96 (39.7) B3: 22 (9.1) p: 32 (13.2)	<0.001
Surgery	170 (31.9)	10 (15.2)	72 (33.3)	88 (36.4)	0.004
Median CDAI (min-max)	245 (6-557)	278.5 (43- 470)	230 (32-557)	245 (6-534)	0.021
Median CRP value at initiation (min-max)	11.2 (0.15-270)	8 (0.4-54)	21 (0.7-76)	9.3 (0.15-270)	<0.001
Median time from diagnostic to start of biologic Months (min-max)	8 (1-444)	5.5 (1-38)	6 (1-180)	6 (1-202)	0.001

Conclusion: Patients that received anti-TNF alpha antibodies had more severe forms of Crohn's disease. All three biological agents used in real life for Crohn's disease therapy show similar efficacy, with a complete response rate of aprox. 80% and a nonresponse rate of 6.5%, but persistence on therapy at 2 years was significantly better for Ustekinumab (64%) compared to Adalimumab and Infliximab (45%) (p=0.03). Serious adverse events leading to therapy discontinuation were more frequent in patients treated with Infliximab (10%) compared to those who received Ustekinumab (6%) or Adalimumab (3%).

Introduction: Biologic therapies such as anti-TNF-alpha agents (infliximab, adalimumab), interleukin modulators, and gut-selective integrin antagonists like vedolizumab have significantly improved outcomes in inflammatory bowel disease (IBD), leading to enduring remission, better quality of life, and reduced surgical intervention and hospitalizations. However, many patients may eventually lose response, often due to factors like the formation of anti-drug antibodies, altered drug metabolism, or individual patient characteristics. Dose escalation—by increasing dosage or reducing intervals—is commonly used to counteract this loss, especially for anti-TNF therapies guided by therapeutic drug monitoring. Vedolizumab poses a greater challenge in this regard due to the lack of standardized monitoring protocols. We aimed to investigate the effectiveness of dose-escalated infliximab, adalimumab, and vedolizumab in IBD patients who worsened after initial response, evaluating outcomes such as treatment persistence and clinical remission, to guide more personalized, cost-effective treatment strategies.

Aims & Methods: We conducted a retrospective analysis of IBD patients who underwent Infliximab (IFX), vedolizumab, or adalimumab (ADA) therapy dose escalation between 2020-2024 at a tertiary IBD centre. Primary outcomes included clinical remission using disease activity scores (Simple Clinical Colitis Activity/SCCAI Index for UC, Harvey-Bradshaw Index/HBI for CD), biochemical markers (CRP, faecal calprotectin) and treatment persistence, evaluated at 3-12 months, 12 months, and annually up to 36 months post-escalation.

Results: A total of 155 patients (median age 31 years, 46% female) were included, of which 89 patients (57%) were prescribed dose-escalated IFX, 48 patients (31%) were prescribed dose-escalated ADA and 18 patients (12%) were prescribed dose-escalated Vedolizumab. Of those included, 118 patients (76%) had Crohn's disease, 36 patients (23%) had ulcerative colitis (UC) and 1 patient (1%) had indeterminate disease. Indications for dose escalation included secondary loss of response (SLOR) (105/155; 68%) and/or low drug levels (65/155; 42%). Dose-escalated IFX led to significant improvements in disease activity scores at 3 months (HBI: p=0.002; SCCAI: p=0.0003). Improvement in SCCAI was maintained at 12 months (p=0.00007), 2 years (p=0.0008) and 3 years (p=0.025). Improvement in HBI was maintained at 2 years (p=0.01) and 3 years (p=0.049). Significant improvement in CRP following dose-escalated IFX was reported at 3 months (p=0.011), 12 months (p=0.004), 2 years (p=0.006) and 3 years (p=0.03). Dose-escalated ADA led to a significant improvement in HBI at 3 months (p=0.023). This improvement was maintained at 12 months (p=0.005) and 2 years (p=0.008). Early improvement in faecal calprotectin was reported at 3 months (p=0.046). Significant initial improvement in SCCAI following dose-escalated Vedolizumab was reported at 3 months (p=0.043). This improvement was not maintained at any further follow-up points (p>0.05). Minor adverse events were reported in 3 patients receiving dose escalated ADA and in 6 patients receiving dose escalated IFX.

Conclusion: Our study demonstrates that biologic dose escalation is an effective and safe mechanism to recapture clinical remission, with high rates of treatment persistence.

Introduction: Upadacitinib has shown to be more effective than placebo for treating extraintestinal manifestations (EIM) in post-hoc analyses. However, real-world data on the effectiveness of upadacitinib in patients with inflammatory bowel disease (IBD) and EIMs are lacking.

Aims & Methods: A multicenter, retrospective and observational study was conducted at 19 Spanish hospitals. Patients with IBD and active EIMs when initiating upadacitinib were eligible.

The primary outcome was EIM improvement at weeks 8-12. The EIM assessment was based on the physician's subjective evaluation and categorized into clinical remission, partial response, nonresponse and worsening. EIM improvement was defined as either clinical remission or partial response.

Axial arthropathy, peripheral arthropathy, pyoderma gangrenosum, erythema nodosum, sweet syndrome, aphthous stomatitis, uveitis, episcleritis, primary sclerosing cholangitis and bronchiectasis were considered. In patient experiencing >1 EIM, all had to be resolved or improved to be considered. If not, the worst outcome was recorded. Patients' visits were scheduled at weeks 0, 8-12, and 6 months. Multivariate analysis was performed to find factors associated with EIM improvement at w8-12.

Results: A total of 160 patients were included, 120 patients with Crohn's Disease (75.6%), 90 females (56.3%) with a median age of 46.6 years (IQR 37.9-56.7). Upadacitinib was initiated in one hundred twenty-six (78.8%) patients due to EIMs and luminal activity and 35 patients (21.3%) exclusively due to EIMs. All patients were bio-experienced with 84 patients previously treated with ≥3 biologics (52.5%). Baseline EIMs assessment was for at least 1 EIM in 107 patients (66.9%), 42 patients presented 2 EIMs (26.3%) while 11 patients (6.9%) experienced ≥ 3 EIMs.

At w8-12, 99 patients (61.9%) achieved EIM improvement, 40 patients (25 %) clinical remission, 58 patients (36.9%) partial response, 58 patients (36.5 %) nonresponse and worsening in 3 patients. Patients initiating Upadacitinib due to exclusively active EIMs was associated with EIM improvement at weeks 8-12 (OR 2.99 95% CI 1.06-8.42; p=0.04). IBD clinical remission at w8-12 was achieved in 75 patients (61%).

Evaluation at 6 months was available for 103 patients, 73 patients (70.9%) presented EIM improvement, 41 patients (39.8%) clinical remission, 32 patients (31.1%) partial response, 20 patients (19.4%) nonresponse and 10 patients (9.7%) worsening. IBD clinical remission at 6 months was achieved in 51 patients (62.2%).

During the follow-up, Upadacitinib was ceased in 27 patients (16.9%). Adverse events were detected in 39 patients (24.3%) and 7 patients (4.4%) experienced worsening of previous inactive EIMs.

Conclusion: Upadacitinib was highly effective in the short term for treating bio-experienced patients with active EIMs, particularly for patients without luminal activity

Introduction: Systemic corticosteroids are the first-line treatment for moderate to severe immune checkpoint inhibitor-induced enterocolitis (ICIec). Infliximab (IFX) is recommended for steroid-refractory cases; however, up to 28% of patients do not respond. Repeated-dose IFX regimens may improve outcomes and reduce recurrence, but optimal management strategies remain undefined. Here, we describe a series of patients treated with dashboard-guided IFX for ICIec.

Aims & Methods: A retrospective, descriptive case series was conducted at the IBD clinic of Hospital Universitari Vall d'Hebron between January 2021 and February 2025. The study included adult patients with ICIec who received IFX guided by a pharmacokinetic (pK) model. Demographic and clinical data were collected and analyzed.

Results: The dashboard model was applied in five patients to provide additional guidance for treatment decisions. The median age was 60 years, and three patients were female. The median time between the first immunotherapy dose and development of ICIec was 14.8 weeks. Endoscopy

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

revealed extensive disease in 60% of patients, and 40% also had upper GI involvement. At baseline, 40% had severe inflammation. Median IFX levels at weeks 1 and 2 following the first IFX dose were 23.5 µg/mL and 22.3 µg/mL, respectively. The median interval between the first and second IFX doses was 12 days. Clinical remission was achieved in 4 out of 5 patients (80%). With a median follow-up of 16.7 ± 8 weeks, 4 of 5 patients (80%) remained in clinical remission without ICIec recurrence; one patient died due to an infectious complication.

Conclusion: Dashboard-guided IFX dosing showed benefit in ICIec patients. Use of pharmacokinetic modeling may support more tailored IFX dosing strategies, potentially improving treatment outcomes in a subset of ICIec patients with severe or extensive disease. Prospective studies are needed to better define optimal treatment strategies for ICIec.

COMPARISON OF MIRIKIZUMAB VS. USTEKINUMAB EFFICACY FOR INDUCTION OF REMISSION IN ULCERATIVE COLITIS – A 1:2 MATCHED ANALYSIS

L. Johann[1], A. Huth[1], G. Lamprecht[1], J. Reiner[1]
[1]University of Rostock, Rostock, Germany

Contact E-Mail Address: lisa.johann94@googlemail.com

Introduction: Interleukin (IL) inhibitors are monoclonal antibodies that have been shown to be effective in inducing and maintaining remission in moderate to severe ulcerative colitis (UC).

Ustekinumab (UST) was approved in the EU for the treatment of UC in 2019 and binds specifically to the p40 protein subunit of IL-12 and IL-23. Mirikizumab (MIRI) was approved 4 years later and selectively binds to the p19 subunit of the IL-23 cytokine. By binding to the IL subunits, the interaction with the IL-23 receptor is inhibited.

In this study, we compared the response rate to induction therapy with UST and MIRI in patients with moderately to severe UC.

Aims & Methods: All patients with active UC who began induction therapy with UST or MIRI at our outpatient clinic between 2019 and 2024 were analyzed retrospectively with a follow-up period until April 2025. Patients who received the IL-23 inhibitor due to a disease other than UC or following a prednisolone therapy exceeding 20 mg and patients with pouchitis were excluded from the study.

We determined the response to IL-23 therapy 8 to 24 weeks after the start of treatment and documented this either as clinical remission (Mayo-Score ≤1), improvement (Mayo-Score reduction by at least 3 points), inadequate response (Mayo-Score reduction between 0 and 2) or no response (lack of benefit, switch to another medical class or colectomy).

We examined the levels of calprotectin in the stool 0 to 24 weeks before the start of IL-23 therapy up to 24 weeks after initial administration.

Our study included 40 patients treated with UST and 23 patients treated with MIRI, in the latter group 26% have previously been treated with UST. Patients in both groups were similar in age (mean age, 47.75 vs. 44.59 y; P 0.28), gender, disease duration (mean duration, 11 vs. 9 y; P 0.32), and extent of disease (pancolitis, 40% vs. 48%).

Results: After completion of induction, 25% in the UST group and 57% in the MIRI group reached clinical remission. MIRI after UST achieved clinical remission in 67%. Improvement was shown in 20% vs. 30%, UST vs. MIRI. For UST, 5% were non-responder. For MIRI, no non-responder was noted. In general, the difference between the pre- and post-induction Mayo-Score is significantly higher for MIRI, indicating a better response to the newly started drug (mean Mayo-Score difference, UST vs. MIRI, 2.95 vs 4.5; P 0.0003).

The mean calprotectin level before treatment was not significantly different (mean calprotectin, UST vs. MIRI, 1652 vs. 2452 mg/kg; P 0.17). The post-treatment calprotectin level was significantly higher for UST vs. MIRI (mean calprotectin, 1092 vs. 278 mg/kg; P 0.0083).

Conclusion: Mirikizumab is an effective induction treatment for patients with active ulcerative colitis, including those who previously did not respond adequately to Ustekinumab therapy.

Disclosure: Nothing to disclose.

Introduction: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive inflammation and fibrosis of the intra- and extrahepatic bile ducts. It is frequently associated with inflammatory bowel disease (IBD), particularly ulcerative colitis (UC). The coexistence of PSC and IBD poses clinical challenges due to the complex management of both intestinal and hepatic manifestations. While biological therapies have improved IBD outcomes, treatment options for PSC remain limited. Assessing the impact of IBD-targeted biological therapies on clinical outcomes in patients with concomitant PSC and IBD is therefore essential.

Aims & Methods: This observational multicenter retrospective study included 81 adult patients diagnosed with both PSC and IBD at three Italian tertiary referral centers between January 2004 and November 2024. Data collected included demographic and clinical characteristics, endoscopic findings, administered treatments, and clinical outcomes. Patients were grouped based on the treatment received: biological therapies (anti-TNF, anti-integrins, anti-ILs, JAK inhibitors) or conventional therapies (5-ASA, UDCA, corticosteroids, azathioprine). Time-to-event outcomes—including episodes of cholangitis, IBD-related surgery, colorectal cancer, cholangiocarcinoma, and liver transplantation—were analyzed using Kaplan-Meier estimates and compared by log-rank tests. Cox proportional hazards models were used to identify independent risk factors. Statistical significance was defined as $p < 0.05$.

Results: The cohort was predominantly male (70.4%), with median ages at PSC and IBD diagnoses of 35.0 ± 14.9 and 25.0 ± 13.7 years, respectively. UC was more prevalent than Crohn's disease (72.8% vs. 27.2%), with pancolitis being the predominant UC phenotype (79.7%).IBD exhibited a generally indolent phenotype across the cohort, with rare complications in Crohn's disease and frequent mucosal healing in UC (Mayo 0–1 in 64.8%). Biological therapies were administered to 49.4% of patients. Patients receiving biologics were younger at PSC diagnosis compared to those on conventional therapies (32.5 ± 14.85 vs. 39.6 ± 15.74 years; $p = 0.05$). Patients with Crohn's disease had a significantly higher risk of intestinal

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

surgery compared to those with UC (HR 4.2; 95% CI 1.2–14.2; p = 0.037). No significant difference in intestinal surgery incidence was observed between patients treated with biological versus conventional therapies. Kaplan-Meier analysis revealed no significant difference in the incidence of cholangitis between patients receiving biological and conventional therapies (log-rank p = 0.36). Likewise, there were no significant differences between the two groups regarding colorectal cancer, cholangiocarcinoma, or liver transplantation.

Conclusion: Biological therapies appear effective in controlling intestinal inflammation in PSC-associated IBD, with a favorable safety profile regarding malignancy and transplantation risk. However, they do not significantly impact the incidence of cholangitis. These findings provide a foundation for future studies and may help guide evidence-based therapeutic strategies in this complex patient population.

LONG-TERM SAFETY AND EFFICACY OF THE HIGHLY SELECTIVE TYROSINE KINASE 2 INHIBITOR ZASOCITINIB FOR THE TREATMENT OF INFLAMMATORY BOWEL DISEASE: DESIGN OF A PHASE 2 OPEN-LABEL EXTENSION TRIAL

G. Parkes[1], S. G. Rajendra[2], L. Zaru[2], V.A. Nguyen[2], L. Ayodele[2], F. Nordio[2], T. Freeney[2], L. Sears[2], N. Singh[2]

Contact E-Mail Address: gareth.parkes@nhs.net

Introduction: Tyrosine kinase 2 (TYK2) inhibitors block signaling downstream of multiple pro-inflammatory cytokines involved in immune-mediated inflammatory diseases, including inflammatory bowel disease, and may have an improved safety profile relative to Janus kinase inhibitors. Phase 2 studies of the highly selective and potent TYK2 inhibitor zasocitinib in Crohn's disease (CD; NCT06233461) and ulcerative colitis (UC; NCT06254950) are ongoing.[1,2]

Here, we describe the design of a combined open-label extension trial (NCT06764615), which will include patients from both parent trials who are responsive to treatment.

Aims & Methods: Patients are eligible for the phase 2 parent studies in CD and UC if they are aged 18–75 years with moderately to severely active disease, and have inadequate or loss of response to, or intolerance of, ≥ 1 standard or advanced therapy. Patients who have failed treatment with ≥ 3 classes of advanced therapy are excluded. Patients are randomized to one of three (CD) or two (UC) doses of zasocitinib, or placebo, for a 12-week double-blind induction phase followed by a 40-week sponsor-open (CD) or open-label (UC) maintenance period.

At the end of the parent trials, patients will be eligible for the combined open-label extension if they are clinical (CD) or symptomatic (UC) responders at Week 52, defined as: (1) CD: a ≥ 30% decrease in average daily very soft or liquid stools and/or a ≥ 30% decrease in average daily abdominal pain from baseline; and (2) UC: a ≥ 1-point and ≥ 30% decrease from baseline in partial modified Mayo score, and a ≥ 1-point decrease from baseline in rectal bleeding (RB) subscore or achievement of an absolute RB subscore of ≤ 1.

All enrolled patients will receive the same dose of open-label, oral, once-daily zasocitinib for a maximum of 108 weeks, with study visits every 12 weeks, followed by a 4-week safety follow-up period. Data analysis will be descriptive, with no formal statistical comparisons performed.

Results: The primary objective of the study is to determine long-term safety and tolerability, assessed through the incidence of treatment-emergent adverse events or adverse events of special interest. Secondary endpoints will assess the long-term efficacy of zasocitinib, including clinical, symptomatic, or endoscopic response or remission by visit or at Weeks 48 and 108, according to indication, and effects on patient-reported outcomes, including fatigue, bowel urgency, abdominal pain, and disease-specific health-related quality of life.

Conclusion: This open-label extension trial will provide data on the long-term safety of zasocitinib, as well as durability of treatment response among patients with CD or UC who experience treatment benefit in the phase 2 parent studies.

RANDOMIZED COMPARISON OF DAILY VERSUS ALTERNATE DAY ORAL IRON THERAPY IN PATIENTS WITH ULCERATIVE COLITIS WITH IRON DEFICIENCY ANEMIA

U.K. Mangipudi[1], P. Bhatia[2], H. Mandavdhare[1], V. Jearth[1], A. Sekar[3], A. Patil[4], U. Dutta[1], V. Sharma[1]
[1]Postgraduate Institute Of Medical Education And Research, Gastroenterology, Chandigarh, India, [2]Postgraduate Institute Of Medical Education And Research, Pediatric Hemato-Oncology, Chandigarh, India, [3]Postgraduate Institute Of Medical Education And Research, Histopathology, Chandigarh, India, [4]Postgraduate Institute Of Medical Education And Research, Pharmacology, Chandigarh, India

Contact E-Mail Address: dr.udaykm@gmail.com

Introduction: Alternate day oral iron therapy is better than daily oral iron therapy in Iron deficiency anemia (IDA) as it increases the fractional absorption of iron. In Ulcerative colitis (UC) with IDA increased fractional absorption of iron with alternate day iron may not only be better in improvement of anemia but also results in reduced unabsorbed iron delivery to distal bowel and may hence reduce adverse effects.

Aims & Methods: In a randomized, open label trial, from February 2023 to December 2024 patients of UC in remission (Mayo ≤2 OR partial Mayo ≤1 with fecal calprotectin <150mcg/gm for last 3 months) with IDA (ferritin <30mcg/l, transferrin saturation <20%, Hb 8-12 gm/dl) were randomized to every other day 132mg (EOD group) or daily 66mg (OD group) elemental oral iron given as ferrous fumarate for 8 weeks.

Primary outcome was the difference in mean change in Hemoglobin (Hb) at 8 weeks. Secondary outcomes were the difference in mean change in RBC indices, iron indices and adverse events at 8 weeks.

Results: 54 patients were randomized between both groups. One patient in EOD and 2 in OD group withdrew before treatment initiation. Eleven patients had disease flare on oral iron therapy (5 in EOD and 6 in OD group) p= 0.62 and two patients in EOD group had intolerance requiring oral iron stoppage. Thirty-eight patients completed treatment. The mean change in Hb at 8 weeks in EOD and OD groups was 2.08±1.0gm/dl and 2.09±1.11gm/dl respectively in per protocol analysis (p=0.797).

The mean change in serum ferritin, serum iron, transferrin saturation and total iron binding capacity in both the groups is not significant. Disease flare within 6 months prior to oral iron therapy correlated with increased incidence of flare on oral iron therapy. (P=0.04)

Conclusion: Alternate day oral iron is not better than daily oral iron in improving Hb levels, iron indices and with similar incidence of adverse events in patients of UC in remission. A recent flare has increased chances of disease flare with oral iron therapy

Disclosure: Nothing to disclose.

Contact E-Mail Address: vipul.jairath@robartsinc.com

Introduction: Resolution of pain, fatigue and other symptoms are key treatment goals for many patients (pts) with Crohn's disease (CD);[1,2] however, time to symptomatic improvement in pts treated with vedolizumab (VDZ) has not been formally evaluated.

Aims & Methods: VOICE (NCT06249555) is a prospective, observational study in pts with CD aged ≥18 years initiating VDZ or anti-IL-23 antagonist treatment (tx) per product labelling as part of standard of care, with the main objective to explore the time course of response to VDZ as measured by the Patient-Reported Outcomes Measurement Information System (PROMIS) domain Short Form (SF) scores. Inclusion criteria include baseline PROMIS Pain Interference (PI)-SF T-score ≥55 (0.5 SD above general population). We enrolled pts via Takeda pt support program in Canada, with additional pts enrolled at US and Canada sites. Planned sample size is 300 pts (VDZ, 200; anti-IL-23 antagonist [reference group not for formal comparison], 100); planned follow-up is 52 weeks (wks), with PROMIS PI data reported weekly for the first 14 wks. The primary endpoint is time to the first meaningful clinical improvement in PROMIS PI-SF T-score, defined as ≥2-point decrease in PROMIS PI-SF T-score from baseline. We also collect data on improvement in 7 PROMIS domains with clinical improvement defined as 5-point (0.5 SD)[3] change in T-score from baseline, Short Inflammatory Bowel Disease Questionnaire (SIBDQ; including SIBDQ improvement [≥9 point increase from baseline] and SIBDQ remission [score of ≥60]) and safety. Here, we report the results from pts with ≥1 VDZ dose and ≥1 post-baseline PI assessment included in the interim analysis (IA; prespecified to occur after 50 pts from VDZ group completed or discontinued before the wk 14 assessment to provide an early evaluation of tx response and safety).

PROMIS domain T-score, mean±SD	Baseline (n=64)	Week 14 (n=49)	Change from baseline (n=49)
Pain Interference	61.7±5.2	55.0±10.2	–6.5±10.0
Fatigue	62.0±6.4	53.9±11.5	–8.4±10.6
Anxiety	60.2±7.4	54.7±10.2	–5.5±8.6
Depression	56.4±8.6	52.9±10.9	–3.9±8.6
Physical Function	42.0±6.2	45.3±9.0	3.5±7.8
Sleep Disturbance	56.3±6.9	54.5±9.9	–1.5±7.2
Ability to Participate in Social Roles and Activities	43.2±6.3	49.0±11.2	5.9±10.1

T-score of 50±10 reflects the mean±SD score of the general US population.[3] Higher T-scores in PROMIS Pain Interference, Fatigue, Anxiety, Depression and Sleep Disturbance domains reflect greater impairment (poorer quality of life); higher T-scores in PROMIS Physical Function and Ability to Participate in Social Roles and Activities domains reflect less impairment (better quality of life).[4]

Table. Summary of PROMIS domain T-scores.

Results: Overall, 64 pts with ≥1 VDZ dose and ≥1 post-baseline PROMIS PI assessment (mean±SD age, 43.1±17.0 years, 35.9% male, 92.2% White) were included in the IA. Disease duration (mean±SD) was 6.4±12.1 years; 84.4% of pts were anti-TNF-naïve. Data collection is ongoing for 57 pts (49

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with and 8 without completed wk 14 PROMIS PI questionnaire); 7 pts discontinued from the study. The median time to achieve the first ≥2 point decrease in PROMIS PI-SF T-score (in n=56 pts) was 12 days (95% CI, 6-13). Baseline PROMIS domain scores indicated notable impairment; by wk 14, improvements in mean PROMIS scores from baseline were observed in all 7 measured domains, with ≥5-point improvements in 4/7 domains (Table). At wk 14, 37.5% (24/64) and 7.8% (5/64) pts achieved SIBDQ improvement and remission, respectively. One pt had serious adverse events of appendicitis and diverticulitis, and another pt had a fatal event; none of these were related to VDZ tx.

Conclusion:

The IA results through wk 14 show an early improvement across multiple symptom domains and quality of life in pts with CD starting VDZ tx. Time to first ≥2-point decrease in PROMIS PI-SF T-score was short, with a benefit observed after 12 days from VDZ initiation. Study recruitment and data collection are ongoing.

Introduction: In Crohn's disease (CD), an exposure-response relationship is suggested for ustekinumab, with higher serum levels associated with better outcomes. Pharmacokinetic data are scarce, with suggested target maintenance trough level associated with remission at 0.8-1.4 µg/mL.[1,2] The REScUE study (NCT04245215) investigated the effect of two different re-induction regimens with ustekinumab in patients with CD. No significant difference was observed on clinical, endoscopic and biological outcomes.[3] Here we present the pharmacokinetic and pharmacodynamics results of the REScUE study.

Aims & Methods: This Belgian multicentre prospective double-blind randomized placebo-controlled trial included adult patients with CD treated with ustekinumab who presented with secondary loss of response to ustekinumab after documented primary response. All patients received a single IV re-induction with ustekinumab (≈6mg/kg) and were then randomized 1:1 to blinded maintenance ustekinumab 90 mg SC Q4W (intervention) or 90 mg SC Q8W (control) for 48 weeks. PK samples were obtained at baseline, week 4-8-12-20-28-36-48.

Results: In total, 108 patients were included: 67% female, median [IQR] age 41 [32-54] year, median disease duration 14 [7-22] years. Prior anti-TNF exposure was reported in 92% of the patients. Baseline ustekinumab trough levels at moment of loss of response were similar in both groups and at the suggested target level of 0.8-1.4 µg/mL[1]: median (IQR) q4 week 1.39 (0.84-2.74) µg/mL and q8 week 1.31 (0.91-2.34) µg/mL (p>0.9).

Eight weeks after induction, there was a statistically significant difference in ustekinumab trough levels between both groups 10.8 (8.0-15.9) µg/mL versus 8.2 (4.9-11.1) µg/mL for q4weeks vs q8weeks respectively (p=0.002). After 48 weeks of treatment the statistically significant difference persisted with 6.0 (4.8-9.6) µg/mL versus 2.1 (1.6-2.9) µg/mL (p<0.001).

No significant association between baseline/week 8/week 48 ustekinumab trough levels and (*steroid free*) clinical remisison [PRO2 (AP ≤ 1 AND SF ≤ 3) and FCP <250µg/g and *no steroids for 90 days prior to week 48*] or endoscopic remission [SES-CD <3 at week 48] was seen.

However, there was a significant association between baseline/week 8/week 48 ustekinumab trough levels and biomarker remission [CRP <5 mg/L and FCP <250 µg/g at week 48]; OR (95% CI) 2.98 (1.85, 5.23), 1.12 (1.06, 1.19) and 1.35 (1.13, 1.66) (all p<0.01) respectively. As per quartile

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. analysis of the ustekinumab trough levels at week 48, the lowest quartile (ustekinumab <0.9 µg/mL) had the lowest steroid free clinical remission in each treatment group.

Conclusion: In patients with CD experiencing secondary loss of response to ustekinumab, baseline ustekinumab levels are low. Dose optimization with a single IV re-induction followed by intensified maintenance dosing (90 mg SC q4W) leads to higher ustekinumab levels compared to IV re-induction followed by conventional maintenance dosing (90 mg SC q8W). No association was found between ustekinumab levels and different outcomes except for biomarker remission. This suggests that treatment with ustekinumab should be personalized on a patient level, guided by drug-clearance rather than guided by target trough levels.

THERAPEUTIC ROLE OF AZATHIOPRINE FOLLOWING INITIAL INTESTINAL RESECTION IN CROHN'S DISEASE: CHALLENGES IN A RESOURCE-LIMITED SETTING

A. Hassine[1], A. Hammami[1], H. Jaziri[1], M. Ksiaa[1]
[1]Sahloul University Hospital, Hepato-Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: amaninterne18@gmail.com

Introduction: Crohn's disease (CD) is a chronic condition characterized by a relapsing-remitting course, often requiring intestinal resection. Postoperative management primarily aims to maintain clinical remission. The advent of biologic therapies has undoubtedly improved disease prognosis following initial surgery. However, access to this therapeutic class remains limited in lower-middle income countries such as Tunisia, necessitating the use of alternative agents, notably azathioprine (AZA), which has been widely used for this indication, albeit with controversial results.

Aims & Methods: This study aimed to evaluate the effectiveness of AZA in maintaining remission after a first intestinal resection in patients with ileal or ileocolonic Crohn's disease, and to identify factors associated with treatment failure.

We conducted a retrospective, descriptive, and analytical study in the gastroenterology department of Sahloul University Hospital in Sousse (Tunisia) over a 4-year period (2020–2024). We included all patients with ileal or right ileocolonic CD who underwent intestinal resection and received AZA in the postoperative period.

Results: A total of 66 patients were included, with a mean age at diagnosis of 31.50 ± 12.24 years and a male-to-female ratio of 1.06. The median interval between diagnosis and surgery was 21.5 months. During follow-up, AZA failure occurred in 63.6% of patients (n=42), with a mean time from surgery to failure of 44.71 ± 37.74 months. In univariate analysis, ileocolonic disease location (p=0.042), the total number of flares (p=0.007), and the number of severe flares (p<0.001) prior to surgery were significantly associated with AZA failure. Failure rates were also significantly higher in patients who underwent emergency surgery (p=0.007). Inflammatory resection margins (p<0.001) and severe inflammatory activity (p=0.007) were also significantly associated with treatment failure. In multivariate analysis, three independent risk factors were identified: the number of severe flares before surgery (p=0.031), preoperative inflammatory syndrome (p=0.008), and histopathological evidence of disease at the resection margins (p=0.004).

Conclusion: Our findings suggest that thiopurines remain a valuable therapeutic option in the management of Crohn's disease, particularly in our setting, where access to alternative therapies is limited and associated with high costs.

Disclosure: Nothing to disclose.

PP0570

FIVE-YEAR PERSISTENCE OF VEDOLIZUMAB IN CROHN'S DISEASE: A REAL-WORLD MONOCENTRIC RETROSPECTIVE STUDY

M. Harb[1], J. Aoun[1], A. Hoyois[1], V. Muls[1]
[1]CHU Saint-Pierre, Brxuelles, Belgium

Contact E-Mail Address: marc_harb@Hotmail.com

Introduction: Vedolizumab, a α4β7 integrin monoclonal antibody represents an effective and well-tolerated therapeutic option for patients with moderate to severe Crohn's disease (CD)[1]. Its use as a first-line biologic therapy is authorized in some European countries, particularly Belgium, providing an opportunity to assess its performance when introduced early in the treatment algorithm. Real-world data on long-term treatment persistence, particularly beyond three years, remain limited.

This retrospective monocentric study aims to assess Vedolizumab persistence over five years in patients with CD, as well as evaluating the ability to predict treatment persistence based on the CDST (Crohn's Disease Subtype Tool) score.

Aims & Methods: This is a retrospective monocentric study including 60 patients with CD, followed at a central university hospital in Brussels. All patients were treated with Vedolizumab administered intravenously, between 2015 and 2024. We evaluated treatment persistence defined as the continuation of Vedolizumab without interruption assessed at 6,12,24,36,and 60 months.

Patients who had not yet reached the pre-set follow-up time points at the time of inclusion were excluded from the analysis at that specific time point, without being considered as treatment discontinuation. Persistence was described cross-sectionally at each time point. A CDST score was retrospectively calculated for all patients based on the available data before treatment initiation.

Results: A total of 60 patients with CD treated with Vedolizumab were included. Follow-up duration ranged between 1 and 107 months. The cohort consisted of 52% males with a mean age of 45.4 ± 14.5 years. 58 patients had completed at least 6 months of follow-up. Treatment persistence with Vedolizumab was 93% at 6 months (54/58), 87% at 12 months (47/54), 76.5% at 24 months (39/51), 67.4% at 36 months (31/46), and 56.1% at 60 months (23/41). 62% of patients were bio-naïve. The mean CDST score for all patients was 20.6 ± 2.6. The distribution of patients according to their predicted response to Vedolizumab was as follows: low probability of response (CDST ≤ 13): 1 patient (2%); intermediate probability (13 < CDST ≤ 19): 12 patients (20%); high probability of response (CDST > 19): 47 patients (78%).

A comparative analysis of the CDST scores between patients who discontinued treatment and those with treatment persistence was performed at each follow-up time point. At 6 months, the mean CDST score was 20.47 in the treatment discontinuation group versus 21.2 in the persistence group (p = 0.713). At 12 months, the means were 21.6 and 21.0, respectively (p = 0.713). Similar trends were observed at 24 months (19.2 vs 20.9; p = 0.304), at 36 months (18.23 vs 20.9; p = 0.136), and at 60 months (19.7 vs 20.6;

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

p = 0.523). These results suggest a trend toward higher CDST scores in patients with treatment persistence, although these differences did not reach statistical significance. Of the patients who completed five years of vedolizumab treatment, 9 out of 23 (39%) were biologic-naïve, while 14 out of 23 (61%) had prior exposure to biologic therapies.

Conclusion: This real-world retrospective study provides valuable insights into the long-term use of Vedolizumab in patients with CD, with a follow-up period extending up to five years. Treatment persistence over time was favorable in both biologic-naïve and exposed patients, particularly among those with a high CDST score.

The extended follow-up period reinforces the durability and safety of Vedolizumab as a long-term therapeutic option in clinical practice. Prospective studies are needed to confirm these findings and identify predictors of sustained response.

HO VS OXFORD VS CRP/ALBUMIN RATIO: WHICH TOOL WINS THE BATTLE AGAINST STEROID-REFRACTORY COLITIS?

I. Qarch[1], N. Lagdali[1], F.-Z. Chabib[1], M. Kadiri[1], M. Borahma[1], F.Z. Ajana[1]
[1]Ibn Sina University Hospital Center, Faculty of Medicine and Pharmacy, Mohammed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ismail.qarch@gmail.com

Introduction: Severe acute colitis (SAC) is a life-threatening complication of inflammatory bowel disease (IBD), particularly ulcerative colitis, This requires immediate treatment with intravenous corticosteroids. Patients who are likely to fail treatment with a first-line approach need to be identified early in order to expedite second-line therapy or surgery.

Aims & Methods: This study aimed to evaluate the prognostic performance of the Ho score(day1), the Oxford score (day 3), and the CRP/albumin ratio in predicting corticosteroid response in SAC.

This was a retrospective, single-center analytical study including all patients hospitalized for SAC in a north african gastroenterology department. Clinical and biological data were collected at admission and on the third day of corticosteroid therapy. The Ho score was based on three criteria: CRP > 100 mg/L, albumin < 30 g/L, and > 8 stools/day (positive if ≥ 2). The Oxford score was considered positive on day 3 in cases of > 8 stools/day or ≥ 3 stools with CRP > 45 mg/L. The CRP/albumin ratio was analyzed with a cut-off value of 3.0. Corticosteroid response was defined as clinical improvement without rescue therapy or surgery. Statistical analysis included Chi² test for associations, Student's t-test for comparing means, and calculation of diagnostic performance (sensitivity, specificity, positive and negative predictive values).

Results: Forty-three patients were included. The mean age was 35.5 years (range: 18–58), with a female-to-male ratio of 2:1.

SAC was inaugural in 25 patients (58.1%), while 18 patients (41.9%) had a known history of IBD.

The overall corticosteroid response rate was 44.2%.

The Ho score was positive in 26 patients, with a response rate of 15.4% versus 56.7% for negative scores (p = 0.030). Its diagnostic performance was modest: sensitivity 10.5%, specificity 54.2%, positive predictive value (PPV) 15.4%, and negative predictive value (NPV) 43.3%.

The Oxford score was positive in 31 patients, with a response rate of 29% compared to 83.3% in the negative group (p = 0.004). It showed higher sensitivity (47.4%) but lower specificity (8.3%), with a PPV of 29.0% and NPV of 16.7%.

The CRP/albumin ratio was significantly higher in non-responders (3.86 vs. 2.30; p = 0.038). When using a cut-off of 3.0, this marker had a sensitivity of 15.8%, specificity 29.2%, PPV 15.0%, and NPV 30.4%.

Conclusion: The Oxford score, despite low specificity, showed the best performance in identifying patients at risk of corticosteroid failure by day 3. The Ho score, though less sensitive, remains useful at admission for early risk stratification. The CRP/albumin ratio, while simple and biologically relevant, demonstrated limited predictive performance at the fixed threshold of 3.0. Further studies are needed to refine these tools or develop composite models for early decision-making in SAC.

Disclosure: Nothing to disclose.

PP0572

BIOLOGICS AND OTHER IMMUNOTHERAPIES AS RESCUE TREATMENTS FOR STEROID-REFRACTORY ACUTE SEVERE ULCERATIVE COLITIS: A NETWORK META-ANALYSIS

M.S Beshr[1], M. Al Hayek[2], M.V. Nounou[3], D. Alatefi[4], M. Elhadi[5]

Introduction: Acute severe ulcerative colitis (UC) refractory to intravenous corticosteroids is a serious form of severe UC and may result in colectomy. In this network meta-analysis, we aim to assess the efficacy of biologics and other immunotherapies as rescue treatments for patients with acute severe UC unresponsive to standard therapy, with a focus on their ability to prevent colectomy.

Aims & Methods: On March 1, 2025, a data search was conducted using PubMed, Scopus, and the Cochrane Library. We included controlled clinical trials that evaluated the use of biologics and other immunotherapies in patients with severe ulcerative colitis refractory to intravenous steroids. The primary outcomes were clinical response at week 1 and the colectomy rate at week 12. We used the odds ratio with the 95% confidence interval to estimate the effect size, and a random-effects model was applied. Data analysis was performed in RStudio using the *netmeta* package.

Results: Out of 2,186 articles screened, only 5 met our eligibility criteria, with a total of 734 patients. Four treatment strategies were included in the network meta-analysis: infliximab intensified dosing (10 mg/kg at week 0 and week 1 if responsive, or earlier if not), standard infliximab dosing (5 mg/kg at weeks 0, 2, and 6), accelerated infliximab dosing (5 mg/kg at weeks 0, 1, and 3), and cyclosporine.

For preventing colectomy, infliximab 10 mg/kg (OR 0.11; 95% CI: 0.02–0.79), infliximab 5 mg/kg standard dose (OR 0.21; 95% CI: 0.06–0.73), and cyclosporine (OR 0.20; 95% CI: 0.05–0.79) were all associated with a statistically significant reduction in colectomy risk compared to placebo at week 12. Accelerated infliximab dosing did not show a statistically significant difference.

For clinical response at week 1, infliximab 10 mg/kg, infliximab 5 mg/kg (standard dose), and cyclosporine had similar response rates, with no significant differences observed.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Infliximab (both standard and intensified doses) and cyclosporine, as rescue therapies, had lower rates of colectomy at week 12 in patients with acute severe ulcerative colitis refractory to corticosteroids. Clinical response at week 1 was comparable across these therapies.

REAL WORD DATA: THE VEDOLIZUMAB EXPERIENCE IN A TERTIARY CENTRE

B. Abdalla[1], A. Trikola[1], C. Miles[1], A. Herath[1], D. Durai[1], A. Kokrashvili[1], C. Tibbatts[1]
[1]University Hospital of Wales, Gastroenterology, Cardiff, United Kingdom

Contact E-Mail Address: artemis.trikola@yahoo.gr

Introduction: Vedolizumab, a $\alpha_4\beta_7$integrin antagonist has been established as an effective therapy in the treatment armamentarium of inflammatory bowel disease (IBD). Although previously recommended either as first line or second line treatment in patients with IBD; patient specific characteristics (like advanced age, history of malignancies, susceptibility to infections) and reimbursement, national and local policies may influence the drug choice.

Aims & Methods: The aim of the study is to evaluate real-world data on Vedolizumab use at a tertiary national centre. Data was retrospectively collected from patients' electronic medical records in our national healthcare database (Welsh Clinical Portal) for patients who started on Vedolizumab between 2018 and 2021, with a three-year persistence assessment. Patient characteristics and reasons for discontinuation were documented.

Results: A total of 247 patients were enrolled, mean age 52,19 years old (SD 17,6), 55.9% females. The diagnosis was split predominantly between Crohn's in 48.4% of patients and UC in 44.2%, (IBD-U 7.4%). Subcutaneous (SC) vedolizumab was the commonest formulation administered in 71.3% of patients, while 28.7% were given intravenous (IV).

Those receiving Vedolizumab as a first line treatment were found to be significantly older (p<0.001) and in instances where it was given as a second line option, anti-TNF therapy was the agent previously used in 100% of patients.

The overall persistence was 70% at 1 year and 46 % at 3 years (table) with secondary loss of response (30.8%) being the main reason to stop treatment, followed by primary non-responders (14.6%), side effects (7.3%) or other reasons (6.1%). We found in our cohort, a significant difference in persistence when used as an initial treatment, versus later in the pathway. There was a significant correlation between the response to Vedolizumab and factors such as prior biologic exposure, age, and treatment persistence. During the observation period, 5.8% of patients required a form of surgical treatment, 4.9% required a 'hot clinic' review and only 0.9% required admission. The cohort of patients had many significant co-morbidities, but to date, none had experienced a deterioration in their condition whilst on Vedolizumab therapy.

Year	N of new patients	1-year persistence	2-year persistence	3-year persistence
2018	41	71%	51%	44%
2019	37	76%	49%	27%
2020	81	68%	57%	46%

Conclusion: Our data contributes to the growing body of evidence that Vedolizumab is a safe and effective therapy, regardless of the delivery method. It is particularly beneficial for vulnerable patients, demonstrating good persistence of response beyond the initial induction of remission. Additionally, when used as a first-line treatment in the appropriate patient, it offers a better chance for a sustained drug response.

Disclosure: Nothing to disclose.

THERAPEUTIC DRUG MONITORING FOR MANAGEMENT INFLAMMATORY BOWEL DISEASES IN CHILDREN TREATED WITH TNF-A ANTAGONISTS: EXPERIENCE OF THE REGIONAL CENTER

E. Yablokova[1], A. Rimskaya[1], M. Erochina[2]
[1]First Sechenov University, Childhood Diseases, Moscow, Russian Federation, [2]Research Clinical Institute of Childhood of the Moscow Region, Childhood Diseases, Moscow, Russian Federation

Contact E-Mail Address: catcom@list.ru

Introduction: Every second child with inflammatory bowel disease (IBD) gets biological therapy with the development of 15% of secondary drug ineffectiveness that requires switching to other biological drugs (high costs, number of side effects of treatment). Therapeutic drug monitoring (TDM) (routine assessments of trough concentration with dose adjustments of tumor necrosis factor (TNF)α antagonists and anti-drug antibodies assessments) has been proposed to improve outcomes in IBD patients.

Aims & Methods: *The aim* of this study was to evaluate the effect of TDM in pediatric IBD biological therapy management and to determine indications for timely switching to the second-line biological therapy. *Materials and Methods:* 81 (35 with Crohn's disease (CD), 46 with ulcerative colitis (UC); 43 boys, 38 girls; 2-17 (11,23±4,58) years old)) of 146 IBD children (57 with CD, 89 with UC;) from Moscow Region IBD children center received a-TNFα biological therapy. TDM methods: assessments of infliximab or adalimumab concentration level to the 6 and 14th week of drug induction, a-infliximab or a-adalimumab antibodies appearance to the 20th week of drug induction (Quantitative rapid immunochromatographic tests). In case of clinical a-TNF therapy ineffectiveness, the level of biological a-TNFα drugs and antibodies was tested to correct the therapy with drug dose escalation or switching to out-of-class biological. Pediatric IBD clinical activity indexes (PUCAI, PCDAI), fecal calprotectin (FC), endoscopic scores (SES-CD, UCEIS), morphological activity IBD-DCA score were used to control IBD activity.

Results: 81\146 (55%) IBD children (35 with CD (L3, L3+L4, B2 stenosing phenotype, perianal CD), 46 with UC (E4 pancolitis); severe clinical\endoscopic\morphological IBD activity) had a-TNFα biological therapy ini-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tiation: 55 infliximab, 26 adalimumab. The level of infliximab was higher (16.3–42 µg/ml) than 15 µg/ml (target level) in 48/55 (87%) children by the 6th week of induction; >5 µg/ml in 100% cases by the 14th week. They had significant decrease in clinical activity indexes and fecal calprotectin to the end of induction period - clinical remission (PUCAI, PCDAI less than 10 p.) in 27/31 (87%) patients (ANOVA Chi Sqr. p<0,0001). 7 (13%) children with low infliximab level (5 - below the detectable values <0.4 µg/ml) still had high clinical end fecal activity (PUCAI >35 b., PCDAI >25 b.), fecal calprotectin 457±103.2 µg/g so they required dose adjustment (drug escalation). The level of adalimumab was >7.5 µg/ml (9.1–38.9 µg/ml) - target level- by 14 weeks in 25/26 (96%) children. We have not detected the appearance of a-biologics antibodies at least to 20 weeks in any sample. TDM was helpful to manage the drug inefficiency.

We had primary inefficiency in 6/81 (7.4%), secondary inefficiency – 30/81 (37%) of our IBD children so it comes to the drug escalation in 19\81 (23.5%) cases, switching to 2nd line of biologics (2-to adalimumab, 6-to ustekinumab, 22-to vedolizumab) in 30/81 (37%) of children with significant clinical improvement after 3 months of therapy (ANOVA Chi Sqr. p<0,0032 by FC).

Conclusion: The target therapeutic concentrations of a-TNFα biologics, sufficient for mucosal healing, appear in 90% of children by the end of initiation period with significant decrease in clinical, endoscopic, and morphological activity scores without a-TNFα biologics antibodies appearance to 20 weeks. TDM helped to make the early dose biologics adjustment and switching to 2nd line of biologics to overcome inefficiency of biological therapy.

Introduction: Despite the progress in advanced therapies (AT) for ulcerative colitis (UC), selecting a second-line treatment after failure remains challenging. Recent guidelines recommend Ustekinumab (UST), Tofacitinib (TOFA), or Upadacitinib (UPA) as high-efficacy options after prior AT failure. However, no real-world studies have compared all three therapies.

Aims & Methods: Retrospective multicenter study (8 centers) of UC patients who failed ≥1 advanced therapy. Patients were stratified into UST, TOFA, or UPA groups and assessed at 16 and 52 weeks. The primary outcome was steroid-free clinical remission (SFCR) based on the Patient Reported Outcomes-2. Secondary outcomes included biochemical remission (fecal calprotectin ≤ 250 µg/g) and endoscopic remission (Mayo Endoscopic Subscore=0). Time to remission was assessed using Cox regression analysis. A subanalysis was performed including only second-line use after anti-TNF failure. Multivariate analysis was performed, adjusted for duration of disease, extent and number of prior therapies.

Results: We evaluated 259 cases [54.4% (n=141) female; diagnostic age 32.3 ± 15.1 years] who initiated UST (n=105; 40.5%), UPA (n=87; 33.6%) or TOFA (n=67; 25.9%). The groups were similar in disease duration (UST: 11.6 ± 8.0; UPA: 9.8 ± 6.4; TOFA: 10.4 ± 5.4 years) and 49.8% (n=129) had failed ≥2 previous AT

At week 16, UPA showed higher SFCR compared to UST (OR 2.1; p=0.014) and TOFA (OR 2.1; p=0.040), with no difference at week 52. Biochemical remission was higher with UPA at week 16 *vs* UST (OR 2.3; p=0.015) and TOFA (OR 2.1; p=0.039) and at week 52 *vs* UST (OR 4.7; p=0.010) and TOFA (OR 4.6; p=0.013). At week 16, endoscopic remission was higher with UST (OR 3.5; p=0.036) and UPA (OR 3.1; p=0.041) compared to TOFA; and at week 52, UPA was associated with higher endoscopic remission *vs* UST (OR 3.6; p=0.036).

In Cox regression, UPA achieved earlier biochemical remission than UST (HR 1.9; p<0.001) and TOFA (HR 1.8; p=0.011). JAK inhibitors led to earlier endoscopic remission than UST (*vs UPA*: HR 3.2; p<0.001; *vs TOFA*: HR 1.4; p=0.002).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In the subanalysis, UPA as second-line therapy demonstrated higher SFCR than TOFA (OR 3.6; p=0.035) and higher endoscopic remission at week 52 than TOFA (OR 12.0; p=0.017), and trend-wise compared to UST (OR 4.5; p=0.090).

Conclusion: Even though all three medication demonstrated high efficacy in bio-exposed UC patients, UPA achieved better results in this real world study.

Introduction: Ulcerative colitis (UC) has increasingly been recognized as a progressive disease. However, the benefit of starting early biologic therapy (BT) has not been established, contrary to Crohn's disease. We aimed to assess if early intervention improves UC outcomes, particularly in preventing disease progression.

Aims & Methods: We conducted a retrospective multicenter study (11 centers) including adult UC patients who initiated BT until 2019 (minimum follow-up [FU]: 5 years). Early intervention was defined as BT initiation within ≤12 months of diagnosis. The primary outcome was UC progression at 5 and 10 years, defined as a composite of proximal extension, colonic structural changes (stenosis/ tubularization) and dysplasia/cancer. Secondary outcomes included clinical endpoints: hospitalizations, colectomy and corticosteroid use. Multivariate analysis was performed, adjusted for disease severity, extent, and prior activity.

Results: A total of 236 patients were included, with 28.8% (n=68) initiating BT within ≤12 months (mean FU after BT initiation: 8.06 ± 4.12 years).

Early intervention was associated with a reduced risk of proximal extension after BT initiation (p=0.012).

In multivariable Cox regression, later BT initiation was an independent predictor of colonic structural changes at 10 years (HR 8.54; 95% CI 1.15-62.63; p=0.036). Later BT initiation independently predicted the composite outcome of progression (23.2% vs 5.9%) at 5 years (HR 5.97; 95% CI 1.42-25.13; p=0.015) and 10 years (HR 4.58; 95% CI 1.41-14.88; p=0.011). No differences in clinical outcomes were observed.

Longer disease activity before BT was also a predictor of the primary outcome at 5 years (HR 4.20; 95% CI 1.27–13.82; p=0.018) and 10 years (HR 3.60; 95% CI 1.28–10.12; p=0.015).

Conclusion: Starting BT early in the disease course may reduce the long-term risk of disease progression, reshaping the window of opportunity in UC.

PATIENT REPORTED ATTITUDES TO INTRAVENOUS AND SUBCUTANEOUS ADMINISTERED THERAPIES FOR INFLAMMATORY BOWEL DISEASE

N. Hollos[1], L. Ellis[1], A. Verma[1]

[1]Kettering General Hospital, Department of Digestive Diseases, Kettering, United Kingdom

Contact E-Mail Address: Nora.Hollos@nhs.net

Introduction: 'Biologic therapies' are the mainstay treatment for moderate to severe Inflammatory Bowel Disease (IBD), resulting in fewer hospitalisations, adequate treatment response and mucosal healing. [1] Adalimumab, Golimumab, Ustekinumab & Risankizumab are administered subcutaneously (SC), Infliximab and Vedolizumab are administered intravenously (IV), and have additionally been available SC since 2020. SC Infliximab was used during the pandemic to limit exposure to hospitals & reduce risk of Covid-19, [2] as well as for convenience.

Aims & Methods: We explore patient's views of IV and SC administered treatments via a paper-based survey for those patients who were on IV treatment when attending for infusions, and a telephone survey on patients with IBD who have been on SC treatment.

Results: IV survey

- 122 completed the survey.
- 50/122 (41.0%) were on Vedolizumab (41.0%), 64 (52.5%) Infliximab, 8 (6.6%) others / didn't specify.
- 25/120 (20.8%) had been on IV therapy for 2-6 months, 17 (14.2%) for 7-12 months, 29 (24.2%) for 1-3 years, 21 (17.5%) for 3-5 years, 21 (17.5%) for >5 years.
- 107/120 (89.2%) rated treatments as easy, 13 (10.8%) intermediate, 0 difficult.
- 25/112 (22.3%) were previously on SC injections. Of this group: 15/24 (60.0%) favoured the IV route, 9 (36.0%) favoured the SC route.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

- 4/15 who favoured the IV route "did not like to inject themselves" or "found it difficult". 3/15 preferred IV route as they were being monitored.
- 104/110 (94.5%) attended all scheduled blood tests, 4 (3.6%) attended most of them
- 106/109 (97.2%) attended all OP appointments, 2 (1.8%) attend most
- 91/111 (82.0%) had no concerns, 10 (9.0%) had concerns over side effects (SE)
- 31/104 (29.8%) reported SE.
- 6/29 (20.7%) stated SE not affected their quality of life (QoL), 12 (41.4%) little impact QoL, 10 (34.5%) moderate impact, 1 (3.4%) severe impact.
- 96/105 (91.4%) would recommend IV route

SC survey

- 106/113 (93.8%) completed the survey..
- 54/106 patients were on Adalimumab (50.9%), 24 (22.6%) Ustekinumab, 13 (12.2%) Vedolizumab , 13 (12.3%) Infliximab, 2 (1.9%) Golimumab
- 10/106 (9.4%) for 1-6 months, 21 (19.8%) for 6-12 months, 33 (31.1%) for 1-3yrs, 21 (19.8%) for 3-5 years and 20 (18.9%) for >5 years.
- 89/106 (83.9%) rated treatment administration as easy, 10 (9.4%) intermediate, 2 (1.9%) difficult
- 59/106 (55.7%) were previously on IV infusions. Of this group: 43/59 (72.9%) favoured the SC route, 8 (13.6%) favoured IV, and 8 (13.6%) no preference.
- 24/43 who favoured who favoured SC route stated 'convenient", "easy", "not have to attend hospital" as reasons.
- 86/106 (81.1%) attended all scheduled blood tests, 5 (4.7%) attended most of them,
- 102/106 (96.2%) attended all OP appointments, 3 (2.8%) attend most,
- 68/106 (64.2%) had no concerns, 21 (19.81%) concerned about fewer face to face episodes
- 40/106 (37.7%) reported SE. 8 (20%) skin reactions
- 11/40 (27.5%) stated SE not affected their quality of life (QoL), 14 (35%) little impact QoL, 9 (22.5%) moderate impact, 6 (15%) severe impact.
- 87/106 (82.1%) recommend SC route

Conclusion: The survey found that both IV and SC treatments were easy to administer for the vast majority (89.2% & 84.9%), For patients on SC therapy who previously had IV infusions, 75.6% preferred SC as "convenient", "easy" and "no (need to attend) hospital".

For patients on IV therapy who previously had SC, 60.0% preferred IV as "did not ned to self inject / found it difficult", and "preferred monitoring".

Overall there are high levels of satisfaction with 91.4% of patients on IV treatment, and 82.1% of patients on SC treatment recommend their current route of administration.

Introduction: There has been an increasing trend in the incidence of Crohn's disease (CD) in the population >60 years of age. Although biological therapies have transformed the management of CD, providing better clinical outcomes, in elderly individuals they are often underutilized due to concerns about their efficacy and safety, as this population presents greater frailty, comorbidities and polypharmacy.

Aims & Methods: This systematic review and meta-analysis aimed to compare the efficacy and safety of ustekinumab (UST) versus vedolizumab (VDZ) in the treatment of elderly patients with CD. We performed a systematic search of the PubMed, Embase, and Cochrane Library databases in January 2025. Article screening was conducted independently by two authors using Rayyan software. Inclusion criteria were studies comparing UST and VDZ in the treatment of CD in patients >60 years, with follow-up >9 months, and that evaluated at least one of the outcomes of interest.

The primary outcome was clinical remission, and secondary outcomes included clinical response, general infection, and serious infection. For statistical analysis, we used Review Manager software, applying a random-effects model to calculate the odds ratio (OR) in binary outcomes.

Results: Five studies were included, totaling 404 patients, of whom 209 (51.73%) received treatment with UST and 195 (48.27%) with VDZ. The mean age of the patients was 67.9 years. In the UST group, 145 patients (78.8%) received prior treatment with anti-TNF, while in the VDZ group this number was 88 patients (51.2%). No statistically significant differences were observed regarding clinical remission (OR 0.87; 95% CI 0.51-1.48; I^2=0%), clinical response (OR 1.69; 95% CI 0.81-3.53; I^2=0%), general infection (OR 1.51; 95% CI 0.76-2.99; I^2=0%) and severe infection (OR 2.60; 95% CI 0.54-12.52; I^2=50%) between the groups treated with UST and VDZ.

Conclusion: Comparing efficacy and safety outcomes between UST and VDZ treatments in elderly patients with CD, no significant differences were observed between the groups. Randomized clinical trials are needed to confirm these findings.

Disclosure: Nothing to disclose.

Introduction: The development of intestinal strictures (IS) marks a critical stage in the progression of Crohn's disease (CD). Despite therapeutic advances, IS remains a complex management challenge. Identifying predictive factors for response to medical therapy is essential for optimizing treatment strategies and improving outcomes.

Aims & Methods: This study aimed to identify clinical, biological, and radiological factors associated with the efficacy of medical treatment in patients with CD-related strictures. We conducted a retrospective cohort study including patients treated medically for IS between 2013 and 2023. Data on demographics, stricture characteristics, therapeutic interventions, and clinical outcomes were collected. Patients were classified into two groups based on their response to medical therapy: responders and non-responders. Comparative analysis was performed to identify variables associated with treatment response.

Results: Among 80 patients with stricturing CD, 65 received medical therapy. The mean age at diagnosis was 38.3 ± 12.6 years, with a male-to-female ratio of 1.6. Active smoking was reported in 24 patients (37%), and 25% had a family history of IBD. IS was symptomatic in 88% of cases. Elevated C-reactive protein (CRP) was present in 84%, and hypoalbuminemia in 55%.

Strictures were most commonly ileal (n=33), followed by anastomotic (n=13), colonic (n=8), ileocecal (n=6), duodenal (n=3), and jejunal (n=2). Colonoscopy confirmed luminal narrowing in 85% of patients. Upper GI endoscopy, performed in three patients with high obstructive symptoms, revealed ulcerated duodenal strictures. Cross-sectional imaging confirmed IS in 75% of cases. Median stricture length was 10 cm [5–20], with a median wall thickening of 9 mm [6–11]. Pre-stenotic dilation was observed in 59% of cases.

Treatment included oral corticosteroids in 24 patients (37%; median initiation time: 35 days [16.2–70.5]) and anti-TNFα agents in 41 (63%), with infliximab prescribed in 80% and adalimumab in 20%. Smoking cessation was achieved in 29% of smokers.

Univariate analysis identified several predictors of favorable response: female sex (p=0.01), absence of active smoking (p=0.02), CRP < 23.5 mg/L (p<0.001), CRP/albumin ratio < 0.72 (p<0.001), stricture length < 13.5 cm (p=0.032), absence of pre-stenotic dilation (p=0.035), and smoking cessation (p=0.009). In multivariate analysis, two factors remained significantly associated with treatment success: absence of active smoking (p=0.003, OR=70.4, 95% CI [4.1–1188.8]) and CRP < 23 mg/L (p=0.001, OR=117.6, 95% CI [6.6–2076.6]).

Conclusion: In patients with stricturing CD, the absence of active smoking and lower systemic inflammation (as measured by CRP) were independent predictors of favorable response to medical therapy. These findings underscore the importance of smoking cessation and early inflammatory control to improve therapeutic outcomes in this patient population.

Disclosure: No Conflict of interest.

Introduction: The use of biologics has become an increasingly common treatment option for inflammatory bowel disease (IBD). However, data on maternal and fetal exposure to ustekinumab (UST) and vedolizumab (VDZ) remain scarce.

Aims & Methods:

This systematic review and meta-analysis aimed to assess the safety of UST and VDZ in pregnant women with IBD. We systematically searched PubMed, Embase, and Cochrane Library databases in March 2025. The inclusion criteria were randomized and non-randomized studies comparing UST and VDZ for the treatment of IBD in pregnant patients and evaluating at least one predefined outcome of interest.

Primary outcomes were spontaneous abortion and preterm delivery. Secondary outcomes included live birth, low birth weight, serious infections, neonatal intensive care unit (NICU) admission, and malignancies. Statistical analysis was performed using RStudio, applying a random-effects model to calculate the pooled risk ratios (RRs) for binary outcomes.

Results: This systematic review included six studies. Median maternal age ranged from 30 to 33 years, with similar distributions between groups. The average disease duration ranged from 8 to 14 years. Crohn's disease was more prevalent in the ustekinumab group, while ulcerative colitis was more common in the vedolizumab group.

No statistically significant differences were observed in spontaneous abortion (RR 1.66; 95% CI 0.89–3.10), preterm delivery (RR 0.60; 95% CI 0.31–1.16), live birth (RR 0.97; 95% CI 0.90–1.05), low birth weight (RR 0.65; 95% CI 0.31–1.40), serious infections (RR 1.34; 95% CI 0.39–4.66), NICU admission (RR 1.02; 95% CI 0.56–1.85), or malignancies (RR 1.25; 95% CI 0.67–2.32) between UST and VDZ treatments.

Conclusion: No significant differences were observed across the outcomes analyzed when comparing ustekinumab and vedolizumab for the treatment of pregnant patients with IBD.

Disclosure: Nothing to disclose.

Introduction: Lateral lymph node dissection (LLND) is considered for patients with advanced lower rectal cancer because of possibility of metastasis. The standard surgical procedure for ulcerative colitis (UC)-associated cancer is total colectomy; however, the significance of LLND in UC-associated rectal cancer remains unclear.

Aims & Methods: The aim of this study is to clarify the outcomes of LLND for UC-associated rectal cancer. Of 1,249 patients treated for UC-associated colorectal neoplasms between 1983 and 2020 at 43 Japanese institutions, we retrospectively analyzed 415 patients with rectal cancer.

Results: LLND was performed in 45 (10.8%) patients with UC-associated rectal cancer: 33 of 139 (23.7%) patients with pT3–4 cancer and 12 of 276 (4.3%) patients with pTis–T2. Of the 45 patients with LLND, 11 (24.4%) had lateral lymph node metastasis (LLNM). LLNM-positive group (n = 11) had a significantly higher proportion of patients with pT3-4 cancer (100% vs. 64.7%, $P < 0.0046$) and poorly differentiated adenocarcinoma/ signet-ring cell carcinoma/ mucinous adenocarcinoma (por/sig/muc) (70% vs. 17.7%, $P = 0.002$) than LLNM-negative group (n = 34).

There was no significant difference in R0 resection rate between the LLND and non-LLND groups (81.8% vs. 91.2%, $P = 0.41$). The LLNM-positive group showed significantly worse 5-year overall (30.8% vs. 82.8%, $P = 0.0005$) and 5-year disease-free (0% vs. 72.4%, $P < 0.001$) survival rates than the LLNM-negative group. There was no significant difference in the administration of adjuvant chemotherapy between the two groups (54.6% vs. 40.6%, $P = 0.42$).

Conclusion: The LLND rate for UC-related rectal cancer was 23% in patients with T3-4 cancer in Japan. The LLNM-positive group had more advanced disease, more por/sig/muc histology, and showed poor prognostic outcomes even after LLND.

Disclosure: Nothing to disclose.

Introduction: Crohn's disease (CD) complicated with intra-abdominal abscess often requires surgical intervention. Image guided percutaneous drainage (PD) can help to avoid surgical interventions, however there is limited evidence on the optimal management after PD.

Aims & Methods: Our study aimed to analyze the long-term outcomes of CD complicated with intra-abdominal abscess after intervention. In this multicenter, interational retrospective trial penetrating CD patients with simplex intra-abdominal abscess were enrolled and followed until 12-24 months. Baseline was the day of the first detection of abdominal abscess. Patients with urgent resection were excluded. Patients were grouped based on elective surgical need during follow-up after a successful PD, while the control group consisted of patients who underwent resection without PD.

Primary outcome was the abscess recurrence, while stoma rate, post procedural complications rate (<30 days), need for re-drainage and postoperative luminal recurrence were analyzed as secondary outcomes.

Results: A total of 151 CD patients from 9 countries were recruited and 86/151 patients had PD due to simplex abdominal abscess (Table 1.). Abscess recurrence rates were similar (12.8% vs. 7.7%, p=0.231). Need for re-drainage was more common amongst PD patients (OR=0.088, 95% CI=0.011-0.682), while hospital admission need was more frequent in control patients (OR=2.56, 95% CI=1.22-5.37).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Postoperative luminal recurrence, new stoma, and biological treatment escalation needs were similar between groups based on PD. Surgical complications were coupled with increased odds in patients without prior PD (OR=3.3, 95% CI=1.09-10.0), septic complications, perforation and new fistula formation were reported the most, while PD associated complication did not occur. Higher baseline diameter of the abscess increased the odds for postoperative recurrence (OR=1.05, 95% CI=1.02-1.08) and new biological treatment initiation (OR=0.98, 95% CI=0.96-0.98). Elective resection was delayed after PD compared to control (24 vs 10 week, p=0.003). Time until resection increased the odds for redrainage (OR=1.03, 95% CI 1.01-1.05), and outcome was worse exceeding 17 weeks.

Variables	Total (n = 151)	PD group (n = 86)	Control group (n = 65)	Sig.
FU duration, weeks, median (IQR)	103 (71-109)	104 (64-112)	101 (77-105)	0.895
Sex, male (%)	88 (58.3)	49 (57.0)	39 (60.0)	0.419
Age at inclusion, years, median (IQR)	33.0 (26-44)	36.3 (27-46)	30.2 (25-38)	0.006
CD disease duration at inclusion, years, median (IQR)	11 (6-17)	11 (5-18)	11 (7-17)	0.916
Disease activity at baseline				
CDAI, mean (± SD)	302 (109)	290 (126)	307 (115)	0.389
CRP, mg/l, mean (±SD)	92 (57)	112 (88)	107 (80)	0.753
SES-CD, mean (±SD)	10.0 (8.1)	7.1 (5.8)	12.0 (9.0)	0.071
Elective resection during FU, n (%)	126 (83.4)	61 (70.9)	65 (100)	-

Conclusion: The size of the abscess determines the outcomes, while surgical treatment alone may be associated with post-procedural complications. PD may delay resection; however, this delay can necessitate re-drainage.

Disclosure: Nothing to disclose.

PP0583

END-TO-END VS. LATEROLATERAL ANASTOMOSIS IN ILEOCAECAL RESECTION FOR CROHN'S DISEASE: AN OUTDATED TECHNIQUE OR A VALID OPTION?

H. Benazzouz[1], N. Lagdali[1], M. Kadiri[1], F.-Z. Chabib[1], M. Borahma[1], F.Z. Ajana[1], H. Sekkat[2], M. El Alaoui Mhamdi[2], F. Sabbah[2], M. Raiss[2], Y. Bakali[2], A. Hrora[2]

Introduction: Ileocolic resection is the most common intestinal surgery performed in patients with Crohn's disease (CD). Despite advances in both surgical techniques and medical therapy, postoperative recurrence remains frequent. Various anastomotic techniques differing in configuration and construction have been proposed to reduce recurrence and postoperative complications.

In this study, we aimed to compare laterolateral and end-to-end anastomoses in terms of surgical and medical outcomes following ileocaecal resection in patients with Crohn's disease.

Aims & Methods: This retrospective study included patients with Crohn's disease who underwent ileocaecal resection. Patients were divided into two groups based on the type of anastomosis: laterolateral or end-to-end. Clinical, surgical, and postoperative variables were collected and compared. Categorical variables were analyzed using the Chi-square test, while continuous variables were compared using the Student t-test. Endoscopic recurrence was assessed at 6 months using the Rutgeerts score. Univariate and multivariate logistic regression analyses were performed to identify factors associated with endoscopic recurrence.

Results: Among 1,210 patients followed for Crohn's disease, 221(18.26%) underwent ileocaecal resection. The mean age was 31 ± 12 years, and the female-to-male ratio was 1.24. Tobacco use was reported in 52(23.5%) patients, and a history of appendectomy was noted in 46(20.8%) patients. The inflammatory phenotype (B1) was present in 46(20.9%) patients, the stricturing phenotype (B2) in 95 (43.1%) patients, the penetrating phenotype (B3) in 49 (22.2%) patients, and a combined stricturing and penetrating phenotype in 30(13.7%) patients. Perianal lesions were observed in 67(30.6%) patients.

Corticosteroid use within 4 weeks prior to surgery was reported in 67(30.6%) patients. Use of 5-aminosalicylates was noted in 40(18.2%) patients, immunosuppressants in 74(33.7%) patients, and anti-TNF agents in 50(22.6%) patients.

A total of 136(61.8%) patients underwent ileocaecal resection with a laterolateral anastomosis, while 85(38.2%) received a manual end-to-end anastomosis. The median duration of surgery was 170[120;180] minutes. Ileostomy was performed in 12 (5.4%) patients, while 94.6% underwent immediate restoration of bowel continuity. Postoperatively, 22(10%) patients showed elevated CRP and white blood cell counts, and 19(8.6%) had a Clavien-Dindo score>1.Surgical reintervention was required in 30(13.5%) cases. Clinical recurrence was observed in 38(17.4%) patients, and 60(27%) were initiated on biologic therapy.At 6 months, all patients underwent colonoscopy: 52(23.6%) had Rutgeerts score i0,21(9.7%) had i1, 76(34.7%) had i2, 36(16.6%) had i3, and 33(15.2%) had i4.

When comparing the laterolateral and end-to-end anastomosis groups, statistically significant differences were observed in several parameters: age (38.5vs42 years,p=0.039), duration of surgery>3 hours (4.4%vs9.4%,p<0.001), use of ileostomy (5.8%vs.8.2%,p=0.004), need for surgical reintervention (2.2%vs8.2%,p<0.001), and the presence of a Rutgeerts score ≥ i1 (30.4%vs59.9%,p=0.002). No statistically significant differences were found between the two groups regarding sex, Clavien-Dindo score, or clinical recurrence.

In univariate and multivariate analysis, after adjustment for sex, smoking status, presence of perianal lesions, duration of surgery, restoration of bowel continuity, and postoperative complications,the use of end-to-end anastomosis was associated with an increased risk of endoscopic recurrence (OR = 2.94,95%CI[1.58–25.25],p=0.009).

	Laterolateral anastomosis (N=136)	End-to-end anastomosis (N=85)	p
Sex Men Women	 74(54.8%) 82(60.6%)	 39(45.2%) 33(39.4%)	0.441
Age	38.5±13.8	42±14.5	0.039
Long duration of surgery (>3h)	6(4.4%)	8(9.4%)	<0.001
Ileostomy	8(5.8%)	7(8.2%)	0.004
Clavien-Dindo > 1	7(5.1%)	9(10.5%)	0.115
Surgical reintervention	3(2.2%)	7(8.2%)	<0.001
Clinical recurrence	15(11.02%)	8(9.4%)	0.468
Rutgeerts score ≥ i1	41(30.4%)	50(59.6%)	0.468

Conclusion: The choice of anastomotic technique significantly influences postoperative outcomes in Crohn's disease surgery. In our study, End-to-end anastomosis was associated with longer operative time,higher rates of reintervention, and increased endoscopic recurrence compared to the laterolateral technique. Laterolateral anastomosis offers better postoperative outcomes in ileocaecal resection for Crohn's disease

Disclosure: Nothing to disclose.

Introduction: Surgical management of hemorrhoidal disease (HD) in patients with inflammatory bowel disease (IBD) remains controversial due to concerns about impaired wound healing and disease flare, especially in Crohn's disease (CD). In Europe, current evidence is mainly based on small historical single-center case series.[1]

Aims & Methods: We sought to evaluate the safety and effectiveness of surgical treatments for HD in IBD patients and identify potential risk factors for complications. HEAD-IBD is a retrospective cohort study promoted by the Italian Group for the study of Inflammatory Bowel Disease (IG-IBD) and the Italian Society of Colorectal Surgery (SICCR). Patients with established IBD who underwent surgery for HD between December 2004 and March 2024 were included. Data were collected across multiple centres using the REDCap system. IBD activity was measured by the Harvey-Bradshaw Index for CD and the partial Mayo score for ulcerative colitis (UC). Surgical techniques, short- and long-term complications, disease flare, and continence status were analyzed. Only patients with ≥1 year follow-up were considered.

Results: A total of 38 patients were initially identified from 8 centres. Two patients with unclassified IBD were excluded from stratified analysis, leaving 36 patients (Table 1): 21 (58%) with UC and 15 (42%) with CD. Overall, 53% were male. The median age at surgery was 49 years (IQR 13) in UC and 37 years (IQR 22) in CD. At the time of surgery, biologic therapy was ongoing in 10% of UC and 40% of CD patients. Clinically active disease at the last gastroenterology visit was reported in 6 CD patients (40%) and 5 UC patients (24%). The time interval between the last IBD evaluation (clinical or endoscopic) and surgery was significantly longer in UC compared to CD patients (Table 1).

Distribution of Goligher grade suggested a higher proportion of grade III–IV disease in UC (72%) than in CD (53%). Open hemorrhoidectomy was the most frequent procedure in both groups (66% UC, 73% CD). Non-excisional techniques (DG-HAL +/- mucopexy) were used in 29% of UC and 27% of CD patients. Stapled hemorrhoidopexy was performed only in UC (10%). Median hospital stay was 1 day (IQR 1) in both groups. No 30-day or 6-month postoperative complications were reported in CD, while 14% of UC patients experienced early or mid-term complications. One UC patient experienced IBD flare at 6 months. At 12-month follow-up, one UC patient reported new-onset soiling; continence was otherwise preserved in all cases.

	Crohn's disease (n=15)	Ulcerative colitis (n=21)
Female, n (%)	8 (53)	9 (43)
Age (years), median (IQR)	37 (22)	49 (13)
Perianal disease, n (%)	3 (20)	0
Therapy at time of surgery	12 (80)	20 (95)
Topic therapy	1 (7)	8 (38)
Oral mesalazine/sulphasalazine	5 (33)	15 (71)
Steroids	3 (20)	1 (5)
Immunosuppressors	1 (7)	1 (5)
Biologics	6 (40)	2 (10)
Time interval between IBD evaulation and surgery		
Clinical	81 (188)	192 (330)
Endoscopic	150 (367)	375 (599)
Clinically active IBD at last GI visit before surgery, n (%)	6 (40)	5 (24)
Goligher grade, n (%)		
I	3 (20)	1 (5)
II	2 (13)	4 (19)
III	6 (40)	6 (29)
IV	2 (13)	9 (43)
Not available	2 (13)	1 (5)
Procedure		
Open hemorrhoidectomy	11 (73)	14 (66)
Closed hemorrhoidectomy	0	1 (5)
Doppler-guided dearterialization (DG-HAL)	1 (7)	0
DG-HAL and mucopexy	2 (13)	2 (10)
Mucopexy	1 (7)	2 (10)
Stapled hemorrhoidopexy	0	2 (10)
Complications		
30-day	0	3 (14)
6-month	0	3 (14)
12-month	0	1 (5)

Conclusion: This multicenter study represents the largest European series on surgical treatment of HD in patients with IBD, confirming its safety, with low complication rates and no new perianal disease. Short- and mid-term complications occurred only in UC patients, possibly reflecting both more advanced HD (Goligher grade III–IV) and less intensive preoperative monitoring. These findings highlight the need for close gastroenterological pre-operative assessment and shared decision-making. The ongoing HEAD-IBD II prospective study will provide further insight into optimal management strategies.

Introduction: Intestinal resection is often required in Crohn's Disease (CD), yet postoperative recurrence remains a major clinical challenge. This study aimed to assess the rate of CD recurrence within 2 years following intestinal resection and to identify associated predictive factors.

Aims & Methods: Intestinal resection is often required in Crohn's Disease (CD), yet postoperative recurrence remains a major clinical challenge. This study aimed to assess the rate of CD recurrence within 2 years following intestinal resection and to identify associated predictive factors.

Results: Seventy-six patients were included, with a mean age of 31.7 ± 13.3 years; 51.3% were female. The mean disease duration was 10.0 ± 9.1 years, with 9.2% undergoing surgery at diagnosis. Disease location was ileocolic (46.1%), ileal (44.7%), and colonic (9.2%), with a predominance of penetrating phenotype.

Approximately 38% had perianal disease, and 22.4% were smokers. Most surgeries were elective (72.4%) and involved small bowel resection, with a mean length of 25.2 ± 19.4 cm. Following surgery, 50% of previously untreated patients initiated therapy, while 11.3% discontinued prior medication.

Clinical recurrence occurred in 30% of cases, of which 39.1% were early. Surgical recurrence was observed in 11.0% of patients, with 37.5% occurring early. Microscopic inflammatory activity at the resection margins—despite macroscopically normal margins—was associated with clinical (p=0.04; OR=1.3; 95% CI: 1.0–14.7) and surgical recurrence (p=0.03; OR=1.8; 95% CI: 1.1–36.2) at two years

Conclusion: This study underscores the clinical relevance of postoperative recurrence in CD and identifies microscopic inflammatory activity at resection margins as an independent predictive factor for both clinical and surgical recurrence at 2 years.

These findings highlight the importance of histopathological assessment of resected specimens and the need for early strategies to prevent recurrence in high-risk patients.

Disclosure: Nothing to disclose.

POSTOPERATIVE COMPLICATIONS FOLLOWING INTESTINAL RESECTION IN CROHN'S DISEASE: A MULTICENTER STUDY

M. Teixeira[1], S. Ramos Lopes[1], D. Tomás[1], A. Bastos[1], D. Simas[2], I. Caetano[2], M. Ferreira[2], R. Oliveira[3], M. Pestana[4], C. Sequeira[1], C. Teixeira[1], A.L. Alves[1]

Introduction: Complicated Crohn's Disease (CD) frequently requires intestinal resection (IR) for disease control. However, postoperative complications remain particularly prevalent in this population.

Aims & Methods: The aim of this study was to characterize patients with CD undergoing IR, assess 30-day postoperative complications, readmission and reoperation rates, and identify factors associated with these adverse outcomes.

Results: A total of 76 patients were included, with a mean age of 31.7 ± 13.3 years; 51.3% were female. Fewer than 20% had comorbidities, and 22.4% were smokers. Disease duration at the time of surgery was 10.0 ± 9.1 years. CD location was ileocolic (46.1%), ileal (44.7%), and colonic (9.2%), with a predominantly penetrating phenotype (57.8%). At the time of surgery, 26.3% of patients were on corticosteroids and 63.2% on biologic therapy, of whom 75% were receiving anti-TNF agents.

Most procedures were elective (72.4%), 48.7% were laparoscopic, and 80.3% included a primary anastomosis. Small bowel resection was performed in the majority of cases, with a mean length of 25.2 ± 19.4 cm. In 77.8% of surgical specimens, resection margins showed no inflammatory activity. Enteral feeding was resumed at 2.7 ± 1.8 days, and mean hospital stay was 12.3 ± 9.8 days.

Within 30 days postoperatively, 38.7% of patients experienced complications, 4.0% were readmitted, and 12.0% underwent a second IR. No mortality was reported. The presence of granulomas (p = 0.047), elevated preoperative CRP (p = 0.019), and delayed initiation of enteral feeding (p = 0.018) were associated with complications, with CRP identified as an independent predictor (p = 0.049, OR = 1.307). Longer disease duration (p = 0.009), more extensive small bowel resections (p = 0.016), and anti-TNF therapy (p = 0.010) were associated with infectious complications. Stoma creation was linked to readmission (p < 0.001), while COPD (p < 0.001), diabetes (p = 0.049), and absence of biologic therapy (p = 0.034) were associated with a second IR within 30 days.

Conclusion: The high rate of postoperative complications among CD patients undergoing IR underscores the need for dedicated research and a tailored multidisciplinary approach. The presence of granulomas, elevated preoperative CRP, longer disease duration, and lack of prior biologic therapy were all associated with adverse outcomes.

Introduction: Despite optimal medical therapy, patients with ulcerative colitis (UC) may still require surgical intervention. Biologics and other immunotherapies are widely used in the management of UC and have been associated with a range of reported complications. This network meta-analysis aims to evaluate post-operative outcomes associated with prior biologic and immunotherapy use in patients with UC undergoing colon surgery.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Aims & Methods: On March 8, 2025, a database search was conducted using PubMed. We included studies that evaluated postoperative outcomes in patients with ulcerative colitis (UC) who had prior exposure to biologic therapy and subsequently underwent colon surgery. The outcomes assessed were overall postoperative complications and postoperative infections, both measured within 30 days. Effect sizes were calculated as odds ratios (ORs) with 95% confidence intervals (CIs) using a random-effects model. All analyses were performed using RStudio with the *netmeta* package.

Results: Out of 2,759 articles screened, only 14 retrospective studies were eligible, comprising a total of 2,679 patients. The analysis included ustekinumab, tofacitinib, vedolizumab, and anti-TNF agents, each compared to a control group. For overall postoperative complications, both ustekinumab (OR: 0.18; 95% CI: 0.05–0.68) and tofacitinib (OR: 0.47; 95% CI: 0.28–0.78) were associated with a significantly lower risk compared to anti-TNF agents. Similarly, when compared to the control group, ustekinumab (OR: 0.20; 95% CI: 0.05–0.76) and tofacitinib (OR: 0.52; 95% CI: 0.30–0.90) also showed significantly lower complication rates. Vedolizumab was associated with a significantly lower risk of complications compared to anti-TNF agents (OR: 0.65; 95% CI: 0.43–0.98); however, no significant differences were observed when compared to the control group.In terms of postoperative infections, no significant differences were observed among ustekinumab, tofacitinib, vedolizumab, anti-TNF agents, and the control.

Conclusion: In patients with ulcerative colitis undergoing colorectal surgery, prior exposure to ustekinumab, tofacitinib, and vedolizumab was associated with a lower risk of overall postoperative complications compared to anti-TNF therapy. For postoperative infection, no significant differences were observed across all treatment groups.

Introduction: Inflammatory bowel diseases (IBD) carry a high risk of complications if not diagnosed promptly and are often misdiagnosed as irritable bowel syndrome (IBS). Delayed IBD detection leads to an increase in complicated cases and missed opportunities for timely therapy initiation.

Aims & Methods: The study aimed to develop an AI-based clinical decision support system (CDSS) for IBD diagnosis.

We created three databases, containing clinical-laboratory data, endoscopic and histopathological images. Patients enrolled from 2014 to 2024 included those with confirmed IBD (ulcerative colitis (UC) and Crohn's disease (CD) with colonic involvement) during flare-ups and IBS with normal endoscopic and histopathological findings.

Separate artificial neural networks were designed for IBD differentiation: multilayer perceptrons (MLPs) for clinical-laboratory data analysis and a pre-trained VGG16 convolutional neural network (CNN) for digital image analysis (initialized with ImageNet weights).

Results: A retrospective database of 1,406 patients with clinical and laboratory data was compiled. For IBD vs. IBS differentiation, the cohort was reduced to 390 patients that had all the fulfilled data, while UC vs. CD analysis included 964 patients.

An MLP (13:13-5-1:1) achieved 92.7% and 99.0% accuracy in IBD diagnosis, incorporating stool frequency/consistency, absence of extraintestinal/perianal manifestations, functional disorders, family history of autoimmune diseases, prior surgeries, CRP, and fecal calprotectin ($p \leq 0.019$).

Another MLP (9:9-8-1:1) detected 70.16% of CD and 86.40% of UC cases, using data on constipation, diarrhea, bloody stools, absence of extraintestinal manifestations, fever, perianal lesions, strictures, and prior bowel surgeries ($p<0.001$).

The endoscopic database comprised 5,693 JPEG images: 3,400 of normal mucosa, 1,357 - CD, 935 - UC. Model sensitivity and specificity were for CD - 91%/79%; UC - 90%/97%; normal - 90%/97%.

The histopathological dataset included 398 whole-slide images (1280×960 px), segmented into 224×224 px tiles. The final set included 8,620 images: 2,360 - CD, 2,320 – normal mucosa, 3,950 - UC. Sensitivity and specificity were for CD - 91% and 95%, UC - 96%, 95%, normal - 96%, 93%, respectively.

The integrated clinical DSS was constructed using Bayesian belief networks implemented in Hugin Lite 8.3 software and integrated clinical, endoscopic, and histopathological nodes. The network architecture replicated the stepwise diagnostic process and incorporated the following nodes: clinical and laboratory data, endoscopy (IBD/IBS differentiation), histopathology (IBD/IBS differentiation), IBS, IBD, endoscopy (UC/CD diagnosis), histopathology (UC/CD discrimination), final diagnosis. The system was validated using six patients per diagnostic category (IBS, UC, CD), with complete sets of clinical, endoscopic, and histopathological data required for all component models. The integrated model demonstrated an overall diagnostic accuracy of 83.3%.

Conclusion: The developed CDSS shows promise for earlier IBD detection but requires further validation studies.

ENHANCEMENT OF SENNOSIDES AVAILABILITY IN CHRONIC CONSTIPATION VIA CO-ADMINISTRATION WITH MESALAZINE

Y. Hara[1], R. Kawashima[2], S. Tamaki[2], T. Maekawa[2], T. Ichikawa[2], C. Kusano[1]
[1]Kitasato University Graduate School of Medical Sciences, Department of Gastroenterology, Sagamihara, Japan, [2]Kitasato University Graduate School of Medical Sciences, Department of Regulation Biochemistry, Sagamihara, Japan

Introduction: Chronic constipation leads to an increased risk of heart disease, stroke, and kidney disease[1]. Stimulant laxatives provide quick relief and are preferred by patients and pharmaceutical companies; "sennosides" and "bisacodyl," are more popular compared with bulk-forming laxatives[2].

However, with prolonged use, the human body becomes habituated to them. The laxatives induce prostaglandin production[3] through immune cell aggregation and local cytokine expression[4].

Thus, prolonged use of stimulant laxatives leads to inflammation and damages the intestinal nervous plexus, leading to intestinal exhaustion[5].

Mesalazine can remove reactive oxygen and inhibit the biosynthesis of cytokines including interleukin (IL)-1β and leukotrieneB4, and hence, is used for treating inflammatory bowel disease[6].

Concurrent intake of mesalazine and stimulant laxatives might suppress leukotriene and the subsequent adverse inflammatory responses, thus allowing the safe and long-term use of sennosides.

Herein, we observed stool characteristics of animal models and performed pathological analyses of their colon tissue to establish the stable use of mesalazine-adapted stimulant laxatives. Lamina propria mononuclear cells (LPMCs) of the colon were then collected for flow cytometry analysis (FACS) and real-time polymerase chain reaction (PCR).

Aims & Methods: Six-week-old BALB/cAJcl mice were assigned to one of the four groups: control, mesalazine (100 mg/kg), sennosides (4.8 mg/kg), or mesalazine and sennosides combination groups, (n = 8 for each group). Each drug was suspended in 0.5% carboxymethylcellulose (CMC). Doses were administered orally once daily for 21 days. Stool samples were collected on days 0, 7, 14, and 21; looseness and weight of each stool sample were measured. Feces were then freeze-dried and weighed to calculate the water content percentage.

Mice were euthanized after 21 days, and their colons were harvested. Inflammatory cell aggregation was detected on pathological evaluation, which was performed via H&E staining. Composition of the aggregated LPMCs was evaluated via FACS. Real-time PCR was performed to detect cytokine mRNA expression in LPMCs.

Results: No differences in food intake, water consumption, and body weight were observed among the groups during the experimental period. On day 21, the sennosides group exhibited significantly greater stool looseness compared with the control group. Stool looseness was similar in the sennosides and combination groups. Water content percentage in the stool was significantly higher in the sennosides group compared with in the control group, and this increase was not influenced by the addition of mesalazine. Inflammatory cell aggregation was detected in sennosides and combination groups. A drastic increase in the level of killer T cells was revealed in the sennosides group on FACS, and mesalazine administration resulted in restoration to normal composition. Regarding mRNA expression, IL-1β, IL-2, and IFN-γ levels were elevated in the sennosides group, which was alleviated by mesalazine co-administration.

Conclusion: Sennosides is predicted to provoke IL-2 and IFN-γ biosynthesis that induces killer T cell aggregation and subsequent IL-1β production. As the combination group did not show any inflammation, it is assumed that mesalazine prohibits the inflammatory process. These results provide further evidence to indicate that mesalazine can alleviate sennosides-induced inflammation without adversely affecting its efficacy. This finding may promote the effective use of laxatives in patients with chronic constipation.

Introduction: Intestinal biofilms are microbiological colonies that colonize biotic and abiotic interfaces, occurring in various adult diseases like IBD, IBS, and CRC.

Aims & Methods: This study investigates the occurrence and characteristics of visible biofilms in the colon of paediatric patients across different disease groups undergoing colonoscopy, aiming to record frequency, location, extent, and adherence in relation to diagnoses and intestinal sections. The prospective, multicentre observational study included 157 paediatric patients undergoing ileocolonoscopy for diagnostic purposes. The presence, extent, and adherence of visible biofilms were documented using high-resolution white light endoscopy. Biofilms, defined as yellow-greenish adherent layers, were classified by extent (small, medium, large) and adherence (weak, medium, strong), then subdivided by diagnostic categories and colonic segments. 43 endoscopies with a Boston Bowel Preparation Score (BBPS) <6 were excluded. Individual diseases that could not be assigned to these patient groups accounted for 7% (n=8).

Results: Biofilms were found in 86.7% of patients with systemic disease and normal colonoscopy, 84.6% with ulcerative colitis, 72.7% with Crohn's disease, 85.7% with IBS, and 87.5% with colorectal polyps. There was a

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

decreasing trend in extent and adherence from proximal to distal bowel segments across all groups. The caecum had the highest adherence and extent in all groups, while the rectum had the lowest. No significant differences in biofilm occurrence and characteristics between disease groups were observed. However, biofilms were significantly more common in proximal bowel segments (ileum, caecum, ascending colon).

Biofilm in …	Systemic disease, normal colonoscopy (n=15)	Ulcerative Colitis (n=26)	Crohn's Disease (n=22)	IBS – normal colonoscopy (n=35)	Polyps (n=8)
Ileum	9 (60%)	17 (65,4%)	12 (54,5%)	12 (34,3%)	5 (62,5%)
Cecum	12 (80%)	18 (69,2%)	14 (63,6%)	29 (82,9%)	6 (75%)
Ascending colon	10 (66,7%)	13 (50%)	14 (63,6%)	23 (65,7%)	3 (37,5%)
Transverse colon	9 (60%)	9 (34,6%)	11 (50%)	15 (42,9%)	3 (37,5%)
Descending colon	6 (40%)	9 (34,6%)	7 (31,8%)	6 (17,1%)	0 (0%)
Sigmoid colon	6 (40%)	5 (19,2%)	3 (13,6%)	3 (8,6%)	0 (0%)
Rectum	3 (20%)	2 (7,7%)	0 (0%)	1 (2,9%)	0 (0%)

Conclusion: Macroscopically visible biofilms are frequently detected in paediatric patients across various diagnoses, showing a predilection for proximal bowel segments. Particularly, patients with IBD, systemic diseases, and IBS are predisposed to biofilms, supporting the hypothesis that biofilms play a pathophysiological role in gastrointestinal diseases. These findings highlight the need for systematic investigation of biofilms in paediatric GI disease diagnosis and treatment.

Introduction: Chronic intestinal inflammation, increased permeability, and dysbiosis are hallmark features of cystic fibrosis (CF), yet the molecular underpinnings of gut barrier dysfunction in people with CF (pwCF) remain incompletely understood.

Aims & Methods: This study aimed to characterize epithelial markers of intestinal permeability using both immortalized and primary human intestinal epithelial cell models, with and without functional CFTR. A secondary objective was to investigate the impact of inflammatory stimuli on barrier integrity and explore lipid-based strategies for restoring epithelial function in CF. Caco-2 cells (~5000/well) were cultured in 96-well transwells (Corning) for 4 weeks to develop confluent monolayers. Healthy primary human colonic epithelial and endothelial cells (Emulate Inc.) were cultured in a microfluidic colon-on-a-chip system simulating peristalsis and blood flow. CF models were generated by CFTR gene knockdown via liposomal siRNA transfection, validated by RT-qPCR and western blotting.

Epithelial permeability was assessed by transepithelial electrical resistance (TEER) and FITC-dextran flux at 48-, 72-, and 96-h post-treatment. Cells were fixed and stained for DAPI, ZO-1, and VE-cadherin, then analyzed by confocal microscopy.

To assess cytoprotection, Caco-2 monolayers were pretreated with phosphatidylinositol (PI) lipids PI(16:0/18:1(9Z), PI(18:0/20:4), and LPI(20:4/0:0) (Avanti Polar Lipid and Sigma-Aldrich, 10 µM, 15 min), followed by exposure to a panel of toxins (*C. difficile* TcdA/B, *Pseudomonas* exotoxin A, *Staphylococcus aureus* delta-toxin) and the chemical inflammatory agent DSS (dextran sulfate sodium) for 24 h. Experiments were performed in triplicate.

Results: CFTR knockdown in Caco-2 cells (siCFTR) significantly reduced TEER compared to non-targeting controls ($p < 0.05$, $n = 3$), indicating increased epithelial permeability. This disruption was dramatically exacerbated following exposure to *C. difficile* toxins A and B (50 pg/mL), which caused a profound TEER decline ($p < 0.0001$). Immunofluorescence imaging revealed mislocalization and downregulation of ZO-1 in siCFTR cells. In the colon-on-a-chip model, CFTR depletion also disrupted ZO-1 and VE-cadherin architecture in both epithelial and endothelial layers, confirming widespread junctional compromise.

Among the tested lipid metabolites, PI (18:0/20:4) significantly preserved barrier function, by reducing FITC-dextran flux at 48 h following DSS exposure ($p < 0.001$) and against *C. difficil*e toxins A/B and *S. aureus* delta-toxin at 96 h ($p < 0.0001$). Other lipids showed no significant cytoprotective effects under these conditions, suggesting a metabolic-specific and time-dependent cytoprotective effect. TEER and cytokine assays are underway.

Conclusion: Loss of CFTR function leads to impaired epithelial barrier integrity in both immortalized and primary CF gut models, with pronounced vulnerability to microbial toxins and proinflammatory stimuli. Junctional protein disruption (ZO-1, VE-cadherin) appears central to this phenotype. Notably, PI (18:0/20:4) emerged as a promising cytoprotective agent capable of restoring epithelial resistance.

Importantly, PI and its derivatives are essential for cell membrane structure, intracellular signalling, and cytoskeletal dynamics. Ongoing studies will expand screening of anti-inflammatory and barrier-stabilizing therapeutics and leverage these platforms to develop patient-specific "gut avatars" for personalized therapeutic testing in CF.

PATIENT CARE DURING ADMISSION WITH IMMUNE CHECKPOINT INHIBITOR (ICI) RELATED COLITIS

V. Sivanathan[1,2], C. John Kiely[2], S. Nario[2]
[1]University of Sydney, Department of Medicine, Sydney, Australia, [2]Royal North Shore Hospital, Sydney, Australia

Contact E-Mail Address: vithoo.sivanathan@gmail.com

Introduction: Immune checkpoint inhibitor (ICI)-related colitis is a recognised adverse event associated with this groundbreaking oncological therapy. It affects approximately 20–50% of patients receiving ICIs and may be associated with significant morbidity. Corticosteroids remain the cornerstone of treatment, with prompt escalation to biologic therapies required in more severe cases.

Aims & Methods: The aim of this study is to present the clinical and endoscopic findings of all ICI related colitis patients requiring admission. All presentations with ICI-related colitis to a quaternary Sydney hospital over a 5 year period (July 2019 to June 2024) were included. Clinical, laboratory, endoscopic and histologic data were extracted through chart review of the admission and the 6 months following.

Results: A total of 59 patients were admitted for the management of ICI-related colitis. The cohort comprised 42 males (71.2%) with a median age of 71 years (IQR 55.5–76.5). Melanoma was the most common malignancy (76.3%, n=45), with the majority (86.4%, n=51) presenting with metastatic disease and preserved premorbid functional status (ECOG 0 in 42.4%, n=25; ECOG 1 in 35.6%, n=21). The median time from initial ICI exposure to hospital admission for colitis symptoms was 4 months (IQR 2–11). The median length of stay was 7 days (IQR 5–15.5).

All patients presented with diarrhoea (100%, n=59), while abdominal pain and fever were reported in 37.3% (n=22) and 18.6% (n=11) respectively. Most patients experienced diarrhoea graded as either Grade 2 (44.6%, n=26) or Grade 3 (39.0%, n=23) according to the Common Terminology Criteria for Adverse Events. Stool microscopy was conducted in 93.2% of patients (n=55), while testing for *Clostridium difficile* was performed in 83.1% (n=49). Faecal calprotectin was measured in 72.9% (n=43), with 83.7% (n=36) of these patients recording levels greater than 100.

All patients underwent either sigmoidoscopy (96.6%, n=57) and/or colonoscopy (5.1%, n=3), with procedures performed at a median of 3 days post-admission (IQR 2–4). Endoscopic evidence of active colitis was observed in 71.2% (n=41), with histological confirmation in 74.6% (n=44). Ulcerations were identified in 8.5% (n=5). Corticosteroids were administered to the majority of patients (94.9%, n=56), with intravenous delivery used in 72.9% (n=43). 8.5% (n=5) patients received antibiotics for a concurrent infection.

Second-line immunosuppressive therapy was required in 44.1% (n=26), most commonly infliximab (80.8%, n=21), followed by cyclosporin (23.1%, n=6) and vedolizumab (15.4%, n=4). Infliximab was initiated at a median of 5 days following admission (IQR 3–8). Immune checkpoint inhibitor was frequently discontinued either prior to admission (18.6%, n=11) or during the hospital stay (32.2%, n=19). Readmission within six months occurred in 10.2% (n=6) of patients, and 13.6% (n=8) were transitioned to best supportive care during or after their hospital stay.

Conclusion: ICI-related colitis led to significant adverse events, typically emerging around four months after initial ICI exposure. The use of second-line immunosuppression was common, with infliximab being the most frequently administered agent. This complication resulted in treatment cessation for many patients; however, rates of readmission for recurrent symptoms were low.

EXPLORATORY ANALYSIS INDICATES THAT CHANGES IN STOOL SHORT-CHAIN AND BRANCHED-CHAIN FATTY ACIDS LEVELS MAY SERVE AS OBJECTIVE MARKER OF SUCCESSFUL DIETARY INTERVENTION OF IRRITABLE BOWEL SYNDROME SYMPTOMS

A. Kasti[1], D.E. Pavlidis[2], K. Katsas[1], M. Nikolaki[1], K. Papadimitriou[3], J. Kapolos[2], K. Triantafyllou[4]
[1]Attikon General University Hospital, Nutrition And Dietetics, Athens, Greece, [2]University of Peloponnese, Kalamata, Greece, [3]Agricultural University of Athens, Athens, Greece, [4]Attikon University General Hospital, 2nd Dept of Internal Medicine-Propaedeutic, Athens, Greece

Introduction: Biomarkers, like stool short-chain fatty acids (SCFA), metabolites by fermented nondigestible carbohydrates and branched-chain fatty acids (BCFA) derived from the metabolism of essential amino acids may allow for objective measurements of IBS biological changes without self-reporting bias. Diets low in FODMAP significantly reduce the abnormal fecal total SCFA in IBS patients, indicating that the diet normalizes the IBS patients' abnormal fecal SCFA output.

Aims & Methods: By conducting an exploratory analysis, we aimed to measure stool SCFAs/BCFAs level changes in a subgroup of subjects enrolled in an RCT evaluating the efficacy of a Mediterranean version of the Low-FODMAPS diet (MED-LFD) compared to the nutritional recommendations of the British National Institute for Health and Care Excellence (NICE) for managing non-constipation IBS.

A subset of 40 (23 MED-LFD & 17 NICE) patients provided stool samples at 3 time points: Before dietary intervention, at the 1st (4 weeks after initiation of intervention for NICE and at the end of phase 2 for MED-LFD), and the 2nd folow-up (FU), 6 months after intervention initiation. We measured symptoms severity using IBS-SSS. Table 1 shows the detailed measurement of the consumed FODMAPs per day assessed using a triple-pass 24-hour dietary recall twice at the two FUs.

	1st Follow-up			2nd Follow-up		
FODMAPs, M(IQR)	MED-LFD (N=20)	NICE (N=17)	p	MED-LFD (N=19)	NICE (N=15)	p

Table 1.

SCFAs/BCFAs were extracted from frozen samples and analyzed using Gas Chromatography/Mass Spectrometry. SCFAs and BCFAs levels were measured in umol/g of stool. A paired/unpaired t-test was performed to illustrate the organic acid changes among and within two groups. In multiple groups comparison, significant differences between means were examined using one-way analysis of variance. A polynomial regression model was used to describe the relation between BCFAs/SCFAs levels change with IBS-SSS change from baseline at the 1st FU.

Results: We detected a significant reduction in the concentrations of total SCFAs and BCFAs in the MED-LFD (-21.4±20 and -0.429±0.882) and the NICE (-9.9±17.7 and -0.819±0.933) groups, respectively, at the 1st FU. At the 2nd FU, similar reductions from the baseline concentration levels were

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

detected in both intervention groups (total SCFAs: -20.2±18.7 in MED-LFD vs. -10.9±7.4 in NICE; total BCFAs: -0.494±0.806 in MED-LFD vs. -0.76±0.83 in NICE). A polynomial association was observed between the changes in IBS-SSS scores and the changes in stool concentrations of BCFAs and SCFAs from baseline to the 1st FU.

Specifically, there was a slight upward trend in the difference of BCFA levels, indicating that a decrease in IBS-SSS scores is associated with a reduction in BCFA levels during the 1st follow-up. This trend peaked around an IBS-SSS change of minus 50 points, the cut-off value for clinical response. Beyond this point, this association slightly declines. A similar trend was noted for SCFA level changes, with the peak occurring around an IBS-SSS change of minus 100 points, after which the association diminishes.

Conclusion: SCFA/BCFA stool levels changes from baseline might be an objective measure of successful dietary intervention for IBS

ANTISPASMODIC IMPACT OF AN HERBAL PREPARATION ON SMALL INTESTINE: PROMISING THERAPEUTIC BENEFITS FOR PATIENTS WITH IRRITABLE BOWEL SYNDROME

M.-R. Piqué-Borràs[1], J. Röhrl[1], M. Mennet-von Eiff[1], G. Künstle[1]
[1]Weleda AG, Arlesheim, Switzerland

Contact E-Mail Address: mpiqueborras@weleda.ch

Introduction: Amara-Drops is a traditional herbal preparation containing nine individual extracts (*Artemisia absinthium* Herba, *Centaurium erythraea* Herba, *Cichorium intybus* Planta tota, *Gentiana lutea* Rhizoma, *Juniperus communis* Summitates, *Achillea millefolium* Herba, *Peucedanum ostruthium* Rhizoma, *Salvia officinalis* Folium, and *Taraxacum* Planta tota) used to treat gastrointestinal dysmotility. Previous studies have demonstrated that Amara extract targets the muscarinic receptor M2, inducing relaxation in carbachol-contracted guinea pig fundus strips, potentially improving impaired fundus accommodation in functional dyspepsia patients [1].

However, its antispasmodic properties to alleviate visceral hypersensitivity, a major factor in abdominal pain experienced by Irritable Bowel Syndrome (IBS) patients, have yet to be studied.

Aims & Methods: Anticholinergic agents are commonly used to treat IBS, but they often come with broad side effects. Herbal medicines have shown excellent antispasmodic properties without significant adverse reactions [2].

Therefore, following preliminary results indicating Amara extract's antagonist activity on and binding to M2 muscarinic receptors expressed in CHO cell lines, we investigated the antispasmodic effect of Amara extract on guinea pig small intestine with or without carbachol-induced contraction. Dry extract was obtained from the commercial product Amara-Drops. Guinea-pig ileum muscle strips were prepared and set up in organ baths in a longitudinal orientation to study the relaxation effect of Amara extract (94, 283, 450, 650, 850, and 1,000 µg/mL), isoprenaline as a positive control (100 pM, 1, 10 and 100 nM, 1 and 10 µM), or vehicle, with or without carbachol-induced contraction (10 µM).

Results: *In vitro* studies revealed that Amara extract binds to and inhibits M2 receptor activity (IC_{50}: 294 and 219 µg/mL, respectively) via inhibition of their respective reference agonist activity. Exposure of Amara extract to ileum muscle strips induced significant relaxation already at 450 µg/mL (25%, $p<0.01$), with stronger effects observed at 650, 850, and 1,000 µg/mL (27-31%, $p<0.0001$), showing a generally stronger relaxation than the positive control isoprenaline (9.8-18%, $p<0.05$ - $p<0.001$).

Significant relaxation was also observed in carbachol-contracted muscle strips already at 283 µg/mL (50%, $p<0.01$), with stronger effects at higher concentrations (78-132%, 450-1,000 µg/mL, $p<0.0001$) compared to isoprenaline, which only showed significant relaxation at the highest concentration (71%, $p<0.05$).

Conclusion: The findings highlight the potential of Amara-Drops in modulating visceral hypersensitivity and alleviating abdominal pain in IBS patients through the inhibition of cholinergic-induced contraction in the small intestine. Further research is necessary to identify which specific extracts contribute to the anticholinergic effect. This study lays a promising molecular foundation for the therapeutic use of Amara-Drops in IBS treatment.

HOMOCYSTEINE EXACERBATES IRRITABLE BOWEL SYNDROME BY IMPAIRING THE MUCUS LAYER AND ALTERING GUT MICROBIOME

S. Zhu[1], S. Lu[1], S. Liu[1], H. Ye[2]
[1]Beijing Friendship Hospital, Capital Medical University, Beijing, China, [2]Beijing Friendship Hospital, capital medical university, Beijing, China

Introduction: Gut metabolites are suggested to be potential etiological factors of irritable bowel syndrome (IBS). However, the potential mechanisms remain unclear.

Aims & Methods: This study aimed to elucidated the effect and mechanism of gut metabolite homocysteine(Hcy) in IBS development. A stress-induced IBS model was established using neonatal maternal separation (NMS), while a post-inflammatory IBS (PI-IBS) model was constructed by intracolonic administration of trinitrobenzene sulfonic acid (TNBS). A high-methionine diet was applied to elevate homocysteine levels in both blood and feces of mice or rats. Visceral hypersensitivity was assessed by measuring abdominal withdrawal reflex (AWR) and visceral motor responses (VMR). Carmine red was used to determine whole intestinal transit time. The composition of the gut microbiota in rats fecal samples was analyzed by using 16S rRNA sequencing. A series of cell and molecular experiments, including immunostaining, western blot and ELISA was conducted to illustrate the mechanism.

Results: We found that fecal Hcy levels were significantly elevated in both patients with IBS and rats with IBS induced by water avoidance stress (WAS). Moreover, fecal Hcy levels were positively correlated with the severity of IBS symptoms in patients. Next, we investigated the effects of Hcy on the gut-brain axis in NMS rat model and TNBS mice model. Our study showed that elevated Hcy in stool exacerbated visceral hypersensitivity,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

increased intestinal permeability and disrupted the mucus barrier of IBS rats/mice. Interestingly, folic acid supplementation lowered the Hcy levels and alleviated the effect of Hcy in exacerbating IBS phenotype.
Mechanistically, treatment of Hcy inhibited the expression of NLR family pyrin domain containing 6 (NLRP6) and downregulated mucin MUC2 expression in LS174T and intestinal organoids, and impaired the expression of tight junction proteins ZO1 and Occludin in Caco2. Genetic overexpression of NLRP6 and PPARγ agonist Rosiglitazone rescued the inhibitory effect of Hcy on MUC2 expression. In addition, by using 16S rRNA sequencing, we found that Hcy reduced gut bacterial diversity and lowered the abundances of *Coprococcus, Roseburia and Acetitomaculum* in NMS rats.
Conclusion: Our study showed that gut metabolite Hcy was involved in the pathogenesis of IBS by disrupting mucus barrier and disturbing gut microbiota, indicating Hcy as a therapeutic target and folic acid administration as a potential strategy for IBS management.
Disclosure: Nothing to disclose.

DIFFERENT EFFECT OF LOCAL SPHINCTER STIMULATION ON ANAL FUNCTION AND SYMPTOMS OF URGE VS. PASSIVE FECAL INCONTINENCE

P. Liptak[1], B. Malý[1], M. Vojtko[1], P. Banovcin[1]
[1]Jessenius faculty of Medicine in Martin, Comenius University, Slovakia, Clinic of Internal Medicine- Gastroenterology, University Hospital in Martin, Martin, Slovakia

Contact E-Mail Address: liptak@jfmed.uniba.sk
Introduction: Fecal incontinence is a diagnosis represented by recurrent uncontrolled passage of fecal material for at least 3 months. It is relatively common, with an assumed prevalence of up to 7% of the worldwide population. The therapy is challenging and often with insufficient clinical results. It should be specifically tailored to different symptom presentations meaning urge or passive incontinence. One of the relatively and therefore not widely used treatment options for incontinence is local sphincter stimulation which is a safe non or minimally invasive method. This stimulation could be performed in at home setting, so it presents a substantial time and cost-saving option for the patient and for the healthcare system. However, the data published on this topic so far are scarce with heterogeneous studied populations and results with no universally accepted treatment protocol.
Aims & Methods: This study aims to evaluate the effect of local sphincter stimulation on the functional parameters of sphincters and symptoms based on the different phenotypes. This is a retrospective single-center study analysis on patients with fecal incontinence (age> 18 years). The duration of the training was 12 weeks, with training once daily for 6 days a week. The parameters of the home stimulation device were as follows: Frequency: 40 Hz; Impulse Width: 0.2 s; Ramp-up time: 1s; Workout time: 6s; Rest: 15s. Training duration: 20min. During the perceived stimulation patients were instructed to squeeze the sphincter. 3D anorectal manometry was performed according to the IAPWG protocol at the initiation visit and the control visit. Clinical evaluation was performed by self-reporting Wexner's score for fecal incontinence at both visits.
Results: Twenty-three patients (23) were consecutively screened for eligibility and assigned for the therapy. Three patients (3) did not adhere to the training due to various personal reasons one (1) patient did not tolerate stimulation. Therefore, 19 patients (10 passive, 9 urge) completed the full treatment protocol for 12 weeks and were considered for the final analysis. The total average increase in sphincter rest medium pressure was 22.53%, with significantly higher improvement in the urge group compared to the passive group (46.24% vs. 1.18% respectively). The total average increase in sphincter rest maximum pressure was 25.69%, with significantly higher improvement in the urge group compared to the passive group (46.92% vs. 6.59% respectively). The total average increase in sphincter maximum squeeze pressure was 36.13%, with significantly higher improvement in the urge group compared to the passive group (57.82% vs. 16.61% respectively). The average improvement in Wexner score was 3.1 points, with higher improvement in the urge group compared to the passive group (4.2 points vs. 2.1 points respectively).
Conclusion: The home-administered local anal sphincter stimulation for 12 weeks seems to be an effective treatment option for both types of fecal incontinence and significantly more effective in the urge type. Therefore this could be considered as a cost and time-effective treatment option compared to standard office-based therapy. Although a home stimulation device is simple to use, the ability of the patient to adhere to the protocol should be evaluated during the screening process.

NEAR-INFRARED HYPERSPECTRAL MICROSCOPE FOR HIRSCHSPRUNG'S DISEASE: VISUALIZATION OF ENTERIC NERVE PLEXUS IN MOUSE

S. Hayashi[1], T. Takamatsu[2], N. Shimojima[3], M. Kobayashi[4], K. Sumiyama[4], T. Futakuchi[4], H. Takemura[1]
[1]Tokyo University of Science, Department of Mechanical and Aerospace Engineering, Chiba, Japan, [2]National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, [3]National Center for Child Health and Development, Tokyo, Japan, [4]The Jikei University School of Medicine, Department of Endoscopy, Tokyo, Japan

Contact E-Mail Address: 7524546@ed.tus.ac.jp
Introduction: Hirschsprung's disease is caused by the absence of ganglia in the deep intestinal wall, leading to dysfunction [1]. Resection of the affected area is the only cure, so accurate margin detection is essential. Currently, intraoperative rapid pathology is used, requiring tissue sampling and staining, but each test takes over 30 min and may need multiple samples, sometimes delaying decisions up to 3 h. A quick on-site method to detect ganglia around 200 μm deep is needed.
Various methods, including confocal microscopy [2], have been studied, but issues remain, such as dye toxicity and limited depth (>200 μm) imaging.
Aims & Methods: For non-destructive and stain-free visualization of tissues, we focused on Near-Infrared Hyperspectral Imaging (NIR-HSI)[3][4]. Near-infrared light—particularly in the 1000–1400 nm range—exhibits high tissue penetrability and is effective for detecting deep tissues.
In addition, the near-infrared region provides spectroscopic information based on molecular vibrations, enabling component analysis. NIR-HSI holds promise for the identification of cancer and other biological tissues without the need for fluorescence or external marking [4][5].
To implement NIR-HSI, we developed a novel microscopic optical system capable of guiding near-infrared light. The near-infrared light source, which combines a supercontinuum light source and an acousto-optic tunable filter, allows for the selection of arbitrary wavelengths and irradiation of the target by adjusting the applied voltage [6]. This configuration enables the acquisition of near-infrared spectral images (NIR-HSI) at arbitrary wavelengths.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

For performance validation, ex vivo experiments were carried out using mouse intestine in which the nerve plexus was selectively labeled with GFP (Green Fluorescent Protein). In these experiments, near-infrared light ranging from 850 to 1400 nm was irradiated in 10-nm increments, and 77 spectral images were captured. As a reference, GFP fluorescence images were acquired in the same field of view as the near-infrared images. Based on the fluorescence images, annotations were performed to delineate the enteric nerve plexus, and near-infrared spectra were obtained from both the nerve and non-nerve regions. Furthermore, using pixel-wise spectral data, segmentation of the nerve regions was performed with a machine learning model, and the accuracy of identification was evaluated.

Results: The NIR images captured by the system showed nerve distributions and mesh-like patterns similar to those in the GFP images. Spectral differences were observed between nerve and non-nerve regions. This likely reflects tissue composition differences, as muscle tissue has higher transmittance and nerve tissue higher reflectance in the NIR range [4][5][6].

Segmentation based on spectral data successfully extracted nerve contours and distribution patterns, achieving ~80% classification accuracy.

Conclusion: To enable non-invasive, label-free visualization of deep nerve distributions, we developed a NIR-HSI microscope by integrating near-infrared hyperspectral imaging with a microscopic optical system. In mouse intestine experiments, spectral differences were observed between enteric nerve plexus and surrounding tissue. The results suggest that mesh-like nerve structures can be estimated and outlined using NIR images alone. Future work will focus on imaging human samples.

Introduction: Gastrointestinal involvement is common in patients with multiple sclerosis (MS). It is estimated that 35–54% of MS patients experience constipation, while 29–51% develop faecal incontinence (FI), with both conditions frequently coexisting[1]. The underlying pathophysiology is complex, as MS can affect the central nervous system at multiple levels. Despite its high prevalence and significant impact on quality of life, few studies have specifically addressed anorectal dysfunction in these patients. The aim of our study was to describe the clinical and manometric features of MS patients presenting with constipation and/or FI.

Aims & Methods: 26 patients with MS were included. High-resolution anorectal manometry (HRAM; Medtronic®), following the London protocol, and balloon expulsion test (BET; Matla Systems®) were performed in all subjects. Reference values were derived from 20 healthy controls assessed at our centre (Table 1).

Parameter	Value
Mean Resting Pressure (Atmospheric ref.)	86.4 ± 17.9 mmHg
Short Squeeze Pressure (Atmospheric ref.)	229.6 ± 81.6 mmHg
Long Squeeze Duration	26.2 ± 8.3 s
First Sensation	50.5 ± 25.2 mL
Second Sensation	125.4 ± 32.7 mL
Maximum Tolerated Volume	156.5 ± 36.5 mL

Table 1. HRAM Parameters in Healthy Subjects in left lateral decubitus.

Results: Faecal incontinence was observed in 21 patients (80.8%), predominantly mixed (42.3%), complete (stool and gas; 34.6%), and with Wexner scores >9 in 26.9% of cases. Constipation was reported by 15 patients (57.7%), of whom 14 (53.8%) perceived obstructive defecation. Constipation and FI coexisted in 10 patients (38%). Urinary incontinence was also present in 17 patients (65.4%).

Manometric findings revealed a tendency towards resting anal sphincter hypotonia (67.06 ± 19.85 mmHg) and reduced maximum voluntary contraction pressure (median 105.35 mmHg [IQR 86.48–149.28 mmHg]). Median contraction duration was 30 seconds (IQR 8–32 s). Rectal sensitivity assessment showed median thresholds for first sensation at 55 cc (IQR 40–70 cc), second sensation at 125 cc (IQR 100–160 cc), and maximum tolerated volume at 170 cc (IQR 135–190 cc). Sensory abnormalities were identified in 11 patients (42.3%), 4 due to hypersensitivity (15.4%) and 7 (26.9%) due to hyposensitivity.

An impaired push manoeuvre was observed in 20 patients (83.3%): type I dyssynergic defecation (DD) in 5 patients (20.8%), type II in 5 (20.8%), type III in 4 (16.7%), and type IV in 6 (25%). BET confirmed dyssynergia in 10 patients (41.7%).

Note: Results are expressed as mean ± standard deviation or median (interquartile range), depending on data distribution. Reference values are presented as mean ± standard deviation.

Conclusion: FI was the most prevalent symptom, often coexisting with constipation and obstructive defecation. The tendency observed in manometric findings towards anal hypotonia and hypocontractility, as well as the presence of dyssynergia in a significant number of patients, may allow the selection of individuals suitable for targeted therapies.

ORO-ANAL TRANSIT TIME IN PATIENTS WITH BOWEL SYMPTOMS: A SINGLE CENTRE STUDY

A. Aliyu[1], M. Prenke[1], R. Katsumata[1], M. Simrén[1], H. Törnblom[1]
[1]University of Gothenburg, Molecular and Clinical Medicine, Gothenburg, Sweden

Contact E-Mail Address: abdulsalam.ibrahim.aliyu@gu.se
Introduction: Gastrointestinal (GI) symptoms and their relationship with measures of GI function are incompletely understood.
Aims & Methods: We included patients investigated with OATT by use of radiopaque markers (ROM) between 2000 and 2022; one clinical audit cohort investigated because of disturbed bowel habits, and a cohort from IBS trials. In the clinical audit cohort, information on bowel habits were retrieved from referral notes and severity of abdominal pain, bloating and flatulence were rated daily by the patients during the week of the OATT measurement. In IBS patients, information on IBS subtype (IBS-C, IBS-D, IBS nonCnonD), severity of GI symptoms (GSRS), and stool frequency and consistency (Bristol stool form) from stool diaries were available. The aim of this study was to assess the outcome of oro-anal transit time (OATT) investigations in patients with disturbed bowel habits and its association with GI symptoms.
Results: We included 1142 patients (75% females) with a median age of 37(range 20-65) years with bowel symptoms. In the clinical audit cohort, slow transit was most common among patients with constipation (41%), whereas rapid transit was most frequent in patients with diarrhea (32%). In line with this, slow transit was predominantly seen in IBS-C (17%) and rapid transit in IBS-D (30%). However, in both cohorts, normal transit was most frequent.
Among patients in the clinical audit cohort, a positive correlation between OATT and the severity of bloating (r=0.17, p<0.001) was seen, but there was no association with abdominal pain (r=0.02, p=0.72) or flatulence (r=-0.10, p=0.07). In IBS patients, inverse correlations were seen between OATT and stool consistency (r=-0.38, p<0.0001), and frequency (r=-0.32, p<0.0001). In line with this, OATT was associated with the severity of diarrhea (r=-0.16, p<0.05), and constipation (r=0.27, p<0.001).
In addition, a weak, but significant association was seen with satiety (r=0.16, p<0.05) but not with abdominal pain (r=0.06; p=0.23) or bloating (0.08; p=0.09).

Patients	Rapid transit	Normal transit	Slow transit
Clinical audit (n=457)			
Patients with constipation (n=292)	4%	55%	41%
Patients with diarrhea (n=99)	32%	64%	4%
Patients with undefined bowel habit abnormality (n=66)	11%	68%	21%
IBS trials (n=685)			
IBS-C (n=198)	6%	77%	17%
IBS-D (n-228)	30%	68%	2%
IBS NonCnonD (n=205)	14%	81%	5%
IBS without subtyping information (n=56)	28%	61%	11%

Table.

Conclusion: Abnormal OATT is prevalent among patients with disturbed bowel habits and is a pathophysiologic mechanism of importance for the understanding of stool frequency and consistency, and the severity of diarrhea and constipation but less so with other GI symptoms.
Disclosure: Nothing to disclose.

SCREENING FOR ARFID IN IRRITABLE BOWEL SYNDROME: CLINICALLY OR USING THE NIAS-FR QUESTIONNAIRE?

F. Wuestenberghs[1], A.-S. Schmitt[1], P. Jouet[1], L. Attelly[1], M. Benallaoua[1], N. Ezratty[1], J.-J. Raynaud[1], R. Benamouzig[1], J.M. Sabate[1]
[1]APHP, Avicenne Hospital, Sorbonne Paris Nord University, Gastroenterology and Digestive Oncology, Bobigny, France

Contact E-Mail Address: fabien.wuestenberghs@hotmail.com
Introduction: Approximately 15-19% of patients suffering from irritable bowel syndrome (IBS) have an eating disorder (ED) based on a screening score or dietary assessment (1).
Avoidant/restrictive food intake disorder (ARFID), a long-recognised eating disorder in children, is now recognised in adults. In a Swedish study, 13.2% of patients suffering from IBS reported severe dietary avoidance or restriction, suggestive of ARFID (2).
A screening questionnaire for this disorder has recently been validated in French (NIAS-Fr, for Nine Item ARFID Screen in French) (3).
Aims & Methods: This study aims to assess the prevalence of ARFID in IBS in France, by comparing the NIAS-Fr questionnaire and the assessment by a specialised dietitian, and to look for links between its presence and the clinical phenotype of patients.
This study was conducted between February and September 2024 in consecutive patients suffering from IBS and evaluated in a multidisciplinary day hospital structure. Clinical characteristics (age, gender, BMI, IBS subtype and its severity [IBS-SSS], presence of functional dyspepsia, diet and disease duration) and presence of ARFID (clinically or one abnormal NIAS-Fr subscale) were collected.
A dietitian assessed the presence of "clinical ARFID". The NIAS subscales allow for the diagnosis of patients as "picky eaters" (score ≥10), with "poor appetite" (score ≥9) and/or with a "fear of eating" (score ≥10). Patients with a history of ED diagnosed by a psychiatrist and/or an abnormal ED screening score (SCOFF ≥ 3 and/or global EDE-Q8 ≥ 4.0) were excluded from the analysis.
Results: Of the 95 patients with IBS according to Rome IV, 55 (57.9%) had at least one positive NIAS-Fr subscale, with 10 (10.5%) having an abnormal "picky eater" subscale, 16 (16.8%) an abnormal "poor appetite" subscale, and 49 (51.6%) an abnormal "fear of eating" subscale. Of these 95 patients, 15 were excluded from the analysis because of a history of eating disorders or an abnormal screening score.
We therefore included 80 patients for analysis (77.5% women; mean age 48.5 ± 16.8 years, BMI 22.6 ± 4.6 kg/m^2; 40.0% IBS-D, 38.8% IBS-C, and 20.0% IBS-M; 51.3% had associated dyspepsia; 62.5% were on a special diet at the time of assessment). The mean IBS-SSS score was 319.5 ± 88.2 points (severe forms in 61.2%). Among these 80 patients, 43 (53.8%) had at least one positive NIAS-Fr subscale, including 10.0% of "picky eaters," 16.3% of "poor appetite," and 48.8% of "fear of eating." Patients with at least one positive NIAS-Fr subscale had more frequent functional dyspepsia than those with a negative NIAS (65.1 vs. 35.1%, p = 0.013), but there were no differences in the other parameters assessed. According to the dietitian's assessment, 19 (23.8%) patients in our cohort had clinical ARFID, i.e., 44.2% of those with at least one positive NIAS-Fr subscale. In an

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

IBS population, the specificity of the NIAS-Fr questionnaire for diagnosing clinical ARFID was 55.8% (95% CI: 41.1-69.6). None of the assessed parameters distinguished patients with and without clinical ARFID (p > 0.05).

Conclusion: ARFID symptoms are found in more than half of IBS patients treated in a tertiary care centre based on an abnormal NIAS-Fr screening questionnaire, after excluding other eating disorders. These patients frequently have associated functional dyspepsia and a normal BMI. Based on a dietary assessment, clinical ARFID is found in approximately one-quarter of IBS patients. The specificity of the NIAS-Fr in IBS is too low to allow a diagnosis of ARFID in this population.

KNOWLEDGE AND MISCONCEPTIONS OF PATIENTS WITH IRRITABLE BOWEL SYNDROME ENROLLED IN A THERAPEUTIC PATIENT EDUCATION PROGRAM

F. Wuestenberghs[1], P. Jouet[1], N. Ezratty[1], L. Attelly[1], A.-S. Schmitt[1], M. Benallaoua[1], J.-J. Raynaud[1], R. Benamouzig[1], J.M. Sabate[1]

Contact E-Mail Address: fabien.wuestenberghs@hotmail.com

Introduction: Irritable bowel syndrome (IBS) is a common disorder of gut-brain interaction affecting 5 to 10% of the population, combining chronic abdominal pain and altered bowel transit. Its varied and complex mechanisms make management difficult and can be responsible for impaired quality of life. Patient education is recommended for managing chronic diseases. As part of a patient education program, the first step is to assess patients' knowledge and needs by conducting a shared educational assessment.

Experiments conducted in various countries have shown that therapeutic patient education (TPE) can be effective, reducing severity, improving quality of life, and reducing care seeking. These studies have also shown that patients often have a lack of knowledge and/or misconceptions about IBS (1).

Aims & Methods: This study aimed to assess the baseline knowledge level of patients enrolled in a patient education program. Patients with IBS were selected for participation in a TPE program following a multidisciplinary day hospital for IBS. All patients had to have seen a general practitioner and/or a gastroenterologist outside the team without sufficient improvement in their condition. The TPE was based on a document developed in collaboration with a patient organisation (APSSII).

This program was divided into five 1-hour sessions (training and discussion time) conducted by different professionals (neurogastroenterologists, clinical psychologist, dietitian) covering the following points:

1. Understanding my illness (epidemiology, diagnosis, mechanisms),
2. Talking about my illness and expressing my needs (interaction with loved ones, work, doctor, school, rights and support);
3. Organizing my daily life, improving my quality of life (impact of IBS on QoL, work, exercise, intimate life);
4. Taking advantage of different treatments and care options (placebo, adverse effects, symptomatic and long-term treatment, alternative treatments);
5. The role of eating and diets (balanced diet, lactose-free, gluten-free, low-FODMAP, food allergies, risks of diets). Before the start of each session, questionnaires testing participants' knowledge on the session topic were completed.

Results: From November 2023 to September 2024, 135 questionnaires completed by 43 patients with IBS were included. 70% were women, mean age 45 ± 18 years, subtypes based on IBS transit: IBS-C 55%, IBS-D 33%, IBS-M 12%, with a mean severity (IBS-SSS) of 331 ± 72 points, EQ5D health score of 50 ± 21. Among the most common misconceptions, 25% believed that a diagnosis by endoscopy was possible, 48% believed the disease could be complicated by IBD, and 13% by colon cancer.

Regarding treatments, 11% of patients believed that the placebo effect only concerned medications, 58% believed that faecal microbiota transplantation could currently be offered in clinical routine for IBS care, 78% believed that hypnotherapy was only effective if you believe in it, and 68% believed that multi-strain probiotics were more effective than single-strain ones.

Conclusion: This study, conducted in France on patients with moderate or severe forms of IBS, shows a highly variable level of knowledge about their disease depending on the questions, with some significant misconceptions that need to be addressed. These results justify the implementation of therapeutic education for these patients.

A study is underway to verify the improvement in patients' knowledge and the existence of a positive impact of this strategy on symptom severity and quality of life.

INTEGRATING ANORECTAL MANOMETRY, BALLOON EXPULSION AND DEFECOGRAPHY: INSIGHTS INTO DIAGNOSING PELVIC FLOOR DYSFUNCTION

N. Zoabi[1], D. Zelikovich[2], F. Kanani[3], E. Ram[1], A. Issa[1], D. Carter[1]

Introduction: Defecatory dysfunction (DD) is a common cause of chronic constipation resulting from functional abnormalities or structural pelvic pathologies. Accurate diagnosis requires combining anorectal manometry (ARM), balloon expulsion test (BET), and defecography. This study evaluates the diagnostic utility of these modalities and explores uncertainties in their performance and interpretation.

Aims & Methods: This retrospective study included 325 adult patients assessed for DD between 2020 and 2023. All patients went through ARM, BET in the left lateral position, and defecography. Statistical associations between test outcomes were analyzed to assess diagnostic concordance and significance.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A strong correlation was observed between ARM and defecography, with 65% of patients with normal anal relaxation on ARM achieving normal rectal evacuation on defecography ($p < 0.0001$). Conversely, patients with paradoxical contraction during ARM demonstrated a higher likelihood of evacuation failure. BET demonstrated high specificity but limited sensitivity in association with relaxation on ARM and evacuation on defecography. BET failure did not demonstrate a significant association with the presence of pelvic floor pathologies.

Conclusion: Combining ARM, BET, and defecography provides a comprehensive framework for diagnosing DD, addressing its functional and structural components. This integrated approach facilitates targeted interventions, ultimately improving clinical outcomes.

References:

Chronic constipation is a common disorder with multifactorial pathophysiology, including pelvic floor dysfunction (Bharucha & Lacy, 2020). Symptomatic pelvic floor disorders affect a significant proportion of women (Nygaard et al., 2008). High-resolution anorectal manometry (HRAM) and rectal balloon expulsion tests are critical for diagnosing defecatory disorders (Prichard et al., 2017; Bharucha & Coss-Adame, 2022). Standardized protocols, including the London Classification, have improved the diagnostic accuracy of anorectal functional tests (Carrington et al., 2020; Carrington et al., 2018). Imaging modalities such as magnetic resonance defecography complement functional testing (Reiner et al., 2011; Carter et al., 2020). Variations in body position influence anorectal test results (Su et al., 2019; Wu et al., 2017; Tsunoda et al., 2022; Ratuapli et al., 2013). Comparative studies emphasize the complementary role of manometry, balloon expulsion, and defecography (Blackett et al., 2022; Heinrich et al., 2015). Recent advances suggest HRAM improves detection of specific defecatory mechanisms (Deb et al., 2022; Sharma et al., 2020), supported by international consensus guidelines (Wald et al., 2021; Rao & Tetangco, 2020; Lee & Bharucha, 2016).

Disclosure: No conflict of interest.

POSITIVE EFFECTS OF *L PLANTARUM* 299V AND *L PLANTARUM* GOS42 ON THE GASTROINTESTINAL FUNCTION IN ADULTS WITH OCCASIONAL CONSTIPATION. A RANDOMIZED, DOUBLE-BLIND, PLACEBO CONTROLLED, PARALLEL CLINICAL STUDY

G. Önning[1], E.D. Lewis[2], M. Moulin[2], D.C. Crowley[2], N. Guthrie[2], C. Montelius[1], C. Vegge[1]
[1]Probi AB, Lund, Sweden, [2]KGK Science Inc., London, Canada

Contact E-Mail Address: gunilla.onning@probi.com

Introduction: Constipation is a common gastrointestinal concern associated with less frequent defecations, with reduced faecal bulk and harder stools, or both. It greatly affects quality of life, with a significant impairment of both mental and physical components. One way to relieve constipation can be by intake of probiotics. *Lactiplantibacillus plantarum* 299v (LP299V®) is one of the most clinically studied *L plantarum* strains and has been shown to have positive effects on IBS symptoms in several clinical trials (Arvidsson Nordström et al. 2021).

In the present study, the effect of LP299V and a small amount of another *L plantarum* strain (LPGOS42) on occasional constipation was investigated. Gut transit time was also evaluated, using a novel marker (Asnicar et al. 2021).

Aims & Methods: The aim of the study was to investigate if LP299V and LPGOS42 (LP) could improve gastrointestinal function in adults with occasional constipation. After a 2-week run-in period, 100 subjects were randomized to receive either LP or placebo capsules for 8 weeks. The change in frequency of complete and spontaneous bowel movements (CSBM), frequency of bloating and flatulence, stool consistency, digestive function (modified Gastrointestinal Symptom Rating Scale (GSRS)) and the quality of life (Patient Assessment of Constipation Quality of Life questionnaire (PAC-QoL)) were followed. The gut transit time was assessed with a blue dye method (Asnicar et al. 2021).

Results: The number of weekly complete and spontaneous bowel movements increased significantly over time in both groups (LP +2.4, placebo +1.9, p=0.182 between groups at week 8). Stool consistency transitioned from hard to softer stools in both groups, with the mean score significantly higher after 8 weeks in the LP group, indicating softer stools in this group. The LP group also had significantly more bowel movements without hard lumpy stools compared to the placebo group at week 8. The frequency of flatulence was reduced over time in the LP group, reaching a significantly lower frequency of flatulence in the LP group vs placebo in week 8.

The subjects scored low for most of the symptoms in the GSRS, indicating that the study population were healthy subjects without abdominal pain, reflux, diarrhea or indigestion. The only subscale in GSRS where the mean score was over 1 (= more than occasional problems) was constipation and this decreased significantly over time in both groups, with a more pronounced decrease seen in the LP group (p=0.073 between groups at week 8).

The total score for PAC-QoL improved significantly over time in both groups, with no difference seen between the groups. The highest score detected among the four subscales was for satisfaction and it improved significantly more in the LP group compared to the placebo group (p=0.007 between groups in week 8).

Measuring the gut transit time with a blue dye method gave large differences between subjects and no significant changes over time or between groups could be detected.

Conclusion: In conclusion, this study demonstrates that intake of probiotics (*L plantarum* 299v and *L plantarum* GOS42) helps to alleviate constipation and flatulence, as well as improves quality of life in healthy subjects with occasional constipation.

Introduction: Chronic constipation (CC) is a frequent gastrointestinal disorder which significantly affects patients' quality of life. International guidelines recommend the use of polyethylene glycol (PEG) as part of the first-line management of CC after the failure of diet and lifestyle modifications. However, limited data are available on how PEG is used in daily clinical practice. Therefore, a national survey among gastroenterologists (GEs) and general practitioners (GPs) was conducted to evaluate its use in the management of CC.

Aims & Methods: Members of Italian Association of Hospital Gastroenterologists and Endoscopists (AIGO) and Italian Federation of General Practitioners (FIMMG) were invited to complete a 44-item online survey. The questionnaire was structured to explore several dimensions regarding the use of PEG (*e.g.* type of PEG used, formulations and dosages recommended, etc.).

Results: The survey was completed by 1188 physicians (317 GEs, 871 GPs). GEs were significantly younger (mean age 44.9 vs. 51.0 years, p<0.01) and more likely to have less than 10 years of experience compared to GPs.

PEG was prescribed as part of first-line treatment in addition to dietary and behavioral advice more frequently by GEs than GPs (92.4% vs. 82.9%, p<0.001). GPs preferred to prescribe PEG in the early morning or evening before bedtime compared to GEs (p<0.001), which preferred mid-morning or midafternoon (p<0.01). GPs more often recommended taking it away from other drugs and/or supplements compared to GEs (76.7% vs 61.5%, p<0.001).

GEs considered PEG products to be taken continuously more often than GPs (36.9% vs 18.6%, p<0.001) and were more inclined to avoid setting a fixed treatment duration (62.8% vs 38.2%, p<0.001), while GPs often recommend a short-term or an on-demand use. GEs also more often preferred to discontinue PEG gradually compared to GPs (74.8% vs. 63.0%, p<0.001)

PEG's formulation choices varied: GEs favored the powder formulation less than GPs (58.7% vs 78.9%, p<0.001), and more often started therapy at higher dosages (Table 1). Moreover, GEs gave more importance on palatability compared to GPs (71.9% vs 60.4%, p<0.001).

Safety perceptions were similarly high across the groups, GEs were more likely to prescribe PEG than GPs to patients with comorbidities such as chronic kidney disease (75.7% vs 64.0%, p<0.001) and during pregnancy/lactation (71.3% vs 48.8%, p<0.001).

	Overall (N = 1180)		GEs (N = 317)			GPs (N = 871)			Difference between GEs and GPs		p-value
	N	%	N	%	95% CI	N	%	95% CI	%	95% CI

Table 1. Prescription of PEG as part of first line management of CC and PEG's initial dosage answers.

Conclusion: To the best of our knowledge, this is the first national survey to assess how PEG is prescribed by GEs and GPs in daily clinical practice. The survey highlighted a certain heterogeneity in prescription behaviors. GEs tended to adopt longer-term therapeutic strategy, starting with higher doses. Moreover, they paid greater attention to PEG palatability and were more confident on PEG safety in patients with chronic comorbidities. These findings underscored the need for shared knowledge and approaches to optimize constipation management across different care settings.

Disclosure: Nothing to disclose.

THE ACCURACY OF A SIMPLIFIED ANORECTAL MANOMETRY PROTOCOL IN DIAGNOSING FUNCTIONAL DEFECATION DISORDERS: ARE 5-SECONDS PUSHES RELIABLE?

C. Lambiase[1,2], A. Grosso[1,2], R. Tedeschi[1,2], L. Cancelli[1,2], F. Rettura[1,2,3], A. Bottari[1,2], G. Chiarioni[4,5], N. de Bortoli[1,2], M. Bellini[1,2]

Introduction: Anorectal manometry (ARM) is required to diagnose functional defecation disorders (FDD) in constipated patients. The International Anorectal Physiology Working Group introduced into clinical practice a standardized sequence of manoeuvres to perform ARM (London Protocol) (1). The London protocol suggests performing three push attempts,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

each of 15s duration, to assess recto-anal coordination and therefore to diagnose FDD, with a consensus <75% between experts. However, some papers consider a 5s push sufficient to detect FDD (2,3).

Aims & Methods: Therefore, the aim of this study was to assess the diagnostic accurac of a simplified ARM protocols featuring three pushes attempts (each of 5s) in comparison with IAPWG recommendations.

High-Definition ARM (HD-ARM) traces from 105 constipated patients (82 F, mean aged 53.5 ± 16.7 years) who had performed HD-ARM for clinical practice were retrospectively reviewed. HD-ARM were performed according to the IAPWG Protocol. All patients underwent the balloon expulsion test at the end of HD-ARM as suggested by IAPWG protocol. HD-ARM traces were re-evaluated considering the first five seconds of each push (as if each push featured only five seconds).

New diagnosis was made based on this modified protocol and compared with the one made according to London Protocol, to evaluate whether these modifications could affect the final diagnosis.

Results: According to the London Protocol, the qualitative best pushes were the first, the second or the third in 35.2%, 28.6% and 36.2% of patients, respectively. Eighty-seven patients (82.9%) failed the balloon expulsion test.

Mean rectal pressure did not differ between the modified protocol and the London protocol (37.1 ± 23 vs 34.3 ± 23.2, p=0.38). However, we observed a significant increase in the mean anal pressure with the modified version of the protocol compared to the London protocol (75.6 ± 33.1 vs 90.8 ± 37.3, p<0.002).

Regarding the diagnostic accuracy, we observed a moderate concordance between the modified protocol and the London protocol k=0.77, Table 1). In details, if we had used this modified version of protocol, 18 patients (17.1%) would have changed their final diagnosis (Table 1).

	Absormal expulsion with dyssynergia	Abnormal expulsion with normal manometric pattern of rectoanal co-ordination	Abnormal expulsion with poor propulsion	Abnormal expulsion with poor propulsion and dyssynergia	No disorders of rectoanal co-ordination	Normal expulsion with abnormal manometric pattern of rectoanal co-ordination	Total
Absormal expulsion with dyssynergia	23	4	1	0	0	0	28
Abnormal expulsion with normal manometric pattern of rectoanal co-ordination	0	5	0	0	0	0	5
Abnormal expulsion with poor propulsion	0	1	11	0	0	0	12
Abnormal expulsion with poor propulsion and dyssynergia	6	0	3	33	0	0	42
Normal expulsion with abnormal manometric pattern of rectoanal co-ordination	0	0	0	0	3	15	18
Total	29	10	15	33	3	15	105

Table 1. Cohen's K diagnosis concordance according to London Protocol (k=0.773)

Conclusion: Based on our results, a simplified ARM protocol using three 5s pushes shows moderate diagnostic agreement with the standard London protocol. While rectal pressures remained similar, anal pressures increased significantly, and 17.1% of patients received a different diagnosis. Therefore, the simplified protocol could reduce the diagnostic accuracy for FDD.

Introduction: High-definition anorectal manometry (HD-ARM), balloon expulsion test (BET) and magnetic resonance defecography (MR-defecography) are important tools in studying constipation.

Aims & Methods: Evaluate the prevalence of functional defecation disorders and structural anorectal alterations in patients with constipation and compare the findings of HD-ARM and BET with MR-defecography.

Retrospective cohort study including patients with functional constipation (FC) or irritable bowel syndrome with constipation (IBS-C) submitted to HD-ARM, BET and MR-defecography.

Patients were divided into three groups:

1. Normal anorectal evacuation pattern in HD-ARM and BET;
2. Abnormal anorectal evacuation pattern and BET;
3. Normal anorectal evacuation pattern and abnormal BET, or abnormal anorectal evacuation pattern and normal BET.

Results: A total of 64 patients were included, 49 with FC (76.6%) and 15 with IBS-C (23.4%). There were 20 patients in group 1 (31.3%), 11 in group 2 (17.2%) and 33 in group 3 (51.5%). In MR-defecography, 47 patients had relevant structural anorectal alterations (73.4%) and 15 had an abnormal contraction of the puborectalis during the defecatory maneuver (23.4%). Nineteen patients were diagnosed with dyssynergic defecation (29.7%). These patients had significantly higher residual anal pressure and lower percentage of anal relaxation during defecation (109.6±43.2 *vs* 85.8±29.7 mmHg, p=0.038 and 9% *vs* 24%, p=0.018, respectively), as well as a lower differential of rectoanal pressure (-32.2±31.4 *vs* 3.0±29.6 mmHg, p<0.001). Patients with structural anorectal alterations had a significantly higher body mass index (BMI) (27.4±4.5 *vs* 23.5±3.3, p=0.002), and all obese patients had structural alterations.

Comparing the findings of HD-ARM and BET with MR-defecography: in group 1, 15 patients had structural alterations (75.0%); in group 2, 8 patients had structural alterations (72.7%); in group 3, 22 patients only had structural alterations (66.7%), 6 only had dyssynergic defecation (18.2%), 2 patients had both (6.0%) and 3 did not have any findings (9.1%). In 24.2% of patients with inconclusive findings in HD-ARM and BET, MR-defecography allowed the diagnosis of dyssynergic defecation.

Conclusion: Patients with structural anorectal alterations had a significantly higher BMI. Almost three quarters of patients with FC and IBS-C had relevant structural anorectal alterations and one third had dyssynergic defecation. Therefore, it is important to combine MR-defecography with HD-ARM and BET in the study of constipation.

Disclosure: Nothing to disclose.

Introduction: SRUS and UC can affect anorectal function, yet no study has directly compared HRAM findings and the efficacy of biofeedback therapy in these two conditions.

Aims & Methods: This study aimed to compare HRAM findings and the efficacy of biofeedback therapy in these two conditions to better understand the gut-brain disturbance in Solitary Rectal Ulcer Syndrome (SRUS) and Ulcerative Colitis (UC). 20 SRUS, 5 UC, and 20 healthy controls were included. HRAM was performed using a solid-state catheter following the London Protocol, with analyses conducted via the Laborie MMS system. Biofeedback therapy was delivered using a solid-state probe via the GatlTec system. Data on HRAM parameters, biofeedback, demographics, symptoms, and diagnoses were analyzed.

Results: Among SRUS patients, 9 (45%) were female, with a median age of 22.5 years (IQR: 15–73). UC patients included 3 (60%) females, with a median age of 28 years (IQR: 21–73). Healthy controls comprised 10 (50%) females, with a mean age of 25 years (±10 years). HRAM revealed that 14 (70%) SRUS patients had hypertensive, hypercontractile anal sphincters, while 3 (60%) UC patients exhibited hypotensive, hypocontractile anal sphincters. Mean squeeze anal pressure and endurance squeeze time were significantly higher in SRUS than in UC (132 ± 14.5 mmHg vs. 63.7 ± 20.1 mmHg; $p < 0.024$ and 14.3 ± 3 sec vs. 3.5 ± 2.5 sec; $p < 0.018$, respectively). Push relaxation percentage of the anal sphincter was significantly greater in SRUS than in UC (10 ± 6% vs. -7 ± 1.5%; $p < 0.011$). Both groups exhibited defecation dyssynergy. 15 (75%) SRUS patients displayed rectal hypersensitivity, while 4 (80%) UC patients exhibited rectal hyposensitivity. Sensory thresholds for the first constant sensation volume and defecatory desire volume were significantly lower in SRUS than in UC (19.5 ± 3 mL vs. 30 ± 15 mL; $p < 0.03$ and 70.6 ± 6 mL vs. 80 ± 23 mL; $p < 0.04$, respectively). Biofeedback therapy led to significant improvements across the anorectal motor and sensory functions in both groups, however, SRUS patients demonstrated a greater overall responsiveness.

	Solitary Rectal Ulcer Syndrome (SRUS)	Ulcerative Colitis (UC)	P	Healthy Controls
Resting Anal pressure (mmHg)	71.7 (6.8)	57.3 (11.8)	0.16	65 (15.2)
Squeeze Anal Pressure (mmHg)	132 (14.5)	63.7 (20)	0.02	122(15)
Endurance Squeeze (Sec)	14.2 (3.2)	3.3 (2.8)	0.01	25(5.6)
Anal Pressure (mmHg) „during cough“	101 (13)	78.7 (7)	0.07	90(7.6)
Ballon Expulsion Test (Sec)	42.6 (8)	167(103)	0.05	32(3.5)
Anal Residual Pressure „during push“ (mmHg)	64.5 (8.6)	51 (6.8)	0.13	59(10.8)
Push Relaxation (%)	9.5 (6.6)	-7.3 (1.4)	0.01	32(7.8)
First constant sensation volume (ml)	19.4 (3)	30 (15.3)	0.02	23(6.4)
Defecatory desire volume (ml)	70.5 (6)	80 (23)	0.03	73(9.2)

Table 1. Mean values of High Resolution Ano-Rectal Manometry metrics for Solitary Rectal Ulcer Syndrome, Ulcerative Colitis, and healthy controls.

Conclusion: SRUS and UC show distinct anorectal dysfunction patterns, SRUS with hypercontractile sphincters and rectal hypersensitivity, and UC with hypocontractile sphincters and hyposensitivity. Both groups had defecatory dyssynergia, but SRUS patients responded better to biofeedback. These findings support tailored physiologic assessment and therapy in defecatory disorders. Future research should include larger sample sizes to validate these findings and explore the long-term outcomes of biofeedback therapy in both SRUS and UC patients.

THE PREVALENCE AND BURDEN OF DISORDERS OF GUT-BRAIN INTERACTION (DGBI) BEFORE VERSUS AFTER THE COVID-19 PANDEMIC

O.S. Palsson[1], M. Simrén[2], A.D. Sperber[3], S.I. Bangdiwala[4], J. Hreinsson[2], I. Aziz[5]
[1]University of North Carolina, Chapel Hill, Dept. of Medicine, Chapel Hill, NC, United States of America, [2]Sahlgrenska University Hospital, Gothenburg, Sweden, [3]Ben-Gurion University of the Negev, Faculty of Health Sciences, Farod, Israel, [4]McMaster University, Hamilton, Ontario, Canada, [5]University of Sheffield, Division of Clinical Medicine, Sheffield, United Kingdom

Contact E-Mail Address: imran.aziz1@nhs.net

Introduction: COVID-19 infection may increase the risk of developing Disorders of Gut-Brain Interaction (DGBI). However, the extent of this effect on a population level is poorly understood. We performed a two-country survey to address this issue.

Aims & Methods: A population-based Internet survey with pre-defined demographic quotas was conducted across the UK and USA in 2017 (pre-pandemic, n=4050) and repeated in 2023 (post-pandemic, n=4002). The surveys included the Rome IV diagnostic questionnaire, and questions about non-gastrointestinal somatic symptoms, anxiety and depression, quality of life, and healthcare utilization. The 2023 survey also included questions regarding COVID-19 infection and illness history.

Results: The overall DGBI prevalence, i.e., meeting diagnostic criteria for at least one DGBI, has significantly increased from the pre- to post-pandemic era (38.3% vs. 42.6%, OR 1.20, 95% C.I 1.09-1.31), with similar findings independently noted in the UK and USA. The rise in DGBI was observed within the oesophageal (8.8% vs. 10.1%, OR 1.16), gastroduodenal (11.9% vs. 16.4%, OR 1.45), and bowel domains (30.1% vs. 32.5%, OR 1.12). The two most widely investigated DGBI showed large post-pandemic prevalence increases, with functional dyspepsia rising from 8.3% to 11.9% (OR 1.48) and irritable bowel syndrome from 4.7% to 6.0% (OR 1.31).

In multivariable analysis, factors significantly associated with having DGBI in the post-pandemic era included younger age, female sex, anxiety, depression, medium-to-high somatic symptom severity, increasing number of COVID-19 infections, experiencing abdominal pain or diarrhoea during COVID-19 infection, and suffering with long-COVID.

Individuals with DGBI in the post-pandemic era, in particular those with long-COVID, reported reduced quality of life and higher mood disturbances, somatic symptom reporting and healthcare use than individuals with DGBI in the pre-pandemic era.

Conclusion: The population prevalence and burden of DGBI have increased following the COVID-19 pandemic. Healthcare services and research funding bodies need to adapt to this post-COVID surge in DGBI and address how to best manage this patient group.

Introduction: Functional bowel disorders are characterized by the presence of altered bowel habits with or without abdominal pain.[1] Irritable bowel syndrome (IBS) is diagnosed based on recurrent abdominal pain; however, distinctions in the clinical phenotypes of IBS subtypes and other functional bowel disorders (FBDs), such as functional diarrhea (FD) and functional constipation (FC), remain underexplored.[2,3]

Aims & Methods: Aims: This study aimed to characterize the clinical presentation of IBS with predominant constipation (IBS-D) and IBS with predominant diarrhea (IBS-C), differentiating them from FD and FC, while recognizing the overlapping symptoms and the continuum between these conditions. Additionally, we examined the prevalence of psychological disorders and extra-intestinal comorbidities and identified potential mediators linking IBS to anxiety and depression.

Methods: Using data from the Rome Foundation Global Epidemiology Study, we analyzed 54,127 participants across 26 countries, including 2,195 patients with IBS. Clinical, dietary and psychological characteristics were assessed using validated questionnaires. Subgroup analyses compared IBS subtypes with FBDs, while mediation analyses (using the PROCESS macro and Baron and Kenny's method[4]) identified mediators of IBS-psychological distress relationship.

Results: As compared to patients with IBS-D, patients with IBS-C reported more severe pain characteristics, including prolonged pain episodes (50.7% vs. 47.0% of the time with pain lasting >30 minutes, p=0.030) and pain episodes that escalated to a sustained severe intensity (44.2% vs. 38.1%, p=0.026), frequently accompanied by back pain (36.7% vs. 30.9%, p<0.001). Regular use of prescribed pain medications was also more frequent in IBS-C (39.3%) than IBS-D (31.8%, p=0.004). In contrast, as compared to IBS-C, patients with IBS-D showed a stronger association of pain with changes in stool consistency (70% vs. 60% of time with pain, p<0.001) and frequency (mean 61.3% vs. 57.8% of time with pain, p=0.008). These associations remained significant in multiple regression models, which confirmed that IBS-C is more strongly linked to prolonged and escalating pain episodes, while IBS-D is more closely linked to pain associated with changes in stool frequency and consistency. As compared to FD, IBS-D patients reported greater dissatisfaction with bowel function (57.3±28.4 vs. 44.2±29.8, p<0.001), and more frequent loose stools (without constipation treatments) (60.0% vs. 50.0% of bowel movements, p<0.001), particularly after meals (60.0% vs. 40.0% of loose stools, p<0.001). IBS-C shows more severe constipation-related symptoms compared to FC (p<0.001). Mediation analyses revealed that concerns about bowel function, embarrassment discussing it, and work-related impairments partially mediated the relationship between IBS and psychological distress.

Conclusion: IBS-C is associated with more severe pain episodes, including prolonged and escalating pain, while in IBS-D pain is more strongly linked to bowel habit changes.

These findings highlight the distinct clinical profiles of IBS subtypes and emphasize the need for personalized, multimodal management strategies. Identifying mediators of psychological distress in IBS can guide targeted interventions, improving patient outcomes.

SURVEY OF MANAGEMENT HABITS & EMOTIONAL IMPACT IN PATIENTS WITH SELF-REPORTED IRRITABLE BOWEL SYNDROME (IBS)

J. Wray[1], F. Alves[2]
[1]Reckitt, Medical Affairs, Hull, United Kingdom, [2]Reckitt, Professional Marketing, Slough, United Kingdom

Contact E-Mail Address: joshua.wray@rb.com

Introduction: IBS is a a condition which is highly denigratory to patients' quality of life, is often under-diagnosed and is managed through a mixture of diet/lifestyle modifications, treatments and psychological interventions. The following piece of research aims to understand the management patterns and emotional impact of the condition in the IBS population.

Aims & Methods: Surveys were deployed in ten countries (n=1,250 per country, total n=12,500). People were invited to complete the survey if they were aged 18-75, suffering from at least one of the following; constipation, diarrhoea, wind/bloating, abdominal pain, irregular bowel movements or 'IBS'. With at least one incident in the past month.

Results: 9% of the surveyed population reported IBS, with 78% of this group having a diagnosis from a healthcare professional. Key triggers of symptoms were; stress (48%), food allergy/intolerance/sensitivity (20%), poor sleep (19%), infection (18%).

37% used medication, 31% used biotics, 22% diet and home remedies, 18% used supplements. Dissatisfaction with regular treatment were that most treatment options only treat the symptom but not the underlying cause, with females managing their symptoms through diet/lifestyle changes more than males.

The emotional impact in the IBS is very high in prevalence and broad in scope. 71% of IBS sufferers felt worried, anxious or stressed about their symptoms. 62% felt frustrated and fed up. 39% felt embarrassment and negative impact to their confidence. Only 5% were not bothered by their symptoms.

Conclusion: The survey gave insight into management patterns of IBS patients, demonstrating a variety of treatments used. Surprisingly, a high number of IBS patients use biotics despite low quality of evidence. It was

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

evident that IBS is a condition with a high emotional toll. Further qualitative research should delve further into these insights to further understand the patient population.

DISTINCT VOLATILE ORGANIC COMPOUND SIGNATURES IN EXHALED BREATH DIFFERENTIATE IRRITABLE BOWEL SYNDROME PATIENTS FROM HEALTHY CONTROLS USING GAS CHROMATOGRAPHY-QUADRUPOLE TIME-OF-FLIGHT MASS SPECTROMETRY

E. Moonen[1], K. Lamote[1], S. Velichkova[1], K. Zwijsen[1], L. Truyen[1], J. De Man[1], B. De Winter[1,2], H. De Schepper[2,1]
[1]University of Antwerp, Translational Sciences in Immunology and Inflammation, Antwerp, Belgium, [2]Antwerp University Hospital, Department of Gastroenterology Hepatology, Edegem, Belgium

Contact E-Mail Address: elias.moonen@uantwerpen.be

Introduction: Non-invasive biomarkers that enable accurate diagnosis, patient stratification, and therapy monitoring in irritable bowel syndrome (IBS) are still lacking in clinical practice. Volatile organic compounds (VOCs) produced by the host metabolism, inflammatory processes, and the gut microbiota are present in exhaled breath and have recently gained attention as promising biomarker candidates. Prior research (Van Malderen et al. (2020)) demonstrated that breath VOC profiling could accurately distinguish IBS patients from healthy controls using multicapillary column/ion-mobility spectrometry (MCC/IMS).

Aims & Methods: The present study aimed to assess the potential of high-resolution gas chromatography-quadrupole time-of-flight mass spectrometry (GC-QTOF-MS) profiling of breath VOCs to define distinct compound classes that enhance the mechanistic understanding of breath-based biomarkers in IBS. To this end, breath samples from 12 IBS patients and 11 healthy controls were collected, together with matched ambient air samples and were analyzed using GC-QTOF-MS.

Breath samples were corrected by background subtraction and least-absolute-shrinkage-and-selection-operator (LASSO) regression was applied with leave-one-out cross-validation (LOOCV) to identify discriminative VOC signatures. The feature set was subsequently filtered to exclude sporadically detected VOCs and compounds of exogenous (non-host) origin. Finally, the remaining VOCs were mapped to putative pathways.

Results: IBS patients had a mean ± SD age of 36 ± 15.3 years, compared with 56 ± 15.4 for the healthy controls. The male-to-female ratio was 3:9 in the IBS cohort and 5:6 among the healthy controls. Within the IBS group, 7 patients had diarrhea-predominant IBS, 4 had constipation-predominant IBS, and 1 had mixed-type IBS. The LASSO regression model, validated with LOOCV, demonstrated high discriminative performance in differentiating IBS patients from healthy controls, with the corresponding model metrics in Table 1.

Furthermore, the feature selection identified a panel of discriminative VOCs - predominantly alkanes, aldehydes, and ketones - that were up-regulated in the IBS breath profiles. These elevated compound classes could putatively be linked to mechanisms relevant to IBS pathophysiology, including altered microbial metabolism, increased oxidative stress, and low-grade inflammation.

Metric	LASSO-LOOCV
Sensitivity	91.3%
Specificity	81.8%
PPV	77.8%
NPV	64.3%
Accuracy	69.6%
AUC	0.88

Table 1: Model metrics.

Conclusion: Volatomic breath profiling in IBS, shows great potential for discriminating IBS from healthy controls and for defining clinically relevant biomarkers composed of specific VOCs. Nonetheless, the limited sample size might risk model overfitting and introduces uncertainty in the estimates. Further research including larger, confounder-controlled cohorts is necessary, along with the targeted validation of the identified VOCs to further confirm their mechanistic role in IBS.

Introduction: An in-depth analysis of the gut microbiota plays a crucial role in modern research exploring the relationship between intestinal microorganisms and human health. The use of molecular-genetic methods, particularly next-generation sequencing (NGS), provides a comprehensive understanding of the structural and functional characteristics of microbial ecosystems associated with the development of gastrointestinal pathologies.

Aims & Methods: To assess the features of the gut microbiome composition in different clinical variants of irritable bowel syndrome (IBS) in order to establish a foundation for microbiome-targeted personalized therapy. The study included 100 fecal samples, 90 from individuals with clinically confirmed IBS, and 10 samples from relatively healthy volunteers who formed the control group. The average age of participants was 55±2.23 years. DNA extraction from the samples was performed using the Zymo-BIOMICS DNA Mini Kit according to the official protocol. Taxonomic identification was conducted based on 16S rRNA gene amplification, which is considered the gold standard in phylogenetic studies of prokaryotes.

Results: The analysis revealed clear differences in the microbial composition between IBS subtypes and the control group. Specifically, for IBS-D (diarrhea-predominant type): the Firmicutes to Bacteroidetes ratio shifted towards Firmicutes (55.5% to 32.4%), indicating dysbiosis characteristic of metabolic disorders. For IBS-C (constipation-predominant type), a decrease in Bacteroidetes to 34% and an increase in Firmicutes to 52% were noted, which is associated with an increased risk of obesity and insulin resistance. In IBS-M (mixed type): partial stability of the microbial profile was observed, but with a predominance of Firmicutes (53%), possibly indicating altered intestinal motility. In all clinical variants of IBS, microbial

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. imbalance, reduced production of short-chain fatty acids, weakened mucosal barrier, and increased endotoxin activity of the microbiota were recorded. Additionally, a potential impact on the neuropsychological status of patients was traced, supporting the connection between the gut microbiome and the central nervous system.

Conclusion: The identified microbiome disturbances in various forms of IBS highlight the need for an individualized therapeutic approach, including diet therapy, the use of probiotic and prebiotic supplements, as well as promising pharmabiotics. A promising direction is the implementation of personalized microbiome corrections based on the patient's metagenomic profile.

ASSOCIATION BETWEEN PERCEPTION OF CONSTIPATION AND ROME IV CRITERIA: A CROSS-SECTIONAL STUDY AT THE NATIONAL HOSPITAL SRI LANKA

P. Perera[1], R. Wannakuwatte[1], D. Wickramasinghe[1], D. Wickramasinghe[1]
[1]University of Colombo, Department of Surgery, Colombo, Sri Lanka

Contact E-Mail Address: piyumiperera3350@gmail.com

Introduction: Constipation is a prevalent gastrointestinal disorder, commonly assessed using the Rome IV (R-IV) criteria for functional constipation. However, there is often a disconnect between a patient's subjective perception of constipation and the clinical criteria used for diagnosis. Patients may either perceive constipation when they do not meet the diagnostic criteria or fail to recognize it despite fulfilling the criteria. This gap in understanding can lead to over- or under-diagnosis and inappropriate treatment.

Aims & Methods: This study aimed to investigate the association between patients' subjective perception of constipation and the fulfillment of Rome IV (R-IV) diagnostic criteria, addressing potential discrepancies that may impact clinical diagnosis and management.

A cross-sectional study was conducted with 501 participants from the National Hospital Sri Lanka, who completed a self-reported questionnaire assessing bowel habits. Participants were categorized into four groups based on perceived constipation and R-IV fulfillment.

Pearson's chi-square test evaluated the association between these variables, while logistic regression analyzed predictors (gender, physical activity, water intake, stool consistency, and manual maneuvers) of constipation perception.

Results: Among the 501 participants (51.1% female), 36% reported perceiving constipation, whereas 25.5% met the R-IV criteria for functional constipation. A significant association was found between perceived constipation and R-IV criteria fulfillment ($\chi^2 = 12.77$, $p < 0.001$).

Notably, 23.6% of participants (Group 2) perceived constipation without fulfilling the criteria, while 13.0% (Group 3) met the criteria without perceiving constipation.

Only 12.6% both perceived constipation (Group 1) and met the R-IV criteria, and 50.9% (Group 4) neither perceived constipation nor met the criteria.

Manual defecation maneuvers were reported by 20.8% of participants, with digital evacuation (49%), bidet use (32.7%), and water enemas (31.7%) being the most common. The logistic regression model was statistically significant ($\chi^2(5) = 60.222$, $p < 0.001$), explaining 15.5% of the variance (Nagelkerke R^2) and correctly classifying 70.7% of cases. Participants requiring manual maneuvers were 5.17 times more likely to report constipation ($p < 0.001$), while higher Bristol Stool Category scores were associated with a reduced likelihood of constipation perception (OR = 0.85, $p = 0.009$). Gender, physical activity, and water intake did not significantly influence the model.

Conclusion: This study highlights the significant association between perceived constipation and fulfillment of the Rome IV criteria. However, a substantial proportion of participants either perceive constipation without meeting the criteria or meet the criteria without recognizing the condition. These findings emphasize the limitations of relying solely on patient-reported symptoms, which may not always align with clinical diagnoses. A comprehensive approach that integrates objective diagnostic measures and patient perception could enhance diagnostic accuracy, reduce unnecessary interventions, and improve patient care in resource-limited settings like Sri Lanka.

A MULTI-SPECIALTY RETROSPECTIVE EVALUATION OF DIAGNOSTIC AND MANAGEMENT STRATEGIES FOR BILE ACID DIARRHOEA IN TERTIARY CARE HOSPITALS

A. Javed[1], L. Hicks[1], J.R.F. Walters[1], A. Ruban[1]
[1]Imperial College Healthcare NHS Trust, Gastroenterology and Hepatology, London, United Kingdom

Contact E-Mail Address: anum.javed@nhs.net

Introduction: Bile acid diarrhoea (BAD) is a common yet often underdiagnosed cause of chronic diarrhoea. Despite its prevalence, BAD remains frequently overlooked in clinical practice. It is estimated that up to 30% of patients with diarrhoea-predominant irritable bowel syndrome (IBS) have underlying BAD, highlighting the importance of distinguishing between these two conditions for effective management. SeHCAT testing remains the gold standard modality for diagnosing BAD. Management typically involves bile acid sequestrants; however, notable variation exists in management approaches across clinical settings.

Aims & Methods: We retrospectively reviewed all SeHCAT tests performed across Imperial College Hospitals, London between 01/01/2023 – 31/12/2023. Electronic health records were interrogated to extract patient demographics, including age, gender, and ethnicity.

The results were analysed to determine the proportion of positive findings, which were subsequently stratified by severity. Corresponding management strategies were recorded to evaluate treatment patterns across clinical specialties.

Results: A total of 313 records were identified, of which 13 were excluded due to incomplete data. The average age of patients was 50 years. The predominant ethnicity was White (50.7%) and the majority of the patients were females (64.7%). Among the 300 remaining records, 154 had positive SeHCAT results with a 7 -day retention between 0 and 15%. Of these, 15.7% were categorised as having moderate bile acid malabsorption, followed by severe (13.3%), mild (11.0%), and borderline (11.3%) cases.

The majority of the requests originated from Gastroenterologists (86%), with a smaller proportion from Endobariatrics (5.3%), Hepatobiliary Surgeons (3.7%), Hepatologists (2%), Colorectal Surgeons (1.3%) and other specialities (1.7%). Colestyramine was the most commonly prescribed treatment, with 91% of patients initiated on a 4g once-daily dose. Approximately 26.9% of patients on colestyramine experienced side effects,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

necessitating a switch to colesevelam. The common side effects noticed were abdominal bloating, abdominal cramps, constipation and reflux. Conversely, 87% of patients on colesevelam continued treatment due to better tolerability, with only 13% exhibiting no clinical improvement. The most frequently prescribed dose was 1.25g daily in 45.3% cases. Among patients with normal SeHCAT results, the majority were diagnosed with diarrhoea-predominant irritable bowel syndrome (47.3%).

SeHCAT results	Number of patients	Percentage of patients
Borderline	34	11.3%
Mild	33	11.0%
Moderate	47	15.7%
Normal	146	48.7%
Severe	40	13.3%
Total	300	

Table 1: SeHCAT results.

Conclusion: Bile acid diarrhoea continues to be a prevalent factor contributing to chronic diarrhoea in healthcare. While existing treatment modalities have proven effective in managing this condition, they remain poorly tolerated. Our study confirms that colesevelam demonstrates improved tolerability compared to colestyramine.

Introduction: Irritable bowel syndrome (IBS) is a chronic gut-brain disorder that can be responsabil for a variety of uncomfortable gastrointestinal symptoms (laid out in the Rome Criteria) that can reduce quality of life. Although the precise mechanism remains unknown, recent research suggests that an imbalance in intestinal microbiota and a dysfunctional gut-brain axis may be involved in the development of IBS. Because of this, methods to restore the microbiota have been explored as treatment for this condition.

Aims & Methods: Randomized placebo controlled trial 180 patients: active group (probiotic formula, 3g/day- 92, placebo group – 88. men and women aged 24 to 75 who met the Rome IV criteria. One sachet probiotic (3 g) contains 7.5 billion bacteria: Lactobacillus casei W56, Lactococcus lactis W19, Lactobacillus acidophilus W22, Bifidobacterium lactis W52, Lactobacillus paracasei W20 Lactobacillus plantarum W62, Bifidobacterium lactis W51, Bifidobacterium bifidum W23, Lactobacillus salivarius W24. Assessments were made at 4, 8, 12 weeks. All patients agreed to maintain their lifestyle behaviors during their participation in the study.

Exclusion criteria: chronic gastrointestinal condition (other than IBS), including inflammatory bowel disease, lactose intolerance, celiac disease, diabetes, neoplasms.Patients have complete weekly data on stool frequency and consistency (Boston scale) and intensity of IBS symptoms (abdominal pain/discomfort, bloating, flatulence/borborygmi, and difficulty defecating) on a Likert scale of 0 (absent) to 7 (severe). Participants completed an IBS-specific quality of life questionnaire (IBS-QoL) at randomization (V1), fallow-up (V2) and at the end of the intervention (V3). Primary endpoint was mean weekly scores of gastrointestinal symptoms. Responders of abdominal pain were defined as subjects who experienced a reduction of at least 30% of the mean daily abdominal score reported at baseline (week 0). Secondary endpoints were the total AUC (W0-W12) of abdominal symptoms (abdominal pain, bloating and flatulence/borborygmi).

Results: There is a significant reduction in abdominal pain and bloating scores trough all 12 weeks of supplementation versus placebo. A higher overall IBS-QOL score, indicative of better QOL was reported at the end of the intervention (specially for interference with activity P=0.05, body image P=0.040, food avoidance P=0.03)

Conclusion: The probiotic treatment provides statistically significant and clinically relevant benefits for individuals with IBS. Improves gastrointestinal symptoms and quality of life in IBS patient

EFFICACY OF PROBIOTICS ON IRRITABLE BOWEL SYNDROME: SYSTEMATIC REVIEW AND META-ANALYSIS WITH TRIAL SEQUENTIAL ANALYSIS

S. Chong[1], J. Hsu[2], F. Sulaimi[3], A. Tang[1], B. Sim[1], T. Ong[1], E. Soon[1], C. Goh[1], J. Quek[1], K.T.H. Siah[4], Q.X. Ng[5]

Introduction: Recent years have seen a significant increase in randomized controlled trials (RCT) published on the efficacy of probiotics on irritable bowel syndrome (IBS), which several reviews have tried to comprehensively review. Two recent trials, Yang et al. 2024[1] and Chen et al. 2023[2] report the safety and efficacy of probiotics for IBS, which seems to reflect prevailing favorable view of this therapeutic option by most reviews conducted. Yet, despite efforts in this field, major organizations have not changed their stance in this and make no assertive recommendation for probiotics in afflicted patients[3,4].

While further investigations are required, two challenges are faced:

1. Repeated reviews have been undertaken in this field, resulting in a "multiplicity problem",

2. Traditional meta-analytic techniques may also fail to provide a conclusive answer on the sufficiency of evidence, particularly when the data are sparse, and the risk of type I and type II errors is significant.

This indicates a need for.

Aims & Methods: This study aims to evaluate the efficacy of probiotics in alleviating symptoms of IBS and improve quality of life through a timely implemented trial sequential analysis (TSA) and rigorously evaluate the evidence for recommendations on future studies. Medline, Embase, Web of Science, and Cochrane were screened for randomized controlled trials (RCTs) comparing probiotics to placebo in adult patients with IBS. Primary outcomes included IBS Symptom Severity Score (IBS-SSS) and IBS Quality of Life (IBS-QOL) scores comparing probiotics and placebo groups. Tra-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ditional pairwise meta-analysis conducted in restricted maximum likelihood was conducted, with subsequent TSA . Study quality was graded according to risk-of-bias 2 (ROB-2) and certainty of evidence was evaluated using the Grading of Recommendations Assessment, Development and Evaluation (GRADE).

Results: 42 studies were included. Overall, probiotics demonstrated non-significant improvements in IBS-SSS (MD: -27.64; 95% CI: -56.90 to 1.63; p=0.06) and IBS-QOL (MD: 1.33; 95% CI: -3.65 to 6.30; p=0.59). TSA was conducted on IBS-SSS demonstrated current evidence has not reached the required information size. The representative cumulative Z-curve demonstrated neither futility, benefit nor detrimental effect, indicating the need for further trials. Assessment with ROB-2 indicates high quality amongst most trials included in this study. GRADE evaluation of the evidence demonstrated low certainty of existing evidence.

No. of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Probiotics	Placebo	Relative (95% CI)	Absolute (95% CI)	Certainty
Probiotics effectively reduces a patient's IBS-SSS score											
24	randomised trials	not serious[a]	very serious[b]	not serious	very serious[c]	publication bias strongly suspected[d]	2237	1599	-	MD 27.64 lower (56.9 lower to 1.63 higher)	⊕◯◯◯ Very low[a,b,c,d]
Probiotics effectively reduces a patient's IBS-QOL score											
24	randomised trials	not serious[a]	very serious[a]	not serious	not serious[e]	publication bias strongly suspected[d]	2292	1712	-	MD 1.33 higher (3.65 lower to 6.3 higher)	⊕◯◯◯ Very low[a,b,d,e]

Table 1: GRADE Evaluation
CI: confidence interval; MD: mean difference.

Two contributing factors to the low certainty of current evidence include:
1. Inconsistency of existing trials – there exists high level of heterogeneity as detected by statistical analysis through I^2 and Cochran Q amongst studies;
2. Suspected publication bias through inspection of a funnel plot, though Egger's regression did not demonstrate statistical significance.

Conclusion: Existing evidence is insufficient to make conclusive recommendations regarding the role probiotics should play in the management of IBS in symptoms and QOL. Given the persistent heterogeneity and potential publication bias, future research should focus on standardizing probiotic interventions and clarifying their clinical utility to truly advance the field.

MICROBIOME PREDICTORS AND LONGITUDINAL DYNAMICS IN ASIAN PATIENTS WITH IRRITABLE BOWEL SYNDROME-DIARRHEA (IBS-D) CONSUMING A LOW FODMAP (FERMENTABLE OLIGOSACCHARIDES, DISACCHARIDES, MONOSACCHARIDES AND POLYOLS) DIET

J. Kuang Ziyang[1], A. Chung Chi Kong[2], S. Chang[2], Y.C. Ng[1], S. Wong Hei[2]

Contact E-Mail Address: dragoneti@hotmail.com

Introduction: Response rates to the Low FODMAP Diet (LFD) in IBS vary and predictors of benefit remain poorly defined. While several studies from Western populations have identified microbial signatures linked to response, data from Asian cohorts remain limited.

Aims & Methods: This study aims to identify microbial predictors and longitudinal microbiome shifts in Asian IBS-D patients consuming a LFD. We recruited 20 adult Asian patients with IBS-D diagnosed according to the ROME-IV criteria. All subjects received LFD dietary advice from a dietitian at initiation and were followed-up for a total of 28-days. Clinical response was assessed by a ≥50-point improvement in the IBS Symptom Severity Score (IBS-SSS) from Day 0 (baseline) as compared to follow-up at Day 28. Stool samples were collected at baseline, Day 14, and Day 28.
Microbial DNA was extracted using bead-beating and Qiagen PowerFecal kits, and the V3–V4 region of the 16S rRNA gene was amplified and sequenced on the Illumina MiSeq platform. Bioinformatic processing included denoising with DADA2, taxonomic assignment using the SILVA 138 database, and rarefaction to even sequencing depth. Microbiome metrics included alpha diversity (Shannon and Simpson), beta diversity (Bray-Curtis PCoA with PERMANOVA), and differential abundance testing with DESeq2.

Results: By Day 28, 11 of 20 patients (55%) achieved clinical response, with a median IBS-SSS reduction of 172 points (IQR: 88–248), compared to 24 points in non-responders (IQR: −11 to 55; p=0.003). Alpha diversity was not significantly different between groups, but responders exhibited a trend toward higher Shannon and Simpson diversity at baseline. Beta diversity analysis using Bray-Curtis dissimilarity revealed partial clustering by responder status (PERMANOVA p=0.06), and PCoA plots showed individual-specific shifts in community structure across time, indicating that the LFD induces personalized microbiome trajectories.
At baseline, responders had significantly higher relative abundances of butyrate-producing and anti-inflammatory genera, including *Ruminococcus*, *Blautia*, *Eubacterium siraeum*, and *Bifidobacterium bifidum* (adjusted p<0.05). These findings are consistent with prior reports, including Bennet et al. (2018) and Vervier et al. (2022), where such taxa were part of a "health-like" IBS-P (pathogen-enriched) to IBS-H (health-like) axis. The enrichment of *Blautia* and *Ruminococcus* is particularly noteworthy as these are established butyrate producers involved in maintaining colonic barrier function and reducing visceral hypersensitivity. By Day 28, differential abundance analysis revealed that responders exhibited increases in *Ruminococcus bicirculans*, *Parabacteroides gordonii*, and *Weissella cibaria*. In contrast, non-responders showed persistence or increases in taxa such as *Tyzzerella* and *Olsenella*, which have been associated with inflammation or IBS severity in prior studies (Chuah et al., 2024).

Conclusion: This study provides novel microbiome insights from an underrepresented Asian IBS population consuming a LFD. Despite dietary and baseline microbiota differences from Western populations, we observed remarkably consistent microbiome predictors of response, including higher baseline levels of butyrate-producing taxa and favorable microbial restructuring during the intervention.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Contact E-Mail Address: sevandrea96@gmail.com

Introduction: Functional constipation (FC) and constipation-predominant irritable bowel syndrome (IBS-C) are highly frequent conditions characterized by chronic constipation (up to 24% in adults) (1).

The initial management of chronic constipation typically involves dietary and lifestyle modifications, fiber supplementation, and laxative therapy. For patients who do not respond to these interventions, second-line therapies, such as medications with prokinetic effects, are recommended. Pyridostigmine, an anticholinesterase agent commonly used in the treatment of myasthenia gravis and paralytic ileus, might play a role in refractory chronic constipation, but evidence is still not available.

Aims & Methods: We carried out a retrospective observational study involving all patients diagnosed with functional constipation (constipation-predominant irritable bowel syndrome [IBS-C] or chronic idiopathic constipation) according to the Rome IV criteria, who met the criteria for severe chronic constipation (2) (defined as two or fewer spontaneous and complete bowel movements per week for a minimum of 6 months, associated with hard stools, sensation of incomplete evacuation, or straining during defecation in at least 25% of bowel movements), who were refractory to first-line treatments (dietary and lifestyle counseling, bulk-forming laxatives, osmotic laxative such as polyethylene glycol and stimulant laxative such as bisacodyl) and who were treated with pyridostigmine in our outpatient gastroenterology clinic from April 2021 to December 2024. Patients were included if they attended at least one follow-up visit within 12 weeks after treatment.

We excluded all patients with organic gastrointestinal disorders. We evaluated the improvement in constipation at follow-up, defined as patients having three or more spontaneous, complete bowel movements per week during the follow-up period. (2)

We also evaluated any improvement in other gastrointestinal symptoms and the safety profile of the treatment.

Results: Overall, 110 patients were included in the study, of whom 77 (70%) met the criteria for IBS-C and 33 for chronic idiopathic constipation (30%). Other gastrointestinal symptoms included bloating (n=88, 80%), abdominal pain (n=77, 70%), dyspepsia (n=17, 15%). Overall, 74 (67%) patients experienced an improvement in constipation. Additionally, 51(46%) patients exhibited improvements in other gastrointestinal symptoms: 38/77 (49%) patients experienced relief from abdominal pain, 35/88 from bloating (40%), and 10/17 (59%) from dyspepsia. Finally, Four (4%) patients have discontinued therapy due to pyridostigmine intolerance (2 patients experienced muscle fasciculation, 2 patients fatigue); no severe therapy-related adverse events were observed.

Conclusion: In our cohort, pyridostigmine was an effective and safe treatment for IBS-C and chronic idiopathic constipation in patients unresponsive to first-line treatments, providing benefits not only in alleviating constipation but also in ameliorating other gastrointestinal symptoms. Further prospective and randomized studies are warranted to confirm our findings.

Contact E-Mail Address: mohsin.butt@nhs.net

Introduction: Behavioural therapies, including cognitive behavioural therapy (CBT), are effective in the treatment of irritable bowel syndrome (IBS), which has a population prevalence of 4.3% in the UK (1). Mahana™ IBS is a Food and Drug Administration-cleared prescription mobile application designed to deliver 3 months (10 sessions) of gut-directed CBT to adults with IBS.

This prospective study evaluated patient compliance with the Mahana™ application and the change in gastrointestinal (GI) and psychological symptoms in a real-world UK setting.

Aims & Methods: Patients diagnosed with Rome IV IBS in a neurogastroenterology outpatient service were offered the Mahana™ CBT application, alongside standard medical management consistent with British Society of Gastroenterology IBS guidelines. At baseline and 3-month follow-up, patients completed the IBS Symptom Severity Scale (IBS-SSS), Patient Health Questionnaire-9 (PHQ-9), and Generalised Anxiety Disorder-7 (GAD-7) scale to measure severity of IBS symptoms, depression, and anxiety, respectively. Matched samples, unmatched samples, and correlations were determined using the Wilcoxon signed-rank, Mann–Whitney U, and Spearman's ρ, respectively, using SPSSV29.0.

Results: Seventeen patients (females: 12/17 (70.1%), mean age: 45.8 [15.9]) enrolled onto the study, among whom 9 (52.9%), 5 (29.4%) and 3 (17.6%) were diagnosed with IBS-C, IBS-M and IBS-D, respectively. Twelve patients (70.6%) completed the entire intervention. At baseline, the mean

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

IBS-SSS, PHQ-9 and GAD-7 scores were consistent with severe IBS (321.3 [73.7]), mild depression (7.7 [5.8]), and mild anxiety (7.2 [6.0]), respectively. Compared to baseline, there was a reduction in the mean IBS-SSS (321.2 [73.7] vs 241.1 [88.5],*P*<.001), PHQ-9 (7.7 [5.8] vs 5.9 [4.7],*P*=.1) and GAD-7 (7.2 [6.0] vs 4.7 [3.7],*P*=.04) scores at follow-up. Eleven (64.7%) patients had a clinically significant reduction in IBS symptom severity at follow-up compared to baseline.

There was a statistically significant correlation between the duration (in months) from when a patient was diagnosed with IBS to when they were prescribed the application and symptom improvement in the PHQ-9 (ρ=-0.5,*P*=.04), but not the IBS-SSS (ρ=-0.3,*P*=.4) nor GAD-7 (ρ=-0.1,*P*=.8). Similarly, age was correlated with symptom improvement in the PHQ-9 (ρ=-0.5,*P*=.04), but not the IBS-SSS (ρ=-0.3,*P*=.3) nor GAD-7 (ρ=-0.2,*P*=.5).

There was no statistically significant difference in the change in IBS-SSS (-83.3 [84.1] vs -72.6 [37.4],*P*>.99), PHQ-9 (-2.8 [3.5] vs 0.8 [3.7],*P*=.1) nor GAD-7 (-3.8 [4.5] vs 0.2 [3.3],*P*=.08) scores among patients who completed the entire application vs those who did not. Symptom improvement in the IBS-SSS score was greater among males than females (*P*=.04), but sex did not affect change in the PHQ-9 nor GAD-7 scales.

Conclusion: The Mahana™ IBS application was associated with a significant improvement in GI and psychological symptoms in a real-world UK setting.

Introduction: Postbiotics, non-viable microbial components with health benefits, are increasingly used due to their safety and stability. However, evidence supporting their efficacy and safety in irritable bowel syndrome (IBS) remains limited.

Aims & Methods: This first-ever systematic review and meta-analysis evaluates the efficacy and safety of postbiotics in IBS management. Four databases (PubMed, Scopus, Embase, Web of Science) were searched up to April 2025 for randomized controlled trials (RCTs) assessing postbiotics in Rome III/IV-diagnosed IBS adults.

Primary outcomes were IBS Symptom Severity Scale (IBS-SSS) scores and ≥30% pain reduction; secondary outcomes included QoL and treatment-emergent adverse events (TEAE). Cochrane RoB 2.0 assessed bias, and random-effects meta-analyses were conducted (RevMan 5.4).

Results: Of 1,053 records, 768 duplicates removed, 281 articles were excluded, and eventually four RCTs were analysed. The participants' mean age ranged from 34.88 to 47.47 years old, and the intervention lasted from two to twenty-six weeks. The RCTs were executed in countries including Germany, Sweden, and India and published between 2020 and 2024.

The studies investigated different postbiotic formulations included non-viable *Bifidobacterium bifidum* HI-MIMBb75 cells (two capsules daily for 8 weeks), nonviable bacterial lysate of *Escherichia coli* and *Enterococcus faecalis* (gradual dose escalation over 26 weeks), fermented oat gruel with *Lactobacillus plantarum* 299v (administered as an enema for 2 weeks), and heat-treated *Bifidobacterium longum* CECT 7347 (HT-ES1) (two capsules daily for 12 weeks).

Of these postbiotic formulations, *Bifidobacterium longum* CECT 7347 was specifically heat-treated, whereas the other formulations were not heat-treated but were non-viable. Three of the four formulations (Andersen 2020, Mack 2021 and Srivastava 2024) were administered orally (as capsules or drops) and only one (fermented oat gruel) (Bednarska 2022) was administered by enema (Table1).

Postbiotics significantly improved IBS symptom severity (P < 0.001) with moderate heterogeneity (I^2 = 69%; P = 0.07). For pain intensity, postbiotics also showed significant reduction (P = 0.02) with substantial heterogeneity (I^2 = 87%; P = 0.0005). QoL improvement was significant after excluding one study using postbiotic enema preparation (P < 0.001) with no residual heterogeneity (I^2 = 0%). Safety analysis found no significant difference in TEAE between postbiotics and placebo (RR 0.68, 95% CI 0.35-1.34; P = 0.26; I^2 = 54%).

			POPULATION			INTERVENTION			COMPARATOR

Introduction: Colonic angiodysplasia is a common endoscopic finding with strong associations to gastrointestinal bleeding. Despite its clinical relevance, documentation in examination reports is often inconsistent and image-based identification varies widely. Artificial intelligence (AI) offers the potential to standardize the detection and documentation of such findings.

Aims & Methods: In this study, we develop and evaluate an AI for identifying angiodysplasia in colonoscopy images. Furthermore, we evaluate the potential of such a model in improving the frequency and consistency of documentation for this finding. Examination data from 34,953 colonoscopies containing both examiner reports and corresponding image documentation were retrospectively evaluated. Initially, 993 examination whose report contained angiodysplasia-related terms were identified, yielding 10,908 associated images. The collected images were manually annotated and used to train an AI for identifying colonic angiodysplasia. External validation was performed on 3,936 annotated images from 240 examinations at a second clinic. Subsequently, AI predictions were collected for images from examinations from the second clinic, in which angiodysplasia was not mentioned in the reports, to identify potential underreporting.

Results: On the external validation set, the AI achieved an accuracy of 94.3% (95% CI: 93.5%–95.1%), with a sensitivity of 80% (95% CI: 76.8%–84%) and specificity of 96.5% (95% CI: 95.9%–97.2%) for detecting angiodysplasia. Using this AI we were able to identify 112 examinations with angiodysplasia findings in the recorded image documentation that had not been mentioned in the corresponding reports.

Conclusion: AI can reliably identify colonic angiodysplasia from endoscopic images. Integrating such technology into the reporting workflow has the potential to improve the completeness and consistency of endoscopic documentation.

Introduction: Colonic diverticulosis is a prevalent gastrointestinal condition that is often diagnosed incidentally. However, its association with chronic polyps and rectal hemorrhoids remains underexplored, particularly in the northern region of Saudi Arabia.

Aims & Methods: This study aimed to assess the relationship between colonic diverticulosis and colonic conditions while considering demographic and clinical factors. This retrospective observational study was conducted at a tertiary referral center over four years. Data from 4,014 patients who underwent colonoscopy were analyzed. Statistical tests, including chi-square and independent sample t-tests, were used to determine associations between diverticulosis, polyps, hemorrhoids, and bowel preparation adequacy.

Results: Diverticulosis was observed in 14.2% of the patients, with a higher prevalence among males (16.1%) than among females (12.1%) ($p < 0.001$). Patients with diverticulosis were significantly older (mean age 61.35 years) than those without diverticulosis (mean age 48.25 years) ($p < 0.001$). Hemorrhoids were more frequent in patients with diverticulosis (18.6%) than in those without diverticulosis (11.9%) ($p < 0.001$).

A similar association was found between diverticulosis and polyps, with the polyp prevalence being higher in patients with diverticulosis (21.4%) than in those without (11.7%) ($p < 0.001$).

Additionally, inadequate bowel preparation was more common among patients with diverticulosis (17.1%) than among those with adequate bowel preparation (13.6%) ($p = 0.023$).

Conclusion: This study highlights a significant association between colonic diverticulosis and the presence of polyps and hemorrhoids. Older age and male sex were identified as the key risk factors.

These findings emphasize the importance of targeted screening and optimized bowel preparation in at-risk patients. Further research is required to explore the underlying pathophysiological mechanisms and to develop preventive strategies.

IMPACT OF MEDITERRANEAN DIET AND PHYSICAL ACTIVITY IN PATIENTS WITH SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE (SUDD)

A. Ferronato[1], A. Violi[2], K.I. Rodriguez-Castro[3], M. Costalunga[3], M. Franceschi[3]
[1]AULSS 7 Pedemontana, Gastroenterology Unit, Bassano del Grappa, Italy, [2]ASST Mantova, Gastroenterology Unit, Mantova, Italy, [3]AULSS 7 Pedemontana, Endoscopic Unit, Santorso, Italy

Contact E-Mail Address: antonio.ferronato@aulss7.veneto.it

Introduction: Symptomatic Uncomplicated Diverticular Disease (SUDD) is a widespread gastrointestinal condition linked to sedentary lifestyles and unhealthy dietary patterns, often requiring medications. Mediterranean Diet (MedDiet) and physical activity (PA) have been proposed as potential protective factors against various diseases, including SUDD.

Aims & Methods: The aim is to evaluate if a counseling program which encourages MedDiet and PA can influence SUDD symptoms, drug use and quality of life.

In this prospective, monocentric, observational study, we enrolled consecutive patients with diagnosis of SUDD at colonoscopy. They were divided into two groups: the Study Group (SG) received a 3-month lifestyle counseling promoting MedDiet and regular PA, while the Control Group (CG) followed a free diet. Lifestyle counseling consisted of 3 medical visits (every 6 weeks) and 4 phone calls (every 2 weeks). Patients were evaluated at baseline (T0), 12 weeks (T12, end of counseling) and 52 weeks (T52). We collected clinical data and anthropometric data, MediLite score (a validated adherence score for MedDiet), questionnaires assessing PA and symptom burden expressed both as specific item and as multiparametric scores including Irritable Bowel Syndrome Severity Scoring Scale (IBS-SSS) and Visual Analogical Scale for patients with SUDD (VAS-DICA), and SF-12 for the assessment of quality of life.

Results: 84 patients (F=48) were enrolled, of whom 41 subjects were included in SG while 43 in CG. At T12, while CG characteristics remain unchanged, the Medi-Lite score in SG rose from 9,12±2,0 to 10,3±2,23 (p=0,011) and daily walking time increased, with 92,5% of SG reporting walking for 30–60 minutes daily compared to 42,5% at T0 (p< 0,001). At T52, SG had still a high % of patients with high adherence to MedDiet (MediLite >10) (from 46,34% to 56,01%, p<0.001) and PA adherence was 63,41% (p=0,001).

Compared to CG, SG showed a reduction of abdominal pain (SG/CG at T0 51,22/58,14%, at T12 24,4/46,51%, p=0,012, at T52 31,71/53,49%, p=0,018), constipation (at T0 19,51/25,58%, at T52 7,32/44,19% p<0,001), and IBS-SSS score (at T0 141±98,5/150±94,1, at T12 71±61,6/123±104, p=0,002, at T52 69,1±52,4/101±97,5, p<0,001).

Subjects in SG who reported medication use for SUDD dropped from 43,9% to 26,83% at T12 and 24,39 at T52 (p<0,05) while an increase of overall medication use was observed in the CG (from 25,58 to 51,16, and 83,72% at T0, T12, and T54, respectively), in particular regarding the use of rifaximin (from 6,98% to 13,95% and 34,88%), both at T12 (p=0,01) and T52 (p<0,001). Overall, the CG had a higher rate of diverticular disease complications including acute diverticulitis, need for hospitalization and surgery: 12 vs 1 patient in the CG vs SG, respectively (at T52=0,001).

Conclusion: Higher adherence to MedDiet and PA are associated with symptom relief, reduced use of medication, and reduction of disease-associated complications in patients with SUDD, suggesting a therapeutical role of MedDiet and PA which goes beyond the already recognized preventive action. Clinical benefits of a 3-month counseling may still be present at 1 year.

Disclosure: Nothing to disclose.

PP0623

RESULTS OF A MULTICENTER STUDY ON THE IMPACT OF COMBINATION THERAPY WITH RIFAXIMIN AND TRIMEBUTINE ON QUALITY OF LIFE AND DISEASE COURSE IN UNCOMPLICATED DIVERTICULAR DISEASE IN REAL CLINICAL PRACTICE (ALLIANCE)

Sechenov, Moscow, Russian Federation

Contact E-Mail Address: mamievazarina@mail.ru

Introduction: Uncomplicated diverticular disease (UDD) is common bowel disease and significantly reduces the quality of life of patients. *The normokinetic agent trimebutine and the non-absorbable antibiotic rifaximin are proposed* to treat UDD and improve the quality of life of patients.

Aims & Methods: To evaluate the effect of combination therapy with rifaximin and trimebutine on improving the quality of life in patients with UDD in routine clinical practice. This multicenter observational study included patients with UDD who complained of abdominal pain, constipation/diarrhea, bloating, and/or tenesmus. Patients received combination therapy with rifaximin 400 mg/d for 7 days and trimebutine 300 mg bid for 21 days each month for 6 months. In addition to these drugs, mesalazine could be prescribed.

The primary outcomes were the improvement of quality of life and symptoms (pain, constipation/diarrhea bloating).

Secondary outcomes included treatment adherence and safety.

Quality of life was assessed using the SF-12 questionnaire. Symptoms (abdominal pain, constipation/diarrhea, bloating, tenesmus) were assessed on a 4-point scale: no symptom, mild and *minimally affecting daily life*), moderate (bothers the patient, but does not interfere with daily activities), or severe (impairs daily activities) one. Treatment adherence was assessed using Morisky-Green questionnaire. These parameters were assessed at baseline (Visit 1) and at Days 30, 65, 100, 135 and 170 after the inclusion (Visits 2–6).

Results: The study included 100 patients aged 40–70 years (58.2 ± 9.5 years). The most common complaints were abdominal pain (84%) and bloating (72%), while constipation (33%) and tenesmus (30%) were less frequent.

After the first month of therapy, patients showed a significant reduction in the severity of all symptoms (p<0.001 for each symptom) and an improvement in quality of life (p<0.001), which was maintained throughout the entire observation period.

Symptoms		V1 (day 1-2)	V 2 (day 28-30)	p, (V2/V1)	V3 (day 70-72)	p, (V3/B1)	V6 (day 166-168)	p, (V6/V1)
Pain (N=99)	Mean ± SD	2,1±0,6	1,2±0,7	<0,001	0,6±0,7	<0,001	0,1±0,3	<0,001
Bloating (N=98)		1,8±0,6	1,1±0,6	<0,001	0,6±0,7	<0,001	0,3±0,5	<0,001

Table. Dynamics of symptoms of UDD across the study.

A clinically significant positive effect of the therapy was achieved by Visit 2 in 82% of patients (82/100). By Visit 6, complete remission was achieved in 55% of participants. The treatment adherence was high in 76% of patients, moderate in 21% of patients and poor in 3% of patients. There were no reports of any serious adverse events and adverse reactions.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The combination of rifaximin and trimebutine reduces symptom severity and improves quality of life in patients with uncomplicated diverticular disease without the development of any serious adverse events and adverse reactions.

Disclosure: Current study was conducted with the financial support of Binnopharm Group.

PP0624

EFFICACY OF SYNBIOTIC SUPPLEMENTATION IN PATIENTS WITH SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE: A SINGLE-CENTRE, DOUBLE-BLIND, RANDOMISED, PLACEBO-CONTROLLED TRIAL

C. Sbarigia[1], C. Ritieni[1], G. Galli[2], M. Carabotti[1], B. Annibale[1]
[1]University Sapienza, Medical-Surgical Department of Clinical Sciences and Translational Medicine, Rome, Italy, [2]Tivoli Hospital, Rome, Italy

Contact E-Mail Address: cate.sbarigia@gmail.com

Introduction: Symptomatic uncomplicated diverticular disease (SUDD) is characterized by recurrent gastrointestinal (GI) symptoms in patients with colonic diverticula. Different treatments have been proposed to improve GI symptoms, but with low-level of evidence.

Aims & Methods: We aimed to evaluate the efficacy of a synbiotic formulation combined with a diet rich in fibre (DRF) in improving GI symptoms in SUDD, compared to a DRF and placebo. We conducted a single-centre, no-profit, randomised, double-blind, placebo-controlled trial (Local Ethics Committee n.182 SA_2020). Patients diagnosed with SUDD (colonic diverticula and recurrent abdominal pain with or without altered bowel habits or bloating, in the absence of signs of systemic inflammation) were included.

After a 14-day run-in period, all participants completed structured questionnaires [long- and short-lasting abdominal pain, abdominal bloating, Rome IV for IBS, food frequency questionnaire and quality of life (SF-12)], received a dietary counselling, and were randomised to receive either (I) Enterolactis duo (containing the probiotic strain Lacticaseibacillus Paracasei DG and the prebiotic fibre inulin) 1 sachet bid plus advice on DRF (arm A), or (II) Placebo, 1 sachet bid plus advice on DRF (arm B) for 12 weeks. During treatment, patients completed a weekly diary of GI symptoms and bowel habits. At the end of treatment, patients completed all questionnaires again and were followed up after 4 weeks.

Results: After screening 81 patients, 34 (55.9% female; mean age 64±8.6yrs) were included and randomised to arm A (n=17) and arm B (n=17). At baseline, there were no significant differences in terms of clinical characteristics between the two arms. Thirty patients (arm A=14; arm B=16) completed the study. Compliance with the DRF was poor in both arms (0% vs 14.3%).

Patients experienced significant improvements in GI symptoms (bloating, short- and long-lasting abdominal pain) and bowel habits compared to baseline in both arms, but no differences were observed between the two arms.

Neither arm A nor arm B reported significant changes in the quality of life scores. Mild self-limited adverse events were reported with no differences between arms. Follow-up at 4 weeks showed no clinical changes in either arm, with no differences between arms.

Conclusion: This synbiotic supplementation is as effective as placebo in relieving symptoms in SUDD patients, suggesting the relevant role of the placebo effect also in diverticular disease.

Disclosure: Nothing to disclose.

PP0625

THE MANAGEMENT OF A RARE CASE OF A RECTAL HPV-INDUCED HIGH-GRADE SQUAMOUS INTRAEPITHELIAL LESION

E. Kaya[1], V. VandenDriessche[1], H. Vandenbulcke[1], P. Yengue[1], C. Boland[2], M.A. Denis[3], L. Capirchio[1]

Contact E-Mail Address: kayaeda@hotmail.com

Introduction: Ano-genital infection by human papillomavirus (HPV) is an increasingly common sexually transmitted disease that often causes anal *condylomata acuminata* and is associated with the development of anal intraepithelial neoplasia (AIN). The management of which is widely discussed in the current literature; however, no international recommendations exist regarding the treatment and follow-up of HPV-induced lesions of rectal localization, which are extremely rare.

Aims & Methods: Our aim is to describe the management and follow-up of a rare rectal HSIL induced by HPV with a combined step-up endoscopic-surgical approach that led to an R0 resection.

For many years, surgery was the standard treatment for managing HPV-related ano-rectal lesions. More recently the approach to screening and follow-up for anal intraepithelial neoplasia and dysplasia has evolved, with new international guidelines [1 - 2].

However guidelines on the management of HPV-related rectal lesions are scarce. Endoscopic submucosal dissection (ESD) is a promising less invasive alternative. It allows for simultaneous diagnosis and resection while providing clear visualization of the tumor margin, potentially reducing the risk of recurrence.

Nevertheless few case reports and studies demonstrating the effectiveness of ESD in the treatment of HPV-induced anal and rectal lesions have been published [3 - 6].

Results: We present an unusual case of a 65-year-old male with a high-grade HPV-induced squamous intraepithelial lesion (HSIL, classified as AIN 2 or 3) of rectal topography. The lesion extended 8 cm from the anal margin to the middle rectum. A patient history revealed our patient was an immunocompetent man who had sex with men (MSM) including regular receptive anal intercourse with multiple partners, anal penetration of foreign objects and iterative rectal enema following dyschezia. This could explain a secondary inoculation of HPV onto a post-traumatic scarred rectal tissue. Initial management involved surveillance at 6-month intervals, combined with the cessation of intrarectal penetrating activity.

This approach was based on an extrapolation of the current guidelines from the Société Nationale Française de Colo-Proctologie (SNFCP) for anal precancerous lesions associated with HPV infection, aiming for spontaneous dysplasia regression.

However, the rectal lesion persisted at the 6-month follow-up. Pelvic magnetic resonance imaging revealed limited expansion, and the lesion was consequently managed through a multidisciplinary endoscopic-surgical step-up approach. Initial treatment with ESD was attempted but limited by extensive fibrosis and the lesion's depth. As a result, surgical intervention was required, and a full-thickness resection (FTR) was performed within the same sedation period. This approach led to a monobloc resection measuring 9.7 x 6.8 x 0.3 cm, achieving a complete R0 resection with a minimal 3 mm healthy margin.

Conclusion: Rectal HPV-induced HSIL are extremely rare, therefore data regarding treatment is limited. This case demonstrates the successful R0 resection by combining a step-up endoscopic-surgical approach. Endoscopic resection proved challenging due to extensive fibrosis and the lesion's substantial depth, necessitating a subsequent surgical FTR to

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ensure complete excision. Follow-up at a 3-month interval, in accordance with the AIN guidelines, revealed no recurrence of dysplasia. However, the long-term effectiveness of this approach in maintaining sustained remission remains uncertain, and there is currently no established follow-up protocol for rectal HPV-induced HSIL.

Introduction: Approximately 50% of people have problems with hemorrhoids at some point in their lives. We aimed to investigate the effectiveness of a new rectal micro-encapsulated sodium butyrate suppository in the treatment of hemorrhoid disease.

Aims & Methods: All consecutive patients attending the outpatient clinic of the 5 participating hospitals with symptoms of pain, pruritus or passing of bright blood per rectum due to hemorrhoid disease were eligible for entering the study. Pregnant women and patients with rectal cancer were excluded. The intensity of symptoms was evaluated with a 5-point Likert scale, while hemorrhoids were classified as internal or external. All patients received once a day for 10 days a suppository that weighs 2,0gr and contains sodium butyrate, sodium alginate, carboxymethylcellulose, triglycerides of saturated fatty acids with the addition of monoglycerides and diglycerides. The effectiveness of treatment was evaluated at the end of the 10-day administration and was defined as the complete disappearance of pain, pruritus and hemorrhage. The concomitant use of lidocaine or phlebotropic drugs that were administered according to the treating physician's judgment was also recorded.

Results: From January 2024 till March 2025, 179 patients [male/female: 106/73, mean±SD age: 51±24, mean±SD BMI: 27.42±5.91) received the rectal micro-encapsulated sodium butyrate suppository for the treatment of pain (n=82), pruritus (n=55) and hemorrhage (n=143). Twenty-one patients (11.7%) had also diabetes mellitus, 18 (10.0%) were receiving anticoagulants and 51 (28.5%) were active smokers. Ninety (50.3%) patients had external and 135 (75.4%) internal hemorrhoids [grade 1=52 (38.5%), grade 2=54 (40.0%), grade 3=21 (15.5%), grade 4=6 (4.4%)]. The mean±SD intensity of pain and pruritus was 2.10±1.24 and 1.90±1.34 respectively. Thirty-two (17.8%) patients had also an anal fissure. Forty (22.3%) patients were receiving lidocaine ointment and 29 (16.2%) were receiving phlebotropic drugs during the time of the rectal suppository administration. After the 10-day administration period success of treatment was seen in 161 (89.9%) patients. No adverse events from the use of the rectal suppository were seen.

Conclusion: The use of micro-encapsulated sodium butyrate in suppository form appears to be safe and effective for the treatment of symptoms due to hemorrhoid disease.

Disclosure: No conflicts of interest.

THE DISTENSIBILITY INDEX, ASSESSED BY IMPEDANCE PLANIMETRY (ENDOFLIP™), DIFFERENTIATES WOMEN WITH SUSPECTED FUNCTIONAL DEFECATION DISORDER FROM THOSE WITH FECAL INCONTINENCE AND HEALTHY VOLUNTEERS: PRELIMINARY RESULTS

A. Ezquerra-Durán[1], J. Nuñez[1], J. Siles[1], M. Lleixà Rioboo[1], I.K. Araujo Acuña[1], C. Ros[2], E. Barba Orozco[1]

Introduction: Pelvic floor dysfunction is highly prevalent. Posterior compartment disorders include fecal incontinence (FI) and obstructive defecation syndrome (ODS). Assessment of the sphincter complex's (SC) ability to resist or yield to distension may provide a valuable method for evaluating continence and defecatory function.

Aims & Methods: Women with FI, chronic constipation (CC) and suspected functional defecation disorder (FDD), as well as healthy volunteers (HV) were included. Impedance Planimetry (IP) was performed using the anal functional lumen imaging probe [EndoFLIP™ System (Medtronic®) with an 8-cm catheter (EF-325N)]. A "stepwise" measurement protocol was applied, with bag filling from 0 to 50ml in 10-ml increments. Distensibility index (DI) was recorded at rest, voluntary squeeze, cough maneuver and during simulated evacuation at 30-, 40- and 50-ml volumes. Simulated defecation was evaluated by calculating the percentage change in the DI relative to resting values at each volume.

Results: Fifteen women were included: 4 HV (26.7%), 7 with FI (46.7%) and 4 with CC (26.7%). Women with FI were older than those in the CC and HV groups (median age: FI 72 years [66–75], CC 55 years [42-63], HV 48 years [43–53], p = 0.009. Median BMI was similar among groups [HV 24.0 Kg/m^2 (21.6 – 25.3), FI 27.0 Kg/m^2 (24.3 – 30.0) and CC 26.2 Kg/m^2 (21.5 – 30.5), p=0.367]. The DI was significantly higher in the FI group compared to CC and HV groups at rest, during squeeze and during cough maneuver across 30-, 40- and 50-ml volumes. The percentage change in DI during simulated defecation at 50 ml was significantly reduced in CC compared to HV (p=0.030). When groups were categorized based on suspected FDD (CC vs HV+FI), the percentage change in DI was significantly lower in CC at 40 ml [74% (37 – 109) vs 175% (100 – 250), p=0.037] and at 50 ml [81% (43 – 96) vs 111% (96 – 119), p=0.048].

50 ml Percentage change in DI (%). Median (IQR)	117 (113 – 301) ¶	99 (95 – 110)	81 (43 – 96) ¶	0.030

†=Statistically significant difference (p<0.05) between FI and CC groups.
§= Statistically significant difference (p<0.05) between FI and HV groups.
¶= Statistically significant difference (p<0.05) between CC and HV groups.

Conclusion: Impedance planimetry proves to be a valuable tool for distinguishing pelvic floor dysfunctions, as women with FI show higher DI values, whereas those with suspected FDD exhibit reduced DI changes during simulated defecation. These findings support the hypothesis that impaired rectal distensibility is a key feature of FDD, highlighting its role in continence and evacuation disorders.

Contact E-Mail Address: chiaramocci94@gmail.com

Introduction: Patients (pts) with rectal adenocarcinoma who undergo Low Anterior Resection (LAR) are susceptible to developing anorectal dysfunctions, such as fecal incontinence, constipation, urge to defecate with altered defecation patterns, collectively termed Low Anterior Resection Syndrome (LARS). High-resolution anorectal manometry (HRAM) is a crucial diagnostic tool to assess the functional integrity of the anal sphincters and rectal sensory perception in these pts.

Aims & Methods: The aim of this study is to evaluate anal and rectal sphincter functionality in pts undergoing LAR by analyzing HRAM data. In this retrospective observational study, we analyzed the HRAM reports of 42 pts who underwent LAR for rectal adenocarcinoma between 2016 and October 2024. The assessments followed the London protocol. The average time between LAR and HRAM was two years.

Results: We enrolled 42 pts (16 males and 26 females, mean age 65 ± 11 years at the time of HRAM), including 10 pts with a stoma. HRAM showed a mean basal pressure of 43 ± 24 mmHg, with 71% of pts presenting basal hypotonia. The mean contraction pressure was 104 ± 46 mmHg, with 76% of pts showing hypocontractility. At 'push' manoeuvre, 52% of pts didn't show adequate relaxation. Regarding residual rectal sensitivity, 76% of pts presented hypersensitivity. In particular the maximum tolerable stimulus was evoked with a mean pressure of 57 ± 30 mmHg. The rectoanal inhibitory reflex (RAIR) was evoked in only 40% of pts. In 14 pts, the balloon expulsion test (BET) couldn't be performed, while in the remaining 28 pts, 54% had a negative BET and 46% a positive BET.

Conclusion: Our data confirm the presence of anorectal functional alterations after LAR. Most pts presented alterations of the anal sphincter apparatus with hypotonia and hypocontractility. Moreover, in half of the pts, there was no adequate sphincter relaxation during 'push' manoeuvre.

Additionally, most pts presented hypersensitivity of the residual rectum and a lack of RAIR. These data confirm the importance of HRAM in patients undergoing LAR in the personalized diagnostic therapeutic pathway. Further studies are needed to standardize pressure values in correlation with clinical data.

STUDY OF ANORECTAL FUNCTION AND ANAL DISTENSIBILITY IN PATIENTS WITH CHRONIC CONSTIPATION

C. Ciriza de Los Rios[1], M. Aparicio Cabezudo[2], A. Zatarain Valles[3], L. García Pravia[3], E. Rey Díaz-Rubio[1]
[1]Hospital Clínico San Carlos. Universidad Complutense Madrid, Gastroenterology, Madrid, Spain, [2]Hospital Clinico San Carlos, Madrid, Spain, [3]Hospital Clinico San Carlos, Gastroenterology, Madrid, Spain

Contact E-Mail Address: constanzacarpa@gmail.com

Introduction: High-resolution anorectal manometry (HRAM) is the most commonly used technique for studying functional anorectal disorders, including chronic constipation. However, alterations in the defecatory maneuver are inconclusive for diagnosing defecatory dysfunction, necessitating additional confirmatory testing. The study of the geometry and distensibility of the anal canal may be useful in evaluating patients with chronic constipation.

Aims & Methods: To evaluate the manometric characteristics and anal canal distensibility in patients with chronic constipation compared to a control group of healthy volunteers (HV). The study included 15 healthy controls and 11 patients with chronic constipation. All participants underwent HRAM (Medtronic®), EndoFLIP (Medtronic®), and the balloon expulsion test (BET; Matla Systems®). HRAM was performed according to the London protocol. Distensibility index (DI) values were calculated at rest, during voluntary contraction (VC), and during the defecatory maneuver (DM) with volumes of 30, 40, and 50 mL.

Results: The mean age was 32.4 ± 12.8 in HV and 45.2 ± 12.4 in patients with CC (p = 0.012). Most patients with CC were women, 10 (90.9%). Among CC patients, 9.1% had stool consistency classified as Bristol 3-4 compared to 95% of HV (p < 0.001). The defecatory pattern was < 3 weekly bowel movements in 54.5% of CC patients. Obstructive defecation perception predominated in 7 patients (66.7%), while 1 (9%) had slow transit, and 3 (27.3%) had obstructive defecation and fecal incontinence (multiple sclerosis). All HV had normal BET, with a mean balloon expulsion time of 13.3 ± 10.4 seconds.

The HRAM findings revealed that the percentage of anal relaxation was 31.2 ± 18 in HV and 7 ± 23 in CC patients (p < 0.001). The rectoanal gradient (RAG) measured -28.3 ± 25 in HV and -51.5 ± 36.8 in CC patients (p = 0.06). Significant differences in rectal sensitivity were observed between CC patients and HV. The first sensation threshold was 50.5 ± 25.2 mL in HV compared to 87.3 ± 47.9 mL in CC patients (p = 0.018). Similarly, the urge threshold was 126.8 ± 35.4 mL in HV versus 177.5 ± 44 mL in CC patients (p = 0.004). The maximum tolerated volume also differed, recorded as 157.5 ± 37.9 mL in HV and 224.3 ± 60.3 mL in CC patients (p = 0.008).

EndoFlip results are presented in Table 1. The DI demonstrated better diagnostic performance than HRAM defecatory parameters for predicting balloon expulsion: DI-30 mL: 0.850; 95% CI: 0.701–0.999 (p=0.011); DI-40 mL: 0.817; 95% CI: 0.602–1 (p=0.021); DI-50 mL: 0.775; 95% CI: 0.525–1 (p=0.045); % anal relaxation: 0.742; 95% CI: 0.504–0.980 (p=0.078); RAG: 0.767; 95% CI: 0.540–0.993 (p=0.051).

DI	Maneuver	Healthy controls	CC-normal BET	CC-abnormal BET	p-value
30 mL	Rest	0.6 (0.4-0.7)	0.5 (0.4-1.9)	0.6 (0.4-0.7)	NS
	Squeeze	0.3 (0.2-0.4)	0.3 (0.2-0.5)	0.3 (0.2-0.4)	NS
	Push	0.9 (0.6-1.3)	1.4 (0.4-1.8)	0.4 (0.3-0.5)	0.036
40 mL	Rest	0.4 (0.3-0.6)	0.9 (0.6-3.5)	0.7 (0.3-2)	0.05
	Squeeze	0.3 (0.2-0.4)	0.2 (0.2-1)	0.5 (0.2-0.7)	NS
	Push	1.2 (1.1-3)	2.2 (0.9-2.9)	0.5 (0.2-1.1)	0.05
50 mL	Rest	0.8 (0.5-1)	2.2 (1.4-3.6)	1.7 (0.7-3.4)	0.008
	Squeeze	0.3 (0.2-0.7)	0.6 (0.4-1.8)	0.9 (0.2-1.5)	NS
	Push	3.1 (1.6-4.7)	4.2 (2.7-5.7)	1.2 (0.4-2.7)	0.08

Table 1. EndoFlip results.

Conclusion: Patients with chronic constipation exhibit significant differences in HRAM defecatory parameters and rectal sensitivity compared to control subjects. Although the sample size of patients with constipation is small, the DI demonstrates superior diagnostic performance compared to HRAM defecatory parameters about the BET.

SEXUALLY TRANSMITTED INFECTIONS MIMICKING INFLAMMATORY BOWEL DISEASES: CASE SERIES OF INFECTIOUS PROCTITIS

M. Mattana[1], A. Sbrozzi Vanni[2], L. Lapenna[1], S. Fonte[1], G. Cusi[1], A. Purgatori[1], L. Cantoro[2], R. Faggiani[2], M. Merli[3]
[1]Sapienza University of Rome, Umberto I Hospital, Department of Translational and Precision Medicine, Rome, Italy, [2]San Camillo Forlanini Hospital, Department of Gastroenterology and Digestive Endoscopy, Rome, Italy, [3]Sapienza University of Rome, Department of Clinical Medicine, Gastroenterology, Rome, Italy

Contact E-Mail Address: marco.mattana@uniroma1.it

Introduction: Sexually transmitted infections (STIs) are increasingly recognized as causes of proctitis, particularly among men who have sex with men (MSM). These infections frequently mimic inflammatory bowel diseases (IBD) in clinical, endoscopic, and histological presentations, leading to potential misdiagnosis and inappropriate treatments. Accurate recognition requires detailed sexual history and targeted diagnostic tests.

Aims & Methods: Patients were identified from IBD outpatient visits (2021–2023) and retrospectively selected for suspected infectious proctitis mimicking IBD. Diagnosis was confirmed via clinical evaluation, targeted tests (rectal swabs, PCR, serology), and histology. Follow-up continued for six months post-treatment.

Results:

1. A 42-year-old MSM with secondary syphilis treated with benzathine penicillin presented with bloody diarrhea, tenesmus, anorectal pain, and 10-kg weight loss. Mild anemia (Hb 12 g/dL) and elevated CRP were noted. Rectosigmoidoscopy (RSCS) revealed fibrinous ulcers causing luminal narrowing. Rectal swabs confirmed *Chlamydia trachomatis*. Treatment with doxycycline led to clinical and endoscopic resolution at six months.
2. A 33-year-old MSM with unprotected intercourse reported mucorrhea and tenesmus for one month. Calprotectin levels were elevated (861 µg/g). Colonoscopy revealed mild proctitis with mucosal hyperemia, and histology showed mild-to-moderate inflammation with crypt abscesses. Swabs confirmed *Neisseria gonorrhoeae*. Ceftriaxone resolved symptoms and normalized calprotectin (40 µg/g).
3. A 34-year-old male with primary sclerosing cholangitis (PSC) presented with two weeks of tenesmus, anal bleeding, and pruritus. Colonoscopy appeared macroscopically normal, but histology revealed human papillomavirus (HPV) infection. Anal canal condylomas were identified and successfully treated with cryotherapy, resulting in significant relief.

Conclusion: The rising prevalence of STI-related proctitis highlights the need for awareness among clinicians, as these infections often mimic IBD. Misdiagnosis can lead to inappropriate treatments, including steroids or biologics, causing adverse effects and delays in proper management. Detailed sexual history and targeted diagnostics, such as PCR and rectal swabs, are critical for accurate identification and effective treatment. These cases emphasize the critical role of integrating sexual history into clinical evaluation for proctitis.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Awareness and timely recognition of STI-related proctitis are crucial to avoid misdiagnosis as IBD, ensure effective and targeted treatment, improve patient outcomes, and prevent inappropriate and prolonged follow-up.

Introduction: High-resolution anoscopy (HRA) is the gold standard for assessing HPV-related anal lesions, though its diagnostic accuracy remains limited. While most AI models focus on binary classification, this study aims to develop and evaluate a deep learning model for detection and classification of HRA frames into high-grade (HSIL), low-grade (LSIL), and non-dysplastic lesions (e.g., inflammation).

Aims & Methods: This multicenter retrospective study included 191,951 frames from 107 HRA procedures across five centers using five imaging devices. Frames were labeled as HSIL, LSIL, or non-dysplastic based on matched histopathology. A YOLOv11-based object detection model was trained to detect these lesions using bounding boxes. The dataset was randomly split into training, validation, and test sets. Lesion detection was defined by correct bounding box placement. Classification metrics included recall (sensitivity), precision (PPV), and accuracy, reported as weighted averages across confidence thresholds of 0.45, 0.47, 0.50, 0.52 and 0.55.

Results: The model achieved an overall accuracy of 95.2% (94.7- 95.7) in classifying detected lesions. For HSIL, recall was 97.9% (97.6- 98.2) and precision was 93.9% (92.8, 95.1)). For LSIL, recall was 98.9% (98.8- 99.0) and precision was 98.5% (98.3, 98.7). For non-dysplastic lesions, recall was 98.7% (98.5- 98.8) and precision was 96.0% (94.9- 97.2).

Conclusion: This study introduces the first worldwide AI model capable of simultaneous detection and trinary classification (HSIL, LSIL, non-dysplastic mimickers) of anal canal lesions using heterogeneous, interoperable datasets, a key advancement toward real-world deployment and precision-guided care in AI-assisted HRA.

Introduction: Colorectal cancer (CRC) screening has been widely implemented, and recent advances in fecal immunochemical testing (FIT) have led to a shift in screening modalities from guaiac fecal occult blood testing (gFOBT) to FIT. In Japan, FIT was introduced into the national screening program in 1992, and a two-sample method has been offered to individuals aged 40 years and older. However, there is no standardized use of testing devices or cutoff values. Although hemoglobin concentrations of 100-150 ng/g are commonly used, few studies have evaluated cut-off values in population-based screening. An optimal cut-off value should be defined for adequate quality assurance by considering the benefits and harms of CRC screening.

Aims & Methods: To evaluate the optimal cutoff value for population-based screening, we compared the test performance of FIT according to different cutoff values. A total of 383,793 individuals participated in population-based screening in Ibaraki Prefecture from April 2021 to March 2023. The OC-sensor was used as the testing modality, with a default cut-off value of 100 ng/g. Test performance indicators, including positive rate, detection rate, positive predictive value (PPV), cancer miss rate, and number needed to scope (NNS), were assessed across cut-off values ranging from 100 to 250 ng/g. Detection rate, PPV, and NNS were explicitly calculated for CRC/ Advanced neoplasia (AN). Since the colonoscopy completion rate is typically around 70%, PPV and NNS were calculated on a per-protocol basis.

Results: Subjects who submitted two samples were 370419. Among them, 863 cases of CRC and 1944 cases of advanced adenomas were diagnosed. At a cutoff value of 100 ng/g at the baseline, the positive rate was 6.7% (95%CI: 6.7-6.8) and the colonoscopy completion rate was 76.0% (95%CI: 75.4-76.5) (Table).

For AN, the detection rate was 0.76% (95%CI: 0.73-0.79), 14.8% for PPV (95%CI: 14.3-15.3), and 6.8% (95%CI: 6.5-7.0) for NNS. For CRC detection, the detection rate was 0.23% (95%CI: 0.22-0.25), 4.5% for PPV (95%CI: 4.3-4.8), and 22.0% (95%CI: 22.0-23.5) for NNS.

The NNS decreased as the cutoff value increased, but the CRC miss rate also increased. The cutoff value reached 180 ng/g, the CRC miss rate became 19.5% (95%CI:16.8-22.1), whereas the positive rate was 4.2% (95%CI: 4.2-4.3), 0.19% (95%CI: 0.17-0.20) for CRC detection rate, 5.9% (95%CI: 5.5-6.3) for PPV, and 16.9 (95%CI: 15.8-18.2) for NNS.

Conclusion: The current cutoff value led to high detection rates for both CRC and AN, but it also required a greater number of colonoscopies. The availability of colonoscopy services varies across local municipalities and is often insufficient in rural areas. Adjusting the cutoff value is frequently used to address disparity in access to colonoscopy.

However, the trade-off among benefits, harms, and resources is influenced by the social context, including individual preference and value. Therefore, an acceptable level of cancer miss rates should be carefully evaluated. Since the optimal cutoff value cannot be determined unequiv-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ocally, a comprehensive decision should be made by balancing benefits, harms, and resources, while also considering the preference of local residents.

Introduction: In 2018, a biennial fecal immunochemical test (FIT) screening program for colorectal cancer (CRC) was introduced in northern Portugal, targeting 1.1 million residents aged 50-74 years.

Aims & Methods: This study aimed to evaluate trends in CRC incidence, early diagnosis, and survival before and after the program's implementation.

Population-based retrospective cohort study in northern Portugal. Data on CRC cases diagnosed between 2014-2020 were retrieved from the Portuguese National Cancer Registry (RON). Early diagnosis was defined as stage I/II tumors. Net survival estimates for 2014–2016 vs. 2018-2020 were compared. Data from RON were linked to the FIT-based screening program of the Northern Portugal Regional Health Administration for the years 2018–2020 to assess screening outcomes.

Results: Between 2018 and 2020, the first 3 years of the program, 482,938 invitations for FIT screening were sent, resulting in an adherence rate of 34.4% (165,895). The negative predictive value of FIT was 99.95% (95% CI: 99.94–99.96). Overall, coverage by FIT and/or colonoscopy was 44.9%. The proportion of early cancers was significantly higher among individuals submitted to FIT screening (58.3%) or colonoscopy (62.8%) compared to unscreened individuals (49.2%) ($p<0.001$). Net survival rates at 1-year and 3-years were significantly higher among individuals who accepted FIT screening or underwent colonoscopy compared to those who remained unscreened ($p<0.001$).

Conclusion: Biennial FIT led to an increase in early diagnoses and improved survival compared to no screening shortly after its introduction. A health system's comprehensive capacity boosts population coverage and improves CRC outcomes.

Disclosure: Nothing to disclose.

Introduction: Previous research has shown that categorizing high-confidence (HC) diagnoses as those reached within 3 s without hesitation notably enhanced the optical diagnostic accuracy for colorectal polyps. This study aimed to assess the efficacy of a new computer-aided diagnosis (CADx) system integrated with the 3-second rule in the optical diagnosis of colorectal polyps among endoscopists with different levels of experience.

Aims & Methods: In this multicenter ex vivo study, 35 endoscopists evaluated 100 polyps (51 adenomas, 39 hyperplastic polyps, and 10 sessile serrated lesions) using narrow-band imaging video clips on an online platform. The assessments comprised two phases: individual endoscopist diagnosis and CADx-assisted diagnosis. HC assignments followed the 3-second rule in both phases. Performance metrics assessed included HC accuracy, HC rate, and adherence to the Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) and Simple Optical Diagnosis Accuracy (SODA) thresholds.

Results: HC diagnostic accuracy improved from 78.3% (95% CI: 76.6–80.0) to 89.8% (95% CI: 88.6–90.9) with CADx assistance ($p < 0.001$). The proportion of HC predictions increased from 64.2% to 75.4% with the CADx assistance ($p < 0.001$). Novice endoscopists notably showed a significant improvement in HC accuracy with CADx assistance (74.1% vs. 88.8%; $p < 0.001$). The CADx-assisted diagnoses nearly met the SODA standards and PIVI thresholds when combined with the 3-second rule.

Conclusion: Integrating CADx with the 3-second rule significantly improved the optical diagnostic performance for colorectal polyps, particularly among endoscopists lacking systematic training.

UNMASKING ASPIRATION RISKS: A PROPENSITY MATCHED ODYSSEY OF GLP-1 AGONISTS AND COLONOSCOPY

P. Chhabra[1], R. Singh[2]
[1]Royal Hobart Hospital, Gastroenterology, Hobart, Australia, [2]University of Illinois College of Medicine, Peoria, United States of America

Contact E-Mail Address: puneet.pgi@gmail.com

Introduction: The use of GLP-1 receptor agonists has revolutionized the treatment of Type II Diabetes Mellitus and obesity. Beyond these conditions, their use is being investigated for many other indications. Given the current global obesity pandemic, it is not uncommon to encounter patients on GLP-1 receptor agonists when they present for procedures [1]. GLP-1 receptor agonist's (GLP-1), such as semaglutide (Ozempic), are known to slow gastric emptying, leading to gastroparesis [2-3].

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Consequently, many patients on GLP-1 receptor agonist's experience recurrent vomiting and are therefore at increased risk of pulmonary aspiration during procedures under sedation [4-6].

Aims & Methods: We aim to conduct this retrospective study to evaluate the risk of aspiration pneumonia in patients on GLP-1 receptor agonists undergoing colonoscopy.

Subjects and methods: TThis is a multicentre retrospective cohort study using a large research network (TriNetX, LLC) comprising over 100 million patients. The study period was between 2005 and 2025. Patients who underwent colonoscopy during the study period were included in the cohort and divided into two groups based on whether they were on GLP-1 receptor agonists or not.

The primary outcome was aspiration pneumonia, defined as aspiration pneumonia or the need for mechanical ventilation or respiratory failure within 7 days of undergoing colonoscopy.

The secondary outcome was hospitalization within 7 days of colonoscopy. Outcomes were compared between the two groups.

Results: A total of 126,663 patients on GLP-1 agonists underwent colonoscopy during the study period. A total of 1,380,652 patients without exposure to GLP-1 receptor agonists underwent colonoscopy before propensity score matching. The mean age of patients who underwent colonoscopy was 58.8 ± 10.5 years in both groups. In the group with GLP-1 receptor agonists, 0.03% of patients had aspiration pneumonia compared to 0.06% in the other group. This difference was statistically insignificant (p=0.000). Similarly, no significant differences were observed in the number of patients who underwent mechanical ventilation, were hospitalized, or had type 2 respiratory failure within 7 days of undergoing colonoscopy, between the two groups.

Conclusion: Despite ongoing concerns about the increased risk of aspiration pneumonia in patients with GLP-1 receptor agonists undergoing colonoscopy under sedation, the results indicate otherwise. There is no need to perform a gastroscopy with minimal sedation in patients on GLP-1 receptor agonists undergoing colonoscopy, as recommended by certain anesthetic and gastroenterology societies.

Introduction: The prevalence of adenoma in patients with positive fecal immunochemical tests (FIT) is shown to be higher. Increased adenoma detection and removal during colonoscopy have been shown to prevent CRC and interval cancers. However, there is considerable variation in the adenoma detection rate (ADR) among colonoscopies performed for FIT. We hypothesize that the ability of dye-based chromoendoscopy to stain the colorectal lesion and their borders and increase their contrast against the normal colorectal mucosa would enhance the detection of adenoma and non-polypoid colorectal neoplasms (NPCRN) in patients undergoing FIT positive colonoscopy.

In this randomized control trial, we aim to compare the effectiveness of pan-colonic indigo carmine chromoendoscopy (PCC) to high-definition white light colonoscopy (WLC) in individuals undergoing colonoscopy for positive FIT test.

Aims & Methods: Patients undergoing colonoscopy after a FIT positive test were randomized 1:1 to undergo PCC or WLC. The study was conducted between January 2021 to May 2023 at the Singapore General Hospital, Singapore. Colonoscopy was performed by general and advanced endoscopists, and all received training on PCC before the study. The primary outcome was ADR between the two groups. The secondary outcomes were advanced adenoma detection rate (AADR), NPCRN detection rate, sessile serrated lesion detection rate (SSLDR), and withdrawal time between the groups. We used the two-tailed Mann–Whitney U test and Chi-squared statistics for comparison. The ethics committee approved the study, and it was registered with clinicaltrials.gov (NCT04512612)

Results: We recruited 256 patients (PCC-128; WLC-128). The mean age of the entire cohort was 66 + 8.4 years. The mean ADR was comparable between PCC and WLC (70.3% vs. 64.8%, p-0.350). Likewise, the AADR (19.5% vs. 14.8%, p-0.320], and SSLDR (6.25% vs. 1.56%, p-0.102] were similar between the two groups. We found PCC detected more diminutive adenomas (0.97% vs. 0.58%, p-0.025] and NPCRN per colonoscopy (0.35% vs. 0.17%, p-0.028). The mean withdrawal time was longer with PCC compared to WLC (13.3 min vs. 10.2 min, p-0.001). General and advanced endoscopists had no difference in performance measures for APC and NPCRN per colonoscopy.

Conclusion: The ADR in FIT-positive colonoscopy is higher, and both PCC and WLC yielded comparable results. PCC merits consideration because of its increased ability to detect NPCRNs, which are precursors for interval cancer.

Disclosure: Nothing to disclose.

Introduction: Familial adenomatous polyposis (FAP) is an inherited colorectal cancer syndrome characterized by the development of numerous adenomatous polyps in the colon and rectum, with prophylactic colectomy being the standard treatment to prevent disease progression. Recently, endoscopic intensive downstaging polypectomy (IDP) has attracted attention as a novel disease management strategy, particularly for patients with non-dense FAP who refuse or delay surgery. Since IDP requires the resection of numerous polyps, simpler and safer techniques such as hot snare polypectomy (HSP), cold snare polypectomy (CSP), and hot biopsy (HB) are commonly used. However, the effectiveness of these techniques for the treatment of small adenomas in the context of IDP has not been fully evaluated.

Aims & Methods: This study aimed to evaluate the safety and efficacy of CSP compared with HSP and HB in patients with FAP undergoing IDP. This retrospective study included patients with FAP who underwent IDP using only CSP, HSP, or HB at Hiroshima University Hospital between September 2012 and March 2024. Patients were divided into two groups: the CSP group, treated with CSP from October 2022 onward, and the HOT group, treated with HSP and HB between 2012 and September 2022.

The primary endpoints were the incidence of adverse events and the treatment duration per polyp. Secondary endpoints included the incidence of immediate and delayed bleeding, perforation, total treatment duration per session, number of polyps removed per procedure, R0 resection rate, and the rate of missed polyps ≥10 mm.

Results: During the study period, 46 treatment sessions were performed in 24 patients in the CSP group, resulting in the removal of a total of 3,689 polyps. In contrast, 139 treatment sessions were performed in 27 patients in the HOT group, with a total of 5,912 polyps removed. The average number of polyps removed per session was significantly higher in the CSP group (80.5 polyps) than in the HOT group (42.1 polyps) ($p < 0.01$).

Variables	Total (n=185)	CSP (n=46)	HOT (n=139)	p-value
Treatment duration per procedure (min)	45.9 (22.1)	51.1 (23.2)	44.3 (21.7)	0.06
Polyps removed per procedure	51.6 (52.1)	80.5 (56.8)	42.1 (46.9)	< 0.01
Treatment duration per lesion (min)	1.7 (1.4)	1.3 (1.4)	1.8 (1.3)	0.01
Maximum tumor size per procedure (mm)	5.2 (2.4)	6.0 (2.5)	4.9 (2.4)	< 0.01
Overall adverse events (n (%))	14 (7.6)	0 (0)	14 (10.1)	0.03
Immediate bleeding (n (%))	10 (5.4)	0 (0)	10 (7.2)	0.06
Delayed bleeding (n (%))	2 (1.1)	0 (0)	2 (1.1)	0.41
Perforation (n (%))	2 (1.1)	0 (0)	2 (1.1)	0.41

Additionally, the treatment duration per polyp was significantly shorter in the CSP group (1.3 minutes) than in the HOT group (1.8 minutes) ($p = 0.01$). The total treatment duration per session was slightly longer in the CSP group (51.1 minutes) compared to the HOT group (44.3 minutes), although the difference was not statistically significant ($p = 0.06$). The maximum polyp size was significantly larger in the CSP group (6.0 mm) than in the HOT group (4.91 mm) ($p < 0.01$). The overall incidence of adverse events was significantly lower in the CSP group. Immediate bleeding occurred in 10 cases (7.2%) in the HOT group but was not observed in the CSP group. Delayed bleeding and perforation were also observed only in the HOT group; however, there were no statistically significant differences between the groups.

Conclusion: This study demonstrated that CSP is a safe and effective option for intensive polyp reduction in patients with FAP. Compared with HSP and HB, CSP enabled the removal of more polyps in a shorter duration and reduced the risk of adverse events.

MOTORIZED DOUBLE-BALLOON COLONOSCOPE SUPPORTED WITH MACHINE LEARNING FOR LUMEN NAVIGATION: TOWARD SAFE AND AUTOMATED INSERTION

Y. Ito[1], Y. Tatsuki[1], T. Takamatsu[2], H. Takemura[1]
[1]Tokyo University of Science, Graduate School of Science and Technology, Noda, Chiba, Japan, [2]National Institute of Advanced Industrial Science and Technology, Tsukuba, Ibaraki, Japan

Introduction: The number of deaths caused by colorectal cancer has been gradually increasing in recent years. However, it is treatable if detected early, with five-year survival rates exceeding 90%. As early-stage cancers are often asymptomatic, regular screening is essential.

Expanding the number of endoscopic examinations requires a corresponding increase in the number of trained endoscopists. A physician shortage hinders large-scale screening. Among the various steps in colonoscopy, the insertion procedure is technically demanding, especially in anatomically complex regions such as the sigmoid colon. Mastery of this step requires considerable training and clinical experience, which poses a significant barrier to scalability.

Under these circumstances, there is a strong demand for simplifying and automating the insertion procedure of colonoscopes.

Aims & Methods: In this study, we aim to address this challenge by developing a motorized double-balloon colonoscope. The colonoscope has a double-tube structure, consisting of an outer and an inner tube. Each tube can be independently bent at the tip using wires, allowing the scope to follow the curves of the colon and navigate complex anatomical regions. The inner tube can move axially within the outer tube, and both tubes are equipped with separate balloons. The alternating inflation and deflation of the balloons, one tube can be fixed while the other advances. This mechanism enables stable and controlled insertion along the intestinal lumen. A single operator can perform the procedure by manipulating the outer tube with one hand and operating a dedicated controller with the other. Additionally, 300 images were extracted and annotated from colonoscope insertion videos. These were used to train a YOLO model capable of detecting the direction of the intestinal lumen, with the aim of assisting in steering during insertion in future applications.

Results: To evaluate the insertion performance of the developed colonoscope, we conducted insertion experiments using a colon model. The procedure began with the inner tube placed inside the outer tube, and the device was inserted from the anus. After passing through the rectum, insertion into highly curved regions such as the sigmoid colon proved difficult using the outer tube alone. Therefore, the tip of the outer tube was aligned with the direction of insertion, the intestinal tract was fixed using a balloon, and the inner tube was advanced.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The bending of the inner tube was manipulated to avoid collision with mucosal folds, allowing the device to reach the descending colon without overstretching the colon wall. By repeatedly alternating balloon fixation and tube advancement, the device proceeded through the transverse and ascending colon, eventually reaching the cecum. This sequence of operations was repeated in three trials, all of which resulted in successful insertion into the cecum. These results demonstrate that the developed device is capable of stable and stepwise insertion throughout the colon, including anatomically complex and highly curved segments.

Conclusion: In this study, we developed a motorized double-balloon colonoscope and a machine learning-based technique for detecting the direction of the intestinal lumen. Insertion experiments using a colon model demonstrated the effectiveness and reliability of the proposed insertion method.

As the next step, we aim to construct a prototype system that integrates these technologies. We also plan to implement robotic arm control that mimics endoscopist hand movements to achieve safe, minimally invasive insertion.

Contact E-Mail Address: stefanofanta14@libero.it

Introduction: Despite advances in colorectal cancer (CRC) screening programs, the incidence of post-colonoscopy colorectal cancer (PCCRC) remains significant. Several recent cohort studies have highlighted serrated polyps as key contributors to PCCRC occurrence and related mortality. For this reason, Proximal Serrated Polyp Detection Rate (PSDR) has been proposed as a quality indicator for CRC screening programs, complementing the adenoma detection rate (ADR).

Aims & Methods: This monocentric retrospective cohort study aims to evaluate the impact of optimal bowel preparation - defined as a Boston Bowel Preparation Scale (BBPS) ≥8/9 - on PSDR and ADR, compared to adequate preparation (BBPS score of 6/9 or 7/9).

All consecutive patients aged 50–69 years who underwent screening colonoscopy following a positive fecal immunochemical test (FIT) at the University Hospital of Parma between May 2021 and April 2025 were included. Data on patient demographics, endoscopist characteristics, and histologic findings were collected. The association between bowel preparation quality and PSDR and ADR was assessed using chi-square tests and regression analysis.

Results: Of the 1,070 patients included, 512 were female (47.9%) with a median age of 60 years (IQR 55–66). The Proximal Serrated Polyp Detection Rate (PSDR) was significantly higher in colonoscopies with optimal bowel preparation compared to those with adequate preparation (13.6% vs. 8.2%, p = 0.008).

Multivariate analysis revealed a significant association between PSDR and both the quality of bowel preparation (OR 1.73, 95% CI 1.14–2.62, p = 0.01) and endoscopist expertise in screening procedures (OR 2.10, 95% CI 1.43–3.12, p < 0.001). Detection of Sessile Serrated Lesions (SSLs) was significantly higher with optimal preparation (7.5% vs. 3.7%, p = 0.012). In contrast, the Adenoma Detection Rate (ADR) was similar between groups (50.6% vs. 48.4%, p = 0.493).

Conclusion: Optimal bowel preparation, was associated with significantly higher PSDR and SSL detection rates compared to adequate preparation, highlighting its potential role as a modifiable factor to enhance serrated lesion detection in CRC screening programs. In contrast, ADR did not significantly vary with bowel preparation quality. Striving for optimal bowel preparation may contribute to improving the overall quality and effectiveness of CRC screening.

Introduction: Inspection accuracy on colonoscopy is problematic because of the colon's complex structure and the need for skillful operators. In particular, lesions in the ascending colon (AC) may be difficult to detect because of its high folds. Additionally, it has recently been reported that post-colonoscopy colorectal cancer is often located in the proximal colon. There are only a few reports on the effectiveness of retroflex inspection after forward view inspection in the AC during colonoscopy. While endoscopes and colonoscopy using artificial intelligence or image enhancement systems to detect lesions have been developed, it is important to reconsider basic endoscopic techniques, such as retroflex inspection, during colonoscopy.

Aims & Methods: We performed a prospective study to investigate the usefulness of retroflex inspection after forward view inspection in the AC during colonoscopy. Between August 2022 and December 2024, a single endoscopist enrolled and performed screening colonoscopies for 335 consecutive patients aged ≥40 years. Patients with inflammatory bowel disease, gastrointestinal polyposis, post-colorectal surgery, or poor preparation (≤1 point in at least one of three areas on the Boston Bowel Preparation Scale) were excluded from this study. The AC was inspected in this sequence: forward direction (Inspection 1), retroflex direction (Inspection 2), and forward direction (Inspection 3). The primary endpoint was the adenoma detection rate (ADR) in the AC. Secondary endpoints were the adenoma miss rate (AMR) in the AC per colonoscopy in Inspection 1 and Inspections 1+2, percentage of cases in which lesions were detected in Inspection 2, average observation time in the AC for each inspection, success rate of retroflexion in the AC, average pain score (0 points: no pain, 5 points: most severe pain), and complication rate during Inspection 2.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We evaluated 300 patients with a median age of 66 years. The ADR in the AC for Inspection 1 vs. 1+2 was 18.7% vs. 28.7%, respectively (odds ratio: 1.749; 95% CI: 1.174–2.622; $p = 0.005$); the values for Inspection 1+2 vs. 1+2+3 were 28.7% vs. 30.0%, respectively (odds ratio: 1.066; 95% CI: 0.739–1.540; $p = 0.788$) (Table 1). The average AMR in the AC per colonoscopy for Inspection 1 vs. 1+2 was 12.6% (95% CI: 9.0%–16.2%) vs. 2.6% (95% CI: 0.8%–3.8%) ($p < 0.001$) (Table 1).

The percentage of cases in which lesions were detected in Inspection 2 was 13.8% (41/298; total number of lesions: 47). The average diameter of lesions discovered and resected endoscopically during Inspection 2 was 6.1 mm (range: 3–20 mm). The locations of these lesions were as follows: proximal AC: 27.7% (13/47); mid-AC: 38.3% (18/47); and distal AC: 34.0% (16/47). The average observation times in the AC (Inspection 1 vs. 2 vs. 3) were 80.7 (95% CI: 77.8–83.6) vs. 59.1 (95% CI: 56.9–61.3) vs. 82.1 (95% CI: 79.4–84.8) seconds, respectively. The success rate of retroflexion in the AC was 99.3% (298/300), and the average pain score and complication rate during Inspection 2 were 0.5 points (95% CI: 0.4–0.6 points) and 0%, respectively.

	Adenoma Detection Rate in the AC			Adenoma Miss Rate in the AC (Average rate per colonoscopy)		
	Rate (Number)	OR (95%CI)	p-value	Rate	95%CI	p-value
Inspection 1	18.7 % (56)			12.6 %	9.0–16.2	
Inspection 1+2	28.7 % (86)	1.749 (1.174–2.622)	.005	2.6 %	0.8–3.8	< .001
Inspection 1+2+3	30.0 % (90)	1.066 (0.739–1.540)	.788			

Table 1 Adenoma Detection Rate & Adenoma Miss Rate in the AC.

Conclusion: Retroflex inspection following forward inspection in the AC during colonoscopy detects additional adenomas and is minimally invasive and safe. This technique contributes to improving the accuracy of colonoscopy.

A ENDOCYTOSCOPY STAINING QUALITY SCORE SCALE: INNOVATIVE EXPLORATION FROM DEVELOPMENT TO VALIDATION

H. Zhu[1], J. Fan[1], K. Tao[1], H. Xu[1]
[1]The First Hospital of Jilin University, Department of Gastroenterology, ChangChun, China

Contact E-Mail Address: fanjw22@mails.jlu.edu.cn

Introduction: Endocytoscopy (EC) represents an advanced high-magnification endoscopic modality that permits *in vivo* cellular-level observation and assessment. However, achieving consistent high-quality staining constitutes a primary technical limitation.

This study aimed to develop and validate a novel scoring scale for evaluating EC staining quality, thereby providing clinicians with a straightforward and reliable instrument to enhance procedural quality control.

Aims & Methods: We evaluated the staining quality of images from four perspectives: nuclear clarity, glandular lumen clarity, surface mucus and dye rinsing degree, and image capture quality (including issues such as improper fixation leading to virtual images, out-of-focus causing image blur, and inadequate brightness).

Each evaluation criterion was scored from 0 to 2, with a total possible score of 8. The total image evaluation scores were then classified as follows: ≤2 points for Grade 1 (poor staining quality), 3-5 points for Grade 2 (moderate staining quality), and ≥6 points for Grade 3 (high Staining quality).

Data were retrospectively collected from patients undergoing colonoscopy with EC image acquisition between June 2023 and June 2024. An initial cohort comprising 1000 EC images was utilized to establish the scale's reliability, validity, and internal consistency. Subsequently, an independent validation cohort of 1000 EC images was analyzed using polynomial regression to investigate determinants of staining quality, and external validation was conducted to further evaluate the scale's applicability.

	Nuclear clarity	Glandular lumen clarity	surface mucus and dye rinsing degree	Image capture quality
0	<50% area Nuclear clarity	<50% area Glandular lumen clarity	<50% area Complete mucus and dye wash-out	Poor stabilization: blurry image, poor focus and brightness, details not clearly discernible
1	50%-70% area Nuclear clarity	50%-70% area Glandular lumen clarity	50%-70% area Complete mucus and dye wash-out	Average stabilization and focus, slightly dim brightness, partial clarity of details
2	>70% area Nuclear clarity	>70% area Glandular lumen clarity	>70% area Complete mucus and dye wash-out	Good stabilization: Accurate focus, adequate brightness, clear details
Score				

Image capture quality includes: poor image stabilization resulting in blurred images, out-of-focus leading to image blurriness, insufficient image brightness.

Table 1. Endocytoscopy staining quality score scale and scoring criteria.

Results: A total of 2,964 and 1,946 EC-stained images were analyzed in the initial and validation cohorts, respectively, with each cohort ultimately including 500 EC-stained images. There were no statistically significant differences in age and gender within and between the initial and validation cohorts.

The scale demonstrated excellent inter-rater reliability (agreement metric = 0.992), alongside good internal consistency reliability (coefficient = 0.81) and validity (index = 0.849). A strong positive correlation was observed between Average Optical Density (AOD) values and gold standard scores (Spearman's P= 0.81). Lesion morphology, size, pathological classification, pit pattern type, and physician experience level were identified as significant factors influencing EC staining quality (all $p < 0.05$). A one-month training intervention utilizing the scale significantly enhanced scoring consistency among junior physicians, evidenced by increases in Kappa coefficients measuring agreement with the gold standard (Physician A: 0.61 to 0.81; Physician B: 0.66 to 0.83).

Conclusion: The Endocytoscopy Staining Quality Assessment Scale serves as a reliable and valid instrument for evaluating staining quality. Its implementation can assist endoscopists in improving their proficiency in assessing image staining quality and refining staining techniques, ultimately contributing to enhanced diagnostic accuracy and reliability during EC procedures.

Introduction: Colorectal cancer (CRC) ranks as the third most common cancer globally in both men and women, with a notably higher incidence in developed countries. While early detection, facilitated by screening tools such as the fecal occult blood (FOB) test, has contributed to a decline in mortality rates, CRC continues to pose a significant public health challenge. Meanwhile, extracellular vesicles (EVs), known to be lipid-based particles secreted by cells that carry various macromolecules like nucleic acids and proteins, have emerged as a promising source for the identification of novel fecal biomarkers.

Aims & Methods: Given that FOB testing can produce false positives, often resulting in unnecessary exploratory colonoscopies and placing strain on healthcare resources, the goal of this study is to identify more specific CRC biomarkers within stool-derived EVs to enhance the diagnostic utility of current screening methods.

In this study, 20 stool samples were analyzed from individuals categorized as healthy, low-risk, high-risk, or diagnosed with colorectal cancer (CRC). The low-risk group included individuals with one or two adenomatous lesions exhibiting low-grade dysplasia and serrated lesions without dysplasia, all measuring less than 10 mm.

The high-risk group comprised individuals with three or more tubular adenomas with low-grade dysplasia under 10 mm, at least one adenoma with a villous component, any lesion with high-grade dysplasia over 10 mm, or at least one serrated lesion either displaying dysplasia or exceeding 10 mm in size.

Results: EVs were isolated using an optimized size exclusion chromatography protocol. Characterization of the EVs was carried out according to the MISEV 2023 guidelines, including analysis of particle size and concentration via Nanoparticle Tracking Analysis (NTA), visualization through transmission electron microscopy (TEM) and atomic force microscopy (AFM), and assessment of the tetraspanins CD9 and CD63.

Following isolation, proteomic profiling of the EVs was performed using liquid chromatography–mass spectrometry (LC-MS), aiming to distinguish protein expression patterns between “normal” individuals (healthy and low-risk) and “discovery” patients (high-risk and CRC cases). A subsequent Gene Set Enrichment Analysis (GSEA) was conducted on differentially expressed proteins to explore associated biological pathways.

The study successfully optimized EV isolation from stool samples, effectively separating vesicles from free proteins. From a total of 484 identified proteins, 75 were more abundant in EVs from discovery patients, while 147 were more prevalent in normal individuals, indicating potential biomarker candidates for CRC detection. Gene Set Enrichment Analysis (GSEA) identified multiple inflammation-related pathways significantly enriched in upregulated proteins from discovery-associated EVs.

Conclusion: In summary, this work demonstrates the potential of fecal EVs as a non-invasive platform for early colorectal cancer detection. By improving diagnostic specificity, this approach may help reduce the number of unnecessary colonoscopies.

Future studies will aim to validate these biomarker candidates in larger, more diverse patient cohorts.

RECURRENCE AND COMPLICATIONS AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESECTION: A TWELVE-YEAR PROSPECTIVE COHORT STUDY

R. Regatia[1], M.I. Viegas[1], S. Saraiva[1], M. Areia[1], M. Costa[1], L. Elvas[1], S. Alves[1], D. Brito[1], T. Cadime[1]
[1]Portuguese Oncology Institute of Coimbra, Coimbra, Portugal

Contact E-Mail Address: ritaregatia@gmail.com

Introduction: Colorectal endoscopic mucosal resection (EMR) is the treatment of choice for large colorectal lesions, but it has an important recurrence risk, requiring endoscopic surveillance. This study aims to identify factors associated with relapse and complications, by analysing the 5-year follow-up.

Aims & Methods: Prospective cohort study conducted in a single centre, including all patients submitted to colorectal pEMR between 2009 and 2021 with follow-up ≥3 months. We analysed lesion characteristics, calculated Sydney EMR recurrence tool (SERT) and SMSA (size, morphology, site, access) scores and compared complication and recurrence rates and respective risk factors.

Results: Included 568 mucosal resections, median age 69.5 years (IQR 62.3-76.0), male sex 58.1%. From the lesions included: 32.6% ≥40mm; 51.6% plane and 48.4% sessile; 35.9% in the right colon, 27.6% in the rectum, 23.2% in the transverse colon and 13.2% in the left colon. The median SMSA score was 4 (IQR 3-4) and median SERT score 1 (IQR 0-2), complication rate of 7.0% (bleeding, n=33; perforation, n=4; post-polypectomy syndrome, n=3) and overall recurrence rate of 20.3%: 15.1% in 3 months, 6.3% in 12 months, 2.5% in 36 months and 0% in 60 months.

The variables associated with recurrence were size ≥40mm (35.0% vs. 14.6%, p<0.001), anal location (35.1% vs. 19.7%, p<0.01), SERT score>0 (27.5% vs. 11.8%, p<0.001) and SMSA score=4 (30.6% vs. 11.5%, p<0.001), but not argon plasma therapy (22.8% vs. 18.7%, p=0.26). By logistic regression, size ≥40mm was associated with higher recurrence, but not statistically significant (OR 3.19, CI95% 0.69-1.63).

Use of anticoagulant/antiplatelet drugs was associated with higher risk of complications (12.7% vs. 4.7%, p<0.001), particularly bleeding (11.4% vs. 4.2%, p<0.01), with no difference for size ≥40mm (9.2% vs. 6.0%, p=0.17) or SMSA score=4 (7.6% vs. 6.5%, p=0.61).

Conclusion: The 5-year surveillance proved colorectal EMR’s efficacy. Recurrence is higher in lesions ≥40mm, with anal location, SERT score>0 and SMSA score=4, whereas bleeding is more frequent with the use of anticoagulant/antiplatelet drugs.

Disclosure: Nothing to disclose.

A RANDOMIZED CONTROLLED TRIAL EVALUATING THE SAFETY, EFFICACY, AND PATIENT COMFORT OF A SINGLE-USE ELECTRONIC COLONOSCOPE IN CLINICAL DIAGNOSIS AND TREATMENT

Y. Tian[1], X. Rao[1], H. Yu[1], L. Rong[1]
[1]Peking University First Hospital, Endoscopy Center, Beijing, China

Contact E-Mail Address: doctorty@qq.com

Introduction: Although reusable colonoscopes remain the clinical gold standard, persistent microbial biofilms compromise reprocessing efficacy, elevating cross-contamination risks during endoscope reprocessing cycles[1].

A systematic review of 73 documented endoscopic infection outbreaks (esophagogastroduodenoscopy: 24; endoscopic retrograde cholangiopancreatography: 42; colonoscopy: 7) revealed escalating clinical impacts: attack rates of 3.5%, 7.1%, and 12.8%, with corresponding mortality rates of 6.3%, 12.7%, and 10.0%, respectively[2].

Building on evidence confirming the procedural efficacy and operational safety of disposable gastroscopes[3] [4], this randomized controlled trial systematically evaluates a novel single-use colonoscope through multidimensional assessment of assessing patient comfort, operator performance, and clinical outcomes.

Aims & Methods: This single-center prospective trial randomized 100 eligible patients (1:1) to single use colonoscope or conventional colonoscopy using computer-generated allocation. Primary endpoints included patient comfort assessed via grip strength during colonoscopy, efficacy of endoscopic mucosal resection (EMR) (en bloc resection rate and procedural duration), adenoma detection rate (ADR), adenomas per colonoscopy (APC) and cecal intubation time. Secondary outcomes evaluated device maneuverability using a 3-point Likert scale and overall safety.

Results: The demonstrated comparable baseline characteristics with balanced demographic profiles (all $P > 0.05$). No significant difference was observed in colonoscopy comfort based on grip strength pain assessment ($P > 0.05$). Both groups achieved 100% en bloc resection rates during EMR, with similar median procedure durations (679.23 ± 272.97 vs. 693.92 ± 477.06 s, $P = 0.899$). No significant difference between ADR (56% vs. 60%, $\chi^2=0.164$, $P = 0.685$) and APC (median 1.0 vs. 1.0, $P = 0.349$). Cecal intubation was successful in all participants, with comparable time-to-cecum between the two groups (448.34 ± 348.58 s vs. 368.00 ± 243.39 s, $P = 0.185$). One sigmoid carcinoma was identified in each group. No adverse events (e.g., bleeding, perforation, or device failure) occurred in either group. However, the single use colonoscope showed inferior subjective imaging quality ($P < 0.001$) and luminal far-field brightness/visualization ($P < 0.001$) compared to conventional scopes, potentially impacting lesion characterization in anatomically complex regions.

Conclusion: The single use colonoscope demonstrates clinical efficacy and equivalent safety profiles compared to conventional systems, validating its integration into routine screening. Equivalent ADR and en bloc resection rates indicate comparable diagnostic and therapeutic outcomes. These findings validate the clinical application of this method as a portable and effective option, while emphasizing the need for improved optical performance. Large-scale, multicenter, long-term follow-up studies are needed to confirm its clinical results and practical advantages.

Introduction: Incidence of squamous cell carcinoma (SCC) of the anal canal is increasing. SCC arises from anal intraepithelial neoplasia (AIN) and condylomas. However, destruction of these anal lesions with standard techniques carries a high risk of recurrence and potential functional impairment. Endoscopy can be used to detect and treat colorectal lesions by endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD), but its value in the management of anal lesions has been poorly studied. The aim of this study was to assess the feasibility, efficacy and safety of endoscopic management of AIN and condylomas.

Aims & Methods: We conducted a retrospective study including all patients who had undergone endoscopic resection either by EMR or DSM of anal lesion (AIN or condylomas). The following criteria were evaluated: the rate of residual lesion at the end of endoscopic treatment, the rate of monobloc resection, the rate of complication per procedure and within 30 days after the procedure, the rate of new anal lesion and the rate of SCC during follow-up.

Results: From May 2015 to November 2024, 33 patients were included. Twenty-six (78.8%) were women. Mean age was 62.8 (±11.1) years. Two (6.1%) patients were HIV-positive. Eleven (33.3%) patients had a history of anal lesions, including one (3.0%) case of SCC. The median number of lesions per patient was 1 (IQR 1 - 2), with multifocal involvement in 15 (45.5%) patients. Thirteen (39.4%) patients had anal involvement reaching more than one hemi-circumference. Seven patients (21.2%) underwent ESD, and 26 (78.2%) underwent EMR. At the end of endoscopic treatment, no residual lesions were visible in 31 (93.9%) patients. Lesions were intentionally left in the remaining two patients. Resections were monobloc and macroscopically complete in 19 (57.6%) patients. Intra-procedural hemorrhage was visualized in 18 (54.5%) patients and was treated endoscopically during the same anesthesia without recurrence or clinical impact.

One case of anal stenosis occurred 27 days after circumferential ESD treated with 4 sessions of digital dilatations and one corticosteroid injection. No other complications occurred within 30 days after the procedures. Mean length of hospital stay was 1.12 (+/- 0.33) days. Pathological findings were: condyloma in 6 (18.2%) patients, AIN1 in 8 (24.2%) patients, AIN2 in 5 (15.2%) patients, AIN3 in 10 (30.3%) patients, and SCC in 4 (12.1%) patients (two SCC T1 R0, one of which required additional radiotherapy, and two in situ SCC).

Follow-up data were available for 29 patients. Mean follow-up time was 34.4 (+/- 35.7) months. Of these 29 patients, 8 (27.6%) cases of a new AIN or condyloma (outside the resection scar) were detected during follow-up after an average duration of 4 (+/- 2.1) months, 7 of which were treated by endoscopy. Two (6.9%) cases of scar recurrence were detected 4 and 13 months after treatment. During follow-up, three (10.3%) cases of SCC ≥

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. T1 were diagnosed, including one case of recurrence at one year of a SCC pre-existing endoscopic treatment. The other two cases were diagnosed at one and 6 years.

Conclusion: Endoscopic management (EMR or DSM) of AIN and condylomas is a safe and effective. It should be part of the therapeutic arsenal in the management of these lesions. Increased surveillance is essential, given the high risk of new lesions.

SAFE AND EFFECTIVE PROPOFOL SEDATION BY TRAINED NON-ANAESTHESIOLOGIST PHYSICIANS IN OVER 2000 COLONOSCOPIES: A REAL-WORLD COLOMBIAN EXPERIENCE

C. Rincon[1], J. Frias-Ordoñez[2,3], H. Marulanda[1,3], L. Otero-Parra[1,3], E. Otero[1], W. Otero[3,1]

Introduction:

Propofol (PPF) is a short-acting, highly lipophilic intravenous agent with sedative, hypnotic, antiemetic, and amnestic properties. Acting through GABA receptor agonism and NMDA antagonism, it ensures rapid onset (30–45 seconds) and swift recovery, making it ideal for gastrointestinal endoscopic procedures. Since 1995, the American Society of Anesthesiologists has supported the use of non-anaesthesiologist providers for sedation in endoscopy.

Countries including Colombia have adopted this approach, especially given the limited availability of anaesthesiologists. In the United States, fewer than 20% of colonoscopy sedations are delivered by anaesthesiologists.

Recent studies report comparable safety profiles for trained non-anaesthesiologist and anaesthesiologist-administered sedation, with reduced cardiovascular complications and lower healthcare costs. However, Latin American real-world data on this model remain scarce.

Aims & Methods: This prospective, analytical prevalence study assessed the safety and effectiveness of propofol sedation administered by a general physician with specific training in sedation, airway management, and intensive care, within an ambulatory endoscopy unit.

From March 2023 to April 2024, adult patients (≥18 years) undergoing colonoscopy at the Centro de Gastroenterología y Endoscopia in Bogotá were included. The physician administered age-tailored propofol bolus and maintenance doses according to clinical guidelines and procedure duration.

Exclusion criteria included ASA IV status or contraindications to propofol. Sedation regimens were as follows:

- <40 years: 180 mg IV bolus; 60 mg maintenance every 5 min
- 41–70 years: 160 mg IV bolus; 50 mg maintenance every 5 min
- ≥71 years: 150 mg IV bolus; 30 mg maintenance every 5 min

Patient demographics, comorbidities, ASA classification, procedure indications, and adverse events were recorded.

Results: A total of 2,032 patients were enrolled; mean age 64 years (95% CI: 62.8–65.1), 60% female. The mean BMI was 27 (95% CI: 25.8–27.1). Colonoscopy indications included screening (35%), diagnostic evaluation (40%), surveillance (20%), and therapeutic intervention (5%), including 101 patients undergoing polypectomy. Comorbidity prevalence was notable: cardiovascular (30%), gastrointestinal (30%), respiratory (15%), neurological (5%), allergic (3%), and haematological (3%).

ASA risk classification revealed:

- ASA I: 14% (n=284)
- ASA II: 60% (n=1,219)
- ASA III: 26% (n=528)

Importantly, no complications—cardiopulmonary, allergic, or sedation-related—were recorded. All procedures were completed successfully, with high patient tolerance and efficient recovery times.

Conclusion: This real-world study confirms that propofol sedation administered by non-anaesthesiologist physicians with critical care training is both safe and effective for the vast majority of patients undergoing colonoscopy in ambulatory settings. These findings support a task-sharing model that maximises resource efficiency while maintaining patient safety. In health systems with limited anaesthesiologist availability, this approach allows specialists to focus on higher-risk ASA IV patients in tertiary-level settings. Widespread adoption of this model, with appropriate training, could reduce costs, increase procedural throughput, and improve access to high-quality endoscopic care in Latin America and similar settings.

INSIGHTS INTO TRAINEE ENDOSCOPIST-CADX ARTIFICIAL INTELLIGENCE INTERACTION AND INFLUENCES ON DIAGNOSTIC COMPETENCY – EXPLORATORY ANALYSIS OF DATA FROM A PROSPECTIVE OBSERVATIONAL STUDY OF CADX-SUPPORTED TRAINEE ENDOSCOPIST DIAGNOSTIC COMPETENCY

V. Marko[1], J. Prosenz[2,3], S. Bernhofer[2,3], D. Venturi[2,3], F. Koutny[2,3], A. Maieron[2,3]

Introduction: Artificial intelligence (AI) characterization (CADx) systems for colonic polyps exhibit high diagnostic accuracy. However, they may only support, not replace, clinical decision-making and little is known of this human-AI interaction – even less so with trainee endoscopists.

This issue is difficult to explore, but data from a study investigating CADx-supported trainee endoscopists compared to AI-blinded experts could give insight.

Aims & Methods: This analysis draws on data from a prospective observational study comparing the diagnostic performance of CADx-supported trainee endoscopists (using GI Genius®, Medtronic) to expert endoscopists blinded to AI support.

Two key scenarios were explored:

a. instances in which the CADx system produced a 'no prediction' output, and;

b. cases where trainees actively overruled AI-generated diagnoses.

These were assessed to examine the impact of AI absence and human-AI discordance on diagnostic accuracy.

Results: The baseline cohort included 11 trainees performing 225 colonoscopies, mean age 63.8 years (SD 12.7), 48.9% male patients. Baseline ADR was 57.8%. Of 630 resected lesions (median size 3 mm, IQR 2;4), 40.0% were in the rectosigmoid, and 53.6% were non-adenomatous. CADx failed to provide a prediction in 19.2% (n=121) of cases. These 'no prediction' polyps were smaller (median 3 mm, p=0.048) and more often located in the right colon (72% vs. 58%, p=0.005. In the absence of AI support, trainee diagnostic accuracy declined significantly by 12.8% (63.6% vs. 76.4%, p=0.007).

Interestingly, expert endoscopists—despite being blinded to AI—also performed worse on these polyps (64.7% vs. 73.9%, p=0.045), suggesting an inherent difficulty in classifying these lesions.

Trainees overruled AI suggestion leading to discordant diagnoses in 9.0% (57/630) of polyps, comprised of 20 (35.1%) non-adenomatous, and 37 (64.9%) adenomatous lesions. Trainees incorrectly overruled AI in 59.6% (34/57), which mostly consisted of downgrading lesions to NICE 1. Discordant polyps did not differ in size (3 mm vs. 3 mm, p=0.413), but were more often located proximally (77.2% vs. 58.1%, p=0.005).

The difference in false negative rate (FNR) between trainees and AI was 62.16% (81.07% vs. 18.92%, p<0.0001), demonstrating a risk of missed adenomas when trainees override AI. Blinded expert endoscopists achieved identical overall diagnostic accuracy in those polyps as the AI system (59.6%).

However, their error profiles differed – In this subset, blinded experts and AI performed equally in overall accuracy (59.6%), although with differing error profiles: AI showed a numerically lower FNR (18.9% vs. 35.1%, Δ16.2%, p=0.17), offset by a higher false positive rate (80.0% vs. 50.0%).

	'No prediction' polyps (n=121)	Polyps with AI prediction (n=492)	
Size mm, median (IQR)	3 (2;4)	3 (2;4)	p=0.0483
Location in right colon	72%	58%	p=0.005
Diagnostic accuracy, trainees, % (95%CI)	63.6% (0.55-0.72)	76.4% (0.73-0.80)	p=0.007
Diagnostic accuracy, experts, % (95%CI)	64.7% (0.53-0.72)	73.9% (0.69-0.78)	p=0.0454

Conclusion: CADx systems generate 'no prediction' outputs in a substantial proportion of polyps, significantly impairing trainee diagnostic performance. These cases may represent inherently more challenging lesions. Despite CADx's high accuracy, trainees overrule AI in almost every tenth polyp, most often incorrectly downstaging polyps. Structured training on appropriate use of CADx, emphasizing both its capabilities and limitations, may enhance clinical effectiveness.

Further research on human-AI interaction and trust is warranted, as these factors will be critical for successful integration of CADx into routine endoscopic practice.

Disclosure: The original study (AC-CADx) received technical support by Medtronic. Medtronic was not involved in the design of the study or analysis of the data, neither in the original study nor this exploratory analysis.

PP0648

EFFICACY OF SNARE TIP COAGULATION IN COLONIC POLYPECTOMY: A PREVENTIVE STRATEGY FOR POST-POLYPECTOMY BLEEDING AND LOCAL RECURRENCE

K.M. Sohn[1]
[1]Charm Medical Clinic, Gastroenterology, Seoul, South Korea

Contact E-Mail Address: dr.sohnkm@gmail.com

Introduction: Colonic polypectomy is a widely used endoscopic technique for colorectal cancer prevention. However, post-polypectomy bleeding (PPB) and local recurrence remain notable complications. Snare Tip Coagulation (STC) involves the application of thermal coagulation to the resection margin using the tip of the snare after polyp removal.

This study aimed to evaluate the clinical efficacy of STC in reducing immediate and delayed PPB, as well as local recurrence, following polypectomy.

Aims & Methods: We retrospectively reviewed 156 patients who underwent endoscopic resection—either snare polypectomy or endoscopic mucosal resection (EMR)—for pedunculated or sessile colorectal polyps measuring 6–20 mm at a single center between January 2022 and February 2024.

Patients were divided into two groups: those who received STC (n=78) and those who did not (control group, n=78). Primary outcomes included the incidence of PPB within 14 days and local recurrence at 12-month follow-up colonoscopy.

Results: The STC group demonstrated significantly lower rates of early (0.4%) and delayed (1.6%) PPB compared to the control group (1.9% and 3.8%, respectively; p<0.05). Local recurrence was also significantly reduced in the STC group (1.3%) versus the control group (4.8%; p=0.01). No significant differences were observed between the groups regarding procedure time or major complications such as perforation.

Conclusion: Snare Tip Coagulation is a safe and effective adjunctive technique in colorectal polypectomy, significantly reducing the risk of both post-procedural bleeding and local recurrence without increasing procedural complications. STC may offer particular benefit in the resection of medium-sized colorectal adenomas and should be considered for integration into routine endoscopic practice.

CAN 5-MINUTE COLONOSCOPY WITHDRAWAL TIME BE THE BENCHMARK BASED ON EXPERIENCED ENDOSCOPISTS AND EXCELLENT BOWEL PREPARATION? A MULTICENTER, RANDOMIZED CONTROLLED, BACK-TO-BACK TRIAL IN CHINA

B. Xu[1], H. Zhang[1], C. Xu[1], X. Chen[1], B. Wei[1], Y. Cheng[1]
[1]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi People's Hospital, Wuxi Medical Center, Nanjing Medical University, Jiangsu Branch of the National Clinical Research Center for Digestive Diseases, Gastroenterology, Wuxi, China

Introduction: Current colonoscopy quality indicators recommend a minimum withdrawal time (WT) of 6 minutes. However, this standard may reduce colonoscopy efficiency and does not account for endoscopists' experience or bowel preparation quality. This study aims to investigate whether the 6-minute WT remains necessary for experienced endoscopists with excellent bowel preparation (BBPS≥8) by comparing the impact of 5-minute versus 6-minute WT on adenoma detection rate (ADR) and adenoma miss rate (AMR).

Aims & Methods: This study based experienced endoscopists and excellent bowel preparation (Boston Bowel Preparation Scale score, BBPS≥8) is aimed to compare the effect of 5-minute WT versus 6-minute WT on adenoma detection rate (ADR) and adenoma miss rate (AMR).

This multicenter, randomized controlled trial involving 423 patients was conducted from June 2023 to March 2025 in 5 centers, including Wuxi People's Hospital, Jiangsu Province People's hospital, Xuzhou First People's Hospital, The Second Affiliated Hospital of Soochow University, Taizhou People's Hospital. Colonoscope was inserted and withdrew twice on each patient and all procedures for the same patient were done by the same endoscopist. Participants were randomly divided into the 5-minute WT group (the first WT-5-minute and the second WT-6-minute, n =214) and the 6-minute WT group (the first WT-6-minute and the second WT-6-minute, n=209), and a timer was used to adjust the withdrawal speed. The primary outcome was ADR and AMR.

Results: The baseline characteristics of the two groups were similar (Table 1) and colonoscopy characteristics of the patients in the two groups regarding quality of bowel preparation, cecal intubation rate, cecal intubation time, cecal intubation distance, number of abdominal compression, number of position change were comparable (Table 2). Overall ADR (39.7% vs 43.5%, P = 0.425), ADR in the first (36.0% vs 36.4%, P = 0.935) and second withdrawal (10.7% vs 13.9%; P = 0.327) were not significantly increased in the 6-minute WT group compared with the 5-minute WT group. Likewise, the overall advanced adenoma detection (AADR) (4.7% vs 5.3%, P = 0.780), AADR in the first (4.7% vs 5.3%, P = 0.780) and second withdrawal (0.5% vs 0.5%, P = 0.745) did not differ statistically. Further analysis showed that AMR (10.7% vs 13.9%, P = 0.372) was lower in the 5-minute WT group than in the 6-minute WT group, less adenomas were missed in the 5-minute WT group, although not statistically significant (Table 3).

		5-minute (n=214)	6-minute (n=209)	P- value
ADR, n (%)	Overall ADR	85(39.7%)	91(43.5%)	0.425
	The first withdrawal	77(36.0%)	76(36.4%)	0.935
	The second withdrawal	23(10.7%)	29(13.9%)	0.327
AADR, n (%)	Overall AADR	10(4.7%)	11(5.3%)	0.780
	The first withdrawal	10(4.7%)	11(5.3%)	0.780
	The second withdrawal	1(0.5%)	1(0.5%)	0.745
AMR, n (%)		23/214(10.7%)	29/209(13.9%)	0.327
AAMR, n (%)		1/10(10.0%)	1/11(9.1%)	0.944
PMR, n (%)		67/214(31.3%)	59/209(28.2%)	0.489

Table 3. Lesion-level detection and miss rate in the two groups.
PDR, polyp detection rate; ADR, adenoma detection rate; AADR, advanced adenoma detection rate; AMR, adenoma miss rate; AAMR, advanced adenoma miss rate; PMR, polyp miss rate.

Conclusion: Shortening WT from 6 to 5 minutes didn't reduce ADR based experienced endoscopists and excellent BBPS, a 5-minute WT benchmark was acceptable with experienced endoscopists and excellent bowel preparation quality of colonoscopy.

Disclosure: Nothing to disclose.

Contact E-Mail Address: wettstein_v@ukw.de

Introduction: Identification and precise classification of polyps is essential during screening colonoscopy, but subject to significant interobserver variability. Traditional training approaches depend on patient-derived data, which limits open source resources for educational purposes. AI-generated images enable the training of classification of precancerous lesions without relying on patient-related data.

Aims & Methods: This study aims to evaluate the realism of AI-generated polyp images. Based on over 40 million endoscopy images from over 7,000 examinations, we developed a latent diffusion based AI that generates images of colonic polyps. To prove that our AI-generated polyp images are indistinguishable from real images, we conducted a multicenter, international reader study involving 55 physicians from 47 centers across 15 countries, of whom 48 had performed over 1,000 colonoscopies. Participants were shown 40 images (20 real, 20 synthetic) and were asked to classify each as real or AI-generated, along with rating their confidence in each decision.

Results: Of the 55 participants, 53 were included in the analysis. Overall classification accuracy was 73% (95% confidence interval [CI], 70% – 76%). AI-generated polyps were classified correctly with a sensitivity of 66% (95% CI, 60% – 71%) and a specificity of 80% (95% CI, 76% – 84%). Conversely, for correct classification of real polyps, the sensitivity was

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

80% (95% CI, 76% – 84%) and the specificity was 66% (95% CI, 60% – 71%). The assessment of AI-generated polyps was associated with a significantly increased uncertainty ($p < 0.001$).

Conclusion: Our study demonstrates that even experienced endoscopists struggle to reliably distinguish AI-generated polyps form real ones. This underscores the ability of our AI model to create realistic images in high quality. In future projects, we will use AI-generated images to create a training platform for the classification of precancerous lesions.

Disclosure: Nothing to disclose.

PP0651

CAN ARTIFICIAL INTELLIGENCE IDENTIFY HISTOLOGICAL SUBCLASSES OF HYPERPLASTIC POLYPS BASED ON THEIR ENDOSCOPIC FEATURES?

A. Jans[1,2], B. Callaerts[3,4], P. Sinonquel[1,2], X. Sagaert[5], I. Demedts[1,2], P. Roelandt[1,2], T. Eelbode[3,4], F. Maes[3,4], S. Tejpar[1,6], R. Bisschops[1,2]

Introduction: Recent insights in polyp molecular biology have suggested that hyperplastic polyps (HP) are closely related to sessile serrated lesions (SSL). Their hallmark serrated crypts closely resemble those found in SSL. Furthermore, similar to SSL, specific subtypes of HP can harbor BRAFV600E-mutations. These findings, amongst others, have raised the hypothesis that some HP may have an intrinsic malignant potential through the serrated neoplasia pathway. However, in everyday clinical practice, no routine HP subdifferentiation is performed. Therefore, we aimed to develop a deep learning algorithm to classify molecular subclasses of HP, namely microvesicular hyperplastic polyps (MVHP) and goblet cell-rich hyperplastic polyps (GCHP), based on their endoscopic features.

Aims & Methods: In this single-center trial 238 hyperplastic polyps from 159 patients were retrospectively selected. All polyps had high quality endoscopic video in white light endoscopy and virtual chromoendoscopy (i-scan) using Pentax EC38-i20c and EC34-i10 endoscopes. All histological slides were reviewed by an expert pathologist, updating diagnoses to MVHP, GCHP or mixed HP. We selected the polyps without mixed constitution for development of a deep learning algorithm. These polyps were randomly split into 70% for training, 10% for validation and 20% for testing. Sequences of still images of the polyps were manually annotated and subsequently used to train a deep learning algorithm, with dataset imbalance addressed by randomly oversampling the MVHP.

Results: The 238 HPs were reclassified as 152 GCHP, 59 MVHP and 27 mixed HPs after expert histological review. We subsequently trained a convolutional neural network on the 211 HPs without mixed constitution. This resulted in a model with an AUC of 0.817, corresponding to a sensitivity of 80.0% for predicting MVHP and 78.4% for predicting GCHP.

However, due to the low prevalence of MVHP (28%) the positive predictive value for MVHP is only 33.3%, whilst the positive predictive value for GCHP is 96.7%.

	GCHP (Predicted)	MVHP (Predicted)
MVHP (True)	*1*	*4*
GCHP (True)	*29*	*8*

Table 1: Test set confusion matrix (polyp-averaged prediction).

Conclusion: We successfully developed a deep learning algorithm capable of differentiating between molecular subclasses of hyperplastic polyps (MVHP vs GCHP) based on their endoscopic features. This model demonstrated a robust AUC of 81.7% with a sensitivity of 80.0% and 78.4% for predicting MVHP and GCHP respectively.

However, the low prevalence of MVHP (28%) limited its positive predictive value (33.3%) for predicting MVHP. Despite these challenges, this pilot study serves as a proof of concept that artificial intelligence is capable of predicting hyperplastic polyp subclasses based on endoscopic appearance.

Furthermore, it highlights the potential of artificial intelligence to enhance the diagnostic precision, which could contribute to more tailored surveillance and management strategies in the future.

IMPLEMENTATION OF OPTICAL DIAGNOSIS WITH A RESECT AND DISCARD STRATEGY FOR DIMINUTIVE POLYPS IN THE ENGLISH BOWEL CANCER SCREENING PROGRAMME

A. Ahmad[1,2], S. Hearing[3], J. Stebbing[4], K. Emery-Downing[5], L. Adams[5], R. Maclean[5], B.P. Saunders[1,2]

[1]St Mark's National Bowel Hospital, London, United Kingdom, [2]Imperial College London, London, United Kingdom, [3]Royal Derby Hospital, Derby, United Kingdom, [4]Royal Surrey NHS Foundation Trust, Guildford, United Kingdom, [5]NHS England, London, United Kingdom

Contact E-Mail Address: ahmir.ahmad@nhs.net

Introduction: Optical diagnosis (OD) with a "resect and discard" strategy involves diagnosing diminutive polyps with high confidence, photodocumenting and resecting these without sending to histology.

This greener, more efficient and cost-effective process underwent a comprehensive evaluation in the DISCARD3 study which showed, in a single screening centre, this meets the threshold for implementation and is feasible and safe with a quality assurance (QA) process in place. The NHS Bowel Cancer Screening Programme (NHSBCSP) in England approved implementation in 2023.

Early learning from translating this research into a population based programme is presented.

Aims & Methods: All 506 screening colonoscopists in England have been invited to undertake accreditation in OD.

Part 1 of the process involves attendance at a training day including a pre- and post-training test where 120 polyps are optically diagnosed. Pass criteria is ≥85% accuracy for high confidence optical diagnoses and overall ≥50% high confidence calls.

Part 2 involves supervised OD at each endoscopists' base hospital of 20 consecutive high confidence, optical polyp diagnoses with assessment of photodocumentation quality and diagnostic accuracy. To pass part 2 photodocumentation quality is required to be adequate in ≥90% of cases using the "3C photo quality score" and diagnosis accuracy ≥85%.

Once achieved, individuals are fully accredited to perform OD with a resect and discard strategy for screening cases and must undertake re-accreditation with online assessment of a further 120 polyp images every 2 years to demonstrate competency. Those accredited are supported by

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

"Optical Diagnosis Champions" at each screening centre who monitor performance and support QA. Once in place "Optical Diagnosis Champions" will support those becoming accredited in OD.

Results: 65 screening colonoscopists attended part 1 of the accreditation in March 2024. 85% (55/65) passed the post-test on the first attempt with a further 7 individuals passing on repeat attempts. Overall 62/65 (95%) have completed part 1. Of these, 55/62 (89%) have successfully completed part 2 and are fully accredited.

As of 31 March 2025, 9618 polyps have been resected and discarded with a cost saving equivalent to £355866 (assuming a cost of £37 per polyp). An estimated 3206 hours of histopathology time has been saved (assuming 20 minutes per polyp).

Further training days have been held in September 2024, February 2025 and March 2025 increasing the total number of screening participants to over half of all screeners in England (310/506). The results from these will be reported in due course.

Conclusion: The NHSBSCP is the first population based screening programme in the world to implement OD with a resect and discard strategy. Quality assurance and monitoring is ongoing. In this early stage there have already been cost and time savings for the NHS which are expected to increase substantially once roll out completes in 2027.

Introduction: Propofol-mediated sedation (PMS) is increasingly favored for endoscopic procedures due to its rapid onset, predictable recovery, and safety profile.

Aims & Methods: Propofol-mediated sedation (PMS) has become increasingly favored in gastrointestinal endoscopy due to its rapid onset, short recovery time, and favorable safety profile. While both propofol monotherapy and combination regimens are widely used, direct comparisons remain limited. In this prospective, randomized, single-center trial, 207 patients undergoing colonoscopy, gastroscopy, or bidirectional endoscopy were randomized to propofol monotherapy (n=101) or a combination regimen (n=106). Clinical, procedural, and sedation-related parameters, as well as patient and endoscopist satisfaction, were systematically evaluated.

Results: Both regimens demonstrated excellent safety profiles, with low complication rates that resolved spontaneously or with minimal intervention. Procedural outcomes, including polyp detection rates and duration, were comparable. Propofol monotherapy required a higher mean dose (123.84 ± 33.92 mg vs. 114.56 ± 28.17 mg, P < 0.01). Patient recovery was smoother in the monotherapy group, with higher uneventful recovery rates (74.3% vs. 67.9%) and overall satisfaction (95.1% vs. 90.6%). Endoscopist satisfaction was also slightly higher for monotherapy (94.1% vs. 89.7%), reflecting improved patient calmness.

Conclusion: Both regimens provided safe and effective sedation for endoscopy, but propofol monotherapy was associated with smoother recovery and higher satisfaction, supporting its use as a practical option in routine practice.

Disclosure: Nothing to disclose.

Contact E-Mail Address: r0811mo@jichi.ac.jp

Introduction: A new LED endoscopy system featuring advanced noise-reduction technology for enhanced brightness and minimal halation, the EP-8000 with the EC-860ZP colonoscope (Fujifilm), is scheduled to be released.

Aims & Methods: We conducted a multicenter, observational study to evaluate the new system's potential improvements in image quality compared to a previous system/scope (VP-7000/EC-760ZP). From January 2024 to January 2025, patients undergoing colonoscopy at two institutions were enrolled. Images of the cecum and lesions were captured using white light imaging (WLI), blue light imaging (BLI), and linked color imaging (LCI) under similar conditions about air insufflation, angle, distance, and so on.

Participants were divided into three groups:

Group 1 (EP-8000+EC-860ZP; 50 cases),

Group 2 (EP-8000+EC-760ZP; 50 cases), and;

Group 3 (VP-7000+EC-760ZP; 50 cases).

Cecal images were evaluated for brightness and halation using a four-point scale (1=poor to 4=excellent) by endoscopists and original values by image-analysis software, while lesion images were assessed for brightness, halation, and visibility by endoscopists.

Results: In cecal images, the endoscopists' scores for WLI in Group 1 were significantly better than in Group 3 for brightness (3.71±0.55 vs. 3.51±0.58, p<0.001) and for halation (3.60±0.51 vs. 3.18±0.59, p<0.001). Similarly, for BLI and LCI, Group 1 achieved higher scores than Group 3 regarding brightness (BLI: 3.15±0.85 vs. 2.23±0.92, p<0.001; LCI: 3.83±0.42 vs. 3.54±0.58, p<0.001) and halation (BLI: 2.99±0.69 vs. 2.71±0.78, p<0.001; LCI: 3.33±0.60 vs. 3.10±0.58, p<0.001). Software analysis confirmed that Group 1 had superior brightness values compared to Group 3 for WLI (122.7±6.6 vs. 110.7±7.7, p<0.001), BLI (99.1±10.9 vs. 69.3±11.5, p<0.001), and LCI (139.4±9.2 vs. 113.1±10.7, p<0.001), as well as lower halation values for WLI (1.34±1.80 vs. 3.35±3.59, p=0.031) and LCI (1.48±0.83 vs. 4.06±3.99, p=0.010). Regarding lesion images, brightness, halation, and visibility for WLI, BLI, and LCI were significantly better in Group 1 than in Group 3.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The new LED system provided marked improvements in brightness, halation, and lesion visibility. The software assessment was consistent with endoscopists assessment objective and can be used for the development and evaluation of new endoscopic systems.

THE EFFECT OF BLUE METHYLENE TABLETS ON ADENOMA DETECTION IN NEOPLASIA SURVEILLANCE OF PEOPLE WITH LYNCH SYNDROME

V. Affatato[1], F. Savino[1], G. Losurdo[1], S. Rizzi[1], M. Barone[1], M.R.D. Principi[1], A. Iannone[1]
[1]Section of Gastroenterology, DIMEPREJ, University of Bari, Bari, Italy

Contact E-Mail Address: vito.affatato4@gmail.com

Introduction: Lynch syndrome is a hereditary condition associated with an increased risk of colorectal cancer compared to the general population (66.08% for men and 42.71% for women). Improving adenoma detection rate (ADR) is associated with a reduced risk of interval cancer. Recent studies showed that blue methylene tablets (BMT) significantly improved ADR in the screening population.

This preliminary study aims to evaluate whether the addition of BMT to standard colonoscopy preparation increases ADR in the high-risk population of Lynch syndrome patients.

Aims & Methods: This observational non-randomized study included consecutive people ≥18 years with genetic diagnosis of Lynch syndrome. Participants were assigned to two groups: one receiving split preparation with 2 litres of PEG and the other receiving BMT in addition to the same bowel preparation (3 tablets dissolved in 0.5 L of water the night before the procedure, and 2 tablets 5 hours before). All patients with previous colonic resections were excluded. The primary outcome was ADR. The t-test for independent samples and Fisher's exact test were used for statistical analysis.

Results: Thirty-eight patients were enrolled, 17 in BMT and 21 in the control group. Twenty-one (55.3%) patients were female and 17 (44.7%) male, with a mean age of 45.6 ± 11.3 years. The two groups were comparable for sex (p=0.75), age (p=0.72), mutation types (p=0.16) and previous polypectomy history (p=0.20). The polyp detection rate was 5/21 (23.8%) in the control group and 5/17 (29.4%) in the BMT group, p = 0.73. The ADR was 2/17 (11.8%) in the BMT and 3/21 (14.2%) in the control group (p=0.94). The average number of adenomas per colonoscopy in the BMT group was 1.8 ± 1.7 compared to 1.5 ± 1.22 in the control group (p=0.76). The average number of polyps per colonoscopy in the BMT group was 2.0 ± 1.7 compared to 2.0 ± 2.0 in the control group (p=1).

Conclusion: BMT as add-on to standard colonoscopy preparation did not significantly increase the adenoma detection rate in the high-risk population of patients with Lynch syndrome. Further studies with larger sample sizes may be needed to confirm these findings.

Disclosure: Nothing to disclose.

EVALUATION OF AI-ASSISTED COLONOSCOPY FOR POLYP DETECTION: A NON-INFERIORITY ANALYSIS COMPARING NON-EXPERT AND EXPERT ENDOSCOPISTS

K. Hida[1], T. Maehata[1], K. Shimada[1], Y. Iijima[1], K. Araki[1], K. Tsukamoto[1], T. Komatsu[1], Y. Nakamoto[1], M. Kato[1], H. Kiyokawa[1], Y. Sato[1], K. Tateishi[1]

Contact E-Mail Address: kazuhid08@icloud.com

Introduction: Colonoscopy is vital for colorectal cancer prevention, with adenoma detection rate (ADR) serving as a crucial quality marker. However, significant inter-operator variability exists between expert and non-expert endoscopists. Emerging artificial intelligence (AI) systems promise to support non-experts in achieving detection rates closer to those of specialists.

Aims & Methods: This study aimed to determine whether non-expert endoscopists using an AI-assisted system (CAD EYE™) can achieve a polyp detection rate non-inferior to that of expert endoscopists.

In this prospective, single-center, observational study, 120 patients (aged 20–90 years, ECOG performance status 0–2) with previously detected polyps by expert colonoscopy were enrolled. Non-expert endoscopists performed colonoscopy with AI assistance while experts verified polyp findings in real-time.

The primary endpoint was the overall polyp detection rate, with a pre-defined non-inferiority margin of 10% (assuming an expert detection rate of 100% and an anticipated non-expert detection rate around 95%).

Secondary endpoints included adenoma detection rate, total procedure time, intubation time, and withdrawal time. Statistical analysis was performed using the Clopper–Pearson method for confidence intervals.

Results: Among 120 patients, the non-expert endoscopists using AI achieved a polyp detection rate of 95.8% (95% CI: 92.3–99.3%), which met the non-inferiority criterion compared to the expert detection rate of 100% (non-inferiority confirmed as the lower limit of the CI exceeded 90%). The adenoma detection rate was 36.7% for non-experts versus 38.3% for experts (p=0.62).

Mean total procedure times were comparable between groups, with non-experts averaging 22.4 ± 4.5 minutes and experts 21.8 ± 3.9 minutes (p=0.45). No significant differences were observed in intubation or withdrawal times. The safety profile was similar, with minor adverse events occurring in 2.5% of non-expert cases.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The findings indicate that AI-assisted colonoscopy enables non-expert endoscopists to achieve a polyp detection rate comparable to that of experts, without compromising procedural efficiency or safety.
These results support the clinical implementation of AI systems in colonoscopicpractice to reduce operator-dependent variability and improve screening quality.
Further multicenter studies with larger cohorts are warranted to validate these promising outcomes.

TRENDS IN LOWER GASTROINTESTINAL ENDOSCOPIC POLYPECTOMY AND ENDOSCOPIC MUCOSAL RESECTION: A NATIONAL CROSS-SECTIONAL E-SURVEY

P. Apolito[1], L. Alfarone[2], F. Borrelli de Andreis[3], G. Calabrese[4], P. Soriani[5], M. Manno[5], R. Di Mitri[4], A. Repici[2], V. Cennamo[1]

Introduction: Endoscopic polypectomy and endoscopic mucosal resection (EMR) are widely used techniques, largely due to the increasing number of screening colonoscopies. Recently, the ESGE provided a core curriculum for training in Endoscopic Mucosal Resection (EMR) [1].
Among the recommendations for Hot-EMR, it is suggested that the endoscopist personally takes over the snare from the assistant and closes it to gain a better perception of the grasped tissue, thereby reducing risks. However, data regarding endoscopist preferences and common practices in lower gastrointestinal (GI) polypectomy are lacking.
Aims & Methods: This study aims to elucidate the current practices and preferences of young Italian endoscopists (age <40 years). A national cross-sectional e-survey was conducted in Italy between June and August 2024. Participants were recruited from the Young Endoscopist Polypectomy study group (PolYoung). The e-survey included questions regarding demographics, volume of procedures, perceived proficiency levels, and technical preferences in endoscopic polypectomy. Descriptive and inferential statistical analyses were performed to identify trends and disparities based on demographic and experience characteristics.
Results: A total of 71 GI endoscopists (M 46:F 25, 0 non-binary) responded to the e-survey. Nearly half (52.1%) were aged 30-35 years. Among the participants, 52.1% worked in university hospitals, while 43.7% worked in non-university community hospitals and 4.2% in private hospitals.
Approximately half of the participants (49.3%) had performed more than 1,000 colonoscopies as the first operator. Additionally, 66.2% had performed more than 100 cold snare polypectomies, and almost all participants (98.6%) felt confident performing this procedure independently.
Regarding Hot-EMR, 43.7% had performed more than 50 procedures, and 66.2% felt independent in performing this technique. When asked about their preferences for Hot-EMR, 93% of the participants preferred to instruct the assistant to open the snare to grab the polyp and then cut the lesion themselves, rather than taking over the snare to cut the polyp, in order to maintain control of the scope.
Only 15.5% of participants routinely added adrenaline to the injection solution. However, 58.6% of participants routinely performed prophylactic closure of the post-resection scar in all large (>20 mm) EMRs of the proximal colon, while 22.9% did so for all EMR lesions, regardless of size, when patients were on antithrombotic drugs. Regarding novel EMR techniques, 70.4% and 80.3% of participants had performed underwater-EMR and cold-EMR, respectively.
Finally, no statistically significant differences were observed between demographic factors, years of experience, and proficiency levels for any of the variables considered.
Conclusion: This study provides valuable insights into the common practices of young endoscopists in Italy. Notably, a low adherence to the ESGE-recommended Hot-EMR technique was observed.
This finding highlights the need for further comparative studies between different approaches and underscores the importance of developing new devices that enhance the endoscopist's ability to accurately gauge the amount of tissue captured by the snare without losing control of the scope.

Introduction: Endoscopic placement of self-expandable metallic stents (SEMS) for malignant colorectal obstruction near the dentate line is technically challenging because of the difficulty faced in the precise alignment of the distal edge of the stent with the distal end of the lesion. Furthermore, after stenting, lesions close to the dentate line often induce anal pain. Therefore, positioning of the distal end of the stent at an adequate distance from the dentate line is crucial for reducing discomfort. A proximally release-type SEMS might be particularly advantageous in such cases.
Aims & Methods: This study aimed to assess the safety and efficacy of proximally release-type SEMS for malignant colorectal obstruction placed within 10 cm from the dentate line. The study retrospectively analyzed 12 consecutive patients who had undergone SEMS placement between May 2019 and March 2024 at our institution. The clinical outcomes, technical and clinical success rates, adverse events, and prognosis were evaluated.
Results: The median age of the subjects was 70.5 years, and included five (41.7%) men and seven (58.3%) women. The causes of obstruction were primary colorectal cancer (six patients), gastric cancer (five patients), and cervical cancer (one patient). Colorectal Obstruction Scoring System (CROSS) scores prior to SEMS placement were 0 (2 patients), 1 (10 pa-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tients). Tumor locations included Rs in two patients, Ra in two, and Rb in eight patients, with the median distance from the dentate line being 4.5 cm (range: 2–10 cm). The indications for SEMS placement were bridge to surgery (BTS) in four cases and palliation (PAL) in eight cases. The technical success rate was 91.7% (11/12), and the clinical success within seven days was also 91.7% (11/12). Early adverse events (within seven days) included one case of stent migration (8.3%) No cases of perforation, bleeding, or reobstruction were observed.

All BTS patients underwent successful laparoscopic surgeries and no recurrence has been observed to date. Among the PAL cases, one patient experienced stent migration 314 days after SEMS placement. The migrated stent was manually extricated under general anesthesia.

Conclusion: The proximally release-type colonic stent was effective for treating malignant colorectal obstruction near the dentate line since it facilitated placement of the stent in the right position. It might be the primary option for malignant colorectal obstruction near the dentate line, and can contribute to the expansion of indications for colorectal stent placement for lesions near the anal verge.

Disclosure: Nothing to disclose.

Introduction: The European Society of Gastrointestinal Endoscopy (ESGE) recommends colorectal cancer (CRC) screening for individuals at average risk, aged 50-75 years. However, recent trends indicate an increasing incidence of colorectal neoplasms among younger individuals.

Aims & Methods: The primary aim of this cross-sectional study is to record the prevalence of polyps, adenomas, and advanced neoplasia (high-grade dysplasia and CRC) in individuals up to 49 years old, and secondarily to identify predictors of neoplasia and high-grade dysplasia. The data were collected retrospectively through the hospital's electronic database. All serial colonoscopies, with cecum intubation, from 1/1/2018 until 31/12/2024 were included. Endoscopies in patients with diagnosed familial polyposis syndromes, inflammatory bowel disease and those with poor bowel preparation were excluded. Patients' demographics, CRC family history and the recorded polyps' size, location, Paris classification, and pathology reports were collected. SPSS 23 (IBM, Armonk, NY, USA) was used for the statistical analysis.

Results: A total of 568 colonoscopies were included, involving 306 male patients (53.8%), with a median age of 42 years (IQR: 36-46). Of these, 71 patients (12.5%) had a family history of CRC. At least one polyp was identified in 166 patients (29.2%), with adenomas observed in 68 patients (12.1%) and advanced neoplasia in 20 patients (3.5%), including 3 patients (0.5%) diagnosed with CRC (Table).

	<25 (n=36)	25-29 (n=31)	30-34 (n=61)	35-39 (n=76)	40-44 (n=146)	45-49 (n=218)	Total (n=568)	P
Polyps, n (%)	0 (0)	2 (6.5)	6 (9.8)	20 (26.3)	52 (35.6)	86 (39.4)	166 (29.2)	<0.001
Adenoma, n (%)	0 (0)	1 (3.2)	2 (3.3)	9 (11.8)	21 (14.4)	36 (16.5)	68 (12.1)	0.006
Advanced adenoma, n (%)	0 (0)	1 (3.2)	0 (0)	3 (3.9)	4 (2.8)	12 (5.6)	20 (3.5)	0.266

Table. Polyps, adenomas and advanced adenomas by age groups.

Advanced adenomas were more frequently detected in colonoscopies performed due to visible blood in stools (8.5%) and as follow-up after diverticulitis (7.1%).

In multivariate analysis, in which age, family history of CRC, and bowel preparation quality were included as variables, the presence of adenomas and advanced adenomas was significantly associated with age (adenoma OR = 1.08; 95% CI: 1.04-1.13 and advanced adenoma OR = 1.08; 95% CI: 1.00-1.18).

In total 271 polyps were identified. Ninety-four were adenomas of which 74 had low-grade dysplasia and 20 high-grade dysplasia or cancer. Sixteen of 177 not-adenomatous polyps were found to be serrated and 2 of those had low-grade dysplasia. "Large" polyps [≥10mm] had a higher probability of being adenomas (71.4%) compared to "small" [5-9mm] (26.2%) and "diminutive" [<5mm] (24.4%), Chi square P<0.001. Regarding the Paris classification Ip and Isp presented a higher probability to be adenomas (87.5% and 86.4% respectively) in contrast to Is and 0-IIa (35.6% and 12.2% respectively), Chi square P<0.001.

The resected adenomas were also categorized according to the type of reported dysplasia to identify predictors of high-grade dysplasia. High-grade dysplasia was present in 42.5% of large polyps compared to 4.5% of small and 6.2% of diminutive (Chi square P<0.001).

High-grade dysplasia was also present in a higher frequency in polyps resected from the "left" colon (26.2%) compared to the "right" (10.3%) and in 0-IIa (66.7%) and Ip (38.1%) compared to Isp (21.1%) and Is (12.5%) polyps according to the Paris classification, but not in a statistically significant degree (Chi square P<0.010).

Conclusion: Despite the relatively small sample size of our study, initiation of screening at a younger age should be considered to be lowered, since adenoma and advanced adenoma were identified in 15% and 4.3% of individuals aged 35-49.

SELF-ASSEMBLING PEPTIDE AND ITS EFFECT ON DELAYED BLEEDING AND HEALING OF POST-RESECTION DEFECT AFTER ADVANCED ENDOSCOPIC THERAPY

K. Kmochova[1], N. Brodyuk[1], Z. Vackova[1], T. Grega[1], P. Urbanek[1], S. Suchanek[1]
[1]Military University Hospital, Prague, Czech Republic, Department of Internal Medicine, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

Contact E-Mail Address: klara.kmochova@uvn.cz

Introduction: Delayed bleeding remains a significant complication after endoscopic resection procedures in the gastrointestinal tract. Effective strategies to prevent post-procedural bleeding and promote optimal healing are critical for improving patient's outcomes. Self-assembling peptide (SAP) is a new hemostatic agent that forms protective nanofibers scaffold after contact with body fluids. Its application may reduce delayed bleeding and support tissue healing after endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD). Early clinical data has shown promising results, but evidence is still limited.

Aims & Methods: This study evaluates the impact of SAP use on delayed bleeding rates and healing process after advanced endoscopic therapies. The findings may support the integration of SAP into standard post-endoscopic care protocols.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

A retrospective analysis was conducted on patients after EMR or ESD at a single tertiary endoscopy center. Two primary outcomes were assessed: delayed bleeding and post-resection defect healing. Delayed bleeding was defined as clinically evident bleeding occurring within 30 days following the index endoscopy. Healing was evaluated endoscopically using the Sakita-Fukutomi classification at 4, 8, and 24 weeks. The size of the resection defect was measured during the procedure using endoscopic forceps or a polypectomy snare for reference. Data were collected from medical reports.

Results: A total of 141 patients (55 women, 86 men) were included in the analysis. The majority underwent ESD (n=96; 68 %), followed by piecemeal EMR (n=36; 26 %), hybrid procedure EMR+ESD (n=7; 5 %), and en-bloc EMR (n=2; 1 %). 35 lesions (25 %) were located in upper GI tract, 106 lesions (75 %) in colon and rectum with an average lesion size of 48 mm. R0 resection was achieved in 71 (78 %) of all 91 en-bloc resections. Delayed bleeding occurred in 6 patients (4.3%), with an average onset of 4 days after the procedure. All these patients had subsequent endoscopy with various hemostatic approaches, including SAP alone (n=3), SAP with coagulation (n=1), coagulation with hemoclips (n=1), and coagulation with hemospray (n=1). In all cases hemostasis was achieved. 2 patients required transfusion. The post-resection defect averaged 51 mm after index endoscopy. At 4, 8, and 24 weeks post-procedure, its size decreased to 20 mm, 14.5 mm, and 10 mm, marking reductions of 61%, 72%, and 80%, respectively.

Conclusion: SAP is effective in preventing delayed bleeding and healing post-resection defects. Its use can increase overall safety of advanced endoscopic procedures. Further studies are needed to establish optimal indications and integration into standard post-procedure protocol.

THE RESEARCH ON THE REDUCE OF ADENOMA MISS RATES THROUGH ARTIFICIAL INTELLIGENCE-ASSISTED COLORECTAL ENDOSCOPY SCREENING

M. Zhang[1], K. Yin[1]
[1]The First Affiliated Hospital of Xi'an Medical University, Department of Gastroenterology, Xi'an, China

Contact E-Mail Address: zmx3115@163.com

Introduction: This study aims to evaluate the impact of artificial intelligence (AI)-assisted colonoscopy withdrawal on AMRs (adenoma missed diagnosis rates) during colonoscopy, demonstrating that AI maintains inspection quality while reducing withdrawal time. Additionally, it investigates the dependency of AI effectiveness on operator experience, clarifying its compensatory role in mitigating variation and ensuring stable quality control in colonoscopic procedures.

Aims & Methods: This study enrolled patients from three endoscopy centers from Jan to Dec 2024. Participants were randomized into two groups: the TR-9 (Traditional Withdrawal 9-minute group) and the AI-6 (AI-Assisted Withdrawal 6-minute group). Each patient underwent two consecutive withdrawal procedure by the same endoscopist. In the TR-9 group, the first withdrawal employed TR-9 inspection followed by AI-6.

Conversely, the AI-6 group initiated with AI-6 followed by TR-9 . Baseline characteristics and detected lesions (classified as adenomas or polyps using the Japan NBI Expert Team classification) were documented for both procedures. Non-inferiority of TR-9 versus AI-6 was evaluated for AMR and poly missed diagnosis rates (PMRs), while differences in adenoma detection rate (ADR) and polyp detection rate (PDR) were compared. The AI-6 group was further stratified into AI-assisted withdrawal normal-endoscopist subgroup (AI-N) and AI-assisted withdrawal expert-endoscopist subgroup (AI-E) for comparative analysis of AMRs, ADR, PDR, and PMRs.

Results: 1. In the non-inferiority comparison between TR-9 and AI-6, AI-6 demonstrated non-inferiority toTR-9 in both adenoma missed rates (27.3% vs. 30.2%; $P < 0.05$) and polyp missed rates (24.6% vs. 29.7%; $P < 0.05$). These results confirm the hypothesis AI-6 achieves non-inferior performance .

2. Regarding adenoma detection rate (ADR), TR-9 demonstrated an ADR of 26.8%, while AI-6 achieved 29.6%, with no statistically significant difference observed ($P > 0.05$). For PDR , TR-9 showed a PDR of 36.0% compared to AI-6's 47.9%, revealing a statistically significant advantage for AI-6 over TR-9 ($P < 0.05$).

3. Subgroup Analysis within AI-6 Group:

In terms of missed diagnosis rates, AI-E exhibited AMRs of 26.4%, significantly lower than the 28.6% observed in AI-N ($P = 0.026$). However, for PMRs, AI-E demonstrated PMRs of 22.6% versus 26.3% in AI-N, with no statistically significant difference ($P = 0.059$).

Regarding ADR, the AI-E subgroup demonstrated an ADR of 31.9%, compared to 27.5% in the AI-N subgroup, with no statistically significant difference ($P = 0.424$). For PDR, AI-E showed a PDR of 48.1%, while AI-N achieved 47.7%, also without statistical significance ($P = 0.933$).

Conclusion: 1. The AMRs 2. The AMRs and PMRs of AI-6 are non-inferior to those of TR-9. The AMRs of both AI-assisted 6-minute withdrawal and TR-9 are slightly higher than the national average (26%).

2. Both TR-9 and AI-6 demonstrated high ADR and PDR , confirming the reliability of colonoscopy quality control across the three participating endoscopy centers. Notably, AI-assisted withdrawal maintained superior detection efficacy despite reducing procedural time to 6 minutes. These findings support the integration of AI-assisted withdrawal technology into continuous quality improvement protocols for colonoscopy, positioning it as a strategic approach to further optimize endoscopic examination standards.

3. In the subgroup analysis, there was no statistically significant difference in lesion detection rates between AI-assisted examinations performed by physicians with different levels of experience. The AMRs of AI-assisted examinations by general physicians were non-inferior to those by expert physicians. However, the hypothesis that the PMRs of AI-assisted examinations by general physicians were non-inferior to those by expert physicians was not supported, which may be related to insufficient sample size.

Disclosure: Nothing to disclose.

Introduction: Japan NBI Expert Team (JNET) classification is clinically useful for diagnosing colorectal cancer; however, the major challenge in its application is eliminating the differences in diagnosis among endoscopists. In the JNET classification, Type 1 corresponds to hyperplastic polyps and sessile serrated lesions (SSL); Type 2A, adenomas to Tis; Type 2B, Tis and T1a; and Type 3, T1b or deeper lesions. We believe that diagnostic support using artificial intelligence can contribute to the standardization of the JNET classification of NBI diagnosis. Therefore, we developed a computer-aided diagnosis (CADx) system to support the JNET diagnosis and evaluated diagnostic performance of the CADx.

Aims & Methods: We developed a CADx system that can perform full-screen image classification while providing more detailed segmentation results as an output. This structure uses a deep convolutional network with the backbone of ResNet34 as a feature extractor for the entire system, and a structure of two transformer encoder blocks to perform full-screen classification. Further, we used a single-layer convolutional structure with a convolutional kernel size of 1 as the segmentation head.

We examined 111 lesions: hyperplastic polyp/SSL, 36 lesions; adenoma, 37 lesions; Tis/T1a, 15 lesions; and T1b or deeper, 23 lesions using Olympus CV-290 and CV-1500 processors and Olympus CF-HQ290ZI, CF-XZ1200DI, and CF-EZ1500DI endoscopes. Each lesion was identified according to the JNET classification: Hyperplastic polyp/SSL, Type 1; Adenoma, Type 2A; Tis/T1a, Type 2B; T1b or deeper, Type 3. The accuracy between the histopathological findings and diagnosis by CADx system was calculated.

Results: The accuracy between CADx system and the histopathological findings was 94.4% (34/36) for hyperplastic polyp/SSL, 81.1% (30/37) for adenoma, 60.0% (9/15) for Tis/T1a, and 74.0% (17/23) for T1b or deeper lesions.

Conclusion: We developed a multiclass CADx system for colorectal lesions that performs JNET classification for histopathological findings, which may assist in the NBI-based diagnosis of colorectal lesions in facilities where the NBI diagnosis with magnifying endoscopy is not widespread.

ENHANCED NATURAL RETRACTION WITH TRANS-ANAL PLATFORM COMBINED WITH SPEEDBOAT ASSISTED ENDOSCOPIC SUBMUCOSAL DISECTION FOR DISTAL COLON POLYPS: INTERIM FIRST RESULTS OF SSD /AUDITREGISTRY

T. Alexopoulos[1], S. Zeidan[1], J. Sebastian[1], K. Hills[1], S. El-Kady[1], P. Gatos-Gatopoulos[1], Z.P. Tsiamoulos[1]
[1]East Kent Hospitals University NHS Foundation Trust, Gastroenterology- Endoscopy, Margate, United Kingdom

Contact E-Mail Address: thoalex@windowslive.com

Introduction: Speedboat™ is a novel multimodal endosurgical device. It utilizes the use of advanced bipolar energy for cutting/dissection and super-high frequency microwave energy for coagulation. AirSeal® is a trans-anal access port that creates an "invisible pneumo- dissection" effect by instantaneously responding to changes in intraluminal pressure, with CO2 exchange.

Aims & Methods: This study aims to evaluate the efficacy of Speedboat assisted Endoscopic Submucosal Dissection (S-ESD) with and without AirSeal in the management of complex distal colorectal polyps as well as the speed of dissection.

Data, from a prospectively collected clinical audit and later a dedicated S-ESD registry (2018-2025) was analyzed. Cases were divided into three groups, the pre-AirSeal group (2018-2020), AirSeal group (2021-2025) and non-AirSeal (2021-2025). Lesions characteristics, long and short axis length, time of dissection and clinical outcomes were collected. Lesion surface (cm^2) and Speed (cm2/hr) were calculated. Clinical outcomes and dissection speed were compared between the three groups.

Results: Over the study period, a total of 253 consecutive patients [56.1% male, age 72 (IQR: 65-77)] had a distal colorectal lesion completely excised using S-ESD with median surface of 12.95cm^2 (IQR:6.87-21.68), long axis 5,0 cm (IQR: 3.5-7.0) and speed 9.42cm2/hr (IQR:6.97-15.75).

Pre-AirSeal group included 58 patients [58.6% male, age 72 (IQR 65-77)] with median surface of 9.81cm^2 (IQR:6.72-15.89), long axis 4.5cm (IQR: 3.5-6.1) and speed 7.15 (IQR: 6.86-9.31). Since AirSeal introduction in 2020 195 patients with distal polyps had S-ESD [55.4%male, age 72 (IQR: 64-76)] with median surface of 14.19 cm^2 (IQR:6.91-27.47), long axis 5.0cm (IQR: 3.5-7.0) and speed 11.41 (IQR: 6.17-18.00)].

In the AirSeal group 127 patients underwent S-ESD [58.3% male, age 71(IQR: 63-76), median surface 15.70 (IQR: 8.24-30.90) and speed 11.41 (IQR: 7.06-16.63). In the non-AirSeal group 68 patients were subject to S-ESD [50% male, age 72 (IQR: 66-78), median surface 11.38 (IQR: 5.15-19.28)].

There was not a significant difference in dissection speed between AirSeal and non-AirSeal group (p=0.158) but the median surface of the polyps removed were significantly larger in the AirSeal group (p=0.005). Overall, the speed and surface were significantly increased in the period when AirSeal was used when compared with the pre-Airseal group (p<0.001 and p=0.012 respectively). No statistically significant difference in regards with age and gender was found among any of the groups.

Conclusion: The use of AirSeal combined with S-ESD appears to facilitate excision of distal lesions with larger surface with reasonable speed over time. A randomized trial to investigate the role of pneumo-dissection is warranted.

Disclosure: Nothing to disclose.

PP0664

COMPARISON OF TRANEXAMIC ACID (TXA) VERSUS EPINEPHRINE USE DURING COLONIC ENDOSCOPIC MUCOSAL RESECTION (EMR) PROCEDURES FOR THE REDUCTION OF INTRAPROCEDURAL AND POSTPROCEDURAL COMPLICATIONS: A PROSPECTIVE RANDOMIZED PILOT STUDY

A. Bermont[1], S. Matalon[1], D.L Cohen[1], D. Malkin[1], S. Vosko[1]
[1]Shamir Medical Center, Gastroenterology, Zerifin, Israel

Contact E-Mail Address: bermont@doctor.com

Introduction: Endoscopic mucosal resection (EMR) of colonic lesions is widely used for the removal of superficial gastrointestinal neoplasms, but intraprocedural and postprocedural bleeding remain significant adverse events. Current strategies often involve epinephrine injection, which has uncertain efficacy and potential systemic side effects, including hypertension and increased postprocedural pain. Tranexamic acid (TXA), an antifibrinolytic agent with a well-established safety profile, has shown efficacy in reducing bleeding across various surgical fields and may be an alternative to epinephrine use.

Aims & Methods: The primary aim was to assess whether the addition of TXA into the submucosal injection solution during colonic EMR is non-inferior to epinephrine in reducing the rates of intraprocedural and postprocedural bleeding. Secondary aims included comparing pain levels, the need for opioid analgesia, and the incidence of other complications such as deep mural injury and delayed bleeding.

A prospective, double-blinded, controlled, non-inferiority pilot study was conducted at the Shamir Medical Center. Patients aged >18 years undergoing EMR for colonic lesions ≥20 mm were randomized into two groups. The study group received a standard injectate solution with 100 mg TXA in 10 ml, while the control group received the same solution with 1:100,000 epinephrine.

Outcome measures included intraprocedural bleeding, delayed bleeding, pain (and analgesic use), perforation, hospitalization, and post-polypectomy syndrome.

Results: A total of 112 patients were included (57 TXA, 55 epinephrine). The mean age of the entire cohort was 69.0 years, and 47.3% were women. The average polyp size was 33.4 mm. The groups were comparable in most baseline characteristics, although TXA patients were slightly older ($p = 0.032$) and had higher rates of diabetes ($p = 0.042$). No significant difference was observed in lesion size, morphology, or pathology. Intraprocedural bleeding was similar across groups.

Clinically significant delayed bleeding occurred in 7% of TXA vs 7.3% of epinephrine patients ($p = 0.958$). Notably, postprocedural pain was significantly reduced in the TXA group (5.3% vs 41.8%, $p < 0.001$), as was opioid requirement (0% vs 47.8%, $p < 0.001$). Although not statistically significant, there were no cases of deep mural injury or hospitalization due to post-polypectomy syndrome in the TXA group, compared to four in the epinephrine group ($p = 0.055$).

Conclusion: The addition of TXA to the submucosal injection solution during colonic ER procedures is non-inferior to epinephrine in preventing intraprocedural and delayed bleeding.

Moreover, TXA is associated with significantly reduced postprocedural pain and opioid use, suggesting it may offer a safer and more comfortable alternative to epinephrine. These findings support the feasibility of larger-scale trials to further evaluate the efficacy and safety of TXA in endoscopic interventions.

Contact E-Mail Address: davidescalvini.med@gmail.com

Introduction: Adequate bowel preparation (BP) is crucial for high-quality colonoscopy surveillance in ulcerative colitis (UC), because an inadequate one leads to incomplete colonoscopy and higher rate of missing precancerous lesions, which are usually flat or subtle in this setting. There is conflicting evidence regarding whether disease activity or extension are risk factors for inadequate BP in patients with inflammatory bowel disease (IBD); furthermore, data on the optimal PEG-regimen which should be used in this setting are limited.

The aim of this study was to assess which factors influence the quality of BP in this specific setting.

Aims & Methods: This is a multicentre, cross-sectional, retrospective study carry out in four referral centres between January-2021 and December-2023, including quiescent UC patients with endoscopic remission (Mayo endoscopic score=0) who underwent colonoscopy. Bowel preparation quality was assessed using the Boston Bowel Preparation Scale (BBPS) and performed with 1L-PEG-ASC (Plenvu®) and 2L-PEG (Moviprep® and Clensia®), without any specific allocation or instructions. Demographic, anamnestic and endoscopic data were evaluated and analysed.

Results: Overall, 261 UC patients (F 99, 37.9%, mean age 55.6±14.5) were recruited. Patients with previous maximum extension of proctitis (E1) were 31 (12.1%), with left-sided colitis (E2) were 104 (40.6%) and with pancolitis (E3) were 121 (47.3%); additionally, patients with a history of advanced therapy were 104 (39.8%). Entire cohort adequate preparation rate was 90.4%.

1L-PEG-ASC preparation showed significantly higher adequate BP rate compared to 2L-PEG preparations (93.7% vs 85.4%, $p=0.032$). Right colon adequate BP did not differ among the BPs (93.7% vs 91.3%). Patient demographics, smoking status, maximum disease extension, history of advanced therapy or presence of pseudopolyps did not significantly affect BP quality ($p>0.05$).

Conclusion: In a relatively unbiased setting, such as quiescent UC patients in endoscopic remission, bowel preparation volume, specifically 1L-PEG-ASC, was the primary determinant of BP quality, with neither disease extent nor a history of advanced therapy affecting BP.

These findings suggest that 1L-PEG-ASC preparation may be the preferred option for colonoscopy BP in UC patients when not contraindicated.

Introduction: Colonoscopy is a standard procedure but it is unclear whether a short or long colonoscope is more favorable regarding procedure efficiency and patient comfort. The performance of different colonoscope lengths cannot be objectively compared in live patients due to various limitations. Hence, the choice of colonoscope length is a matter of personal preference or institutional tradition. Preclinical tools to assess scope performance are needed. We evaluated endoscopists' performance using short vs. long colonoscopes in the Mikoto simulator, enabling objective measurements using pressure and distension sensors within a 3D-printed, calibrated colon model.

Aims & Methods: Aims: i) Performance comparison of short vs. long comparison in the Mikoto simulator, enabling objective measurements using pressure and distension sensors within a 3D-printed, calibrated colon model. ii) First evaluation of this novel simulator.

Delegates at ESGE Days and DGE-BV 2024 were invited to perform two simulation rounds—one with each scope length in a random order —and completed a survey. Main outcome was the performance of different scope lengths as measured by the caecal intubation time and the proprietary "Mikoto score" (a combination of pressure and distension measurements exerted on the model).

Results: Of 281 participants, 252 complete datasets were analyzed (187 ESGE, 65 DGE-BV). The Mikoto-Score was lower with long scopes (74 vs. 77; p=0.01), and caecal intubation time was longer (2:59 vs. 2:38 min; p=0.01). A second round did not improve performance. Mikoto-Scores were unaffected by scope preference or sedation strategy but were lower in users of the two-person technique. Scores correlated with self-assessed skill and colonoscopy experience (r=0.43, r=0.47). The median system-usability score was 77.5 indicating a good evaluation by the examiners and a good usability.

Conclusion: Using the Mikoto simulator, long colonoscopes caused more colonic distension and longer insertion times, potentially impacting patient comfort. Objective simulator data can inform scope selection in clinical practice. The Mikoto simulator reflects endoscopist self-assessed skill and previous experience.

Disclosure: Nothing to disclose.

PP0667

COMPARE THE CLINICOPATHOLOGICAL FEATURES OF YOUNG ONSET COLONIC ADENOMA (YOA) WITH PATIENTS AGE OVER 50: A RETROSPECTIVE COMPARATIVE STUDY

K.H. Wan[1], W.-C. Tai[1], C.-C. Yao[1], Y.-C. Li[1], C.-K. Wu[1], L.-S. Lu[1]
[1]Kaohsiung Chang Gung Memorial Hospital, Department of internal medicine. Division of gastroenterology and hepatology, Kaohsiung, Taiwan

Contact E-Mail Address: kevin820813work@gmail.com

Introduction: Although the overall incidence of colorectal cancer (CRC) has declined in individuals over 50 years of age, CRC in young adults (CRCYA) continues to rise. Previous studies suggest that CRCYA is associated with worse prognosis, primarily due to a higher proportion of advanced-stage disease at diagnosis. Accordingly, early detection and resection of young-onset adenomas (YOAs), the precursor lesions of CRCYA, is critical for prevention. This study aimed to characterize the clinicopathological features associated with YOAs.

Aims & Methods: We retrospectively analyzed patients who underwent colonoscopic polypectomy at our institution between January and June 2020. Neoplastic polyps were evaluated for size, histology, morphology, and anatomical distribution. Comparisons were made between patients aged ≤50 years (YOA group, n = 89) and those aged >50 years (elder group, n = 432).

Results: A total of 958 neoplastic adenomas from 521 patients were analyzed—138 in the YOA group and 820 in the elder group. No significant differences were found in gender distribution, mean polyp size, or morphology. However, elder patients had more neoplastic polyps per person than younger patients (1.90 ± 1.31 vs. 1.54 ± 0.88; p = 0.014).

With regard to anatomical distribution, adenomas in the YOA group were more often located in the left-sided colon compared to those in the elder group (63.3% vs. 45.4%; p < 0.001).

Variants	YOA Group Age≤50 (n=89)	Elder Group Age>50 (n=432)	P value
Age(years); mean ±SD	43.44± 5.61	64.92± 8.00	<0.001
Male(n)	61 (68.5%)	265(61.3%)	0.204
Max polyp size(mm); mean ± SD	8.83 ± 7.00	10.15± 8.80	0.197
Total number of Neoplastic polyps(n)	138	820	NS
Number of polyps removed/patient(n); mean ± SD	1.54 ± 0.88	1.90± 1.31	0.014
Location of polyps(n)			
Right	50(36.7%)	448 (54.6%)	<0.001
Left	88(63.3%)	372 (45.4%)	
Morphology(n)			
Is+Isp	121(87.8%)	724(88.3%)	
Ip	13(9.4%)	49(6.0%)	0.266
LST	2(1.4%)	25(3.0%)	
Ulcerative	2(1.4%)	22(2.7%)	
Histology of polyps			
Tubular adenoma(n)	92(66.7%)	606(73.9%)	
TVA+VA(n)	7(5.1%)	87(10.6%)	
HGD + Tis(n)	1(0.7%)	13(1.6%)	<0.001
Adenocarcinoma(n)	2 (1.4%)	29 (3.5%)	
SSA(n)	33(23.9%)	80(9.8%)	
TSA(n)	3(2.2%)	5(0.6%)	
Advanced adenoma(n)	27(19.4%)	163(19.9%)	0.361

Table.

Abbreviation: YOA, young-onset adenomas; SD, standard deviation; NS, nonsignificance; LST, laterally spreading tumor; TVA, tubulovillous adenoma; VA, villous adenoma; HGD, high-grade dysplasia; Tis, carcinoma in situ; SSA, sessile serrated adenoma; TSA, traditional serrated adenoma

Although the prevalence of advanced adenomas—defined as polyps ≥10 mm, with villous histology, or high-grade dysplasia—was also comparable between both groups. (19.4% vs. 19.9%; p = 0.523), histologically high-risk

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

neoplastic lesions (villous adenoma, high-grade dysplasia, carcinoma in situ, and adenocarcinoma) were more frequent in the elder group (15.7% vs. 7.2%). In contrast, sessile serrated adenomas (SSAs) were more common in the YOA group (23.9% vs. 9.8%; $p < 0.001$).

Conclusion: While CRC remains more prevalent among older individuals, the comparable prevalence of advanced adenomas between younger and older adults raises concern for early carcinogenesis in young populations. Distinct histological features were observed: SSAs were more frequent in younger adults. Moreover, YOAs were predominantly located in the distal colon.

These findings emphasize the need for tailored screening strategies and proactive endoscopic surveillance in younger adults. Future prospective studies are warranted to further clarify the epidemiology and risk profiles of YOAs.

A PILOT STUDY ON PURE NOTES: ENDOSCOPIC COLON RESECTION AND ANASTOMOSIS IN A PORCINE MODEL

J. Zhang[1], D. Li[1], L. Zhao[1], B. Liu[1]
[1]The First Affilaited Hospital of Zhengzhou University, Zhengzhou, China

Contact E-Mail Address: drjiyuzhang@163.com

Introduction: Our research aims to establish the feasibility of performing complete endoscopic colon resection and anastomosis using pure Natural Orifice Transluminal Endoscopic Surgery (NOTES) in a preclinical porcine model.

Aims & Methods: The study was conducted on three pigs. Preoperative preparations involved administering sugar water followed by a 12-hour fast. A detachable balloon was positioned in the transverse colon to prevent contamination during the procedure. Initially, a gastroscope equipped with a transparent cap was advanced to the colon, reaching approximately 20-40 cm from the anal verge. A full-thickness incision was then made on the anal side of the colon to transect it, allowing the gastroscope to access the abdominal cavity. The surrounding connective tissue and lymph nodes were meticulously dissected and excised. The oral end of the colon was looped and resected using a snare, resulting in a 3-5 cm segment of colonic tissue being excised and retrieved through the anus. End-to-end anastomosis was facilitated using nylon threads for traction and clips for occlusion. Clips were securely attached to both the anal and oral ends of the colon.

Subsequently, three threads were simultaneously tightened to bring the oral and anal ends of the colon together. Finally, additional clips were placed along the anastomotic ring to ensure the integrity of the connection. Postoperative care included a structured dietary regimen and vigilant monitoring for complications.

Results: The postoperative outcomes were highly favorable, with no significant complications such as infections or anastomotic failures recorded. Endoscopic follow-up at one week demonstrated satisfactory anastomotic healing without evidence of stricture or fistula formation. Anatomical examinations conducted three months post-surgery revealed smooth and tight healing of the colonic anastomosis.

Conclusion: The use of pure NOTES for endoscopic colon resection and anastomosis represents a significant advancement in minimally invasive surgical practices. This technique introduces a new option for future endoscopic treatments of advanced colorectal tumors.

A MULTICENTER REAL-WORLD STUDY ON CLINICAL EFFICACY OF ENDOSCOPIC RETROGRADE APPENDICITIS THERAPY (ERAT) FOR APPENDICITIS

B. Liu[1], D. Liu[1], J. Zhang[1], D. Li[1], Q. Zheng[1]
[1]The First Affilaited Hospital of Zhengzhou University, Zhengzhou, China

Contact E-Mail Address: drjiyuzhang@163.com

Introduction: Appendicitis is a common disease with a 7-10% lifetime prevalence. Endoscopic Retrograde Appendicitis Therapy (ERAT) emerged as a minimally invasive alternative option for appendicitis.

Aims & Methods: This study aims to evaluate the efficacy and safety of ERAT, presenting results from multicenter in China with the longest follow-up period reported to date. This study examined patients treated with ERAT for appendicitis across 21 centers in China from 2013 to 2023. Individuals with confirmed diagnoses via symptoms, lab tests, and imaging are enrolled. Appendicitis in the study was classified as uncomplicated, complicated, or absent based on procedure results. The intraoperative indicators include intubation guidance, use of transparent cap, intubation success rate, appendix condition, and operation time.

Primary outcomes focused on the effectiveness and safety of ERAT, assessing technical success, symptomatic relief, procedure time, and adverse events like perforation and complications. Secondary outcomes examined recurrence rates prompting medical intervention.

Results: 2838 patients underwent ERAT for appendicitis, with an average age of 28.4 years, and 52.5% were male. A history of appendicitis was noted in 96.1% of patients, with 83.3% experiencing an episode within two weeks and 17.7% receiving antibiotic treatment. 83.9% had acute appendicitis while 16.1% had chronic appendicitis. In AA patients (80.1% uncomplicated, 1.5% perforated, and 2.3% with peri-appendiceal abscess, Preoperative imaging found appendicoliths in 38% of patients. The ERAT technical success rate was 97.5%, with a procedural time averaging 29.2 minutes. Procedures guided by X-ray (55.8%), Cholangioscope (15.6%), and Abdominal Ultrasound (13.9%). Most used a tapered (47.7%) or standard transparent cap (31.7%), and others without transparent cap (20.6%). Saline irrigation was done in 89.4% of cases. Appendiceal stents were placed in 35.4% of patients. with a primary adverse event rate of 0.8%. Successful ERAT rates reached 86%, yet 2.5% failed due to mis-intubation and 11.5% due to symptomatic recurrence. The mean hospital stay was 2.9 days, with costs 8498 RMB(1173 USD). Significant postoperative laboratory reductions were observed in leukocyte and CRP levels. The adverse event rate led to reoperations in 1.4% of patients, with a 2.5% re-admission rate due to infections, predominantly new appendicitis or peritonitis.

Conclusion: ERAT is a safe and effective option for appendicitis, with short recovery times, minimal invasiveness, and less adverse events. Larger-scale, long-term multicenter trials are needed for further validation.

Disclosure: Nothing to disclose.

Contact E-Mail Address: pieter.sinonquel@uzleuven.be

Introduction: The development of a computer-aided detection (CADe) model into a clinically reliable plug-and-play device is a complex and challenging process.

Aims & Methods: This study evaluates the performance, stability, and robustness of a new all-in-one plug-and-play device, integrated with a previously in-house developed and clinically validated AI algorithm for colorectal polyp detection.

The ALTER-EGO trial is an investigator-initiated operator blinded multicenter trial conducted in 3 Belgian centers. The AI model performing real-time polyp detection during real-time endoscopy was developed using deep learning on a high-resource/cost graphics processing unit (GPU)-based hardware platform and validated to achieve enhanced adenoma detection. The model was integrated into a lower-cost/resource field-programmable gate array (FPGA)-based hardware device, necessitating implementation adjustments and retraining to account for technological differences between both platforms. The new FPGA-based CADe system was evaluated in the exact same study set-up as the original GPU-based system, using a second observer and real-time unblinding.[1]

We evaluated the number of polyps detected, the extra detection and miss rates in comparison to expert endoscopists and performed analysis of false positive rate and technical failures to reflect system stability. Sample size analysis calculated 660 polyps required for non-inferiority analysis (margin 5%) with the original validation outcomes (CADe sensitivity 0.946±0.03).

Results: A total of 724 polyps were identified in 291 patients, of which 668 (92.1%) were detected by both endoscopist and CADe, 31 (4.3%) were detected by endoscopist alone, 25 (3.5%) were solely detected by CADe. Sensitivity of the CADe was 95.6% (95%CI: 93.7-96.9) versus 96.4% (95%CI: 94.7-97.5) for the expert endoscopists.

In comparison to the original GPU-based CADe system, detection was equivalent with a difference of -0.82% (95%CI: -0.0288 – 0.0124) (p=0.5040). Due to hardware-related adjustments, false positive rate increased from 1.7 to 8.8 per minute (p<0,001). Technical failure occurred in 49 patients, 109 events of technical deficiencies were reported.

Conclusion: Integration of an originally GPU-based AI model into a FPGA-based plug-and-play hardware device resulted in stable performances, equivalent to the GPU-based algorithm. The required technical adjustments of the FPGA-based algorithm however resulted in a significantly higher false positive rate and increased number of technical failures.

HOW ARE POLYPS REMOVED IN CLINICAL PRACTICE? A COMPARISON TO ESGE POLYPECTOMY GUIDELINES

E. Broder [1], K. Besherdas[1]
[1]Royal Free Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: besherdasdr@hotmail.com

Introduction: The polypectomy technique used by endoscopists depends on multiple factors including anticipated histological subtype (eg Paris and Kudo pitt pattern), estimated polyp size and location within the colon. The latest European Society of Gastrointestinal Endoscopy (ESGE) guidelines recommend the most suitable methods which minimise risk of post-procedural bleeding and perforation, whilst ensuring cost-effectiveness. ESGE recommends avoiding cold biopsy due to its high rate of incomplete resection. ESGE also recommends cold snare polypectomy for removal of nonpedunculated adenomatous polyps under 10mm and hot snare with or without endoscopic mucosal resection (EMR) for polyps over 10mm. In addition, ESGE recommends cold snare or cold EMR for sessile serrated lesions (SSL) of all sizes, as well as consideration of endoscopic submucosal dissection (ESD) for certain polyps over 20mm.

Aims & Methods: This study aimed to assess the current practice in our institution in terms of polypectomy technique across all polyp sizes and histological subtypes in comparison to the ESGE standards.

A single centre, retrospective analysis of 100 consecutive patients who have had polypectomies done for polyps of any size from April 2024 at a hospital in North London was undertaken. The data was collected using the Medilogic endoscopy reporting tool, and the electronic patients record. The technique used for polypectomy, along with the type of polyp at histology retrieved, was scrutinized and compared with compliance of ESGE guidance on polypectomy technique.

Results: A total of 177 polypectomies from 100 patients were analysed. 121 polypectomies (68%) followed ESGE recommendations and 56 polypectomies (32%) did not. The 56 non-compliant polypectomies used methods including cold biopsy, hot snare with or without EMR for polyps under 10mm and hot EMR for SSLs (see Table).

Polypectomy method compliant with ESGE		Polypectomy method non-compliant with ESGE	
Cold snare or cold EMR for all SSL	13	Hot EMR for SSL	4
Cold snare or cold EMR <10mm	79	Cold snare or cold EMR > 10mm	12
Hot EMR >10mm	26	Hot EMR <10mm	12
ESD	3	Hot snare <10mm	3
		Cold biopsy	25
Total in line with ESGE:	121 (68%)	Total not in line with ESGE:	56 (32%)

Conclusion: This study shows poor adherence to the ESGE guidelines in our department with regards to colorectal polypectomies, with only two-thirds of polypectomies adhering to the recommended techniques. A third of polypectomies undertaken were not in line with ESGE recommendations (56/177 – 32%), of these 16/56 (34%) polypectomies involved inappropriate diathermy use which could have led to increased risk of complications such as post-polypectomy bleeding and perforation. A significant number of polyps are removed by the cold biopsy technique (25/177 – 14%) which is not advocated due to a higher risk of local recurrence.

We recommend better dissemination and implementation of the ESGE guidelines to enhance clinical practice with regards to polypectomy techniques.

Disclosure: Nothing to disclose.

REMIMAZOLAM IN ENDOSCOPY: A GAME-CHANGER FOR SAFE AND EFFECTIVE SEDATION IN REAL-WORLD PRACTICE

A. Sparacino[1], P. Graceffa[1], I.A. Salerno[1], F. Cartabellotta[2], F. Cipolletta[3], L. Pasquale[4], R. Gallo[5], L. Calderone[5], A. Granata[1]
[1]Buccheri La Ferla Hospital, Digestive Endoscopy, Palermo, Italy, [2]Buccheri La Ferla Hospital, Internal Medicine Unit, Palermo, Italy, [3]Monaldi Hospital, Napoli, Italy, [4]Monaldi Hospital, U.O.C. Gastroenterologia ed Endoscopia Digestiva, Napoli, Italy, [5]Buccheri La Ferla Hospital, Anesthesiology and Intensive Care Medicine, Palermo, Italy

Contact E-Mail Address: alba.sparacino@gmail.com

Introduction: Sedation is integral to gastrointestinal (GI) endoscopy to enhance procedural tolerance and efficiency [1]. Traditional agents like midazolam and propofol, while effective, present limitations related to recovery time, safety, and need for anesthesiologist supervision. Remimazolam, a novel benzodiazepine with rapid onset and offset, may enable effective non-anesthesiologist-administered sedation (NAAS) in routine endoscopy [2].

Aims & Methods: A prospective, multicenter, real-world study was conducted between November 2024 and March 2025. Adult patients undergoing elective upper or lower gastrointestinal (GI) endoscopy under procedural sedation-analgesia (PSA) without the presence of an anesthesiologist were enrolled. Inclusion criteria were: age ≥18 years, American Society of Anesthesiologists (ASA) physical status I–III, and a body mass index (BMI) between 18 and 51 kg/m^2. Exclusion criteria included: known allergy to anesthetic drugs or a history of anesthesia-related adverse reactions; glucose-6-phosphate dehydrogenase deficiency; severe respiratory disease; and pregnancy. All patients undergoing emergency or urgent GI endoscopy were excluded. The primary outcomes were the sedative efficacy and safety of remimazolam during endoscopy. Efficacy was defined as successful completion of the procedure without interruption due to inadequate sedation. Adverse events (AEs) were recorded and classified by severity (major or minor) and type (e.g., hypotension, hypoxia, bradycardia, nausea, vomiting, and injection site pain). Remimazolam was administered by trained endoscopists: induction was achieved with 5–7 mg intravenously, titrated based on individual risk factors, with 2.5 mg supplemental doses as needed (maximum cumulative dose: 33 mg).

Results: A total of 182 patients (EGD n=75; colonoscopy n=112) were included. Procedure completion was achieved in 175 cases (96.3%), with success rates of 97.3% for EGD and 95.5% for colonoscopy. All sedation failures (n=7) were attributed to inadequate sedation and not to ASA class. No serious AEs were reported. Minor AEs included hypotension (n=4), bradycardia (n=1), nausea (n=1), vomiting (n=4), and hiccups (n=1), all managed conservatively. Median cumulative remimazolam doses were 10.9 mg (colonoscopy) and 10.0 mg (EGD), with median recovery times of 6.25 and 5.9 minutes, respectively. No patients required flumazenil or rescue sedation. Among obese patients (BMI >40), remimazolam was both effective and safe.

Conclusion: Remimazolam provides a highly effective and safe sedation alternative for GI endoscopy in real-world NAAS settings, ensuring rapid recovery and minimal AEs, even in patients with elevated ASA status or obesity. This study was prospective real-world and had several limitations. First the number of patients was too small to accurately assess rare adverse events. Further randomized controlled trials with larger populations are recommended to confirm these results.

Biomedical and Clin. Sciences, Leeds, United Kingdom

Contact E-Mail Address: thomas.p.archer@outlook.com

Introduction: Endoscopic suturing allows the closure of mucosal defects, opening the door to a variety of therapeutic utilities. Reducing the risk of post polypectomy bleeding and closing resection related perforations with endoscopic hand suturing have been investigated and further therapeutic indications are feasible. Sutuart is a novel device that facilitates endoscopic hand suturing. In this study we present the initial UK experience using Sutuart for endoscopic closure of defects.

Aims & Methods: This is a multicentre retrospective study of the effectiveness and related outcomes of endoscopic suturing using the Sutuart device in the GI tract. UK based sites undertaking endoscopic hand suturing using Sutuart were invited to participate. Patient records and endoscopy reports were reviewed and data was extracted. Technical feasibility (whether the suture could reach the target), technical success (whether suturing could be completed) and clinical success (intended therapeutic goal was achieved) were assessed. Procedural details, size of closure and time taken to complete Sutuart closure were recorded. Outcomes at 30 days were reviewed.

Results: Four sites participated with 14 closures in 14 patients. The mean age was 59, and 57% were female. The commonest indication was closure of polyp ESD resection site (8/14, 57%), followed by closure of GPOEM incision (4/14, 29%). One patient had a closure of a PEG fistula and one had a closure of a leaking surgical anastomosis.

All polyp resection sites were within the rectum (6/8) or rectosigmoid (2/8). The mean polyp size was 42.8mm (SD +/- 10.1).

Sutuart was technically feasible in all cases, 13/14 (93%) were technically successful and 12/14 (86%) were clinically successful. Of those that were not clinically successful, one attempted closure was for a GPOEM incisional closure in which insufflation was inadequate and one was for a surgical anastomosis that had a persistent leak. Both cases were closed with through the scope clips. Two other cases had additional clip closure. A post procedural bleed was seen in one patient who had a rectal polyp site closure. This was managed conservatively.

The mean length of closure was 35.4mm (SD = +/- 15.4). The mean time to complete closure was 35 minutes (1SD +/- 13.3) with a range of 18 to 65. The median number of suture passes was 6 (IQR = 1).

Conclusion: The Sutuart is a novel device that shows promise in the management of endoscopic closure. The initial experience demonstrated in this study indicates good technical feasibility and success with positive

outcomes and few complications across a range of indications. The time to complete closure at present appears relatively prolonged. Whether increased experience leads to a reduction in this time will be interesting to see. Further studies into larger cohorts and comparative studies with other closure techniques are required.

VIRTUAL RELIEF: VIRTUAL REALITY FOR PAIN AND ANXIETY RELIEF DURING COLONOSCOPY

I. Zouaki[1], A. Ait Errami[1], F.E. Lairani[1], O. Nacir[1], Z. Samlani[1], S. Oubaha[1], K. Krati[1]

[1]Mohammed VI University Hospital, Gastroenterology and Hepatology, Marrakech, Morocco

Contact E-Mail Address: Imane.zouaki.pro@gmail.com

Introduction: Colonoscopy is a routine yet often uncomfortable procedure that can cause significant pain and anxiety for patients, leading to reluctance and many procedural challenges. While sedation and analgesia are commonly used, they may not always provide sufficient relief and even carry certain risks.

Recently, virtual reality (VR) has emerged as a promising tool for reducing pain and anxiety in various medical contexts (surgeries, dental procedures, labor...). By immersing patients in calming environments, VR may offer an effective, low-cost, non-invasive and non-pharmacological alternative to traditional methods. Studies exploring the use of VR in colonoscopy patients receiving minimal sedation have been documented, although in limited numbers.

However, there is a significant lack of research focusing on unsedated patients, especially with no published literature from Morocco. This study aims to evaluate the effectiveness of VR in alleviating pain and anxiety during unsedated colonoscopy.

Aims & Methods: The aim of the study was to assess the impact of virtual reality on five key areas of investigation: Anxiety, pain, comfort, satisfaction and willingness to undergo further colonoscopies and procedural characteristics. We conducted an experimental, randomized, controlled trial to evaluate the effect of VR on reducing pain and anxiety in non-sedated patients undergoing outpatient colonoscopy in the Endoscopy Unit of the Department of Gastroenterology of the university hospital of Mohammed VI in Marrakech.

We've included all patients above 18 years of age undergoing a colonoscopy. A total of 60 patients were sampled and then randomized 1:1 into a group using VR and a control group with routine care but no VR. Collection of data was by a questionnaire based on validated scales and scores for anxiety, pain, comfort and satisfaction.

Results: Our study demonstrates that VR has a positive impact on various aspects of the colonoscopy procedure. Firstly, VR reduced the time to caecum intubation by 4.29 minutes. Additionally, VR showed beneficial effects on procedural anxiety, with greater reduction in anxiety levels pre- to post-colonoscopy in the VR group compared to the control group. In terms of pain reduction and comfort improvement, a significant decrease in pain was noted in the VR group (4.53 vs 5.83 in the control group). Overall satisfaction was higher in the VR group comparing to the control group (74% vs 54%, respectively). The Net Promoter Score was also higher in the VR group (-0.33) compared to the control group (-16.66).

Regarding willingness to return for another colonoscopy, the VR group showed higher willingness, with more patients strongly agreeing and fewer disagreeing with the statement compared to the control group (Strongly agree: 3, Agree: 19, Disagree: 6, Strongly disagree: 2 in the VR group versus 0, 17,10, and 3 in the control group).

Endoscopists' feedback was also positive, with all reporting comfort in incorporating VR into their practice, giving it a mean score of 8. They rated their overall experience with VR as good, with a mean score of 8.3. Endoscopists noted that VR had a relaxing effect on them, with no significant difficulties encountered.

Conclusion: Our study reinforces that VR use in colonoscopy significantly improved both the overall patient experience (lesser pain, more comfort) and the physician experience too (lesser procedure duration, better completion rates, more comfort during procedure). VR, being an easily available, low-cost, non-invasive, and inexpensive, can be recommended for routine use in endoscopy units as a pain relief tool.

Introduction: Histopathology is the accepted gold standard for classifying colorectal polyps. However, the complex pathway from initial polyp detection and resection to final histological diagnosis involves multiple steps (retrieval, embedding, sectioning, interpretation), each potentially introducing diagnostic errors.

Aims & Methods: We aimed to investigate the diagnostic accuracy of autonomous computer-aided optical polyp diagnosis (CADx) versus histopathology, using expert consensus as the reference standard. In this prospective study, three internationally recognized expert endoscopists independently reviewed colonoscopy images and videos of diminutive (≤5 mm) polyps assessed by autonomous CADx. Unanimous, high-confidence expert agreement was defined as the reference standard ('ground truth'), assumed superior due to absence of resection or specimen-management related

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

artifacts. The primary outcome was the proportion of specimens with potential incorrect histopathology diagnosis. Secondary outcomes included comparative accuracy, sensitivity, and specificity of autonomous CADx and histopathology against the expert-defined reference standard.

Results: Among 510 patients, experts provided unanimous, high-confidence diagnoses for 226 diminutive (≤5 mm) colorectal polyps, serving as the reference standard. The proportion of potentially incorrect pathology diagnoses was 23% (95% CI: (17.8,29.2)). Autonomous CADx achieved a higher accuracy of 91.2% (95% CI: 86.5–94.4%), compared with pathology at 77.0% (95% CI: 70.8–82.2%; $p < 0.001$).

Conclusion: These findings highlight that histopathological diagnosis after polyp resection is not infallible and can introduce diagnostic errors in a relevant proportion of cases. CADx diagnosis, obtained during the procedure and unaffected by specimen handling artifacts, may prevent some of these errors, suggesting it could offer superior accuracy for polyp characterization in certain cases.

DOUBLE BALLOON ENDOSCOPIC PLATFORM ENABLES DIAGNOSTIC AND THERAPEUTIC INTERVENTIONS IN THE SMALL BOWEL

S. Kantsevoy[1], V. Gushchin[1], N. Malyutina[2], J. White[3]
[1]Mercy Medical Center, Institute for Digestive Health and Liver Disease, Baltimore, United States of America, [2]QAC, Ellicott City, United States of America, [3]Lumendi, Medical Affairs, Buckinghamsire, United Kingdom

Contact E-Mail Address: skan51@hotmail.com

Introduction: The Double Balloon Endoscopic Platform (DBEP), DiLumen® EZ Glide (Lumendi Ltd, Maidenhead, UK), has been in clinical use since 2017. It has demonstrated safety and efficacy in facilitating diagnostic and complex therapeutic procedures in the colon, including patients with normal and surgically altered anatomy.

Aims & Methods: To evaluate the use of DiLumen® EZ Glide for diagnostic and therapeutic interventions within the small bowel.

The DBEP is a flexible overtube with two balloons at its distal end and is preloaded over a standard colonoscope. Once advanced into the sigmoid colon, the proximal (aft) balloon (rigidly attached to the overtube) is inflated to anchor the device within the colon. The device is then pulled back to shorten and straighten the sigmoid colon. Then the colonoscope is advanced to the next colonic segment, and the process of balloon inflation, retraction, and advancement is repeated until the cecum is reached and the assembly is directed through the ileocecal valve into the ileum. This technique is continued within the small bowel until the target lesion is reached for intervention.

Results: Seven patients (3 males, 4 females; mean age 59.7 ± 9.8 years) underwent ileal interventions using the DBEP. All procedures were technically successful (100%). The furthest advancement of the colonoscope was up to 6 feet proximal to the ileocecal valve. The mean size of small bowel lesions was 23.6 ± 11.4 mm.

Three patients had ileal polyps (30, 35 and 40 mm), all of which were removed *en bloc*: one by endoscopic mucosal resection (EMR) and two by endoscopic submucosal dissection (ESD). Pathology confirmed all polyps were benign, and no further treatment was required.

The remaining four patients had submucosal nodules (mean size 15.0 ± 4.1 mm, range 10–20 mm). Prior biopsies of this lesions covered by normal mucosa were non-diagnostic. All nodules were successfully removed *en bloc* (3 by ESD, 1 by EMR), and post-resection defects were closed using continuous suturing with the OverStitch™ endoscopic suturing system (Boston Scientific, Marlborough, MA, USA), delivered via the DBEP.

Histopathologic analysis revealed large B-cell lymphoma (1 patient) and well-differentiated neuroendocrine tumors (3 other patients). The lymphoma patient was treated conservatively with chemotherapy. All neuroendocrine tumor cases underwent robotic hemicolectomy with ileal resection. Pathological examination of surgical specimens revealed lymph node metastases (pN1) in all 3 patients.

Conclusion: Traditional endoscopic biopsy of ileal submucosal lesions does not provide adequate diagnostic value and cannot determine effective treatment plan. The DBEP significantly facilitates small bowel access and enables effective diagnostic and therapeutic endoscopic interventions inside the small bowel. In this early series, endoscopic excision of ileal lesions provided accurate histological diagnosis and directly influenced clinical management. Most importantly, our findings suggest that even early-stage (pT1 and pT2), well-differentiated ileal neuroendocrine tumors already had lymphatic spread, reinforcing the need for surgical resection despite complete local endoscopic excision.

Contact E-Mail Address: mahtakbar@gmail.com

Introduction: Withdrawal time (WT) is strongly correlated with adenoma detection rate (ADR)[1,2]. Corrected withdrawal time (cWT), defined as the withdrawal time excluding periods spent on therapeutic interventions, provides a more accurate measure of mucosal inspection effort. Optimal WT targets may differ between staff and trainee endoscopists due to differences in experience and inspection technique[3].

Aims & Methods: We aimed to determine the cWT required to achieve ADR benchmarks (≥35%) and compare detection metrics between these two groups.

This prospective study included 1,439 elective colonoscopies of adult patients ≥18 years, performed at Montreal University Hospital Center: 397 by eight supervised trainees and 1,042 by 12 staff endoscopists. All procedures were video recorded, and the corresponding meta-data were documented in real-time by a research assistant present in the endoscopy room. Procedures performed for the purpose of polypectomy, incomplete

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

colonoscopies, procedures performed by endoscopists with experience of fewer than 10 colonoscopies, and procedures with technical failures in recording that prevented video analysis were excluded. Colonoscopy videos were reviewed to precisely measure cWT, defined as total withdrawal time minus therapeutic intervention durations. Performance metrics were stratified by endoscopist training level (staff vs trainees).

Primary outcome was the mean cWT required to achieve ADR ≥35%, stratified by staff and trainees. Secondary outcomes were the mean per-lesion intervention time, ADR, advanced ADR (AADR), Serrated Lesion detection rate (SLDR), APC, and the incremental increase of all detection measures per minute of cWT compared between staff and trainees, adjusting for covariates including patient demographics, bowel preparation quality, indication for colonoscopy, use of computer-assisted detection, and clustering by individual endoscopist using generalized estimating equations (GEEs).

Results: Trainees demonstrated significantly longer mean cWT than staffs (10'01'' vs 7'53'', p<0.001). No significant difference was observed regarding mean per-polyp intervention time (1'33" vs 1'28", p=0.234). On average, staff endoscopists required longer mean cWT to achieve the 35% ADR benchmark compared to trainees (9'47'' [95% CI: 8'04''-12'20''] vs. 7'05'' [95% CI: 0'00''-10'05'']). Overall AADR, SSLDR, and APC were significantly higher for trainees than staff (Table 1; AADR 10.8% vs. 5.3%; SSLDR 8.1% vs 3.6%; APC 0.8 vs 0.6). Overall, the odds of adenoma detection significantly increased with each additional cWT minute for both trainees and staffs (Table 1; 6.6% overall, 6.7% for staff, and 7.0% for trainees).

	Overall Mean (95% CI)	Trainees Mean (95% CI)	Staff Mean (95% CI)	Overall Increase/ additional cWT minute (p-value)	Trainees Increase/ additional cWT minute (p-value)	Staff Increase/ additional cWT minute (p-value)
ADR	34.2% (31.8-36.7)	39.8% (35.0-44.8)	32.1% (29.2-35.0)	6.6% (0.004)	7.0% (0.005)	6.7% (0.029)
AADR	6.8% (5.6-8.3)	10.8% (8.0-14.4)	5.3% (4.0-6.9)	10.6% (<0.001)	9.3 (<0.001)	10.3% (<0.001)
SSLDR	4.8% (3.8-6.1)	8.1% (5.7-11.3)	3.6% (2.5-4.9)	12.4% (<0.001)	6.4% (0.041)	14.9% (<0.001)
APC	0.6 (0.6-0.7)	0.8 (0.7-1.0)	0.6 (0.5-0.6)	7.4% (<0.001)	9.5% (<0.001)	6.3% (<0.001)

Table 1. Metrics' estimated summaries overall and by endoscopist group. Means and 95% confidence interval (CI) are raw estimates. Percent increases and corresponding p-values arise from GEEs.
ADR, adenoma detection rate; AADR, advanced adenoma detection rate; SSLDR, sessile serrated lesion detection rate; APC, adenoma per colonoscopy; cWT, corrected withdrawal time; CI, confidence intervals.

Conclusion: Trainees had longer cWT and higher detection rates overall, while staff required slightly more cWT to reach ADR target of ≥35%. These findings emphasize the importance of tailored WT benchmarks based on endoscopist training level to optimize colonoscopy quality and training outcomes.

Introduction: Serrated polyps (in particular sessile serrated lesions and traditional serrated adenomas according to WHO classification) are recognized as premalignant lesions, responsible of a significant proportion of colorectal cancer via the serrated neoplasia pathway.

Aims & Methods: We aimed to study the prevalence and risk factors of serrated polyps, comparing them with adenomas and with patients with negative colonscopies in a colorectal italian screening population. A retrospective case-control study was performed in a secondary-referral center in Rome (San Filippo Neri Hospital). Data were collected on an Excel database and retrieved from pre-endoscopy questionairres, endoscopic and hystologic reports of screening colonscopies, performed from November 2021 to December 2024.

Results: Preliminary analysis was carried out on 700 screening subjects (331 male and 369 female of age between 50 and 74 years). including 274 subjects (39%) with adenomas and 33 subjects with serrated lesions (4,7%). Exclusion criteria were incomplete colonscopies, inadequate bowel preparation (Boston Bowel Preparation Scale < 6) and symptomatic subjects. In the group of subjects with serrated lesions, 23 (69,7 %) had dysplasia. About 70% of adenomas were in the left colon, while the prevalence of serrated lesions was similar in the left and right colon (51,5% and 48,5 % respectevely). People with hyperplastic polyps, although classified as serrated lesions by WHO classification, are generally considered as benign and were therefore not considered in our analysis.

For multivariable analysis we considered 12 subjects that had only serrated lesions and 218 subjects that had only adenomas, comparing them to 339 subjects that had no polyps. Independent variable considered were: age, gender, smoking, Body Mass Index, hypertension, dyslipidemia and type 2 diabetes mellitus.

From multivariable logistic regression resulted that smoking was significant indipendent risk factor for serrated lesions (OR: 3.646, 95 % CI 0.056-2.532), whilst male sex and smoking were significant indipendent risk factors for adenomas (male sex OR: 1.768, 95 % CI 0.217-0.923; smoking OR: 1.730, 95 % CI 0.196-0.900).

Conclusion: In our study population, the prevalence of colorectal serrated lesions was 4,7%. Risk factors associated with adenomas were male sex and smoking and with serrated lesions was only smoking. However, a larger sample of subjects with serrated polyps is needed to confirm these results.

SUSTAINED LEARNING EFFECTS OF SELF-DIRECTED VIDEO-BASED VIRTUAL SCALE ENDOSCOPY TRAINING: A NOVEL EDUCATIONAL STRATEGY FOR ENDOSCOPISTS

R. Hirai[1], H. Kinugasa[1], M. Ishiguro[1], J. Toyosawa[1], Y. Aoyama[1], Y. Yamasaki[1], T. Inokuchi[1], M. Takahara[1], S. Kawano[1], S. Hiraoka[1], M. Otsuka[1]

Introduction: Accurate assessment of colorectal polyp size is essential for determining appropriate surveillance intervals and therapeutic approaches. However, visual estimation remains inherently imprecise, especially among less experienced endoscopists. While virtual scale endoscopy (VSE)1 offers an in-procedure solution for real-time mea.

Aims & Methods: This study aimed to evaluate the long-term educational benefits of self-directed training using short instructional videos based on VSE. Thirty-three endoscopists (15 experts and 18 non-experts) participated in a structured learning program using four sets of videos (SET1–SET4), each containing 20 colorectal lesions recorded during colonoscopy. Following initial exposure and evaluation with SET1 and SET2, participants underwent two follow-up tests (SET3 and SET4) 8–12 weeks later without interim re-training, to assess retention of estimation accuracy.

The primary outcome was the total absolute error between estimated and actual lesion diameters, summed across 20 lesions per set. Secondary analysis evaluated differences between expert and non-expert groups.

Results: After initial training, participants showed improved size estimation accuracy (SET1: 34.7 ± 6.6 mm vs. SET2: 30.7 ± 7.7 mm, $p = 0.048$). Importantly, this effect was sustained after 8–12 weeks, with mean total error in SET3 (28.6 ± 6.9 mm) remaining significantly lower than the pre-training baseline (SET1, $p = 0.006$). Similarly, SET4 showed continued improvement over baseline (31.7 ± 7.1 mm, $p = 0.025$), despite no further exposure to training content. Non-experts demonstrated a more pronounced benefit, suggesting that the self-learning video format may be particularly effective for early-career endoscopists. No adverse effects or dropouts occurred during the study.

Conclusion: This is the first study to demonstrate that a brief, self-directed video-based training program using virtual scale endoscopy can achieve not only immediate improvements in polyp size estimation accuracy, but also sustain those gains over time. Given its simplicity, scalability, and minimal resource requirement, this educational approach may serve as a valuable adjunct in structured endoscopy training programs, especially for novice endoscopists or in settings with limited access to formal instruction.

Introduction: The prevalence of musculoskeletal disorders (MSDs) among endoscopists is frequent. The aim of this study was to evaluate biomechanical risk factors for MSDs in gastroenterologists performing ESD.

Aims & Methods: An observational study was performed among interventional endoscopists performing ESD in 3 French centers. The physical constraints were assessed using an analog scale of perceived physical effort intensity and physiological sensors to measure joint angulation kinematics and muscle activity levels (flexor and extensor carpi radialis muscles) during diagnostic colonoscopy and ESD. High muscle strain was defined as any muscle activation exceeding 10% of the maximum voluntary contraction (MVC). Two distinct sub-tasks of ESD were identified: lesion marking and circumferential incision phase (ESD-1) and dissection phase (ESD-2).

Results: Six interventional gastroenterologists participated in the study. Perceived physical effort was significantly greater for ESD compared to colonoscopy ($p = 0.03$). Time spent at more than 10% MVC for the right extensor carpi radialis was significantly higher during ESD-1 than during colonoscopy (+15%, $p=0.04$). The greatest strain was observed in the left extensor carpi radialis. This muscle was particularly exposed since more than 50% of the time was spent at more than 10% of MVC during colonoscopy and up to more than 80% during ESD-1 and -2. Time spent in the neck flexion risk zone was significantly higher during ESD-2 than during colonoscopy (+42%, $p = 0.046$).

Conclusion: ESD increased the risk of musculoskeletal strain. It is crucial to develop prevention programs to reduce the risk of MSD in the gastroenterologist population.

Disclosure: Nothing to disclose.

EFFECT OF GRAVITY IN COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION WITH ADAPTIVE TRACTION STRATEGY: A PROSPECTIVE COMPARATIVE STUDY

J. Grimaldi[1], E. De Cristofaro[2], L.-J. Masgnaux[1], J. Rivory[1], F. Rostain[1], A. Lupu[1], P. Lafeuille[1], T. Wallenhorst[3], R. Legros[4], F. Subtil[1], J. Jacques[5], M. Pioche[6]

Introduction: Traction strategies are increasingly becoming the standard approach for endoscopic submucosal dissection (ESD). ‚Natural' traction forces, such as gravity, remain valuable during ESD, helping to optimize dissection and improve procedural speed. However, mechanical traction, particularly the adaptive traction strategy, has recently shown promising results in terms of efficacy and safety, including the highest resection speeds reported in the literature for colorectal ESD (1,2).

The aim of our study was to evaluate resection speed based on initial gravitational force in a prospective cohort of patients undergoing colorectal ESD with adaptive traction strategy.

Aims & Methods: Consecutive patients undergoing ESD of conventional colorectal lesions with an adaptive traction strategy at a tertiary referral center between 2023 and 2025 were prospectively enrolled. The initial gravity was classified as favorable/neutral and unfavorable.

The primary endpoint was resection speed. A non-inferiority analysis was conducted for the primary endpoint, with the non-inferiority margin set at a 20% reduction in resection speed. Secondary endpoints included the rate of En Bloc resection, the rate of R0 resection and the rate of adverse events.

Results: The study included 118 patients, of whom 78 (66%) had favorable or moderate initial lesion severity and 40 (34%) had unfavorable initial gravity. The mean resection speed in the favorable and moderate gravity group was 37.4 versus 35.8 ($p = 0.6067$) in the unfavorable group, the R0 resection rate was 86.2% versus 86.8% ($p > 0.99$), and the perforation rate was 5.9% versus 7.0% ($p = 0.7015$).

After adjustment for lesion location, operator and lesion area, the resection rate in the unfavorable severity group was very close to the non-inferiority margin ($p = 0.07$).

Conclusion: In our cohort of patients undergoing colorectal ESD using an adaptive traction strategy, initial gravity did not alter the speed and quality of resection. We can assume that the use of a mechanical adaptive traction strategy allows overcoming the need for the natural traction force provided by gravity, thus avoiding the need to mobilize patients during the procedure to achieve a more favorable gravitational force.

Introduction: The degree of tumor differentiation (grading) is an important prognostic factor in colorectal cancer (CRC). Poorly differentiated tumors (G3) tend to be more aggressive. They are associated with an increased risk of transmural invasion, lymph node involvement, and distant metastasis compared to well- or moderately differentiated tumors (G1/G2). Tumor grading is performed through histopathological analysis and requires sufficient tissue sampling. Artificial intelligence (AI) can potentially assist in differentiating colorectal tumors through predicting the grading using images captured during endoscopy as input.

Aims & Methods: This study aimed to train an AI model to distinguish poorly from well- and moderately differentiated colorectal carcinoma using white light endoscopic images.

A total of 1.607 endoscopic images of colorectal cancer, recorded from 2014 to 2024, were extracted from 404 patients who underwent colonoscopy, and the corresponding histopathological grading was retrospectively evaluated. Identified cases contained 62 G1, 1179 G2, and 366 G3 tumor images from 17, 305, and 82 patients respectively. Grades 1 and 2 (low-grade) represented the first group, and grade 3 (high-grade) represented the second. Transfer learning using a foundational model for endoscopy (Gastronet-5M[1]) was used to counteract the limited amount of available data. Before the analysis, the data was split into training and validation on a patient level.

Model performance was assessed with accuracy, sensitivity, and specificity for single-image classification. Furthermore, the results of aggregating predictions for multiple images of the same case were investigated.

Results: The validation dataset consisted of 218 images from 61 patients, 181 of which were in the G1/G2 group and 37 in the G3 group. On an image level, the AI model achieved an accuracy of 78% (95% CI: 73%–83%) with specificity of 0.81 (95% CI: 0.75–0.86) and sensitivity of 0.68 (95% CI: 0.52–0.83).

On a patient level, the method achieved an accuracy of 79%(95% CI: 74%–92%), achieving a slightly increased specificity of 0.84 (95% CI: 0.7209–0.9348) and a higher sensitivity of 0.83 (95% CI: 0.58–1.00).

Conclusion: Our AI model can classify CRC regarding their tumor grading using endoscopic images. Aggregation of predictions for multiple images of the same tumor proves to be especially beneficial in terms of sensitivity. Using explainability methods, clinicians may gain valuable insights into key image features that differentiate tumor grading in white light images, supporting more informed diagnostic decisions.

COLORECTAL ESD CAN BE UNDERTAKEN SAFELY AND EFFECTIVELY WITHOUT GENERAL ANAESTHETIC

U. Akbani[1], I. Iqbal[1], T. Archer[1], V. Goodoory[1], C. Winters[1], R. Sood[1], N. Mohammed[1]
[1]Leeds Teaching Hospital Trust, Gastroenterology, Leeds, United Kingdom

Contact E-Mail Address: Iqbal5262@hotmail.com
Introduction: ESD allows en bloc resection of complex colorectal polyps. General anaesthetic (GA) for ESD is standard, requiring routine admission to hospital for monitoring. At our Trust conscious sedation is used preferentially. This study presents clinical outcomes of ESD performed in a high-volume tertiary centre in the UK using this approach.
Aims & Methods:
• To evaluate the clinical outcomes of colorectal endoscopic submucosal dissection performed without general anaesthesia in a high-volume UK tertiary centre.
• To assess the feasibility and safety of ESD under conscious sedation or no sedation, with particular focus on rates of en bloc and R0 resection, adverse events, and post-procedural admissions.
• To identify clinical and procedural factors independently associated with incomplete (R1) resection following colorectal ESD.
• To compare outcomes between patients undergoing ESD with GA versus those without
Colorectal ESD procedures performed between 2018-2024 in a single centre in the UK were included. Data was retrospectively collected from the patient records. Multiple logistic regression was performed to identify independent factors associated with incomplete resection.
Results: A total of 147 patients (91 males ; median age 68 years) were included. Most polyps were rectal (100/150, 66.6%). Median polyp diameter was 42.5 mm.
GA was utilised in 13 patients, 80 had sedation alongside analgesia (median dose midazolam=2mg, fentanyl=100mcg) 44 required no IV sedation or analgesia, 8 had analgesia alone (median dose fentanyl 100mcg), 2 had sedation alone (median dose midazolam 0.75mg).
4 patients were admitted to hospital after their procedure and 14 were admitted within 30 days. There were 4 (2.7%) perforations and 7 (4.7%) post polypectomy bleeds (PPB).
Most procedures were complete ESD (109/147, 74.1%), the rest being hybrid ESD. R0 excision was achieved in 70/109 (64.2%) of those who had a complete ESD resection. No residual tissue was seen in patients with an R0 resection who had a subsequent LGI endoscopy (43/70). In those with R1 resection, a site check was undertaken at the same Trust in 59 patients. Residual tissue was seen in 7/59 (12%).
On univariate binomial regression, R1 resection was associated with polyps involving the dentate line [OR = 5.29 (95% CI = 1.84 – 17.8)], those with severe fibrosis [OR = 20.8 (95% CI = 3.85- 386.4)] and those receiving a GA [OR = 3.56 (95% CI = 1.06-16.3)]. On multivariate analysis, polyps involving the dentate line [OR = 8.17 (95% CI = 2.24 – 35.8)] and those with severe fibrosis [OR = 17.9 (95% CI = 2.57- 366.2)].

Reason for Admission	Number of Cases	Typical Timing (Days Post-ESD)	Treatment(s)	Length of Stay (Range)
Immediate admission – procedural reasons	2	Day 0	Monitoring	1 day
Immediate admission – perforation	2	Day 0	Conservative	2 days
Delayed perforation	2	Day 1, Day 1	Hartmann's procedure; Surgical washout + antibiotics	7–21 days
Post-polypectomy bleeding (PPB) – conservative	5	Days 7–13	Conservative	1–4 days
PPB – endotherapy	3	Days 5–9	Endotherapy	1–2 days
Fever	1	Day 1	Conservative	2 days
Hypotension	2	Days 1–2	Conservative	1 day
Acute Coronary Syndrome (ACS)	1	Day 6	Medical	20 days

Table 1 - Outcomes of admissions following ESD.

Conclusion: ESD is an effective treatment for high-risk complex colorectal polyps, able to provide high rates of en bloc resection. It can be achieved safely in most patients without GA. GA was associated with a higher rate of R1, however, this likely relates to these lesions being more complex.

Contact E-Mail Address: leilaraiss22@gmail.com
Introduction: The indications for colonoscopy are well established, with the primary objective being the detection of neoplasia or lesions that carry a high risk for colorectal cancer, even though benign causes are more commonly encountered. In young adults under 50 years of age, common indications include rectal bleeding and diarrhea.
In contrast, individuals aged 50 years and older are screened more broadly due to the increased risk of colorectal cancer, although recent trends show a rising incidence of neoplastic lesions in younger adults as well.
Aims & Methods: The aim of our study is to compare the indications and outcomes of colonoscopy between individuals younger and older than 50 years, and to identify which indications are most strongly associated with neoplastic findings.
A retrospective, descriptive, and analytical study was conducted over a period of 3.5 years, involving 1,518 patients. Participants were divided into two groups: Group A included patients under 50 years old, while Group B comprised those aged 50 and above. Epidemiological, clinical, and endoscopic data were compared between the two groups. Patients with a known diagnosis of inflammatory bowel disease (IBD) were excluded from the study. Statistical analysis was carried out using SPSS version 21.0.
Results: Among the patients, 65.1% were over 50 years of age, while 34.9% were under 50. The mean age in group A (under 50) was 37.5 ± 9 years, compared to 64.4 ± 9 years in group B (over 50). Females predomi-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

nated in the younger group (55.3%), whereas males were more prevalent among older patients (56.3%) ($p < 0.001$). A personal history of colorectal cancer was more frequent in patients over 50 (10.5% vs. 4.4%; $p < 0.001$). Colonoscopy indications varied by age group: constipation was the most common indication in group B (29.1% vs. 22%; $p = 0.01$), whereas diarrhea predominated in group A (33.3% vs. 19.3%; $p < 0.001$). Pathological findings on colonoscopy were more frequent in older patients (49.1% in group B vs. 32.9% in group A; $p < 0.001$).

In patients under 50, the most common pathological findings were colitis or ulcerative colitis (47.9% vs. 11.7%; $p < 0.001$). In contrast, patients over 50 showed a higher prevalence of polyps (61.5% vs. 41.3%; $p < 0.001$) and rectocolonic neoplasia (16% vs. 5%; $p = 0.002$).

Among the colonoscopy indications, constipation in patients under 50 was associated with a higher risk of neoplastic lesions ($p = 0.007$), while in patients over 50, rectal bleeding and constipation were significantly associated with neoplastic lesions ($p < 0.001$).

Conclusion: The presence of neoplastic lesions was strongly associated with constipation in individuals under 50 years of age, and with both rectal bleeding and constipation in those over 50. Further studies to better define these indications could help improve the appropriateness of colonoscopy, particularly in younger patients.

Disclosure: Nothing to disclose.

Introduction: Endoscopic submucosal dissection (ESD) is an effective technique for treating large colorectal lesions but can result in strictures in 0.49-19.7% of cases. We developed a novel technique called Hybrid Endoscopic Stricturotomy (HES), which combines incision with endoscopic balloon dilation (EBD) to treat post-ESD colorectal strictures. This study aims to evaluate the efficacy and safety of HES.

Aims & Methods: This retrospective study analysed data from a prospectively maintained registry at San Raffaele Hospital, Milan, from November 2019 to October 2024.

HES was performed on patients who developed symptomatic post colorectal ESD strictures defined as a lumen calibre that does not allow the passage of the endoscope (9.2 mm diameter) after conventional EBD treatment.

The HES technique involved incision followed by EBD. An L-shaped knife was used to radially incise the stenotic tissue in four quadrants. After the incisions, a wire-guided balloon dilator was introduced and gradually inflated to a diameter larger than the stenosis.

Follow-up endoscopies were scheduled every 2-4 weeks, and additional HES sessions were performed in in cases where lumen dilatation did not improve.

The primary outcome was clinical success, defined as lumen calibre ≥12 mm and symptom resolution; secondary outcomes included technical success, adverse events (AEs), and stricture recurrence.

Results: Of 265 patients treated with colorectal ESD, 7 patients (median age 71 years, 57.1% male) developed strictures; all in the rectum.

Lesions treated with ESD had a median length of 85mm on the major axis and 70mm on the minor axis. All lesions were classified as IIa+Is according to the Paris classification, except for one lesion arising on an anastomosis classified as IIa. The dentate line was involved in 5/7 cases (71.4%). Resection circumference was 100% in 2/7 patients (28.6%), 91-99% in 1/7 patient (14.3%), 76-90% in 1/7 patient (14.3%), 51-75% in 2/7 patients (28.6%), and 0-50% in 1/7 patient (14.3%). Median initial stricture diameter was 6mm (IQR 2). The median number of conventional EBD sessions before HES was 3 (range 2-5). Median stricture diameter after EBD treatment was 8mm (IQR 2).

Clinical and technical success was achieved in 100% of cases. During HES, the median maximum balloon diameter dilation was 20mm (range 15-20). The median number of HES treatment sessions was 2.3 (range 2-3). No AEs were reported. Over a median follow-up of 225 days (IQR 95 days), no symptomatic recurrences were observed.

Conclusion: HES, which combines incision and EBD, is a novel, safe and effective technique for treating post-colorectal ESD strictures to conventional EBD. Larger studies are needed to validate these preliminary results.

ENDOSCOPIC RETROGRADE APPENDICITIS THERAPY VERSUS ANTIBIOTIC THERAPY FOR ACUTE UNCOMPLICATED APPENDICITIS: A META-ANALYSIS OF PROPENSITY-SCORE MATCHED AND RANDOMIZED STUDIES

S. Faizollah Zadeh Ardebili[1], D. Hantschick Fernandes Monteiro[2], F. Evilda Miralda Matute[3], M. Salah[4], W. Fernandes Oliveira Amador[5]

Introduction: Over the past decade, endoscopic retrograde appendicitis therapy (ERAT) has emerged as a novel, minimally invasive treatment option for patients with acute uncomplicated appendicitis (AUA). However, it is not yet known whether ERAT is a feasible alternative to antibiotic therapy (ABT).

Aims & Methods: This study aims to evaluate the efficacy of ERAT versus ABT in patients with AUA. We performed a systematic review across PubMed, Embase, and Cochrane CENTRAL databases, searching for studies comparing ERAT to ABT in this population. Outcomes of interest included therapeutic success, — defined as the absence of reintervention up to 1 year of follow-up — recurrence rates, mean time to disease recurrence, and length of hospital stay (LOS). Risk ratios (RR) were used to evaluate binary outcomes with their corresponding 95% confidence intervals (CI), while the mean difference (MD) was calculated for continuous outcomes. All statistical analyses were performed using R software (version 4.4.1) with a random-effects model.

Results: This meta-analysis included 3 studies — 2 control-matched cohorts and 1 randomized trial — comparing 457 ERAT patients to 784 patients receiving ABT for AUA. Baseline clinical characteristics were equally

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

distributed between the groups and the time of follow-up ranged from 3 to 12 months. There was no statistically significant difference between ERAT and ABT in treatment success (RR 1.06; 95% CI 1.00 to 1.12; $p = 0.07$) or recurrence rate (RR 0.36; 95% CI 0.11 to 1.22; $p = 0.10$). The difference in time to recurrence was also not significant (MD 116 days; 95% CI -49 to 282; $p = 0.17$).

However, ERAT was associated with a significantly shorter LOS (MD -1.85 days; 95% CI -3.15 to -0.55; $p = 0.005$).

Conclusion: In patients with acute uncomplicated appendicitis, ERAT is non-inferior to antibiotic therapy, while considerably reducing the length of hospital stay. Further studies are warranted to better assess the efficacy of ERAT compared to ABT, and whether it decreases the risk of appendicitis recurrence.

Introduction: A successful colonoscopy aims to thoroughly visualize the entire colon, including the terminal ileum, to maximize the detection of lesions and effectively screen for colorectal cancer. However, approximately 10% of colonoscopies are incomplete, often due to a combination of technical challenges and patient-related factors.

The goal of our study is to identify and analyze the factors that contribute to incomplete colonoscopy procedures.

Aims & Methods: We conducted a retrospective descriptive and analytical study including all patients who underwent a colonoscopy between January 2019 and August 2024. Patients known to have chronic inflammatory bowel disease (IBD) were excluded from our study. An incomplete colonoscopy was defined as non-visualization of the caecum.

Results: Out of 1,518 colonoscopies performed, 105 (11.5%) were deemed incomplete. Factors associated with incomplete colonoscopy included older age (p=0.003), male sex (p=0.026), history of abdominal surgery (p<0.001), constipation (p=0.001), diarrhea (p=0.002), rectal bleeding (p=0.006), and poor bowel preparation (p=0.001).

Multivariate analysis revealed that factors linked to incomplete colonoscopy included: a history of abdominal surgery (OR: 13.8, 95% CI: 4.2–45.1, p=0.001), poor preparation (OR: 224, 95% CI: 57–884, p=0.001), presence of diarrhea (OR: 0.2, 95% CI: 0.08–0.5, p=0.002), and constipation (OR: 0.33, 95% CI: 0.1–0.7, p=0.007).

Conclusion: In this study, 11.5% of colonoscopies were incomplete. The factors most strongly associated with incomplete procedures were a poor preparation, a history of abdominal surgery, and the presence of diarrhea or constipation.

Disclosure: Nothing to disclose.

CHANGES IN BOWEL MOVEMENT FREQUENCY, GUT MICROBIOTA, AND EMOTIONAL ISSUES IN POSTOPERATIVE CONSTIPATION PATIENTS

H. Tian[1], Q. Chen[1]

[1]Tongji University School of Medicine, General Surgery of Shanghai Tenth People's Hospital, Shanghai, China

Contact E-Mail Address: kevin_thl@163.com

Introduction: In recent years, the prevalence of chronic constipation among adults worldwide has shown a yearly increasing trend, with most patients experiencing varying degrees of emotional disorders. Understanding the underlying mechanisms linking chronic constipation, gut microbiota, and emotional status is crucial for developing effective therapeutic strategies.

Aims & Methods: This study aimed to explore the relationship between gut microbiota and emotional status by collecting preoperative and postoperative clinical data, psychological conditions, and gut microbiota profiles from 30 patients undergoing total colectomy with ileorectal anastomosis for chronic constipation. Clinical and microbiota data were analyzed to evaluate changes in emotional status and gut microbiota composition before and after surgery.

Results: The results demonstrated that anxiety and depression levels of patients significantly improved following surgery. Concurrently, gut microbiota diversity noticeably decreased, accompanied by significant alterations in species composition. Postoperative changes revealed that Clostridium-sensu-stricto and Streptococcus were key species contributing to the differences observed between preoperative and postoperative microbiota profiles.

Notably, Streptococcus was negatively correlated with emotional symptoms such as obsession, anxiety, and depression, and positively correlated with the lactose and galactose degradation pathway.

Conclusion: This study suggests that Streptococcus may play a pivotal role in improving emotional disorders in chronic constipation patients by modulating the lactose and galactose degradation I pathway.

These findings provide novel insights into the interplay between gut microbiota and emotional well-being, highlighting the potential of targeting gut microbiota as a therapeutic approach for managing psychological conditions associated with chronic constipation.

INSIGHTS INTO THE VARIABILITY AND TEMPORAL STABILITY OF FECAL MICROBIOTA

D. Rius[1,2], M. Malagón[1], M. Serra-Pagès[1], X. Aldeguer Mante[3], L. Baldo[4], L. Oliver[1]
[1]GoodGut SLU, Girona, Spain, [2]Universitat de Girona, Girona, Spain, [3]H. de gerona dr. j. trueta/ico gerona, Gastroenterology, Girona, Spain, [4]Universitat de Barcelona, Barcelona, Spain

Introduction: Understanding the intra- and inter-individual variability of gut microbiota is crucial for advancing microbiota research and its clinical applications. Gut microbial markers play essential roles in maintaining intestinal health, with functional groups including opportunistic, proteolytic, equilibrium, immunoprotective, mucosal homeostasis, proinflammatory, and methanogenic microbes.
Aims & Methods: This study aimed to evaluate the temporal stability of 15 microbial markers and identify potential transient disruptions associated with lifestyle and dietary factors.
A longitudinal observational study was conducted with 6 participants, including 4 healthy individuals and 2 with mild IBS, each providing 7 fecal samples (42 samples total) over a one-month period on randomly selected days. Microbial DNA was extracted from fecal samples and analyzed using a qPCR kit of a specific microbiota test, which includes a panel of 15 microbial markers.
Participants completed questionnaires on each sampling day, documenting dietary habits, lifestyle factors, and digestive health. To assess the stability of the microbial markers in relation to differences among individuals, the Intraclass Correlation Coefficient (ICC) was calculated after adjusting a mixed effects model for each marker. These metrics provide numerical insights into the consistency and variability of the microbial populations over time.
However, it is essential to contrast these numbers with the nature or behaviour of each marker, allowing for a more accurate and contextualized interpretation of the results, as the observed variability and stability may be influenced by intrinsic factors to each type of microbial marker.
Results: Distinct individual-specific microbiota patterns were observed, with clear inter-individual variability in baseline distributions. Transient alterations were observed in some cases, with many of them associated with dietary factors, such as specific food types or eating habits reported prior to sample collection.
Notably, indicative markers of intestinal health, such as *Faecalibacterium prausnitzii*, *Roseburia*, and *Ruminococcus*, remained stable. In contrast, modifications in *Akkermansia muciniphila* and *Methanobrevibacter smithii* levels were observed coincident with variations in dietary intake suggesting that these could be an influent factor. Particularly, these disruptions were generally short-lived, with markers returning to baseline levels within a few days. The ICC has demonstrated its effectiveness in refining results and quantifying the relationship among intra- and inter-personal variability of markers. For example, *Faecalibacterium prausnitzii* exhibited a low ICC (0.112), indicating minimal differences among participants, whereas *Methanobrevibacter smithii* had a high ICC (0.921), reflecting significant variability among participants.
Conclusion: This study provides preliminary insights into the stability and individual variability of gut microbiota markers analyzed using the qPCR kit of this microbiota test. These findings highlight the importance of establishing personal baselines for accurate diagnostic interpretation and underscore the resilience of the gut microbiota in response to daily lifestyle fluctuations. Moreover, the stability of intestinal health indicators markers supports their potential as reliable indicators of gut health.
These results provide valuable data for a deeper understanding of gut health dynamics and underscore the importance of personalized approaches in microbiota diagnostics and management.

EVOLUTION OF THE FAECAL LIPIDOME IN PRETERM NEONATES AND ITS ASSOCIATION WITH ECZEMA OR WHEEZE DEVELOPMENT - A LONGITUDINAL TWIN STUDY

M. Thomas[1], M. Sani[1], K. Sim[1], J. Kinross[1]
[1]Imperial College London, Department of Surgery & Cancer, London, United Kingdom

Contact E-Mail Address: maya.thomas6@nhs.net
Introduction: The development of the human gut microbiome is a dynamic process whereby rapid maturation occurs in the first year of life. Nutrition, antibiotic use and mode of delivery are important factors in its development, which impacts on the evolution of the faecal metabolome. This study examines the faecal lipidome of preterm twins and triplets through early life to determine genomic and environmental drivers that in turn influence the risk of eczema and wheeze.
Aims & Methods: Neonatal Microbiota (NeoM) is a single-centre longitudinal cohort of preterm infants (<32 weeks gestation) recruited between 2010-11 at Imperial College NHS Trust. Faecal samples were collected. NeoM2 is a follow-up at 2-4 years of age, where a further faecal sample and a parent-completed health questionnaire were collected.
For this study, infants were included if they were from a multiple birth with faecal samples from NeoM and NeoM2. Infants were excluded if they were the only sibling meeting criteria as we wanted to compare siblings. Faecal samples from postnatal days 1-35 and ~3 years were profiled using reversed-phase ultra-performance liquid chromatography mass spectrometry (Acquity UPLC, Q-TOF Premier, negative ESI mode).
Allergic outcomes were defined from the NeoM2 questionnaire: doctor-confirmed eczema, and ≥1 wheeze episode. Multivariate analysis using in-house protocols and recursive feature elimination, with univariate analysis accounting for multiple testing was performed.
Results: Of 369 NeoM infants, 24 met our inclusion criteria (11 sibling sets: 9 twins, 2 triplets). From these 24 infants, 236 faecal samples from postnatal days 1-35 were profiled (2-18 samples per infant; mean age at sample collection 16.9 days). 6 infants had suspected NEC and 3 had sepsis. Of the 11 twin/triplet sets included, 4 sets demonstrated intra-sibling lipidomic variation when comparing all NeoM samples available for each sibling, defined as ≥1 metabolite that statistically differed ($p<0.05$; unpaired t-test for twins, one-way ANOVA for triplets). The number of metabolites that statistically differed was 1, 2, 132 and 1 for the 4 sets, out of 1246 total metabolites.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

There was no clear environmental driver to explain this, although the twins with 132 differing metabolites had the largest disparity in maternal milk consumption. Antibiotic use, nutrition and birthweight were separately investigated as environmental drivers that could influence lipidomic expression. All 236 samples from NeoM were classified into discrete classes based on metadata for each driver. There were 553, 763 and 626 metabolites statistically differing for each driver respectively ($p<0.05$ using one-way ANOVA). Regarding allergic outcomes, 8 infants were eczema positive and 12 wheeze positive. Of the 4 twin sets with lipidomic variation, there was one twin per set positive for eczema and/or wheeze, and one twin per set negative for both. Using recursive feature elimination, lipidomic profiles for the NeoM2 data identified 114 metabolites that differed in those eczema positive compared to negative, and 84 for wheeze. Tentative structural assignment identified two fatty acids (FA 15:0, FA 17:0) of interest that statistically differentiated between twins, antibiotic use, nutrition, and with eczema status.

Conclusion: Preterm twins/triplets maintain similar lipidomic profiles during early life. Antibiotic use, nutrition and birthweight were all drivers of variation, which is of significance as microbial co-metabolic fatty acids (FA 15:0, FA 17:0) are correlated with eczema development. Further validation is required to substantiate these findings.

Disclosure: Nothing to disclose.

Introduction: The modulation of gut microbiota through bioactive nutraceuticals offers promising avenues for managing gastrointestinal diseases such as ulcerative colitis (UC). In this study, we investigated the effects of two nutraceutical formulations, Biointestil® and Clovedin®, both rich in natural bioactive compounds, on the gut microbiota of healthy individuals and UC patients.

Aims & Methods: A standardized in vitro simulation of human gastrointestinal digestion and colonic fermentation was conducted using the MICODE (Multi-Unit Colon Model) platform, which through the replication of intestinal conditions including pH and O_2 milieu and specific gut microbiota enables conduct precise Risk/Benefit Assessment by omics means. Biointestil® or Clovedin®. were subjected to 48-hour colonic fermentation with two different gut microbiota models: that from healthy and that from UC donors in biological duplicates.

Microbial composition was monitored using quantitative PCR (qPCR) targeting key pro-inflammatory and beneficial bacterial taxa. Changes in microbiota structure were evaluated through ecological indicators (i.e. prebiotic index, *Firmicutes/Bacteroidota*, etc), providing insight into gut microbial stability and resilience.

In addition, a comprehensive volatilome analysis was performed using SPME GC-MS to assess the metabolic output of the microbial communities, focusing on short-chain fatty acids (SCFAs), indoles, phenols, and other microbial metabolites.

Results: In addition, a comprehensive volatilome analysis was performed using SPME GC-MS to assess the metabolic output of the microbial communities, focusing on short-chain fatty acids (SCFAs), indoles, phenols, and other microbial metabolites. Treatment with Biointestil® and Clovedin® resulted in a reduction of some opportunistic and pro-inflammatory bacteria (*Clostridiaceae, Collinsella aerofaciens, Desulfovibrio spp.*) and a concurrent increase in some beneficial taxa (*Bifidobacteriaceae, Ruminococcaceae, Faecalibacterium prausnitzii*). These shifts were accompanied by an enhanced SCFA profile and a decreased production of toxic volatiles (p-cresol and skatole), particularly in the UC-derived microbiota.

Conclusion: The combined use of qPCR, volatilomics, and ecological modeling within the MICODE in vitro system provides a robust framework for assessing microbiota-targeted interventions and supports the therapeutic potential of Biointestil® and Clovedin® in inflammatory bowel disorders by remission of gut microbiota dysbiosis.

Introduction: Immune checkpoint inhibitors (ICI) are widely used in the management of numerous solid tumors and act by enhancing T-cell–mediated anti-tumour responses. While this activation boosts the immune response against cancer cells, it may also result in immune-related side effects (irAEs). Gastrointestinal symptoms, mainly colitis and diarrhea, are among the most common irAEs.[1] We have recently (February 2025) opened a dedicated clinic, within our Gastroenterology outpatient service, to manage patients who experience gastrointestinal irAEs during ICI therapy for epithelial cancers.

Aims & Methods: Our aim was to evaluate characteristics and outcomes of patients referred to our dedicated clinic for the management of gastrointestinal irAEs associated with ICI therapy since its start (February 2025). All patients were clinically evaluated and were treated with standard-of-care therapy in accordance to European Guidelines[2]. Patients were followed up for at least 8 weeks following initiation of therapy. We collected data on patient demographics (gender and age), patient's overall health status as assessed by the Charlson Comorbidity Index (CCI)[3], cancer type, oncological therapy, diarrhea severity (graded via CTCAE)[4], time to onset of diarrhea following the initiation of oncological therapy, interruption of ICI, outcomes of colonscopy (if performed), treatment modality for ICI-related gastrointestinal toxicity, time to resolution of diarrhea (in weeks), and whether ICI therapy was subsequently resumed.

Results: We included 14 patients affected by ICI-related diarrhea or colitis (grade 1: n=2 , grade 2: n=9 , grade 3: n=2; grade 4: n=1). Four patients were affected by endometrial cancer, 3 patients melanoma, 3 lung cancer,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 2 breast cancer, 1 ovarian cancer, 1 cervical cancer. Thirteen patients were treated with PD1/PDL1- inhibitors (Pembrolizumab: n=9 , Dostarlimab: n=2, Nivolumab: n=2) and one patient was treated with CTLA-4 (Ipilimumab: n=1). Ten patients interrupted immunotherapy due to ICI-related diarrhea after 17 weeks of therapy on average. As indicated by the European Guidelines[2], all patients with diarrhea grade G2 or higher (6 patients) underwent colonoscopy, which revealed signs consistent with ICI-induced colitis. After standard-of-care treatment,12 patients experienced diarrhea grade 1 or lower. Mean time to resolution of diarrhea was 4.2 weeks. Among the 10 patients who had to interrupt ICI due to gastrointestinal adverse events, 5 patients (50%) resumed ICI after a mean of 4 weeks. No patients experienced any adverse events related to the standard-of-care treatment as defined by CTCAE.[4]

Conclusion: Despite being preliminary, our experience shows that patients managed in a dedicated clinic for gastrointestinal irAEs associated with ICI therapy experience acceptable outcomes. Future studies, aimed at comparing whether this approach is more effective than a non-dedicated management, are warranted.

Introduction: The use of proton pump inhibitors (PPI) has been identified as one of the strongest influences on the gut microbiome in the general population. Long term use can lead to an increase of oral bacteria, such as Streptococcus salivarius and Veillonella parvula, in the gut microbiome which has been associated with gut inflammation and worse outcomes in patients with liver cirrhosis. Beside stringent prescription management, a targeted strategy to reduce PPI-induced alterations in the gut microbiome is crucial to reduce associated side-effects but remains an unmet need so far.

Aims & Methods: Here we aimed to design an evidence-based probiotic intervention to reduce PPI-induced dysbiosis of the gut microbiome. We tested 43 probiotic strains on their ability to inhibit the growth of S. salivarius and V. parvula as well as modulate the response of neutrophil granulocytes to the oral bacteria and selected 7 strains for a multispecies probiotic product. The performance of this evidence-based formulation was then tested with and without additional prebiotic in a bioreactor-based in-vitro model of the oralization of the gut microbiome (MyBioScope, CBmed) against two control substances (vehicle and starch) and prebiotics alone for optimization, before it was introduced in a clinical proof-of-concept, single arm study with a total of 61 included and 53 analyzed participants with long-term PPI use as a 3 months intervention.

Results: Based on their inhibitory capacity against S. salivarius, V. parvula and their immune modulatory effect on isolated human neutrophils, the probiotic strains Bifidobacterium animalis W53, Lactobacillus acidophilus W55, Lactobacillus casei W56, Lactobacillus plantarum W1, Lactobacillus plantarum W21, Lactobacillus rhamnosus W71 and Pediococcus acidilactici W143 were selected for their use in the probiotic formulation. When tested in the MyBioScope model for oralization, the probiotic formulation (with and without prebiotic) was able to significantly reduce the abundance of V. parvula and showed a tendency to reduce S. salivarius, which did not reach statistical significance. Prebiotics alone or control (vehicle or starch) did not show an effect on the abundance of the oral bacteria. In the clinical study, probiotic intervention significantly improved the gastrointestinal quality of life index of the participants and reproduced the results of the in-vitro tests by showing a significant reduction of V. parvula and a less effective reduction of S. salivarius in the gut microbiome. Adherence to the study product and the safety profile were excellent.

Conclusion: In conclusion, our screening procedure for an evidence-based probiotic formulation against PPI-induced dysbiosis resulted in a probiotic product containing 7 potent strains and a prebiotic matrix. This formulation was able to reduce the abundance of V. parvula as well as to a lesser degree S. salivarius in a novel bioreactor-based in-vitro model of the gut microbiome. The results of the in-vitro model could be reproduced in a proof-of-concept, single-arm clinical study where the probiotic was able to reduce the abundance of V. parvula in the gut microbiome of long-term PPI-users. This study shows that targeted probiotic interventions can be used to relieve PPI-induced side-effects, including alterations in the microbiome composition.

PP0694

IMPACT OF SHORT-TERM REDUCTION OF PLASTIC EXPOSURE ON MICROPLASTIC PRESENCE AND GUT MICROBIOME COMPOSITION IN HEALTHY INDIVIDUALS: A PILOT STUDY

C. Pacher-Deutsch[1,2], A. Horvath[1,2], V. Stadlbauer[1,2,3]
[1]Center for Biomarker Research in Medicine (CBmed), Translational Precision Medicine, Graz, Austria, [2]Medical University of Graz, Gastroenterology and Hepatology, Graz, Austria, [3]BioTechMed-Graz, Graz, Austria

Contact E-Mail Address: christian.pacher@cbmed.at

Introduction: Microplastic particles (MPs) have previously been confirmed to be found in the human body and are suspected to lead to systemic health effects (1). One biological matrix in which MPs have been detected is human faeces (2). While there is growing evidence suggesting potential impacts on the gut microbiome from animal (3) and in-vitro/ex-vivo studies (4), studies investigating this relationship in the human are still lacking.

Aims & Methods: This pilot study aimed to investigate the impact of short-term plastic reduction on the gastrointestinal tract of healthy participants, focussing on MP presence and gut microbial composition.

Sixty healthy volunteers participated by providing two stool samples: one prior to and one after a seven-day intervention during which they actively minimized plastic exposure. To facilitate the reduction, participants were provided with plastic-free alternatives (e.g., glass water bottles, wooden kitchen utensils, plastic-free dental care products, tin lunch boxes), together with instructions on how to avoid plastic-packaged goods and find alternatives. Dietary habits and plastic contact were recorded using detailed questionnaires to assess behavioural changes and identify potential sources of exposure. Stool samples were analysed using 16S rRNA gene sequencing for changes in microbial diversity and potential differential taxa. Additionally the samples were frozen at –80°C for future MP quantification, where method development is ongoing.

Results: Fifty-five participants completed the study, with an average self-reported success rate of 76% in adhering to the intervention. Forty percent of participants fully avoided plastic packaging, while 56% achieved partial avoidance. Participants noted challenges, particularly in avoiding plastic in meat and dairy products and during restaurant visits. Despite these obstacles, 92.7% expressed a lasting commitment to reducing plastic use post-intervention, with many reporting intentions to continue purchasing fresh products, reduce fast food intake, and adopt sustainable household practices, especially replacing plastic utensils. Initial microbiome analysis revealed no significant changes in alpha or beta diversity following reduced plastic exposure; however, differential abundance analysis identified potential specific taxa shifts. One species each within the genera *Clostridium*, *Ruminococcus*, and *Blautia* showed reduced abundance post-intervention, while species from the genera *Bacteroides* and *Anaerostipes* were associated with increased abundance after plastic fasting.

Conclusion: A short-term reduction in plastic exposure is feasible and can effectively raise awareness and promote long-term behavioural change in plastic consumption habits. However, no significant changes in gut microbial diversity were observed within the study period, with only shifts in a limited number of species visible. Due to the stability of the gut microbial composition, longer changes in plastic exposure might be necessary to trigger stronger effects.

COGNITIVE ENHANCEMENT AND TIME-DEPENDENT REMODELING OF THE GUT MICROBIOME AND METABOLOME AFTER FECAL MICROBIOTA TRANSPLANTATION: A PILOT STUDY

H.J. Yoo[1], J.-H. Lee[2,3], B. Cha[3], J. Shin[3], J. Hong[3], K.-S. Kwon[3], Y.-W. Shin[3]
[1]Inha University College of Medicine, Department of Biomedical Science, Incheon, South Korea, [2]Inha University Hospital, Department of Hospital Medicine, Incheon, South Korea, [3]Inha University Hospital, Division of Gastroenterology ,Department of Internal Medicine, Incheon, South Korea

Contact E-Mail Address: endlesmile@naver.com

Introduction: Fecal microbiota transplantation (FMT) is established for recurrent *Clostridioides difficile* infection and is being explored for metabolic and neuropsychiatric disorders. Evidence suggests that FMT-mediated modulation of the gut–brain axis can benefit cognition, but combined microbiome–metabolome correlates remain poorly defined.

Aims & Methods: In a prospective observational study, the patients with mild-to-moderate cognitive impairment completed follow-up after colonoscopy-guided FMT (60 g donor stool/400 mL saline). Cognition was assessed with the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA) at baseline, 1, 4 and 12 weeks. Fecal samples collected at 0, 1 and 4 weeks underwent untargeted LC-MS; 28 microbe-derived metabolites were retained after MiMeDB matching, log transformation and Pareto scaling for PLS-DA and heat-map analyses—parallel 16S-rRNA sequencing profiled bacterial diversity and relative abundance.

Results: *Clinical*: Three patients who were able to undergo cognitive testing completed the 30-day follow-up. Median MMSE improved from 1 (IQR 1–12) at baseline to 8 (4–13) at 7 days and 10 (9–18) at 4 weeks; two participants sustained gains at 12 weeks. MoCA rose from 0 (0–6) to 4 (2–7) at 7 days with mixed longer-term trajectories.

Metabolome: Fecal metabolites were collected over four weeks from 11 patients with cognitive dysfunction who underwent FMT. PLS-DA scores migrated progressively up-right across the first 4 weeks, indicating time-dependent restructuring. Short–chain fatty–acid–related metabolites trended upward while selected indole derivatives declined; however, only 3 of 28 features exceeded a 2-fold, $p < 0.05$ threshold owing to limited power.

Microbiome: Alpha-diversity increased numerically after FMT (median observed species from 6.0 to 12.3) but did not reach statistical significance ($P = 0.121$). Relative abundance shifted toward beneficial taxa—*Akkermansia muciniphila*, *Bacteroides ovatus,* and *Bifidobacterium longum* groups

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

expanded—while potential pathobionts such as the *Enterococcus faecium* group contracted; compositional changes paralleled early cognitive improvement.

Conclusion: FMT was associated with rapid and sustained cognitive gains accompanied by concordant remodeling of both the fecal metabolome and bacterial community toward neuro-supportive profiles.

Although statistical confidence is limited by sample size, these integrated data strengthen the gut–brain axis hypothesis and justify larger controlled trials to pinpoint key neuroactive microbes and metabolites driving cognitive benefit.

IN VITRO VS. IN VIVO STUDIES ON THE INTERACTION OF A MEDICINAL PRODUCTS, STW 5, WITH THE GUT MICROBIOTA

J. Wächter[1], L. Köhler[1], O. Kelber[1], M.T. Khayyal[2]
[1]Steigerwald Arzneimittelwerk GmbH, Phyto & Biotics Tech Platform, Phytomedicines Supply and Development Center, Bayer Consumer Health, Darmstadt, Germany, [2]Faculty of Pharmacy, Cairo University, Pharmacology, Cairo, Egypt

Contact E-Mail Address: olaf.kelber@bayer.com

Introduction: Recent evidence suggests that natural products can modulate microbiome composition, offering health benefits. This study evaluates the effects of STW 5 on microbiota in functional dyspepsia (FD) and Irritable Bowel Syndrome (IBS) through a comparison of *in vitro* and *in vivo* data.

Aims & Methods: A comprehensive literature review was conducted using PubMed and other scientific databases to collate data on STW 5's impact on the gut microbiome at phyla and genera levels.

Results: *In vitro* studies demonstrated an increase in *Enterococcus* and a decrease in *Clostridium* and *Bacteroides* [1]. Further *in vitro* research confirmed an increase in Firmicutes and a reduction in Bacteroidetes, with a decrease of *Blautia* and Proteobacteria. Unpublished data of the authors indicated increased *Bifidobacterium* and *Blautia*, with no change in *Lactobacillus* [2].

In vivo studies in healthy Wistar rats reported minor increases in the phyla Firmicutes and Bacteroidetes, and a significant decrease in Actinobacteria. Genus-level changes included increases in *Bacteroides*, *Bifidobacterium*, and *Prevotella*, and a significant rise in *Methanobrevibacter*. In a model of ulcerative colitis, *Lactobacillus*, *Blautia*, and *Bifidobacterium* increased, while Proteobacteria and *Enterococcus* decreased.[3]

In an *in vivo* model of functional dyspspsia, significant increases were observed for *Enterococcus*, *Lactobacillus*, *Blautia*, and Bacteroidetes. Actinobacteria decreased, with elevated *Bifidobacterium* compared to FD control, but lower than in healthy controls [4, 5]

Conclusion: The different responses of some genera like *Blautia* and *Enterococcus* to STW 5 in *in vitro* models as compared to *in vivo* models highlight the complexity of the interactions of the microbiota with STW 5.

The limitations of *in vitro* models due to the absence of host factors, and the challenges of *in vivo* models in extrapolating data to humans underscore the advantages of using diverse research methodologies to identify microbial changes relevant to human health.

Our results demonstrate such an approach, revealing consistent microbial shifts across the models. In particular, the upregulation of *Bifidobacterium*, with the downregulation of Actinobacteria and Proteobacteria, highlight the potential of STW 5 for beneficial gut microbiome modulation, underscoring its multi-target mechanism of action [6].

In conclusion, the presence of different results in different models underscores the need for a multifaceted approach to accurately characterize the intricate interactions between natural products and the gut microbiome. The identification of consistent microbial shifts associated with STW 5 provides mechanistic insight contributing to its clinically-proven health benefits. Further research, will be valuable to confirm the translational relevance of these findings.

IMPACT OF H. PYLORI ERADICATION THERAPY WITH BUTYRIC ACID AND INULIN SUPPLEMENTATION ON GUT MICROBIOTA SHORT-CHAIN FATTY ACID LEVELS

D. Safina[1,2], S. Abdulkhakov[3,1], M. Markelova[1], M. Siniagina[1], D. Khusnutdinova[1], R.A Abdulkhakov[3], T.V Grigoryeva[1]

Introduction: H. pylori eradication therapy induces significant alterations in the gut microbiome. While the composition of gut microbiota has been extensively studied, the levels of gut microbiota short-chain fatty acids (SCFAs), particularly in case of butyric acid and inulin supplementation, have not been investigated.

Aims & Methods: The aim of our study was to evaluate the levels of SCFAs of the gut microbiota during H. pylori eradication therapy adjuvated with butyric acid and inulin (Zacofalk) supplement.

A total of 15 H. pylori-positive patients aged 18 to 65 years were enrolled in the study. The following H. pylori eradication regimen was used: esomeprazole 20 mg, clarithromycin 500 mg, amoxicillin 1000 mg, and bismuthate tripotassium dicitrate 240 mg, twice daily, along with butyric acid and inulin (Zacofalk) supplementation (two tablets daily, each containing 250 mg of butyric acid and 250 mg of inulin), orally, for 14 days. Stool samples were collected from each subject at three time points: prior to eradication therapy (I), after therapy completion (II), and one month post-therapy (III). The levels of SCFAs were analyzed using gas chromatography–mass spectrometry. Differences were assessed using the Wilcoxon signed-rank test (p-value < 0.05 was considered statistically significant).

Results: Immediately after eradication therapy, the relative level of butyric acid (C4) and the absolute levels of butyric acid (C4), isovaleric acid (iC5), and valeric acid (C5) significantly decreased compared to baseline:

• Butyric acid (C4):(0.139±0.068) relative units vs. (0.193±0.044) relative units, p=0.038;

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

• Butyric acid (C4):(0.23±0.15) mg/g vs. (0.59±0.29) mg/g, p=0.0035;
• Isovaleric acid (iC5):(0.11±0.06) mg/g vs. (0.18±0.11) mg/g, p=0.037;
• Valeric acid (C5):(0.05±0.04) mg/g vs. (0.14±0.09) mg/g, p=0.0051.

In one month the levels of most SCFAs restored to baseline levels, with no statistically significant differences identified between time points III and I in terms of the relative level of butyric acid (C4) and the absolute levels of both butyric and isovaleric acids (C4 and iC5):

• Butyric acid (C4): (0.195±0.056) relative units vs. (0.193±0.044) relative units, p=0.414;
• Butyric acid (C4): (0.49±0.32) mg/g vs. (0.59±0.29) mg/g, p=0.0942;
• Isovaleric acid (iC5): (0.17±0.10) mg/g vs. (0.18±0.11) mg/g, p=0.588.

However, even one month after therapy, the absolute level of valeric acid (C5) was still lower than baseline: Valeric acid (C5): (0.09±0.08) mg/g vs. (0.14±0.09) mg/g, p=0.0051.

No significant changes were observed in the absolute levels of acetic acid (C2), propionic acid (C3), isobutyric acid (iC4), caproic acid (C6), and the anaerobic index (acetic acid to butyric acid ratio, units) immediately after and one month after eradication therapy compared to baseline, which may be due to the mitigating effects of butyric acid and inulin (Zacofalk) supplementation.

Conclusion: H. pylori eradication therapy leads to significant changes in the levels of gut SCFAs immediately after eradication therapy, even when adjuvated with butyric acid and inulin (Zacofalk) supplements, which are mostly reversed within a month after therapy.

Disclosure: Nothing to disclose.

PATIENT EXPERIENCES OF MAGNETIC RESONANCE IMAGING DEFECATING PROCTOGRAMS

C. Dell'Oro[1], A. Sergot[2], E.V. Carrington[1,3]
[1]Imperial College London, Translational Colorectal Research Laboratory, Department of Surgery and Cancer, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, Department of Radiology, London, United Kingdom, [3]Imperial College Healthcare NHS Trust, Department of Colorectal Surgery, London, United Kingdom

Contact E-Mail Address: chiara.delloro20@imperial.ac.uk

Introduction: Anorectal dysfunction affects approximately 8% of the global population.[1] Whilst conservative management can manage mild symptoms, surgery is often indicated in patients with structural abnormalities and severe symptoms. A Magnetic Resonance Imaging Defecating Proctogram (MRDP) forms a key part of patients' pre-surgical investigations, visualising the anterior, middle and posterior compartments of the pelvis, and provides a dynamic image of the pelvic floor during defecation. It has been criticised as it is often performed in the supine position, which does not reflect normal physiological positioning for defecation.[2]

However, little is known about how patients themselves feel about how this test reflects their usual defecatory process.

Aims & Methods: As part of a service evaluation, between September 2024 and April 2025, all patients who underwent an MRDP at Imperial College Healthcare NHS Trust in London, United Kingdom, were asked to complete a 21-item questionnaire exploring their experiences, prior to, during and after their MRDP. Five-point Likert Scales (1 - Strongly Disagree, 5 - Strongly Agree) were used for each question, except two concluding questions on overall experience, which were answered using free-text boxes. Patients with insufficient cognitive function or comprehension of English to complete the questionnaires were excluded.

Results: Thirty-eight patients responded to the questionnaire, and after excluding those with missing data, 35 completed questionnaires were included in the analyses (30[86%] female, 28[80%] 50-79 age category). Reasons for referral to MRDP included FI (15/35 [43%]) and/or constipation (13/35 [37%]) and/or POP (9/35 [26%]).

Although 32(91%) strongly agreed that their privacy was respected, and none strongly agreed they felt embarrassed, just 12(34%) strongly agreed that they felt 'comfortable during the test'. Less than a third of patients (10[29%]) agreed that they were able to 'defecate as they do at home' and only a quarter (9[26%]) felt that defecating lying supine was easy.

Whilst 16(46%) patients felt that the contrast mixture inserted gave them a 'normal urge to open their bowels', only 4(12%) reported that the contrast mixture was 'similar to their own stool'.

Nevertheless, 23(66%) patients agreed that the experience matched what they would expect, and most patients (29[83%]) would have the test again if it were necessary. Patients aged 70-79 were associated with disagreeing with the statement that they could 'defecate as they would at home' (neutral/disagree/strongly disagree vs. agree/strong agree: 8/8[100%] vs 0.0[0%], p = 0.011).

Conclusion: Whilst patients reported being able to tolerate the MRDP, the large majority reported that defecating during the investigation did not reflect their usual defecatory process.

Contrary to expectation, it appears that patients' main complaints were not due to embarrassment, but rather patient position and environment. Whilst patient experiences are highly institution and staff dependent, understanding patients' perspectives during an MRDP is useful for optimisation of pre-investigation counselling and expectation setting. Implementing post-MRDP questionnaires, or pro-active clinician exploration of the extent to which patients felt able to replicate their symptoms could facilitate clinical interpretation of MRDP results.

Moving towards evacuation testing that aligns more closely with a patient's normal defecatory habits is likely to yield results that better reflect symptom profiles and therefore provide better insights into specific surgical targets responsible for symptom generation.

PP0699

EVALUATING THE UNDERLYING AETIOLOGY IN PATIENTS WITH REPORTED COLITIS ON COMPUTED TOMOGRAPHY IMAGING

S. Chan[1], I. Shaw[1]
[1]Gloucestershire Royal Hospital, Gastroenterology, Gloucester, United Kingdom

Contact E-Mail Address: sally.chan1@nhs.net

Introduction: Computed tomography (CT) is a common modality used to assess patients who present acutely with gastrointestinal symptoms.[1] The term colitis refers to the thickening of the colonic wall [2] and is often described in CT reports. Causes of colitis are commonly classified into infectious, inflammatory and ischaemic colitis.[3]

Although there are some radiological features that are helpful in suggesting a specific diagnosis,[4] determining the underlying aetiology of colitis often requires correlation with clinical history, laboratory results including stool cultures and endoscopic evaluation.[1]

There is currently limited literature on the prevalence of the different aetiologies in patients with colitis reported on CT.[3]

Identification of the underlying aetiology allows for specific management of patients as treatment options differ depending on the underlying cause.

Aims & Methods: The aim of this study is to identify the aetiology of colitis in patients with reported colitis on CT imaging.

A retrospective review of CT reports and patient case notes was performed. A text search through our radiology system (CRIS) was used to identify patients with CT reported colitis during their inpatient admission. Patients with known Inflammatory bowel disease (IBD), colorectal cancer as well as outpatient CT reports were excluded.

Following identification of our patient cohort, we reviewed their clinical notes as well as laboratory, stool and endoscopic results to determine the underlying aetiology of their colitis.

Results: A total of 138 patients with colitis reported on CT imaging were included. 98 patients (71.0%) had a stool culture sent during their admission whilst 83 patients (60.1%) underwent endoscopic evaluation with a flexible sigmoidoscopy (n=49, 59.0%) or colonoscopy (n=34, 41.0%). In 35 patients (42.2%) there were no significant abnormalities found endoscopically.

74 patients (53.6%) were thought to have infectious colitis with main pathogens including *Campylobacter* spp. in 19 patients (25.7%), *Clostridiodes difficile* in 11 patients (14.9%) and *Salmonella* spp. in 1 patient (1.4%). 4 patients (5.4%) had endoscopic features of infectious colitis. 39 patients (52.7%) patients were suspected to have infective colitis from clinical history and laboratory results.

25 patients (18.1%) had ischaemic colitis either confirmed endoscopically (n=11, 44.0%) or through clinical history and CT features (n=14, 56.0%). Endoscopically, 6 patients (4.3%) had features compatible with IBD, 2 patients (1.4%) with lymphocytic colitis and 1 patient (0.7%) with an adenocarcinoma. 15 patients (10.9%) had diverticulosis.

C-reactive protein (CRP) was higher in patients with infectious colitis (mean of 141.4 mg/L) and lower in patient with ischaemic colitis (mean of 108.6 mg/L). Albumin and haemoglobin levels were highest in those with infectious colitis (mean of 33.4 g/L and 135.5g/L respectively) and lowest in patients with IBD (mean of 26.8 g/L and 108.5g/L respectively).

Conclusion: CT reported colitis was of infectious aetiology in 53.6% of patients, ischaemic in 18.1% and inflammatory in 4.3%. Laboratory results such as haemoglobin and albumin levels can be helpful in determining aetiology.

Despite CT features suggestive of colitis, 42.2% of endoscopic evaluation revealed no significant abnormality. CT findings of colitis should therefore be correlated with clinical history, stool results and endoscopic evaluation when determining the underlying aetiology.

FEASIBILITY OF DIRECT-VISION STENTING: A NOVEL STENT PLACEMENT TECHNIQUE FOR MALIGNANT COLORECTAL OBSTRUCTION USING A NEW THIN THERAPEUTIC SCOPE

Y. Sawai[1], T. Shimada[1], T. Yamagata[1], Y. Kanno[1], K. Korekawa[1], T. Shimizu[1], H. Sato[1], T. Ishida[1], Y. Eto[1], T. Numata[1], K. Ito[1]

Contact E-Mail Address: yosei.sawai@openhp.or.jp

Introduction: Endoscopic self-expandable metallic stent (SEMS) placement for malignant colonic obstruction is commonly performed using the through-the-scope (TTS) technique. However, strategies to reduce radiation exposure remain a clinical concern. We developed a novel technique, Direct-Vision Stenting (DVS), using a new thin therapeutic scope (Fujifilm EG-840TP: outer diameter, 7.9 mm; working channel, 3.2 mm) for malignant rectosigmoid obstructions [1].

After advancing the scope through the stricture, the stent is partially expanded under direct vision, then anchored and gradually released under endoscopic visualization while withdrawing the scope. This technique may minimize radiation exposure by eliminating the need for fluoroscopic confirmation of guidewire placement and contrast injection.

Aims & Methods: This study aimed to evaluate the feasibility of the DVS technique. From January 2024 to March 2025, SEMS placement for malignant rectosigmoid obstructions was initially attempted using the DVS technique. If DVS was unsuccessful, conversion to the conventional TTS technique (without direct visualization of the oral lumen or beginning of the stent expansion) was permitted. Ten consecutive patients were prospectively evaluated for technical success, adverse events, fluoroscopy time, and total procedure time (from scope arrival at the lesion to stent deployment).

Results: The median age was 81 years, and 4 patients were men. The obstruction was located in the rectosigmoid colon in 3 patients and the sigmoid colon in 7. Five procedures were performed for palliative purposes. The technical success rate of the DVS technique was 60%. All unsuccessful cases were resolved by conversion to the conventional TTS technique. Reasons for DVS failure included poor bowel preparation (n = 1), failure of scope advancement (n = 2), and severe colonic angulation (n = 1). No adverse events were observed, and all patients experienced symptomatic relief. Among successful DVS cases, median procedure time was 17 minutes, and fluoroscopy time was 4 minutes. In comparison, in 17 cases treated with the conventional TTS technique prior to the study period, the median procedure and fluoroscopy times were 15 and 11 minutes, respectively, suggesting a trend toward reduced fluoroscopy time with the DVS technique.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The DVS technique using EG-840TP achieved a 60% success rate for malignant colonic obstructions in the rectum or sigmoid colon and allowed safe conversion to the TTS technique when necessary. In appropriate cases, this approach may reduce fluoroscopy time and overall radiation exposure.

ILEOCAECAL STENTING IS SUCCESSFUL IN COLORECTAL CANCER PALLIATION AND AVOIDS STOMA IN OVER TWO THIRDS OF PATIENTS

D.H. Dewar[1], G. Walker[1], I. Mohamed[1]
[1]University Hospital Lewisham, Gastroenterology, London, United Kingdom

Contact E-Mail Address: daviddewar@nhs.net

Introduction: There is minimal data to support a recommendation to perform colonic stenting (SEMs) in the right colon, but particularly in malignancy in the region of the ileocaecal valve, where only small bowel dilatation results from obstruction. This scenario poses technical challenges in endoscopic access in unprepared proximal colon, and relating to the anatomy of the ileocaecal valve. One recent case series included 13 patients with reported success rate and equivalent outcomes to left-sided stents with median survival of 4 months, although a two-step procedure was described[1].

Aims & Methods: In our centre we attempt self-expanding metal stent insertion (SEMs) in cases of malignant ileocaecal obstruction, which constitutes ~9% of our overall SEMs caseload. We report our outcomes and, as an important metric for palliative patients, stoma-free survival in the context of colorectal cancer management.

We perform stenting using colonoscopy to access the stricture and fluoroscopy for wire and stent deployment, with both over the wire and through the scope techniques.

Results: 25 patients, median age 77 years, underwent intention to stent for colorectal malignancy at the ileocaecal junction, where stent deployment into the ileum would be necessary to overcome the obstruction. Clinical success with life-time avoidance of surgery or stoma was 68% without any adverse events from attempting SEMs. Median survival was 206 days, compared to 167 days in those where stenting was unsuccessful. This was not significantly different to median stoma-free survival of 272 days for all SEMs patients in our database.

One patient, after technically successful stent deployment, re-obstructed within 7 days and underwent surgery. There were no other early or late complications in either group. Reasons for technical failure in 6 cases was inability to pass a wire into the ileum, bowel preparation in 1 case, and failure to adequately resolve obstruction in the aforementioned patient.

Conclusion: Stenting malignant colonic obstruction of the ileocaecal region is more technically challenging but does not appear to disadvantage patients after an unsuccessful procedure. Stoma or surgery is avoided in 68% cases in intention to treat analysis of 25 patients and median survival of 206 days is equivalent to other colonic stent locations.

ALL-IN-ONE NOVEL DIAGNOSTIC SYSTEM FOR PELVIC FLOOR DISORDERS – RESULTS FROM FIRST IN HUMAN STUDY

Y. Rudnicki[1], Y. Ringel[2]
[1]Meir Medical Center, Surgery, Kefar Sava, Israel, [2]Meir Medical Center, Tel Aviv University, Division of Gastroenterology and Hepatology, Tel Aviv, Israel

Contact E-Mail Address: yaron217@gmail.com

Introduction: Accurate diagnosis of Pelvic Floor Disorders (PFD) requires multiple tests, including balloon expulsion, anorectal manometry, and defecography. Current diagnostic approaches have significant limitations: they require multiple visits to specialized clinics, are conducted in non-private and often embarrassing environments, and use non-physiologic (lying) positions.

As a result, they (a) provide fragmented, sometimes inaccurate, and difficult-to-integrate information, and (b) are inconvenient and distressing for patients, while time-consuming for providers and payers.

Aims & Methods: To develop a novel, comprehensive, accurate, all-in-one diagnostic system to replace current multi-test approaches.

We developed a disposable balloon and catheter system capable of simultaneously measuring rectal and anal pressures and anorectal angle. These physiological metrics are recorded during balloon expulsion in a physiologic seated position. Data are transmitted via Bluetooth to a nearby computer, enabling the test to be performed in a private toilet room. The system was tested for functionality, convenience, and safety, and compared with balloon expulsion (Mui Scientific) and high-resolution manometry (HRM, ManoScan™, Medtronic) in both lying and seated positions, using standardized protocols (London and IAPWG).

Results: The Ano-Rectal Diagnostic System (ARDiS) reliably measured rectal and anal pressures in both positions, with values comparable to standard HRM. ARDiS also enabled novel assessment of anorectal angle. These parameters were recorded simultaneously in real time during seated balloon expulsion.

Data transmission to a nearby laptop or office computer was seamless. The procedure was well tolerated, with no reported side effects. Patients preferred the private, seated testing environment.

Conclusion: The ARDiS system enables comprehensive, accurate, and simultaneous assessment of anorectal function in one convenient session. Designed for both hospitals and outpatient clinics, ARDiS streamlines the diagnostic process, improves patient compliance, and supports accurate diagnosis and personalized management of PFD. It may fundamentally transform clinical practice by replacing multiple fragmented tests with a single integrated solution.

PP0703

ENDOSCOPIC SUBMUCOSAL DISSECTION OF LARGE ANORECTAL AND LOW RECTAL ADENOMAS

V. Korpiak[1]
[1]Lisod Hospital of Israeli Oncology, Diagnostic and Interventional Endoscopy, Pluty, Ukraine

Contact E-Mail Address: korpyak@gmail.com

Introduction: Large rectal adenomas often spread to the upper part of the anal canal. In this study were retrospectively analyzed 13 of 40 rectal lesions, operated by endoscopic submucosal dissections in 2018-2025, which were localized in lower rectum. 7 lesions have spread on anal canal and 6 lesions were localized in lower rectum without spreading on anal canal.

The study compared the risk of intraprocedural bleeding, completeness of removal, duration of dissection, pain syndrome, and red blood cell indicators based on the size and location of the lesions.

Aims & Methods: A retrospective analysis was conducted on 40 Endoscopic Submucosal Dissections (ESD) of rectal lesions, all performed by a single operator at a single center. Two cases of NETs treated by ESD, two cases of synchronous colorectal locations resected in a single procedure, three ESD cases of recurrent adenomas following endoscopic or surgical treatment, two cases with deeply invasive carcinomas, and eighteen cases with rectal tumors without involvement of the lower rectum and anal canal were excluded. Seven ESD cases of anorectal lesions ranging from 20 to 170 mm in size, and six lower rectal lesions ranging from 30 to 80 cm were compared. Information about duration, location and size was taken from protocol of the operation and reviewed by photo and video fixation of procedures. Medical documentation was checked for red blood indicators and treatment of pain syndrome.

Additionally, a follow-up phone call for all patients will be conducted two weeks after ESD.

Results: All lesions were removed in a single block. Only one tumor was fragmentated during the extraction. Coagulation forceps was needed in 5 of 7 cases in anorectal ESD group and 4 of 6 cases between lower rectal lesions. Forceps were needed in all cases over 70 mm in size. Two cases of massive bleeding were documented in anorectal group: one intraprocedural bleeding and one delayed bleeding.

All patients in the low rectal group were discharged the day after ESD. In the anorectal group, four patients were discharged on the second, third, fourth, and fifth day following the procedure.

Patients in the anorectal group reported symptoms within two weeks after dissection, including pain, episodes of fever, and increased hair loss (in cases involving significant intraprocedural bleeding).

Conclusion: Endoscopic submucosal dissection in lower rectum and anal canal is an effective modality for treatment of large benign tumors. But such operation, especially in cases on anorectal lesions has high risk of massive intraprocedural and delayed bleeding, longer hospital staying and longer recovery after treatment.

Disclosure: Nothing to disclose.

PP0704

FEASIBILITY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE ANAL CANAL LESIONS

L. Wang[1,2], S.-B. Luo[1], H. Hu[1], Q.-L. Li[1], P.-H. Zhou[1]

Introduction: Endoscopic submucosal dissection (ESD) for the anal canal lesions (ACLs) is technically challenging because of the specific anatomical features of the anal canal. We aimed to evaluate the efficacy and safety of ESD for ACLs.

Aims & Methods: We retrospectively investigated 102 patients with ACLs who underwent ESD from August 2010 to August 2023. We collected and analyzed clinicopathological characteristics, procedure-related parameters, outcomes, and follow-up data.

Results: Of the 102 patients with ACLs (mean age 63 years, 46 men), ACLs were located above the dentate line (ADL) in 55 patients, and lesions involved the dentate line (IDL) in 47. The mean procedure duration was 37.0 min. The en bloc resection and en bloc with R0 resection rates were 94.1% and 88.2%, respectively. Adverse events (AEs) included two intraoperative bleeding, two delayed bleeding, and one febrile episode. Anal pain occurred in 5 patients. During a median follow-up of 37 months, local recurrence was revealed in 3 patients, and one had metastases.

Compared with the ADL group, the IDL group had significantly longer procedure duration, larger specimens, lower rates of En bloc with R0 resection, higher anal pain rate, and more AEs. When only adenomas/adenocarcinomas were included in the analysis, the two groups had no significant differences regarding recurrence-free, overall, and disease-specific survival.

Conclusion: The favorable short- and long-term outcomes indicate ESD is a safe, effective, and attractive therapeutic modality for ACLs. A multicenter and prospective study should be conducted to validate this technology.

THE EFFECT OF COLON PSEUDO-STERILIZATION ON DELAYED PERFORATION OF THE COLON AFTER THERMAL INJURY

T. Sakae[1], H. Maeda[1], F. Sasaki[1], N. Koyoshi[1], A. Tanaka[1], S. Kanmura[1]
[1]Kagoshima University Graduate School of Medical and Dental Sciences, Digestive and Lifestyle Diseases, Kagoshima, Japan

Contact E-Mail Address: tksak20@gmail.com

Introduction: Although delayed perforation is a rare complication of endoscopic resection of colonic lesions, the potentially fatal outcomes make this a significant risk. Using a rat model in which delayed colon perforation occurs 48 hours after thermal injury, we have demonstrated that the mechanism of delayed colonic perforation resembles the Jackson's burn model, which is a well-established model of skin thermal injury.

Based on our further discovery that bacterial infection played a role in delayed colonic perforation, we hypothesized that delayed colonic perforation would not occur in pseudo-germ-free rats.

Aims & Methods: The aim of this study is to evaluate the effect of pseudo-sterilization of the colon on delayed colonic perforation after thermal injury.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Eight rats were administered antibiotics (metronidazole, ampicillin, vancomycin, and neomycin) from day 1–5 to create a pseudo-germ-free group (n = 8). Eight further rats were administered sterilized water as a control group (n = 8). Fecal samples were collected on days 7–9 for spectrophotometric analysis of enzyme activity (β-glucuronidase, β-galactosidase, β-xylosidase).

Thermal injury was induced in the colon on day 7 in nine of the pseudo-germ-free group and nine of the control group using a hemostatic forceps through an endoscope. The colon was removed on day 9 and histological evaluation performed.

Results: The activity levels of β-glucuronidase, β-galactosidase, and β-xylosidase on day 7 were significantly reduced in the pseudo-germ-free group compared with the control group (0.012 vs. 0.090, p = 0.003; 0.045 vs. 0.168, p = 0.001; and 0.008 vs. 0.047, p = 0.002, respectively).

On day 9, activity levels of β-glucuronidase and β-xylosidase were significantly reduced in the pseudo-germ-free group compared with the control group (0.007 vs. 0.054, p = 0.000 and 0.015 vs. 0.042, p = 0.000, respectively).

These findings clearly demonstrate the successful achievement of pseudo-sterilization. The rate of delayed perforation and number of MPO-positive cells in the serosa were significantly lower in the pseudo-germ-free group than the control group (11.1% vs. 100%, p = 0.000 and 986.985 /mm^2 vs. 2303.782 /mm^2, p = 0.023, respectively).

Infiltration of Escherichia coli into the submucosal layer was only observed in the control group. Summary of results, tissue degeneration extending to the muscularis propria was observed in both groups after thermal injury; however, delayed colonic perforation was observed only in the control group, while it was significantly reduced in the pseudo-germ-free group.

Conclusion: Pseudo-germ-free conditions in the colon suppressed the occurrence of delayed colonic perforation. Bacterial infection may play a significant role in the expansion of the necrotic zone to the muscularis propria.

Disclosure: Nothing to disclose.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is now widely performed and has become a standard procedure even at core hospitals throughout regional areas. As a minimally invasive treatment, it is frequently applied to elderly patients; however, it is crucial to determine whether such treatment can be achieved safely and effectively across an entire region, especially considering the presence of comorbidities or frailty and the risks associated with limited life expectancy.

Aims & Methods: This study aimed to evaluate the safety and efficacy of colorectal ESD for elderly patients in the Hiroshima region. We used a prospective registry of all colorectal ESD cases performed between August 2013 and December 2018 at 11 core hospitals in the Hiroshima area. Patients were categorized into an elderly group (≥75 years) and a non-elderly group (<75 years). Short- and long-term outcomes were compared between the two groups. Patients with advanced colorectal cancer, inflammatory bowel disease, familial adenomatous polyposis, or missing data were excluded.

Results: A total of 2,226 patients with 2,332 lesions were included: 684 patients with 716 lesions in the elderly group and 1,542 patients with 1,616 lesions in the non-elderly group. Baseline characteristics (elderly/non-elderly) were as follows: proportion of male patients was 56%/61% (*P*=0.024), median age was 79/66 years (P<0.001), and prevalence of comorbidities was 54.4%/35.7% (*P*<0.001), including cardiovascular disease (17%/7%), cerebrovascular disease (10%/5%), diabetes (17%/13%), pulmonary disease (9%/4%), hepatic disease (5%/3%), and other organ cancers (18%/12%).

Antithrombotic drug use was 26%/11% (*P*<0.001). Regarding lesion characteristics, lesion location (right colon/left colon/rectum) was 52%/21%/28% vs. 53%/21%/27% (*P*=0.858), and median lesion size was 30 mm vs. 25 mm (*P*=0.066).

Procedural outcomes were as follows: en bloc/piecemeal/interrupted resection rates were 96%/3%/1% vs. 96%/3%/1% (P=0.998), median procedure time was 65 min vs. 60 min (P=0.025), intraoperative perforation occurred in 3%/3% (P=0.594), delayed bleeding in 2%/2% (P=0.816), delayed perforation in 0.3%/0.4% (*P*=0.903), and emergency surgery in 0.6%/0.4% (*P*=0.523). Histopathological diagnoses were adenoma/pTis/pT1a/pT1b in 36%/46%/7%/11% vs. 38%/44%/7%/11% (*P*=0.830), with poorly differen-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tiated histology of 0.1%/0.2% (*P*=0.652), lymphovascular invasion 6%/7% (*P*=0.543), tumor budding 3%/3% (*P*=0.765), positive vertical margin 8%/7% (*P*=0.161), and curative resection 81%/83% (*P*=0.484).

Among non-curatively resected lesions, additional surgical resection was performed in 42% (56/134) vs. 64% (181/283) (*P*<0.001), and lymph node metastasis was detected in 10% (6/56) vs. 12% (22/181). During a median follow-up of 62 vs. 64 months, disease-specific death occurred in 3 vs. 2 patients, and death due to other causes occurred in 93 vs. 69 patients.

The 5-year overall survival rate was 87.3% vs. 96.1% (*P*<0.001), and the 5-year disease-specific survival rate was 99.6% vs. 99.9% (*P*=0.114). Recurrence (local/distant) occurred in 1.3% (0.7%/0.6%) vs. 0.4% (0.2%/0.2%) (P=0.014), and the 5-year recurrence-free survival rate was 98.5% vs. 99.6% (*P*=0.010).

Conclusion: Although elderly patients had a higher baseline risk due to comorbidities and use of antithrombotic agents, colorectal ESD achieved favorable short- and long-term outcomes comparable to those in non-elderly patients. This study demonstrates that colorectal ESD was safely and effectively implemented throughout the Hiroshima region.

Disclosure: Nothing to disclose.

FULL THICKNESS COLONIC RESECTION USING THE FTRD OVESCO SYSTEM: A RETROSPECTIVE MONOCENTRIC STUDY

B. El Khoury[1], J.-B. Danset[1], C. Medlij[1], M. Harb[1], C. Souaid[1], D. Levoir[1], O. Marty[1], Y. Lebaleur[1]
[1]Paris Saint-Joseph & Marie-Lannelongue Hospitals, Gastroenterology Department, Paris, France

Contact E-Mail Address: ber_kh712@hotmail.com

Introduction: Full-thickness endoscopic resection (FTRD) using the Colonic FTRD Ovesco system represents a significant advancement in the management of complex colorectal lesions (1). This technique is particularly valuable for treating adenomatous recurrences occurring on post-resection scars smaller than 20 mm, especially in cases of failed submucosal lifting, offering an alternative to submucosal dissection (2).

Aims & Methods: This French retrospective monocentric study reports on the use of the colonic FTRD system, performed by two experienced operators, including the first clinician to perform this procedure in France. The study collected data on patient demographics, indications, resection sites, technical and clinical success rates, R0 resection rates, and procedure-related complications.

Results: Between 2016 and 2024, 87 patients (48 women and 39 men) with a median age of 66 years [32–87] were included. The primary indication was adenomatous recurrence after endoscopic mucosal resection (EMR) (69% of cases,n=60). Other indications included appendicular lesions in patient who had undergone appendicectomy (8%, n=7), suspected superficial submucosal carcinoma (7%, n=6), submucosal lesions (SML) (6%, n=5), and diverticular adenomatous lesions (3%, n=3). Most lesions (67%, n=58) were located in the right colon with a median estimated size before resection 18 mm [10–50 mm].

The overall technical success rate—defined as the complete execution of the resection—was 89%. There were 10 failures : failure to reach the site of recurrence (n=2), failure to achieve complete sectioning (n=5), and intraoperative complications (n=3), including three perforations. Two occurred while advancing through sigmoid diverticulosis , and one resulted from current diffusion into the colonic wall.

The R0 histological resection rate was 89% (n=71). 70% were adenomatous (low-grade dysplasia: n=36, high-grade dysplasia: n=13, serrated lesions without dysplasia: n=8). 8 cases (10%) were adenocarcinomas. Five cases involved submucosal tumors, including two neuroendocrine tumors. In 15% of cases (n=12), the resected specimen consisted solely of fibrotic scar tissue.

Early complications included 3 perforations, one of which was managed endoscopically, while the other two required immediate surgical intervention. Delayed complications were observed in 6% of cases, consisting of three episodes of post-procedural bleeding and two ileal perforations. The latter occurred on the suture line of the ileal reservoir in patients with a history of coloprotectomy and ileoanal anastomosis with a J-pouch for familial adenomatous polyposis.

This study confirms the efficacy of using the FTRD Ovesco system for lesions < 20 mm. The primary indications include post EMR recurrences with failed lifting, intra-appendicular adenomas, and submucosal tumors of the colon. Compared to submucosal dissection this technique offers a practical alternative, especially considering its lower morbidity, even with traction-assisted dissection. However, caution is advised in two specific situations, where alternative techniques may be preferable: severe diverticulosis with pseudo-stenosis and lesions developing on surgical anastomoses with a J-pouch reservoir.

Conclusion: The FTRD Ovesco system demonstrates excellent efficacy and safety for complex colonic lesions, including post-resection recurrences, submucosal tumors, and challenging locations such as appendicular sites. This technique represents an essential tool in expert endoscopic centers, offering a valuable alternative to other resection techniques with higher associated morbidity.

LEARNING CURVE FOR ENDOSCOPIC RETROGRADE APPENDICITIS THERAPY: FIRST CLINICAL EXPERIENCE

M. Shi[1], J. Zhang[1], D. Liu[1]
[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Contact E-Mail Address: mmiao9706@163.com

Introduction: Endoscopic Retrograde Appendicitis Therapy (ERAT) is an emerging minimally invasive technique for appendicitis treatment widely practiced in China. Clarifying the learning curve, especially among endoscopists with varying endoscopic experience including endoscopic retrograde cholangiopancreatography (ERCP) skills, is essential for its broader adoption.

Aims & Methods: This study aimed to determine the number of cases required to achieve procedural proficiency across different experience levels. In this multicenter retrospective study, 655 patients undergoing ERAT from October 2021 to March 2024 were analyzed. Nine trainees from three hospitals were categorized into Novice, Non-ERCP Experts, and ERCP Experts groups. Procedural data, technical and clinical success rates, procedure times, pain scores, recurrence, and hospital stay were evaluated. Learning curves were assessed via CUSUM analysis based on procedure time.

Results: Technical and clinical outcomes improved with increasing procedural experience in all groups. ERCP Experts achieved proficiency earliest (case 31st), followed by Non-ERCP Experts (case 55th), and Novices (case

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

59th). ERCP Experts demonstrated the shortest average procedure time (20.9 min) compared to Non-ERCP Experts (27.0 min) and Novices (31.4 min). Recurrence rates were significantly lower in ERCP Experts. Postoperative pain and hospital stay decreased with experience.

Conclusion: Endoscopists with extensive prior experience, particularly in ERCP, achieve proficiency in ERAT more quickly. Structured training tailored to experience levels is essential for global implementation of this technique.

Introduction: Colorectal endoscopic submucosal dissection (ESD) offers en bloc resection of large non-pedunculated polyps (LNPCPs) but requires advanced technical skills. ESGE recommends training with animal or ex vivo models before human procedures. POEM, a standardized third-space endoscopy technique, may provide transferable skills relevant to ESD.

Aims & Methods: This study assessed colorectal ESD outcomes performed by trainees with POEM experience but no model-based ESD training. All consecutive ESDs for LNPCPs (Jan 2022–Dec 2023) performed by four trainees with prior POEM experience (≥10 cases) were included. Trainees had observed ≥20 and assisted ≥5 ESDs, with no hands-on animal/ex vivo training. Procedures were supervised by experts. Outcomes included en bloc and R0 resection, dissection speed, and adverse events (AEs).

Results: A total of 48 LNPCPs (48.5 mm mean size, 1644 mm^2 mean area, 62.5% rectal lesions, 77.1% granular type, 79.2% Kudo III-IV) were resected. Overall, the en bloc resection rate was 100% (48/48), while the R0 resection rate was 93.8% (45/48). AEs occurred in 6.3% (3/48), particularly 2 intraprocedural perforations (2/48; 4.2%) and 1 delayed bleeding (1/48; 2.1%).

All AEs were managed endoscopically, resulting in an AE-related surgery rate of 0% (0/48). When comparing rectal and colonic lesions, en bloc and R0 resection rates were similar, with no statistically significant differences observed (100% vs. 100%, p=1.0; 93.3% vs. 94.4%, p=0.9); similarly, AEs rates and dissection speed showed no statistically significant differences (6.7% vs. 5.6%, p=0.9; 21.6 mm^2/min vs. 18.2 mm^2/min, p=0.4). Dissection speed improved 3.3× during training, though perforations clustered at case 7–9, suggesting overconfidence.

Conclusion: Proficiency in POEM shortens the learning curve for colorectal ESD, supporting its integration into structured ESD training pathways.

Introduction: Besides analgesia, opioids affect gastrointestinal (GI) motility, including decreased bowel peristalsis and delayed gastric emptying. Peripherally acting mu-opioid receptor antagonists, like naloxegol, are approved for treating opioid-induced constipation.

Aims & Methods: We aimed to evaluate the effects of naloxegol on opioid-induced lower GI tract dysfunction using magnetic resonance imaging (MRI) to assess changes in colonic volumes in healthy volunteers (HV).

In this double-blind, randomised, three-way crossover study, 15 HV complete three study visits, separated by ≥1 week washout, with administration of 25 mg naloxegol + 60 mg codeine, 60 mg codeine + placebo, or double placebo. During each visit, five abdominal MRI scans (each 20 min.) are obtained at 30 min intervals, at baseline, after drug intake, after a standardized 44 g oatmeal and 100 mL Nutridrink (313 kCal) meal, after a second drug dose, and after a bisacodyl 10 mg suppository administration. Colonic segmental volumes were quantified from all MRI scans using Entrolytics (Motilent, London, UK) in the ascending, transverse, descending, and rectosigmoid colon. We recorded the passage of stool during the study visit. Results are presented as medians with min. and max. P-values <0.05 are considered statistically significant. Adjusted p-values are used in case of post-hoc analysis.

Results: Interim analysis on 8 HVs (mean age 36±5y, 75% females) revealed that two subjects made stool on 2 mornings before the study visit. Four subjects passed stool in the double placebo group (2 postprandial, 2 post-bisacodyl), and 2 of them passed stool in the other 2 groups as well, around the same time. A significant scan x group effect was found for the whole colon volumes (p<0.05). More specifically, there was a significant difference in median ascending colon volumes between the scans (p=0.03), and especially in the double placebo group (Table).

	Naloxegol + codein	Codein + placebo	Double placebo	Naloxegol + codein	Codein + placebo	Double placebo
Scan1 (fasted, T0)	159 (118-202)	137 (92-247)	148 (122-226)	73 (63-92)	64 (48-105)	75 (53-98)
Scan2 (first drug combination, T50)	154 (119-238)	128 (92-252)	191 (122-239)	95 (71-110)	66 (48-91)	63 (51-101)
Scan3 (postprandial, T100)	172 (122-230)	160 (113-275)	151 (97-238)	74 (61-86)	59 (48-81)	74 (55-85)
Scan4 (Second drug dose, T150)	157 (103-242)	150 (77-254)	144 (94-207)	72 (53-92)	68 (56-80)	63 (41-85)
Scan5 (post bisacodyl, T185)	156 (63-213)	159 (103-233)	156 (106-204)	43 (26-62)	64 (37-86)	40 (27-53)
Adjusted p-value			0.025	0.049		0.04

Table 1. Results of ascending and descending colonic volumes (median with min and max, mL). Bold numbers represent significant differences within groups, between scans. Adjusted p-values are for differences within groups, between scans.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Although there was no significant difference in the median transverse colon volumes, bisacodyl led to a significant decrease in descending colon volume ($p<0.0001$), more specifically in the naloxegol+codein group and the double placebo group ($ps<0.05$), but not in the codein+placebo group. No significant differences in volumes of the rectosigmoid were detected.

Conclusion: Interim MRI analysis of 8 HVs suggests different colonic motility responses across groups and timepoints. Toilet visits were suppressed in both codeine groups. Different responses to drug and food intake were found in the ascending and descending colon between the naloxegol+codein and double placebo group on one hand compared to the codein+placebo group. Expansion and analysis of the full number of subjects will further clarify insights into the acute colonic responses to opioids and potential reversal by naloxegol.

Disclosure: Nothing to disclose.

PP0711

ENDOSCOPIC INTERMUSCULAR DISSECTION (EID) AS NEW PERSPECTIVE FOR T1 RECTAL CANCERS AND HIGH-RISK LESIONS IN THE RECTUM - FIRST COMPARISON OF 12 EID CASES TO 53 LESIONS WITH A HISTOLOGICAL RESULT OF CANCER OR HGIEN RESECTED BY SUBMUCOSAL DISSECTION (ESD)

J. Hochberger[1], M. Ho[2], C. Rickert[3]
[1]Charité University Medicine Berlin, Internal Medicine - Hepatology and Gastroenterology - Virchow Campus, Berlin, Germany, [2]Vivantes Klinikum im Friedrichshain, Gastroenterology, Berlin, Germany, [3]Vivantes Klinikum im Friedrichshain, Pathology, Berlin, Germany

Contact E-Mail Address: juehochber@mac.com

Introduction: In contrast to mucosal T1 rectal cancers with an R0 rate of up to 92% at centers, R0 resection may drop to 30% in case of deep sm infiltration due to thermal artefacts at the basal resection margin. TME often follows as completion surgery. Deep sm infiltration as isolated risk factor excluding L+, V+, G3 and Bd2-3 seems associated with a low risk of LN metastases of only 2.6%. Endoscopic Intermuscular Dissection (EID) is a new flexible endoscopic dissection technique with separation of the circumferential and longitudinal muscular layer. EID ideally provides a specimen incl. the entire submucosa and inner circumferential mp layer. 12 sequential EIDs were compared to 53 historical rectal ESDs with HGIEN or rectal cancer as hp. result.

Aims & Methods: Lesions with biopsy proven ADC or HGIEN of the rectum without endoscopic, EUS or clinical signs of deep local infiltration. 2 pat. included after neo-adjuvant RT/Ch th. 24 and 26 mo before with complete response and refusing definitive surgery. Both with local flat polyps (SSA (1) hyperplastic polyp / LGIEN adenoma (2).

Endoscopy, EUS, MRI, CT and rectal digital examination without suspicion of local malignant infiltration. Pts were offered to prospectively undergo EID after extensive informed consent within a prospective protocol. All procedures were carried out under gen. anesthesia by an exp. interv. endoscopist with >1000 ESDs. Results of EID were compared to a historical collective of 53 cases with rectal ESD and a histological result of rectal cancer or HGIEN (08-2018 to 12-2021).

Results: From 11-2023 to 09-2024, 12 EIDs were carried out in 12 pts (6 f/6 m; mean 63 y; 34-83y). 09/12 lower rectum, 1/12 middle, 1/12 lower and middle, 1/12 upper rectum. ‚En bloc' resection rate was 100%, R0 resection rate 89% for neoplasia / HGIEN. Histopathology: 3x ADC G2, 6x HGIEN, 3x LGIEN including both cases with neodajuvant RT/Ch. R0 resection was achieved in 2 of the 3 ADCs. Both with deep sm infiltration without any other risk factors. Tumor board: close clin. & imaging FU. In the 3rd ADC: TU infiltration of inner muscular layer (T2). Pat. underwent uneventful TME 10 d after EID. Clinical FU in all others. Length of hosp. stay 7.1 days. No serious major complications. All pts. closely followed with uneventful FU.

In the historical ESD group R0 resection was achieved in 100% of the HGIEN cases (45/45) but only in 3/8 lesions (37.5%) of cases with adenocarcinoma.

Conclusion: EID seems a new perspective for the endosc. resection of T1 rectal cancers and suspicious polyps in the rectum. More experience and a comparison to surgical local procedures (TAMIS etc.) is necessary for the final assessment of EID as new promising endoscopic technique.

Disclosure: Nothing to disclose.

Contact E-Mail Address: sevandrea96@gmail.com

Introduction: *Clostridioides difficile* infection (CDI) represents the predominant cause of nosocomial diarrhea, with its incidence having significantly increased over recent decades, both within hospital environments and in the community (1).

Fecal microbiota transplantation (FMT) is recognized as a highly effective and safe intervention for recurrent *Clostridioides difficile* infection (rCDI), and our center has been providing an FMT program since 2013.

This study aims to assess the efficacy and safety of FMT in patients with CDI since the start of our FMT program.

Aims & Methods: Our aim was to report outcomes of FMT in patients with rCDI treated at our centre from June 2013 to September 2024. CDI and rCDI were defined according to international guidelines. Data were collected on patient demographics and CDI characteristics, including disease severity, risk factors, and concomitant diseases. Enrolled patients were followed up to 90 days after the last FMT. Patients who were not assessed at both 8 weeks and 90 days post-procedure were excluded from the analysis, as were those for whom the required data were unavailable. The primary outcome was the clinical resolution of CDI at 8 weeks post-FMT, while secondary outcomes included the identification of risk factors for FMT failure, overall survival at 90 days, and the safety of FMT. Donor stools were screened following international guidelines. Prior to fecal infusion, all patients underwent a 3-day antibiotic pre-treatment regimen with oral vancomycin or fidaxomicin, as well as bowel cleansing. FMT procedures were conducted via colonoscopy using a single-donor solution of at least 50 grams of fresh or frozen feces. A sequential FMT approach was planned for patients with pseudomembranous colitis (PMC) until the disappearance of pseudomembranes, or for patients who experienced diarrhea with persistent C. difficile toxin in stool samples after the first FMT.

Results: A total of 374 patients were enrolled (231 female, mean age 71 years). One hundred and ten patients had severe CDI (29.4%), and 15 had severe complicated CDI (4%). Among them, 73 patients had pseudomembranous colitis (19.5%). The median number of CDI recurrences was 2. A

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sequential FMT protocol was performed in 92 patients (24.6%), resulting in a total of 524 FMT procedures. Among risk factors for CDI, the most frequent were hospitalization (245 patients – 65.5%), antibiotic use in the 30 days prior to infection (212 patients – 56.7%), chronic therapy with proton pump inhibitors (186 patients – 49.7%), and enticement (76 patients – 20.3%). The median Charlson Comorbidity Index (CCI) was 5.

Overall, 337 patients (90.1%) experienced resolution of CDI (97 with severe CDI and 11 with severe-complicated CDI). Twenty-five patients (6.6%) died within the follow-up period, with no deaths attributable to FMT. Severe adverse events occurred in 23, and 9 were potentially associated with FMT and/or failure to cure CDI.

Conclusion: In the experience of our large-volume FMT center, FMT was an highly effective and safe treatment for rCDI.

Introduction: Clostridioides difficile infection (CDI) is the most common cause of nosocomial diarrhoea, and during the last decades its incidence has significantly increased, not only in the hospital setting but also in the community (1).

CDI includes severe clinical pictures of disease. Fecal microbiota transplantation (FMT) is an established treatment for recurrent CDI, but its role in severe clinical pictures of CDI is still not well defined.

Aims & Methods: Our aim is to report efficacy and safety of FMT in a large cohort of patients with severe and severe-complicated CDI. We included patients with severe CDI treated with FMT at our center from June 2013 to August 2024. Severe and severe-complicated CDI were defined according to international guidelines. Data was collected on patient demographics, CDI characteristics, including disease severity, risk factors and concomitant diseases. Enrolled patients were followed up at 12 weeks after the last FMT.

The primary outcome was the clinical resolution of CDI at 8 weeks after FMT, while the secondary outcomes were the overall survival at 90 days and the safety of FMT. Donor stools were screened following international guidelines. Prior to fecal infusion, all patients underwent a 3-day antibiotic pre-treatment regimen with oral vancomycin or fidaxomicin, as well as bowel cleansing. FMT procedures were carried out by colonoscopy using a single-donor solution of at least 50 grams of fresh or frozen feces.

A sequential FMT approach was planned in patients with pseudomembranous colitis (PMC), until the disappearance of pseudomembranes, or in patients who experienced diarrhea after the initial FMT with a persistence of C. difficile toxin on stool samples.

Results: 125 patients were enrolled (60.8% female, mean age 71 years). One-hundred and ten patients had severe CDI (88%), 15 had severe complicated CDI (12%). Of them, 73 patients had pseudomembranous colitis (58.4%). The median number of CDI recurrences was 2. A sequential FMT protocol was performed in 62 patients (49.6%), for a total of 235 FMT procedures.

Regarding risk factors, the most frequent were hospitalization (107 patients – 85.6%), antibiotic use in the 30 days prior to infection (94 patients – 75.2%), chronic therapy with proton pump inhibitors (74 patients – 59.2%) and enticement (39 patients – 31.2%). The median Charlson Comorbidity Index (CCI) was 5.

Overall, 108 patients (86.4%) experienced resolution of CDI (97 with severe CDI and 11 with severe-complicated CDI). 18 patients (14.4%) died within the follow-up period. No deaths were attributable to FMT. Severe adverse events occurred in 11 (8.8%) patients and 6 were potentially associated with FMT and/or failure to cure CDI.

Conclusion: In our cohort of patients, FMT was a highly effective and safe treatment for severe and severe-complicated CDI.

PP0714

COMORBIDITIES AS A RISK FACTOR FOR RECURRENT *CLOSTRIDIOIDES DIFFICILE* INFECTION

R. Jänsch[1], N. Hipler[1], J. Prestel[1], P. Malfertheiner[2], A. Link[1]

[1]Otto-von-Guericke University of Magdeburg, Gastroenterology, Hepatology and Infectious Diseases, Magdeburg, Germany, [2]Ludwig- Maximilians-University Munich, Munich, Germany

Contact E-Mail Address: robert.jaensch@med.ovgu.de

Introduction: *Clostridioides difficile* infection (CDI) is among of the most common causes of nosocomial diarrhea with high morbidity and mortality. Recurrent and refractory disease courses in particular represent a special challenge in the management of these patients. The identification of patients at risk for recurrent courses could improve management, e.g. through the use of new and effective therapies in patients with CDI.

Aims & Methods: The aim of this study was to investigate the relationship between the presence of different comorbidities and the course of CDI.

In a retrospective, monocentric cohort study of a tertiary centre over a period of 10 years, patients with CDI-related hospitalizations were examined. The study included 336 patients with available information on comorbidities (diverticulosis, biliary diseases (cholecysto-, docholithiasis, cholecystitis, cholangitis or cholangiectasis) inflammatory bowel diseases (IBD), liver cirrhosis and malignancies) and the diagnosis of the recurrent CDI (rCDI) vs. non-recurrent course of CDI (nrCDI). Patients on dialysis or immunosuppressed patients were also considered as comorbid.

Results: Among 336 patients included in the study, 227 (67.6%) presented with at least one comorbidity. The most common were malignancy (30.4%), biliary diseases (19.4%), diverticulosis (15.8%), liver cirrhosis (14.3%), and inflammatory bowel disease (IBD, 8.9%). rCDI occurred more frequently in patients with diverticulosis and biliary disease. Diverticulosis was present in 24.4% of rCDI cases vs. 12.6% in nrCDI cases (OR 2.24, 95% CI 1.22–4.17). Biliary diseases were observed in 26.7% of rCDI vs. 16.7% of nrCDI patients (OR 1.82, 95% CI 1.01–3.26). No significant associations with rCDI were found for IBD (OR 0.66, 95% CI 0.27–1.65), malignancy (OR 1.13, 95% CI 0.67–1.88), or liver cirrhosis (OR 0.79, 95% CI 0.38–1.61).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These findings suggest diverticulosis and biliary disease may be independent risk factors for rCDI, whereas other common comorbidities are not significantly associated with recurrence. Structured assessment of risk conditions may help to select patients for tailored management to prevent rCDI disease course.
Disclosure: Nothing to disclose.

EXPLORING THE REALITY OF CLOSTRIDIOIDES DIFFICILE INFECTION: A FOUR-YEAR EXPERIENCE IN A TERTIARY HOSPITAL SETTING

M. Cristiano[1], N.P. Almeida[2,1], P. Narra Figueiredo[2,1]
[1]Unidade Local de Saúde de Coimbra, Gastroenterology Department, Coimbra, Portugal, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Contact E-Mail Address: margarida.cristiano@hotmail.com
Introduction: Clostridioides difficile infection (CDI) has become an increasingly significant concern due to population aging, widespread use of antibiotics and immunosuppression. In this study we explore the natural history of CDI, therapeutic approaches, and mortality in a hospital serving approximately 362,000 inhabitants.
Aims & Methods: We conducted a retrospective cohort study including consecutive patients with CDI requiring hospitalization between January-2020/December-2023. Data regarding risk factors, clinical presentation, antimicrobial therapy, and recurrence were collected.
Results: We identified 460 patients (31.8 cases/100,000 inhabitants/year; female sex - 52.6%; mean age-68.7±21.5 years; median Charlson Comorbidity Index (CCI)-3.1). Major risk factors: previous antibiotic therapy-76.3%; hospital admissions in the previous 3 months-46.4%; immunosuppressive therapy-34.1%; living in nursing homes-29.5%; known gastrointestinal conditions-6.2%. Previous CDI was present in 7.1% of the cases. The diagnosis was made through the C. diff Toxins A/B Assay in all cases except one. Severity of the disease: mild-6.8%; moderate-68.2%; severe-25%. The most frequent first-line therapy was oral vancomycin-79.5% (mean treatment duration-9.3±3.7 days), in second line, metronidazole (50.8%), and in third line, fidaxomicin and metronidazole (37.5% each). Most patients required only one course of antibiotics (80.2%), while 16.6% required two courses and 2.6% required three. Four patients were submitted to fecal transplant. The average length of hospital stay was 25.4±22.4 (range:1-151), with longer hospital stay in patients with known gastrointestinal conditions (Z=-3.566, p<0.05).
Mortality was high: intrahospitalar-15.9%; 30-days-14.9%; 6-months-8.3%, revealing an association with age and CCI (Z=-2.564; Z=-2.997, p<0.05), but not with immunosuppression. Recurrence at 6-months was 11.2% (1 recurrence-9.8%, 2-1.2%; 3-0.8%; 4-0.4%) and revealed an association with previous antibiotic therapy (χ^2=11.273, df=4, p=0.024).
Conclusion: CDI represents a significant issue, which has been on the rise due not only to demographic shifts but also to iatrogenic factors. Incidence and mortality are relevant, and healthcare professionals should prescribe antibiotics judiciously aiming CDI prevention and decreasing of recurrences.

Contact E-Mail Address: Fisentzos.F@hotmail.com
Introduction: *Clostridioides difficile* infection (CDI) is the leading cause of hospital-acquired diarrhoea and pseudomembranous colitis in Europe, with healthcare costs exceeding €3 billion annually. The disease is primarily driven by two potent toxins, TcdA and TcdB. However, the molecular mechanisms underpinning toxin-mediated disruption of intestinal barrier function remain incompletely understood.
This study investigated the role of fluid and ion exchange regulators in intestinal permeability during CDI, and their modulation by faecal microbiota transplantation (FMT).
Aims & Methods: C57BL/6 mice were infected with *C. difficile* and treated with or without FMT. Caecal tissues derived from infected, treated, and control mice were analysed via RT-qPCR for expression of aquaporins (AQP1, AQP4, AQP8, AQP11), carbonic anhydrases (CAI, CAII, CAIV), and ion transporters (ANO1, CLCA1, SGLT1, SLC9A3, SLC26A3, SCNN1A, SCNN1B, SCNN1G). Expression of selected genes was validated in colonic biopsies from CDI patients and controls.
Primary human colonic organoids were treated with TcdA and TcdB. AQP1, AQP11, CAI, and CAII were knocked down in Caco-2 cells using shRNAs, and barrier function was assessed via transepithelial electrical resistance (TEER) in response to TcdB.
Results: CDI significantly downregulated AQP1, AQP11, CAI, CAII, and CAIV expression in murine models, with partial restoration following FMT. Knockdown of AQP1 and CAII in Caco-2 cells impaired basal barrier function, with further deterioration upon TcdB exposure. AQP1 expression was directly suppressed by TcdB in primary human colonic organoids. Validation in human CDI colonic tissues confirmed reduced AQP1 and CAII expression.
Conclusion: AQP1 and CAII are key regulators of gut epithelial barrier integrity during CDI. Their downregulation by *C. difficile* contributes to increased intestinal permeability, a hallmark of disease pathogenesis. Restoration of their expression following FMT suggests a potential mechanism for its therapeutic efficacy. These findings identify AQP1 and CAII as promising targets for future therapeutic intervention to restore barrier function in CDI.
Disclosure: Nothing to disclose.

FIRST EXPERIENCES WITH THE USE OF VACUUM-STENT FOR TREATMENT OF ANASTOMOTIC LEAKAGE IN THE LOWER GI TRACT

A. Herner[1], S. Nennstiel[1], S. Baumeler[2], M. Ramser[1], M. Turina[1], P.R. Aepli[3], C. Schlag[1]
[1]University Hospital Zurich, Zürich, Switzerland, [2]KSSG, St. Gallen, Switzerland, [3]Luzerner Kantonsspital, Luzern, Switzerland

Contact E-Mail Address: alexander.herner@usz.ch

Introduction: Anastomotic leakage is a serious complication following colorectal surgery and is associated with early and long-term morbidity and mortality. Various endoscopic and surgical approaches have been established for management. A new therapeutic option involves the placement of a fully covered VACStent for the lower GI tract (36x80 mm, MICRO-Tech, Düsseldorf, Germany) which offers advantages such as completely covering the defect, continuous drainage, and facilitating stool passage simultaneously. Here we report our initial experiences with the VACStent in the lower GI tract for treatment of anastomotic leakage.

Aims & Methods: The fully covered VACStent (36x80 mm) was placed endoscopically under direct visualization. A continuous negative pressure between -75 and -125 mmHg was applied. The VACStent was flushed daily with 20 ml of saline to prevent adhesions of the open-pored sponge of the stent. Six hours before the stent extraction/exchange, the negative pressure was discontinued. The integrity of the leak closure was confirmed visually and via fluoroscopy.

Results: Between February and December 2024, we treated six patients with anastomotic leakage (rectal leakage n=4, sigmoid leakage n=2) using the VACStent. The leak was detected on the 6th ± 3 postoperative day. The leak was successfully sealed with the VACStent and one to fife exchanges were performed. However, anastomotic leakages larger than 10 mm (n=2) required pretreatment with an EndoSponge (B.Braun, Melsungen, Germany) for a duration of 5 to 10 days. The leak closure with the VACStent occurred after 20 ± 6 days, with inflammatory parameters decreasing by around 85 ± 12%. Four patients received a protective stoma. The distance of the leak from the anal canal averaged 8 ± 7 cm. Patients with leaks involving the anal canal required pain relief. One patient experienced point-shaped erosion bleeding in the anal canal, which was effectively treated with APC. In two patients, the VACStent therapy could be completed in an outpatient setting.

Conclusion: The lower GI VACStent represents a novel promising and effective endoscopic treatment option for colonic anastomotic defects.

Disclosure: Nothing to disclose.

EFFICACY OF OVER-THE-SCOPE CLIP IN PREVENTING REBLEEDING IN COLONIC DIVERTICULAR HEMORRHAGE

Y. Koseki[1], M. Azumi[2], M. Takeuchi[1]
[1]Nagaoka Red Cross Hospital, Department of Gastroenterology, Nagaoka, Japan, [2]Azumi Clinic, Gastroenterology, Niigata, Japan

Contact E-Mail Address: ycnrsmk@gmail.com

Introduction: Endoscopic hemostasis using clips is widely used as a safe and effective first-line treatment for colonic diverticular bleeding, but rebleeding after hemostasis remains a common issue. In recent years, the Over-the-Scope Clip (OTSC) has gained attention as a new endoscopic treatment device due to its stronger tissue grasping ability and potentially higher hemostatic effectiveness compared to conventional clips. However, clinical cases remain limited, and more evidence is needed. This study evaluates the outcomes of colonic diverticular bleeding treated with OTSC.

Aims & Methods: The purpose of this study was to compare conventional clip hemostasis and additional treatment with OTSC for colonic diverticular bleeding. The subjects were patients at our institution from April 2014 to April 2024 in whom the bleeding source was endoscopically identified and treated. Patients treated with clips alone were classified into the clip group, while those who underwent additional OTSC treatment at the same site after clip treatment to prevent rebleeding were classified into the OTSC group. The clip and OTSC groups included 65 and 11 patients, respectively.

There were no significant differences between the groups in terms of sex (female/male: 12/53 vs. 4/7), age (median: 64 [35-96] vs. 70 [53-84]), or anticoagulant use (14/65 vs. 3/11). Rebleeding was defined as the appearance of visible bloody stool after endoscopic treatment, and it was the primary endpoint.

Results: Rebleeding occurred in 33 of 65 cases in the clip group and 0 of 11 cases in the OTSC group, showing a significant difference in rebleeding rate (0% [0/11] vs. 50.0% [33/66]; P < 0.05). Multivariate analysis identified OTSC as an independent preventive factor for rebleeding (p = 0.001). No complications such as bowel perforation, diverticulitis (localized infection), or intestinal stenosis were observed in either group.

Furthermore, when comparing costs, including readmissions due to rebleeding, the average cost in the clip group (15 out of 66 cases readmitted) was €5897 ± 3907, with a median of €4302. In the OTSC group (0 readmissions), the average cost was €4580 ± 2143, with a median of €4284, indicating that OTSC treatment was not inferior in cost-effectiveness compared to clip treatment (p = 0.124).

Conclusion: Treatment using OTSC significantly reduced rebleeding compared to conventional clip treatment, demonstrating high safety and comparable cost-effectiveness, suggesting it is an effective treatment method.

Disclosure: Nothing to disclose.

Introduction: Lower gastrointestinal bleeding (LGIB) is a major medical emergency, and is associated with significant utilization of hospital resources, as well as considerable morbidity and mortality that increases with aging.

Aims & Methods: We aimed to describe patient characteristics, interventions and clinical outcomes of LGIB, and to define the impact of LGIB in elderly patients. This was a retrospective multinational cohort study which included adult patients consecutively presenting LGIB at 10 participating centers over a 12-month period. Data relevant to the initial LGIB episode and for up to 30 days afterwards were collected from patient medical records.

Results: Among the 950 patients included at this moment, 53.5% were men. Patients aged ≥ 65 years comprised 79,7% of the cohort (mean age 74 years); in this group, most comorbidities and use of antiplatelet/anticoagulant therapy were more frequent (p<0.001). 22.8% had a previous LGIB bleeding episode. On admission, hemodynamic instability was present in 12.6% (n=120) and almost 50% required red cell transfusion (n=442).

Most patients (81.6%) required hospitalization and 6% of them were admitted in an intensive care unit. The risk scores Oakland (p<0.001) and ABC (p=0.003) were higher in patients ≥65 years.

Colonoscopy was the most common investigation (63.8%). Hemostatic endoscopy therapy was performed in 20% of patients. Interventional radiology therapy and surgery were necessary in 7 (0.7%) and 24 (2.5%) patients, respectively. Diverticular bleeding (20.5%) was the most common cause of LGIB, followed by anorectal diseases (12.7%) and ischemic proctitis/colitis (10.3%). Median length of stay was 7 days, 12% of patients rebled during hospitalization and readmission with bleeding occurred in 8.4%. In-hospital mortality was 9% (n=86), with 74 deaths attributed to non-bleeding causes.

The multivariate analysis showed that older adults required hospitalization (p<0.001) and longer hospital stays (p<0.001) more frequently, while younger patients had higher ICU admission rates (p=0.018). Antiplatelet (p=0.034) or anticoagulant use (p=0.018), ABC score (p<0.001) and Charlson Comorbidity Index (CCI, p<0.001) were independently associated with in-hospital mortality. The CCI, higher in older patients, also correlated with need of blood transfusions (p=0.035), rebleeding (p=0.048), and re-hospitalization (p=0.027). Table 1 summarizes use of healthcare resources and clinical outcomes.

Country (mean age)	Portugal (74)	Greece (75)	Italy (72)	Ireland (72)	Spain (81)	France (71)
Mean days from admission to endoscopy	3	2	2	5	2	2
Hemostatic endoscopic therapy (%)	67 (20.1)	36 (23.7)	38 (25.3)	5 (3.5)	25 (25)	19 (29.7)
Interventional radiology therapy (%)	1 (0.3)	1 (0.7)	1 (0.6)	0 (0)	2 (2)	2 (3.1)
Hospitalization needed (%)	226 (68)	149 (98.0)	142 (89.3)	142 (100)	99 (99)	58 (90.1)
Days of hospitalization (median)	10	6	6	5	5	8
Intensive care unit admission (%)	19 (5.7)	4 (2.6)	1 (0.6)	1 (0.7)	4 (4)	20 (31.3)
Need of blood transfusions (%)	135 (40.2)	66 (43.4)	71 (43.9)	51 (35.9)	92 (92)	32 (50.0)
Surgery needed in the first 30 days (%)	8 (2.4)	3 (2.0)	4 (2.5)	2 (1.4)	6 (6)	1 (1.6)
In-hospital mortality (%)	30 (9.0)	12 (7.9)	3 (1.9)	21 (14.8)	15 (15)	5 (8.1)

Table 1.

Conclusion: This study analyzed the epidemiological data of LGIB in a large representative sample of the European population. Despite more accurate diagnostic/therapeutic methods and likely earlier detection, higher use of healthcare resources and worse outcomes have increased which may reflect a higher burden of comorbidities in a progressively aged population.

Besides higher prevalence, comorbidities and risk factors in elderly patients, the present study demonstrates that there are several differences in the management of LGIB patients across Europe.

BRAZILIAN TREND IN COLORECTAL CANCER MORTALITY - 2012 TO 2021

V.H. Dresch[1], G. Meine[1], C.R. Lazaretti[1], J. Nunes Greque Couto[1]
[1]Universidade FEEVALE, Novo Hamburgo, Brazil

Contact E-Mail Address: dreschvictor@gmail.com

Introduction: Colorectal cancer (CRC) is the second most common cancer and the third leading cause of cancer-related deaths in Brazil. High-income countries with organized screening programs have achieved significant reductions in CRC mortality in the last decades through early detection, polypectomy, and improved therapeutic interventions. Meanwhile, several low- and middle-income nations continue to experience rising incidence and persistently high mortality rates. Understanding CRC mor-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tality patterns across different age groups and sexes is essential to guide public health policies and optimize resource allocation for prevention, early detection, and treatment strategies.

Aims & Methods: This study aimed to analyze CRC mortality trends in Brazil from 2012 to 2021. We conducted a descriptive analysis of CRC-related deaths (ICD-10 codes C18, C19, and C20) using data from the Mortality Information System of the Unified Health System (DATASUS). The crude annual mortality rate (deaths per 100,000 inhabitants) was calculated by dividing the number of deaths by the estimated population provided by the Brazilian Institute of Geography and Statistics (IBGE).

We also analyzed annual mortality rates by age range and sex and calculated the average annual percent change (AAPC) in mortality rates to assess trends over time.

Results: A total of 175,159 CRC-related deaths were recorded in Brazil between 2012 and 2021, with 86,330 occurring in men and 88,829 in women. Among men, 27.4% of deaths occurred before age 60, 53.8% between ages 60 and 79, and 18.8% at age 80 or older, while among women, these proportions were 27.4%, 47.1%, and 25.5%, respectively. During this period, CRC mortality rates increased in both sexes, rising from 7.06 to 9.73 deaths per 100,000 men and from 7.29 to 9.16 deaths per 100,000 women.

Consequently, the male-to-female mortality ratio grew from 0.97 in 2012 to 1.06 in 2021, leading to a slight predominance of male gender at the end of the assessed period. The AAPC in mortality was higher in men than in women across all age groups, except for those aged 40–59 years (Table 1). Among younger individuals, those aged 30–39 years had a low absolute mortality rate (<0.4 deaths per 100,000 inhabitants) but showed the highest AAPC (3.5% per year in men and 2.8% per year in women). Among individuals within the recommended CRC screening age range, the highest AAPC was observed in those aged 60–69 years (2.1% per year in men and 1.7% per year in women).

Age range	AAPC in men	AAPC in women
20-29	2,8%	1,6%
30-39	3,5%	2,8%
40-49	0,7%	1,0%
50-59	1,1%	1,4%
60-69	2,1%	1,7%
70-79	1,2%	0,7%
80+	0,2%	0,1%

Table 1 –Average annual percent change in colorectal cancer mortality rate by sex and age range.
AAPC, average annual percent change.

Conclusion: The concerning rise in CRC mortality in Brazil underscores the need for enhanced public health strategies, including improved access to screening and better healthcare resources. Additionally, the greater increase in mortality rates from early-onset colorectal cancer, particularly between ages 20 and 39, warrants attention, with a focus on identifying high-risk individuals and addressing modifiable risk factors in the population.

Contact E-Mail Address: sandrabaaile@gmail.com

Introduction: The fecal immunochemical test (FIT) is the preferred non-endoscopic test in programmatic screening worldwide. Compared to other methods, FIT may be better accepted with higher participation rates, which may counteract its lower one-time sensitivities. We performed a systematic review and meta-analysis to ascertain participation patterns, participation rates, and FIT performance in organized multi-round FIT-based screening programs worldwide.

Aims & Methods: We performed a systematic search using Pubmed, Embase, and Cochrane databases. Participation patterns were categorized as “consistent screeners” (participation in 100% of rounds), “intermittent screeners” (including drop-outs, delayed entrants, and intermittent re-screeners), and “consistent non-screeners” (never screened). Data regarding positivity rates and detection rates for adenomas, advanced adenomas (AA), and colorectal cancer (CRC) across subsequent rounds were extracted and summary estimates were obtained. Yields were calculated for 2 populations: 1) Overall Population; 2) Consistent Screeners. A sensitivity analysis was performed including only programs with biennial screening with FIT cut-off of 20µg Hb/g feces.

Results: The literature search yielded 4,414 studies of which 25 were included. Across all studies, the fraction of the population behaving as “consistent screeners”, “consistent non-screeners”, and “intermittent screeners” was 47.1%, 30.3%, and 22.7%, respectively. For the overall population, FIT-positivity from the 1st through 4th rounds was 6.7%, 5.5%, 5.4%, and 5.3%; and detection rates were 5.8%, 3.3%, 2.9%, and 2.5% for CRC; 32.8%, 28.3%, 22.7% and 23% for AA; 48.6%, 46.2%, 48.7% and 44.6% for adenoma. For Consistent Screeners, FIT-positivity across studies from the 1st through 4th rounds was 6.4%, 4.8%, 4.1%, and 3.6%, respectively; and detection rates were 6.9%, 4.6%, 3.6%, and 3.1% for CRC; 38.7%, 30.6%, 28.2% and 24.9% for AA; 53.4%, 46.7%, 42.6% and 42.4% for adenoma. Similar trends were observed for biennial screening with FIT cut-off of 20µg Hb/g feces.

Conclusion: Organized multi-round FIT-based CRC screening programs achieve consistent participation in a minority of participants, and a sizeable proportion of the population do not initiate screening at all after multiple offers. Among those participating, FIT-positivity, and yields for CRC, AA, and adenoma are highest in the 1st round, but may stabilize at a clinically relevant steady state at rounds 3+.

COLORECTAL CANCER TRENDS IN LEBANON FROM 2001 TO 2024

A. Abou Rached[1], A. Samir Geagea[1], P. Haddad[2], F. Hsayan[1], S. Khairrallah[3]
[1]Lebanese University, Gastroenterology, Hadath, Lebanon, [2]Lebanese University, Internal Medicine, Hadath, Lebanon, [3]National Institute of Pathology, Hadath, Lebanon

Contact E-Mail Address: abourachedantoine@gmail.com

Introduction: Colorectal cancer (CRC) is the third most common cancer and second leading cause of cancer death worldwide, with over 1.9 million new cases and 0.9 million deaths in 2020. CRC is a major health burden globally and in the Middle East. Lebanon has reported one of the highest CRC incidences in the region, but detailed trends over the past two decades are not well characterized. This study analyzes the evolution of CRC epidemiology in Lebanon from 2001 to 2024.

Aims & Methods: We conducted a retrospective analysis of CRC cases spanning 24 years, grouped into five intervals: 2001–2005, 2006–2010, 2011–2015, 2016–2019, and 2020–2024. Data were obtained from National Institute of Pathology registry. Variables included patient age, sex, tumor anatomic location, and stage at diagnosis (TNM). Incidence trends were evaluated using national registry. Descriptive statistics and interval comparisons were performed to identify temporal changes in CRC incidence and characteristics.

Results: The annual CRC incidence in Lebanon rose markedly over the study period. Age-standardized incidence rates increased from 16.3 per 100,000 (males) and 13.0 (females) in 2005 to 23.2 and 20.2 by 2016. By 2018, 1109 new CRC cases were diagnosed, making it the second most common cancer among Lebanese women and fourth in men. The median age at diagnosis shifted upward (early 60s in 2001–2005 to 67 years in 2020–2024), although a growing proportion of cases appeared in younger adults (notably the 40–49 age group). The male-to-female ratio remained approximately 1:1 throughout (52% male in early 2000s vs 50% by early 2020s), indicating near parity. Tumor location distribution showed a predominance of left-sided cancers across all periods, but with a modest proximal shift over time. More than 70% of tumors were distal (left colon or rectum) in the early 2000s, whereas by 2020–2024 about 35% were right-sided. Stage at diagnosis remained advanced in most patients, though there was a small improvement: 20% of cases were early stage (I–II) in 2001–2005 versus 25% by 2020–2024. Despite this trend, a majority of patients in the latest interval still presented with regional or metastatic disease.

Conclusion: CRC incidence in Lebanon has increased substantially over the past two decades, reaching levels comparable to Western countries. The patient profile has evolved to a slightly older median age, with hints of an increase in younger-onset cases, and the male-to-female incidence gap has virtually disappeared. Tumors remain predominantly left-sided, although the proportion of right-sided cancers has risen, likely reflecting an aging population. While there are signs of earlier diagnosis (more Stage I–II cases in recent years), most CRCs are still detected at late stages. These findings underscore the need for strengthened national CRC screening and public health strategies – including awareness campaigns and earlier screening initiation – to curb incidence and improve early detection in Lebanon.

SCREENING INITIATION AGES BASED ON BODY MASS INDEX FOR EARLY DETECTION OF EARLY-ONSET COLORECTAL CANCER

T. Seum[1,2], M. Mandic[1,2], F. Safizadeh[1,2], M. Hoffmeister[1], H. Brenner[3]
[1]German Cancer Research Center (DKFZ), Clinical Epidemiology of Early Cancer Detection, Heidelberg, Germany, [2]Medical Faculty Heidelberg, Heidelberg University, Heidelberg, Germany, [3]German Cancer Research Center (DKFZ), Heidelberg, Germany

Contact E-Mail Address: teresa.seum@dkfz.de

Introduction: The rising incidence of early-onset colorectal cancer (eoCRC) in many countries underscores the need for risk-adapted screening approaches. Excess weight is a modifiable and increasingly prevalent risk factor for eoCRC. Given the routine collection of body mass index (BMI) in clinical settings, BMI-based screening initiation may offer a straightforward and scalable strategy to improve early detection.

Aims & Methods: We aimed to identify BMI-specific ages at which individuals reach 5-year cumulative colorectal cancer (CRC) risk levels equivalent to typical screening initiation ages (ages 45 and 50). Using GLOBOCAN 2022 data, we estimated country-specific 5-year cumulative CRC risks for adults aged 30–60 across six North American and European countries (United States, Canada, Germany, France, United Kingdom, and Italy).

As the average BMI at CRC screening initiation ages in the included countries falls within the overweight range (BMI 25–29.9 kg/m^2), we considered these age-specific risk estimates representative of individuals with overweight and reflective of average risk at screening initiation.

Age-specific risks for individuals with normal weight (BMI 18.5–24.9 kg/m^2) and obesity (BMI ≥30 kg/m^2) were derived by proportionally adjusting the risks of the overweight population using odds ratios and confidence intervals from a meta-analysis of 20 cohort studies. Risk-adapted starting ages were defined as the age at which individuals with normal weight or obesity reached the same 5-year CRC risk as those with overweight at age 45 or 50.

Results: Using individuals with overweight as the reference group for average-risk at screening initiation, those with obesity reached the same 5-year cumulative CRC risk observed at age 45 by age 41 (95% CI, 37-45) in Canada and the United States, and by age 42 (95% CIs, 38-45) in the included European countries.

Individuals with normal weight reached this risk level later, by age 47 (95% CI, 46-48) in Germany, the United Kingdom, and Italy and at age 48 (95% CIs, 47-50) in the United States, Canada, and France. For the age 50 benchmark, individuals with obesity reached comparable CRC risk between ages 46 (95% CIs, 41-51) and 47 (95% CI, 44-50) (see Table 1 for detailed results by country and BMI category).

	Risk-adapted starting age [years (95 % confidence interval)]			
	Benchmark: Age 45		Benchmark: Age 50	
	Obesity (BMI ≥30 kg/m²)	Normal weight (BMI 18.5–24.9 kg/m²)	Obesity (BMI ≥30 kg/m²)	Normal weight (BMI 18.5–24.9 kg/m²)
United States	41 (37-45)	48 (47-49)	46 (41-51)	56 (54-58)
Canada	41 (37-45)	48 (47-50)	46 (41-51)	54 (52-56)
Germany	42 (40-45)	47 (46-48)	47 (44-50)	54 (52-56)
France	42 (38-45)	48 (47-49)	46 (42-50)	53 (52-54)
United Kingdom	42 (39-45)	47 (46-48)	47 (44-50)	52 (51-54)
Italy	42 (39-45)	47 (46-48)	46 (43-50)	53 (52-54)

Table 1. Risk-adapted starting ages for colorectal cancer, by BMI category and country

Note. Reference BMI category: overweight, BMI 25–29.9 kg/m²

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These findings support incorporating BMI into CRC screening strategies to enable earlier detection in high-risk individuals. Current age-based guidelines may not fully capture elevated risk in individuals with excess weight, potentially delaying detection in this subgroup. BMI-based risk stratification may be a feasible, low-cost approach that could complement existing screening programs by enabling earlier initiation for those at higher risk. Future studies should evaluate its integration with other risk factors and its impact on healthcare systems.

Introduction: Sudden decrease of colonoscopy (CS) can be related with the status of colorectal cancer (CRC).

Aims & Methods: The aim of this study is to evaluate the status of CS, esophagogastroduodenoscopy (EGD), and CRC according to big national disasters such as the Great East Japan Earthquake in 2011 and the spread of COVID-19 infection in 2020. As a study population, we retrospectively used commercially anonymized health insurance claims data covering 4,601,921 patients ≥50 years old (Male 2,403,826/ Female 2,198,095) from January 2010 to December 2022.

Main outcome was a yearly analysis for 2010-2022 about 1. rate of CS and EGD, 2. rate of CRC and positive rate of CS for CRC, 3. number of surgeries for CRC. Additionally, a monthly analysis for those rates were performed to examinate the effect of the earthquake and COVID-19 infection.

Results: The rates of CS and EGD in 2010/2011/2012 were 3.10%/3.41%/3.42% and 6.94%/6.96%/7.00%. Those in 2019/2020/2021 were 5.20%/4.74%/5.37% and 7.47%/6.42%/6.84%. Deficiencies for CS and EGD were found not in 2011 (The earthquake) but were present in 2020 (COVID-19). The rates of CRC in 2019/2020/2021 were 0.20%/0.17%/0.19% with a decrease rate of 12.0% in 2020. The positive rate for CRC decreased from 6.74% in 2010 to 3.44% in 2022.

However, there were no definite changes in 2011 and 2020. The rate of surgery for CRC in 2019/2020/2021 were 0.087%/0.079%/0.087% and the deficiency was found in 2020.

Conclusion: The rates of CS and CRC decreased in 2020 due to COVID-19. On the other hand, they were not affected by the earthquake.

Introduction: A small-scale study modeled the cost-effectiveness of colorectal cancer (CRC) screening, incorporating productivity factors.

Aims & Methods: Using real-world data, this research aimed to evaluate the cost-utility of Taiwan's CRC screening program, factoring in potential lifetime productivity savings. After interlinkages among databases of the Taiwan Cancer Registry, National Mortality Registry, Taiwan CRC Screening Database, and National Health Insurance claim records, we estimated lifetime survival functions for stage-specific subcohorts using a rolling extrapolation algorithm after stratified by sex and age from 2004 to 2017. We multiplied the survival rates with average utility values of EQ-5D collected from CRC cases at National Cheng Kung University Hospital, to sum up quality-adjusted life expectancy (QALE).

We multiplied monthly medical costs and insured salaries by survival probabilities. We summed them over a lifetime for both the index and age-, sex-, and calendar-year matched reference subcohorts for comparison. Lifetime productivity (LP) was assessed only up to age 65. After weighing different stage distributions, we calculated the differences in total QALE loss, lifetime medical expenditures (LME), and LP between screened versus non-screened groups.

Finally, we estimated the costs associated with implementing fecal immunochemical testing (FIT) in Taiwan's CRC screening program. We applied a 3% annual discount and an exchange rate of 30.58 New Taiwan Dollars per U.S. Dollar (USD) at the end of 2018.

Results: We enrolled 77,169 CRC patients aged 50–74 in the study. After weighted by different stage distribution, a screen-detected CRC case would save 2.6 (95% CI, 2.3–2.9) and 2.5 (95% CI, 2.1–2.6) QALYs for women and men, respectively, accompanied by 7,000 USD (95% CI, 4,000–10,000) and 8,000 USD (95% CI, 6,000–10,000) in LME, and 17,000 USD (95% CI, 16,000–19,000) and 23,000 USD (95% CI, 22,000–25,000) in LP. For every 100,000 persons screened, the program spent 682,000 USD for FIT, 1,051,000 USD and 1,987,000 USD for men and women, respectively, for colonoscopy, 61,000 USD and 133,000 USD for surveillance colonoscopy and 9,000 USD and 15,000 USD for treating complications.

The incremental cost-utility ratio (ICUR) of 6,650 and 6,230 USD per QALY for women and men, respectively, would become 120 and -2970 USD per QALY after accounting for lifetime productivity.

Conclusion: After considering lifetime productivity, Taiwan's CRC screening program would be close to being cost-saving. Future corroboration studies are warranted.

Disclosure: Nothing to disclose.

Introduction: Colonoscopy is the gold standard for diagnosing colorectal cancer (CRC)[1], with post-colonoscopy colorectal cancer (PCCRC) defined by the World Endoscopy Organization (WEO) as CRC diagnosed between 6 and 48 months after a negative colonoscopy[2].

PCCRC rates vary from 2.5% to 7%[2], and the prognosis of PCCRC is generally poorer than that for CRC detected during colonoscopy[3].

Aims & Methods: To evaluate the risk factors associated with PCCRC in a major tertiary medical center.

We analyzed all consecutive colonoscopic procedures conducted between 2001 and 2019. Data was retrieved from electronic medical records (EMR) and cross-referenced with the Israeli Cancer Registry. We defined PCCRC based on the WEO criteria, and two physicians independently confirmed potential PCCRC cases to ensure data accuracy. Root-cause analysis of PCCRC was performed according to the WEO algorithm as follows:

A. Possible missed lesion, index examination adequate;

B. Possible missed lesion, index examination inadequate;

C. Detected lesion, not resected; or

D. Likely incomplete resection of previously identified lesion.

We then identified colonoscopy-detected CRCs (CDCRC, controls) and compared them to the PCCRC cases at a ratio of 1:3. We assessed patient median age at the procedure, gender, religion, family history of CRC, diabetes, smoking status, body mass index (BMI), obesity (defined in the EMR or BMI > 30) and endoscopic parameters: colonoscopy indication [surveillance (follow-up colonoscopy according to recommendations), abnormal imaging, patient symptoms], adequate Boston Bowel Preparation Scale (BBPS>6 and >2 in all segments), cecal intubation rate, diverticulosis, rectal retroflection, and tumor location.

Multivariable logistic regression assessed the association of multiple factors (endoscopy indications and obesity) with PCCRC, maintaining a 95% confidence interval (CI).

Results: Out of 54,154 colonoscopies, 2,339 patients were diagnosed with CRC, of which 49 (2.1%) were confirmed PCCRCs, while 2,157 (92.2%) were detected during colonoscopy. Of patients with PCCRC, 65.4% (n=32) had adequate BBPS, and 91.8% (n=45) cecal intubation was documented. The two most common reasons for PCCRC were category A (n=29, 59.1%), and category B (n=17, 34.6%), although in a lesser extent. We then compared PCCRC cases to 150 randomly selected CDCRC cases.

Significant differences in patient characteristics included BMI>30 (p = 0.041) and obesity (p=0.015). Statistically significant endoscopic factors included colonoscopy indication (p < 0.001), cecal intubation rate (p < 0.001), and tumor location (p < 0.001).

As expected, PCCRC was more commonly detected in the right colon (n=24, 55.8%) or rectum (n=12, 27.9%). Multivariable logistic regression revealed that patients with abnormal imaging as a colonoscopy indication had a lower risk for PCCRC (adjusted odds ratio (aOR) = 0.148, 95% CI: 0.033-0.455), while patients that performed colonoscopy for surveillance had a higher risk (aOR = 7.334, 95% CI: 2.355-25.963). Obesity was also a significant risk factor (aOR = 3.035, 95% CI: 1.326-7.035).

Conclusion: The most frequent cause of PCCRC across various patient populations and colonoscopy indications was a possible missed lesion. Factors such as patient obesity and undergoing colonoscopy for surveillance may increase the likelihood of PCCRC. These findings highlight the importance of physician awareness regarding PCCRC risks during colonoscopy.

Introduction: Colorectal Cancer (CRC) is the third most common cancer worldwide. Most CRCs arise from precursor adenomatous or serrated polyps. Various Screening programs to early detect and remove precancerous lesions before progression to malignancy results in significant decrease of colorectal cancer incidence in developed countries (1).

Guidelines recommend regular screening for adenomatous polyps and colorectal cancer for individuals above the age of 50 (1). However, in 2018 the American Cancer Society prompted substantial controversy by lowering their recommended age to begin from age 50 to age 45 (2).

According to recent studies, starting screening at age 40 or 45 can be cost effective.

According to international agency for research in cancer publication 2022 colorectal cancer is ranked the second between the top 3 cancers related deaths in United Arab Emirates.

Aims & Methods: The aim of this study to estimate the incidence of precancerous adenoma in average risk patients between 40 and 45 years of age.

Results: In this cohort of 703 individuals aged 40 to 45 years undergoing screening colonoscopy, adenomas were identified in 17.5% (n = 123) of patients. The mean age was similar between patients with and without adenomas (42.72 ± 1.84 vs. 42.53 ± 1.78 years; P = 0.293). Male sex was significantly associated with adenoma detection (51% vs. 39%; P = 0.014). No significant differences were observed between groups regarding BMI, alcohol use, diabetes, or family history of colorectal cancer. Smoking was

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significantly more prevalent among patients with adenomas (28% vs. 15%; P < 0.001) and remained an independent predictor on multivariate analysis (odds ratio [OR] 1.862; 95% confidence interval [CI], 1.078–3.217; P = 0.026). Other variables, including age, sex, BMI, alcohol intake, diabetes, and family history, were not independently associated with adenoma presence. The number needed to scope (NNS) to detect one adenoma was estimated at 5.7.

Conclusion: In conclusion, suggesting a non-negligible burden of colorectal neoplasia in individuals younger than 45 years. Early screening strategies, particularly targeted at high-risk individuals, may be warranted. Further multicenter studies with larger sample sizes are needed to confirm these findings and inform guideline recommendations for screening initiation age.

RISK OF SECONDARY MALIGNANCIES FOLLOWING APPENDICEAL CANCER: A SEER-BASED ANALYSIS

E. Hasanin[1], H. Khelifa[2]
[1]University of Tripoli, Faculty of Medicine, Tripoli, Libya, [2]Faculty of Medicine University of Oran 1 Ahmed Ben Bella, Oran, Algeria

Contact E-Mail Address: hamzakhelifa180@gmail.com

Introduction: Appendiceal tumors are considered to be a relatively rare tumor of the gastrointestinal tract, and the prognosis is unclear. The development of the small intestine, colon, peritoneum, omentum, and mesentery as second primary malignancies (SPMs) following appendiceal tumors is rarely mentioned in the literature. No studies discussed the association between small intestine, colon, peritoneum, omentum, and mesentery SPMs and appendiceal cancer.

Aims & Methods: The purpose of this study was to evaluate the risk of small intestine, colon, peritoneum, omentum, and mesentery SPMs following appendiceal cancer .

The Surveillance Epidemiology and End Result (SEER) database was used to obtain data of patients diagnosed with appendiceal cancer from 1975 to 2022. We used the MP-SIR session with multiple outcome analysis, and the event was defined as small intestine, colon, peritoneum, omentum, and mesentery. Excess absolute risk (EAR) was measured per 10,000. The standardized incidence ratio (SIR) was computed as observed/expected (O/E) with a 95% confidence interval (CI).

Results: Among 7723 appendiceal cancer patients, SIRs for second primary malignancies were significantly elevated over all time intervals, with small intestine cancer having an O/E of 20.38 (P<0.05, EAR=8.37, 95% CI: 6.57–47.55) for 2–11 months, 11.58 (P<0.05, EAR=4.86, 95% CI: 5.54–21.30) for 12–59 months, 13.89 (P<0.05, EAR=6.90, 95% CI: 6.34–26.37) for 60–119 months, and 3.81 (P<0.05, EAR=1.84, 95% CI: 1.02–9.75) for ≥120 months, colon cancer with an O/E of 3.34 (P<0.05, EAR=13.58, 95% CI: 1.67–5.98) for 2–11 months, 2.31 (P<0.05, EAR=7.84, 95% CI: 1.51–3.38) for 12–59 months, and 1.99 (P<0.05, EAR=7.00, 95% CI: 1.16–3.19) for 60–119 months, and peritoneum, omentum, and mesentery malignancies with an O/E of 11.55 (P<0.05, EAR=0.97, 95% CI: 1.30–41.70) for 12–59 months, 15.69 (P<0.05, EAR=1.55, 95% CI: 1.76–56.66) for 60–119 months, and overall cumulative O/E values of 9.97 (P<0.05, EAR=4.97, 95% CI: 6.63–14.42) for small intestine, 1.77 (P<0.05, EAR=5.45, 95% CI: 1.37–2.25) for colon, and 6.41 (P<0.05, EAR=0.64, 95% CI: 1.72–16.40) for per.

Conclusion: Appendiceal cancer patients are at significantly higher risk for second primary malignancies, primarily involving the small intestine, colon, and peritoneal-associated sites. The risk is highest within the initial 10 years after diagnosis, supporting the need for scrupulous long-term follow-up in these individuals.

ADENOMA INCIDENCE TRENDS BY GENOTYPE IN LYNCH SYNDROME: A RETROSPECTIVE COHORT STUDY OF 318 MD ANDERSON CANCER CENTER PATIENTS

A. Lincoln[1], S. Thirumurthi[1], E. Vilar-Sanchez[1], N.Y.-Q. You[1], P. Lum[1], Z. Li[1], W. Qiao[1], P. Lynch[1], L. Ricciardiello[1]
[1]MD Anderson Cancer Center, Gastroenterology, Hepatology and Nutrition, Houston, United States of America

Contact E-Mail Address: lricciardiello@mdanderson.org

Introduction: Lynch Syndrome (LS), the most common hereditary colorectal cancer (CRC) syndrome, is associated with increased adenoma and carcinoma risks. Colonoscopy surveillance recommendations generally consider MMR gene-specific risk but remain largely standardized in terms of surveillance intensity and frequency. However, accumulating evidence suggests that genotype-specific differences in neoplasia risk may warrant more tailored approaches.

Aims & Methods: This study evaluated trends in adenoma and CRC incidence across surveillance visits stratified by genotype among LS patients. We analyzed 318 LS patients with pathogenic variants in *MLH1, MSH2, MSH6, PMS2 or EPCAM* each with ≥2 surveillance colonoscopies between 2015–2025 at MD Anderson Cancer Center in Texas, USA. Individuals with prior colorectal surgery, inflammatory bowel disease, incomplete colonoscopy, or sigmoidoscopy-only exams were excluded. Adenoma (tubular, tubulovillous [TVA], SSA) and advanced neoplasia (advanced adenoma or CRC) rates were assessed over three follow-up visits. Statistical comparisons used Kruskal-Wallis and Fisher's exact tests (α=0.05).

Results: Among 205 patients with follow-up (median age 43.4, median follow-up 1089 days), tubular adenomas (TA) were observed in 58.8%, sessile serrated adenomas (SSA) in 16.2%, and advanced neoplasia (AN) in 7.8%. Five CRCs (2.4%) were identified overall. *MSH2/EPCAM* carriers (n=79) had the highest neoplasia burden, with TA in 57.0%, SSA in 20.3%, and 3 of 5 CRCs. *MLH1* carriers (n=50) had TA in 43.4%, SSA in 2.0%, and 2 CRCs (4.0%). *PMS2* (n=37) had the lowest burden (TA 21.6%, SSA 5.4%) and no CRCs. While per-visit incidence trends were not statistically significant, total adenoma count across genotypes differed significantly (p<0.05). Additionally, TA and TVA incidence at first follow-up varied significantly by genotype (p = 0.036 and 0.037, respectively).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Genotype	n (%)	TA (%)	SSA (%)	AN (%)	CRC (%)
MLH1	50 (24.4)	43.4	2.0	6.0	4.0
MSH2/EPCAM	79 (38.5)	57.0	20.3	5.1	3.8
MSH6	39 (19.0)	38.5	12.8	10.3	0.0
PMS2	37 (18.0)	21.6	5.4	2.7	0.0

Table: Neoplasia Outcomes by LS Genotype (n = patients with ≥1 follow-up).

Conclusion: These findings highlight important genotype-specific differences in cumulative adenoma and CRC burden among LS carriers. While *MSH2/EPCAM* and *MLH1* carriers exhibited the highest neoplasia rates, *PMS2* carriers demonstrated consistently low lesion and cancer incidence. These results support the need for genotype-based surveillance strategies to reduce unnecessary procedures while preserving cancer prevention.

Introduction: Colorectal cancer (CRC) remains a major cause of mortality and morbidity worldwide. Projected increases in CRC cases pose a significant challenge to the capacity of colonoscopy programs. Referrals for symptomatic colonoscopy exceed capacity in Ireland and most European nations. Fecal Immunochemical Test (FIT) with a lower cut-off (50ng/ml) has been proposed as a tool to aid triage of referrals which do not meet criteria for urgent colonoscopy, potentially allowing colonoscopy to be avoided.

Aims & Methods: The aim of this study was to evaluate FIT testing outcomes when combined with an endoscopy nurse delivered clinical triage and evaluate suitability as a 'rule out' test for serious gastrointestinal pathology.

This multi-centre study included symptomatic patients from sixteen hospitals across Ireland who were referred for colonoscopy from 2023-2024. All patients received 'FIT testing at the front door'. Using an advanced endoscopy nurse triage approach, assessing patient clinical characteristics and FIT result (positive result determined as FIT≥50ng/mL), patients were triaged into urgent colonoscopy or remained on the routine (P2) colonoscopy list.

Among 7,808 patients sent for FIT testing, 408 were excluded on the basis of missing FIT results (n = 407) or incomplete data (n = 1). The remaining 7,400 patients were included in an analysis assessing FIT positivity rates (FIT≥50 ng/mL) as well as factors associated with positive results. A subset of 1,815 patients from five hospitals, who had lower endoscopy outcomes available, were further analysed to determine frequencies of endoscopy findings (ex: normal, CRC, and IBD) and to evaluate the sensitivity, specificity and negative predictive value of FIT-centered endoscopy nurse clinical triage. IBM SPSS Statistics 29.0.1.0 was used for statistical analysis.

Results: Of 7,400 patients who underwent FIT testing across sixteen sites, 16.4% (n=1,215) had a positive result (FIT≥50ng/mL). Multivariate analysis showed that increased age (OR = 1.029; 95% CI = 1.025-1.033; p-value<0.001) and male sex (OR = 1.44; 95% CI = 1.273-1.63; p-value<0.001) were significantly associated with positive FIT results.

At five sites, 1,815 patients who underwent FIT testing were referred for colonoscopy. At these sites, 79.0% (n=1,433) had a FIT<50ng/mL of whom 0.14% (n=2) had CRC and 1.5% (n=21) had significant findings at colonoscopy (ex: CRC or IBD). In contrast, 21.0% (n=382) had a FIT≥50ng/mL of whom 6.8% (n=26) had CRC and 19.1% (n=73) had significant findings at colonoscopy (ex: CRC or IBD).

The proportion of patients with CRC was significantly greater when FIT≥50ng/mL compared to FIT<50ng/mL (Fisher's Exact Test, p-value <0.001). The sensitivity, specificity, and negative predictive value of FIT≥50ng/mL for CRC at subsequent colonoscopy is 92.9% (95%CI=75.0-98.8%), 80.1% (95%CI=78.1-81.9%), and 99.9% (95%CI=99.4-99.9%), respectively.

Conclusion: FIT testing is useful in low risk symptomatic patients referred for colonoscopy and when combined with enhanced nurse led clinical triage has a very good negative predictive value for serious gastrointestinal pathology.

Contact E-Mail Address: fguarner@telefonica.net

Introduction: *Fusobacterium nucleatum* (*Fn*) and other species typical of the oral cavity are implicated in colorectal oncogenesis. The pathogenesis of serrated polyposis syndrome (SPS), the most common polyposis syndrome, remains unknown, and to date, the oral and gut microbiota of these patients has not been characterized.

Aims & Methods: The primary objective of this study was to describe and compare the composition of the oral and gut microbiota in individuals with SPS versus individuals without polyps, with sporadic serrated polyps, and with adenomas.

A prospective, observational, and bicentric study was conducted. Clinical and endoscopic data were collected, along with information obtained from a questionnaire on diet and dental health. Additionally, saliva and stool samples were obtained from 126 individuals divided into four groups: SPS (n=32), serrated (n=30), adenoma (n=32), and control (n=32). The microbiota was analyzed using 16S rRNA amplicon sequencing, and qPCR was performed for the detection of *Fn*.

Results: The main clinical, dietary, and dental health characteristics of the groups are presented in Table 1. Regarding the oral microbiota, no differences were observed in alpha diversity (species variety) among the groups.

However, the composition of the oral microbiota in the SPS group showed significant differences compared to the other groups, as evidenced by a greater unweighted UniFrac distance (differences in bacterial taxonomy) (p<0.001). In the gut microbiota, the adenoma group exhibited lower species richness than the control group, according to the Chao1 index (p=0.03), while no differences were found in the other groups.

Statistically significant differences in beta diversity, measured using unweighted UniFrac distance, were observed between the SPS group and the adenoma and control groups (p<0.001).

Regarding taxonomy, *Porphyromonas gingivalis*, an oral bacterium associated with colorectal cancer (CRC) development and progression, showed higher oral abundance in the SPS group compared to the control and adenoma groups (p<0.05; FDR p=0.104). *Treponema denticola* and *Prevotella intermedia*, two oral bacteria related to CRC, were more abundant in the SPS group than in the control group (p<0.05; FDR p=0.09).

Additionally, *Peptoanaerobacter stomatis*, an oral bacterium linked to CRC via the serrated pathway, was more prevalent in the SPS group compared to the serrated and adenoma groups (p<0.05; FDR p=0.26).

No differences in the abundance of *Fn* were found among the groups, either in saliva or stool samples.

Conclusion: The oral and gut microbiota of individuals with SPS exhibit a distinct bacterial composition compared to individuals without polyps and those with adenomas. Furthermore, certain oral bacteria associated with colorectal carcinogenesis are increased in SPS patients.

Disclosure: Nothing to disclose.

Introduction: Lipid metabolism dysregulation plays a crucial role in colorectal cancer (CRC) progression. Our perivious study found that upregulation of Slc26a9 promotes colorectal tumorigenesis (Zhang M, *et al.* Cell Death Discov. 2024). This study investigates the role of Slc26a9 in regulating lipid metabolism through the RRBP1-HSPA5 axis in CRC.

Aims & Methods: In this study, we assessed the expression of Slc26a9 in mouse colorectal cancer tissues using immunohistochemistry and immunofluorescence (IF). Slc26a9-interacting proteins in Colo201 cells, such as RRBP1, were identified through immunoprecipitation followed by mass spectrometry (IP-MS). Bioinformatic analysis of the TCGA and GEO databases was performed to evaluate the correlation between Slc26a9 and RRBP1 expression and their clinical significance. Protein interaction sites were predicted using Protein-Protein Docking.

Furthermore, the effects of Slc26a9 overexpression on mitochondrial metabolism, lipid metabolism, the RRBP1-HSPA5 pathway, and endoplasmic reticulum (ER) stress were investigated using Oil Red O staining, Nile Red staining, qRT-PCR, Western blotting (WB), co-immunoprecipitation (co-IP), and IF.

Results: In this study, we employed the widely recognized AOM/DSS protocol to establish a colorectal cancer model in C57BL/6J mice. We observed a significant upregulation of Slc26a9 in colorectal cancer tissues compared to adjacent non-cancerous tissues, consistent with our previous findings in human colorectal cancer samples (Zhang M, *et al.* Cell Death Discov. 2024).

To investigate the precise molecular mechanisms by which Slc26a9 regulates the development of CRC, we performed IP-MS to identify Slc26a9-interacting proteins in Colo201 cells. RRBP1 was found to have the highest

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

binding affinity with Slc26a9 and has been shown to localize at mitochondria–ER contact sites, where it plays a role in regulating organelle interactions. Moreover, GO and KEGG enrichment analyses indicated that Slc26a9 is associated with lipid metabolism in CRC cells. Overexpression of Slc26a9 also promoted endoplasmic reticulum stress, mitochondrial energy metabolism, and lipid accumulation in Colo201 cells.

Moreover, Slc26a9 enhanced the expression of markers related to endoplasmic reticulum stress (PERK-ATF4, IRE1α-XBP1, and ATF6), mitochondrial metabolism (Mitofilin, MFN1, and COXIV), and lipid metabolism (FASN, ACC, and SCD1). Moreover, Slc26a9 upregulation also enhanced the expression of the endoplasmic reticulum stress–related signaling pathway RRBP1/HSPA5.

Protein-protein docking analysis revealed the formation of multiple hydrogen bonds between Slc26a9 and RRBP1, indicating a high degree of structural complementarity and strong binding affinity between the two proteins. Co-IP and IF experiments demonstrated that Slc26a9 interacts with RRBP1 and co-localizes with it.

In addition, bioinformatics analysis of GEO dataset (GSE39582) showed a positive correlation between Slc26a9 and RRBP1 expression in human CRC tissues, with their co-high expression predicting poor overall survival.

Conclusion: These findings highlight that Slc26a9 interacts with RRBP1 to activate the HSPA5-mediated ER stress response, driving mitochondrial metabolism-lipid metabolic reprogramming and promoting CRC progression. Slc26a9 and RRBP1 may serve as potential prognostic biomarkers, and their axis represents a novel therapeutic target for CRC.

Introduction: The number of colorectal cancer (CRC) cases and deaths in Japan is on the increase and is higher than in Western countries. In Europe and US, the increase in CRC among young people is a problem, in contrast to the decreasing trend among middle-aged and older people. In Japan, there is concern about the increase in CRC, and to prevent colorectal tumors (CRTs) in young people aged 40 years or younger, it is necessary to urgently understand the current situation and to carry out efficient screening by clarifying risk factors, together with CRC screening using fecal immunochemical test (FIT).

Aims & Methods: In this study, we conducted a retrospective study of the clinicopathological characteristics and risk factors of 303 CRTs diagnosed by colonoscopy (CS) at our institution in patients aged 40 years or younger.

1. In the CRT group, the pathological diagnosis and location were investigated.
2. The examination period was divided into early (2012-2017) and late (2018-2024), and the frequency of tumor detection was examined.
3. The association of various background factors (family history of CRC, body mass index (BMI), hypertension (HT), dyslipidemia, diabetes, alcohol drinking, smoking and exercise habits) as risk factors for tumors was statistically investigated. SPSS29 (IBM) was used for statistical analysis.

Results: (1) CRTs included 237 adenomas, 38 serrated adenomas and 28 colorectal carcinomas (24 intra-mucosal carcinomas, 3 invasive carcinomas and 1 neuroendocrine tumor). Solitary tumors were 63.7% and 71.3% (89.3% for CRC) were located in the left colon.

(2) The frequency of tumor detection was markedly increased: 2.04% in early male (M)/ 20.2% in late M and 0.29% in early female (F)/ 16.4% in late F.

(3) Risk factors: overall risk factors for CRTs [odds ratio (OR) 95% confidence interval (CI)] were 2.998 (1.244-7.176) for family history of CRC, 1.786 (1.007-3.168) for BMI>30, 3.875 (1.082-13.878) for BMI>35, 2.456 (1.337-4.511) for HT, 1.596 (1.153-2.210) for alcohol drinking, 2.111 (1.306-3.412) for >20g/day alcohol drinking, 1.635 (1.170-2.285) for smoking.

In M, risk factors for CRTs were family history of CRC 2.933 (1.036-8.300), HT 2.240 (1.124-4.463), alcohol drinking 1.760 (1.182-2.619, >20 g/day alcohol drinking 2.409 (1.402-4.138)) and in F, smoking 2.724 (1.223-6.070).

In Logistic Regression, which added age and sex to the factors that were significant in univariate analysis, the risk factors for CRTs were: family history of CRC 3.542 (1.376-9.119), HT 2.032 (1.096-4.147), alcohol drinking 1.524 (1.076-2.159), smoking 1.665 (1.148-2.415).

Conclusion: The frequency of CRTs in young people aged 40 years or younger is increasing in Japan. Family history of CRC, HT, alcohol drinking and smoking are risk factors, and along with FIT, efficient screening based on these background factors is needed.

PP0734

THE CCL7–SOX4–CD44 AXIS ESTABLISHES A TRANSCRIPTIONAL PROGRAM TO PROMOTE COLORECTAL CANCER METASTASIS

F. Du[1], X. Guo[1]

[1]Capital Medical University, BeiJing, China

Contact E-Mail Address: gxs0220@163.com

Introduction: Metastasis is the leading cause of poor prognosis and high mortality in colorectal cancer (CRC). Chemokines play multifaceted roles in cancer immunity and progression. CCL7 is upregulated in CRC, but how CCL7 regulates CRC metastasis at the molecular level remains unclear.

Aims & Methods: In this study, we investigate the regulatory mechanisms and clinical significance of CCL7-mediated CRC metastasis.Immunohistochemistry (IHC) assay was performed to detect the expression of CCL7 and SOX4 in CRC tissue, moreover, the correlation between their expression and tumor distant metastasis, survival, and prognosis was analyzed. To explore their impact on CRC migration, invasion and metastasis, functional experiments and animal experiments were performed in vitro and in vivo, respectively. Gene expression changes were studied by real-time quantitative PCR (qRT–PCR), Western Blot (WB) and RNA-seq analysis. Chromatin Immunoprecipitation sequencing (ChIP-seq), luciferase reporter assay and Electrophoretic Mobility Shift assay (EMSA) were implemented to explore the mechanisms.

Results: Two clinical cohorts showed that CCL7 and SOX4 were upregulated in CRC tissues and correlated with lymphatic metastasis, distant metastasis, and poor prognosis. Functionally, CCL7 and SOX4 promoted CRC

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cell proliferation, invasion and metastasis in vitro and in vivo, respectively. Rescue assays revealed SOX4 as a downstream molecule involved in CCL7-mediated CRC metastasis. Through binding to the promoter region of CD44 directly, SOX4 activated its transcription and promotes CRC metastasis, which we proved via promoter analysis assays and analysis of the results of ChIP-seq and RNA-Seq. The Wnt/β-catenin signaling pathway contributed to the regulation of these processes.

Conclusion: The chemokine CCL7 induces elevated expression of SOX4, which subsequently promotes CRC metastasis by transcriptionally upregulating CD44. The CCL7-SOX4-CD44 axis could be applied as a potential target and strategy for preventing and treating CRC metastasis in clinical settings.

Disclosure: Nothing to disclose.

SORD CORRELATES WITH ANTITUMOR IMMUNITY AND AN IMPROVED PROGNOSIS IN COLON CANCER

Y. Sun[1], X. Bai[2], J. Yang[1]
[1]West China Hospital of Sichuan University, Gastroenterology and Hepatology, Chengdu, China, [2]West China Hospital of Sichuan University, Sichuan University-University of Oxford Huaxi Joint Centre for Gastrointestinal Cancer, Chengdu, China

Contact E-Mail Address: syyywzq@163.com

Introduction: The polyol pathway (PP) bypasses glycolysis and is over-activated following prolonged hyperglycaemia. Of the two key enzymes in the PP, the expression of SORD has previously been reported in various cancers. However, it remains unclear whether SORD is correlated with prognosis of CRC patients and the underlying mechanism of SORD affecting CRC progression.

Aims & Methods: We collected tissue samples and clinical information from colorectal adenoma and CRC patients in a local cohort, as well as RNA-Seq and clinical data from The Cancer Genome Atlas (TCGA) and Genotype Tissue Expression (GTEx) databases. We then compared *SORD* expression between tumour tissues and normal tissues and across different clinicopathological stages, and we tested for correlations between *SORD* expression and survival rate. Gene set enrichment analysis (GSEA) and gene co-expression analysis were conducted to determine the potential biological functions of *SORD*. Single sample GSEA (ssGSEA) method was utilised to evaluate immune cell infiltration correlated with *SORD* expression in TCGA CRC data.

Results: *SORD* expression was elevated in colorectal adenoma and CRC tissues, and lower *SORD* expression was correlated with more advanced N, M, and pathological stages and with lymphatic invasion. However, CRC patients with higher *SORD* expression also had a favourable progression-free interval (PFI). *SORD* expression was negatively correlated with angiogenesis, endothelium development, growth factor binding, and the Ras, Wnt, and TGF-β signalling pathways. The expression of angiogenesis and proliferation-promoting genes was also negatively correlated with *SORD* expression. *SORD* expression level was positively correlated with T helper 2 cell enrichment and negatively correlated with plasmacytoid DC enrichment in CRC microenvironment.

Conclusion: Higher *SORD* expression was significantly correlated with an improved PFI in CRC patients. Moreover, *SORD* may participate in CRC development and progression by affecting Ras, Wnt, and TGF-β signalling and regulating immune microenvironment.

Disclosure: Nothing to disclose.

Contact E-Mail Address: l.dellatti@gmail.com

Introduction: Rectal adenocarcinoma with mucinous components is a relatively infrequent kind of rectal cancer which exhibits two different histotypes: mucinous adenocarcinoma and signet-ring cell carcinoma. When compared to classic adenocarcinoma, these subtypes are associated with a younger age of presentation and a worse prognosis.

Aims & Methods: The aim of this study was to analyse the features of the mucosal immune microenvironment pattern of rectal carcinomas with intra- or extra-cellular mucinous components.

Patients enrolled for IMMUNOREACT 1 and 2 trials (NCT04915326 and NCT04917263, respectively) further analysed based on the subtype of cancer, comparing not otherwise specified (NOS) adenocarcinomas with rectal adenocarcinomas with mucinous components. A panel of immune markers was investigated at immunochemistry: CD3, CD4, CD8, CD8β, Tbet, FoxP3, PD-L1, MSH6, and PMS2 and CD80.

Flow cytometry was used to determine the proportion of epithelial cells expressing CD80, CD86, CD40, HLA ABC or HLA DR and the proportion of activated CD8+ T cells, CD4+ Th1 cells, and Treg. Non parametric tests were used.

Results: In this cohort, 9 patients had an adenocarcinoma with mucinous components, while 115 had a NOS adenocarcinoma. Rectal adenocarcinomas with mucinous components had a higher proportion of CD4+CD25+ T cells (activated T helpers) in healthy mucosa surrounding rectal cancer (p=0.006) and a higher proportion of CD8+ T cells (cytotoxic lymphocytes) in cancer tissue (p=0.027) than NOS adenocarcinomas.

Conclusion: Rectal adenocarcinomas with mucinous components are a distinct subtype of adenocarcinoma and their peritumoral immune microenvironment is associated with an impaired cytotoxic infiltration and a higher activation of T helpers.

These findings may suggest these subtype of rectal cancer cells may be favoured by a less active immunesurveillace that can easily escaped explaining the association of these cancer subtypes with poorer outcomes.

THE IMPACT OF LINE-1 METHYLATION ON THE DEVELOPMENT OF TUBULAR ADENOMAS: A PROSPECTIVE STUDY

I. Kildusiene[1], R. Rynkeviciene[2], A. Kaceniene[1], R. Miknaite[3], K. Suziedelis[2], G. Smailyte[1,4]
[1]National Cancer Institute, Laboratory of Cancer Epidemiology, Vilnius, Lithuania, [2]National Cancer Institute, Laboratory of Molecular Oncology, Vilnius, Lithuania, [3]Vilnius University, Institute of Biosciences, Life Sciences Centrer, Vilnius, Lithuania, [4]Faculty of Medicine Vilnius University, Institute of Health Sciences, Vilnius, Lithuania

Contact E-Mail Address: inga.kildusiene@gmail.com

Introduction: Colorectal cancer is the third most common cancer type worldwide. Changes in DNA methylation is a potential mechanism underlying CRC initiation. Long interspersed element-1 (LINE-1) is a repetitive DNA retrotransposon that constitutes approximately 17% of the human genome. The level of LINE-1 methylation is often used as a marker of global DNA methylation.

Aims & Methods: In this study, we investigated LINE-1 methylation at three CpG islands of the LINE-1 promotor in serrated adenoma, tubular adenoma and tumor tissue and surrounding normal tissue.

Results: In tubular adenoma tissue, the mean LINE-1 methylation level was 72.93±7.73. The surrounding normal tissue exhibited a significantly greater LINE-1 methylation level (81.77±4.03) than did the pathological tissue (p<0,0001). The adenocarcinoma tissues had a mean LINE-1 methylation level in the CpG island of 66.33±10.27. The LINE-1 methylation level in the surrounding tissue was significantly greater (83.76 ±3.49) than that in the pathological tissue (p<0,0001). For serrated adenoma no difference between surrounding and pathological tissues mean LINE-1 methylation levels were observed.

Conclusion: Our findings suggest the different impacts of DNA methylation changes on the formation of different colorectal adenomas (tubular versus serrated) and their further progression to carcinoma. In addition, our findings confirm the potential of LINE-1 methylation levels as an early CRC and premalignant diagnostic marker.

Introduction: Colorectal cancer (CRC) is one of the most common digestive tract malignant tumors, and its incidence rate and mortality rate rank third among all malignant tumors. The IMMUNOGLOBULIN SUPERFAMILY DOMAINS genes has been reported to be hypermethylated in human colorectal cancer (CRC) cell lines and primary tumor tissues.
On the other hand High mobility group genes are characteristically present at high levels in a variety of human cancers including colorectal, ovarian, breast, lung, and pancreatic cancer.

Aims & Methods: The aim of the work to evaluate the gene expression of both leucine-rich repeats and immunoglobulin-like domains 1 (LRIG1) (as an example of immunoglobulin sperfamily domains and High mobility group AT-hook 2 (HMGA2) as an example of high mobility group as diagnostic and prognostic markers in cases of colorectal cancer.
In this study forty-five patients pathologically approved with colorectal cancer were prospectively analyzed for LRIG1 and HMGA2 genes expression at tissue level. SYBR Green Real-Time RT-PCR technique was used for gene expression analyses and β-actin gene was considered as a reference gene for data normalization. Additionally, appropriate statistical analyses were used to assess the expression of LRIG1 and HMGA2 in diseased and adjacent healthy tissues.

Results: HMGA2 mRNA gene expression was over-expressed in CRC tissue than normal tissue (median fold change and median Log^2 ratio are [9.3(0.2, 100.4) and 3.1(-2.6, 6.7), respectively]with positive correlation between HMGA2 and poor differentiation ,more advanced stage and lymph node metastasis(p> 0.05) but not with distant metastasis (p >0.05). The expression of LRIG1 mRNA gene in tumor tissue was low expressed in colorectal tumor tissues (Median fold change and median Log2 ratio are [0.29(0.01, 4.14) and -1.8(-6.1, 2.1), respectively but no correlation of the LRIG1 gene with the the stage, Differentiation and metastasis of the CRC (P >0.05). There is no correlation of both genes neither with tumor biomarkers (CA19-9, CEA) nor with laboratory findings (WBCs, Hemoglobin, Platelet, INR, Albumin, Creatinine) P>0.5%). The overall survival showed no significant association with any genetic expression of both genes (P >0.05).

Conclusion: LRIG1 low expression may be considered for diagnosis but not valuable as prognostic marker in colorectal cancer patients. However, HMGA2 overexpression may be valuable as both diagnostic and prognostic markers in CRC.

Disclosure: No conflict of interest to be disclosed.

Introduction: In the carcinogenic pathway of colorectal cancer, the first concept is the “adenoma-carcinoma sequence” and the second concept is the “ serrated pathway “. In these concepts, adenomas and serrated lesions gradually progress to cancer. The third concept is the “de novo pathway,” in which cancer develops without adenomas or serrated lesions and is also characterized by high malignancy and rapid progression.

We have endoscopically characterized depressed colorectal cancers considered to be of the “de novo pathway” and validated the usefulness of pit pattern and EC classification.

Aims & Methods: A total of 54819 colorectal neoplasms were resected endoscopically or surgically in our institution from April 2001 to December 2024. They were subjects of this study. Advanced cancers were excluded. Of these, 1694 lesions were submucosally invasive (T1) carcinomas, 7330 lesions were classified as high-grade dysplasia and 39977 lesions as low-grade dysplasia. Morphologically, they were divided into 3 types: depressed, flat, and protruded type comprising 1.0 (%), 46.4 (%),and 52.6 (%), respectively.

Specifically, the distinctive features of depressed type neoplasms concerning their pit pattern and EC classification were examined. EC classification is a classification for an endocytoscopy that can evaluate pathology, such as nuclear atypia and glandular structure, by magnifying stained cells. EC1a is diagnosed as normal mucosa, EC1b is diagnosed as hyperplastic polyps, and if slit-like glandular ducts or spindle-shaped nuclei are present, it is classified as EC2 and diagnosed as an adenoma or intramucosal carcinoma. If irregularly shaped glandular ducts or nuclei with a high N/C ratio are found, it is classified as EC3a, and diagnosed as intramucosal carcinoma or SM lightly invasive carcinoma. If the glandular ducts are indistinct and the nucleus is irregularly shaped and darkly stained, it is classified as EC3b and diagnosed as SM highly invasive carcinoma.

Results: Most of the flat (91.5%) and protruded type (94.9%) lesions showed type IIIL or IV pit pattern, which are common findings in adenomas. On the other hand, most of the depressed type lesions (92.6%) classified as type IIIs, VI or VN pit patterns, are typically seen in carcinomas. As for endocytoscopy, most of flat and protruded type lesions were identified as EC2 corresponding to adenomas. In contrast, relatively high rates of depressed type lesions were categorized as EC3a (40.3%) and EC3b (52.4%), consistent with invasive carcinomas.

The proportion of T1 carcinomas in depressed type lesions was 58.7%, whereas in flat and protruded type lesions it was 2.5% and 2.5%, respectively. Additionally, 12.0% of depressed type lesions less than 5mm in diameter were T1 carcinomas, whereas flat and protruded type lesions were 0.01% and 0%, respectively.

Conclusion: This study revealed that depressed lesions were classified as type IIIs, VI or VN pit patterns on magnifying endoscopy and as type EC3a or EC3b on endocytoscopy. Lesions with these features or pit patterns tend to invade the submucosal layer even if they are small size. Despite their high potential for malignancy, depressed lesions are often ignored. However, it is critical to recognize their features and accurately diagnose lesions based on morphology, pit pattern, and EC classification.

Introduction: Patients with inflammatory bowel disease, particularly those with colonic inflammation, are at increased risk of colorectal dysplasia and cancer. Colitis-associated carcinogenesis is believed to follow an inflammatory-driven pathway, potentially modulated by microbiome-derived metabolites, especially those related to amino acid and nitrogen metabolism. However, the precise metabolic signatures underlying this transition remain undefined. We aimed to characterize serum metabolomic profiles across five clinical groups - healthy controls (HC), ulcerative colitis (UC), Crohn’s disease (CD), advanced adenoma (AA), and colorectal cancer (CRC) - to identify disease-specific metabolic shifts and metabolite associations across the inflammatory-neoplastic spectrum.

Aims & Methods: Patients were recruited from the Digestive Center of the National University Hospital, Singapore. Serum was collected and profiled using targeted liquid chromatographic tandem mass spectrometry, quantifying 80 metabolites spanning amino acids, biogenic amines, indoles, kynurenines, and nitrogenous bases. Unsupervised principal component analysis (PCA) was used to assess global metabolic validation, followed by pairwise subgroup comparison using Wilcoxon rank-sum test with false discovery (FDR) correction.

Results: A total of 125 participants were enrolled (25 per group, mean age 61.5 years, 41% female). PCA revealed distinct clustering by disease states, with CRC showing the greatest divergence from healthy controls (ANOSIM $R = 0.264$, $p<0.01$). Comparing IBD and CRC to healthy control, 40 metabolites were significantly differentially expressed (FDR <0.05) with enrichment patterns suggestive of class-based divergence. Amino acid-related metabolites (eg. glutamine, GABA, spermine) were progressively downregulated in CRC. Biogenic amines and microbial indole derivatives (eg. 1-methyhistamine, indole-3-propionic acid) showed distinct alterations, with 1-methyhistamine elevated in IBD, and reduced in CRC. Kynureine pathway intermediates (eg. kynurenine, xanthurenic acid) also displayed differential expression between inflammatory and neoplastic states.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Serum metabolomic profiling distinguishes IBD from CRC with both disease-specific and progressive changes. The marked depletion of amino acids (glutamine, GABA, spermine) and shifts in microbial or immune-associated metabolites (e.g., 1-methylhistamine, indole-3-propionic acid, kynurenines) support a model of colitis-associated carcinogenesis mediated by host–microbial metabolic crosstalk. These metabolites may serve as candidate biomarkers for early detection, disease monitoring, and risk stratification in IBD patients at risk for progression to CRC.

Introduction: Endoscopic submucosal dissection (ESD) is widely recognized as the preferred technique for removing large benign colorectal lesions and those with a risk of submucosal invasive cancer (SMIC), with the goal of achieving en-bloc resection. R0 resection is crucial for enabling organ-preservation strategies, particularly in endoscopically resected T1-colorectal cancer (T1-CRC).
Aims & Methods: This study aims to evaluate R0 resection rates in a large cohort of colorectal ESDs by assessing vertical and lateral margins and identifying predictive factors for vertical margin involvement.
Furthermore, the presence of other prognostic risk factors for lymph node metastasis (LNM) will be analyzed in this large cohort of T1-CRC. This is a multicenter prospective cohort study in 13 centers, including all colorectal ESDs between 09/2019 and 09/2024. Procedural and histological outcomes were analyzed using univariate and multivariate analysis.
Results: 7495 large colorectal polyps were included, of which 781 were T1-CRCs with a median size of 45 [35-65] mm. En bloc resection occurred in 96.7% and R0 resection in 74.9%. Lateral resection margins were free in 92.5%, with positive margins for adenocarcinoma in only 0.8% (low grade dysplasia in 2.6%, high grade in 1.2%, missing data in 2.6%). Vertical margins were free in 80.3%, and decreased significantly when deep SMIC was present to 75.0%, compared to 95.7% for superficial SMIC.
However deep SMIC with up to 2000 µm invasion depth, demonstrated free vertical resection margins in still 80.7%, after which it gradually decreased to 73.1% and 67.7% at an infiltration depth of 2000-3000 µm and >3000 µm respectively. Predictive factors for free vertical resection margins include lesion size >50mm (OR=1.66, [1.01;2.71], p=0.045) and rectal location (OR=1.86, [1.04;3.3], p=0.035).
Significant difference was observed in the presence of prognostic risk factors for LNM between superficial and deep SMIC, with lympho-vascular invasion (LVI) being present in 9.6% and high-grade tumor budding (Bd) in 17.1% in superficial SMIC, compared to 25.0% and 30.0% respectively, in deep SMIC. However, absence of LVI, Bd or poor differentiation was noted in 75.9% of superficial and 61.7% of deep T1-CRC. Concerning deep SMIC, no relation was observed in the presence of these risk factors with respect to the depth of infiltration.
Conclusion: Following ESD for T1-CRC, the likelihood of achieving free vertical resection margins decreases significantly when invasion depth exceeds 2000 µm. Careful lesion selection through optical diagnosis is therefore critical. To push organ preservation, intermuscular dissection should be considered for T1-CRC with deeper invasion in the rectum. Achieving R0 resection remains paramount, as additional prognostic factors are present in approximately 38% of cases, irrespective of invasion depth.
Disclosure: Nothing to disclose.

Introduction: Accurate prediction of lymph node metastasis (LNM) in submucosal invasive (T1) colorectal cancer (CRC) is essential for determining the need for additional surgery following endoscopic resection. Conventional histopathological assessments, however, are limited by interobserver variability. This study aimed to develop and externally validate a stacking-based artificial intelligence (AI) model integrating histopathological whole slide images (WSIs) and clinical parameters to predict the risk of LNM in T1 CRC.

Aims & Methods: This retrospective study included 1,056 patients with histologically confirmed T1 CRC treated at Showa Medical University Northern Yokohama Hospital. Of these, 593 cases were used for model training and 100 for internal testing. External validation was conducted on 25 cases from two independent institutions.

The proposed stacking ensemble model incorporated the Multiple Instance Self-Training (MIST) score derived from WSIs, patient sex, and tumor location (colon vs. rectum). Base learners included logistic regression, XGBoost, and random forest, with a meta-learner synthesizing their outputs to generate the final LNM prediction. Model performance was evaluated using the area under the receiver operating characteristic curve (AUC) in both internal and external cohorts.

Results: LNM was observed in 69 (11.6%) training cases, 15 (15.0%) test cases, and 2 (8.0%) external validation cases. The model achieved an AUC of 0.6965 in the internal test cohort and 0.7500 in the external validation cohort, demonstrating stable and generalizable predictive performance.

A representative case involved a 64-year-old man with a 16-mm type 0-Is lesion in the sigmoid colon resected via endoscopic mucosal resection (EMR). Histopathology showed well-differentiated tubular adenocarcinoma (tub1 > tub2), submucosal invasion depth of 3,300 μm (T1b), tumor budding grade BD1, Ly0, V1a, and negative resection margins (HM0, VM0). Despite guideline-based recommendations prompting additional surgical resection, no LNM was found (N0, 0/16), and the patient remained recurrence-free five years postoperatively—consistent with the AI model's prediction.

Conclusion: The stacking-based AI model exhibited robust and generalizable performance in predicting LNM in T1 CRC, both internally and across external institutions. This approach offers a complementary tool to conventional pathology and may enhance individualized decision-making regarding the necessity of additional surgical intervention.

ANALYSIS OF COLORECTAL LESIONS FOLLOWING THE IMPLEMENTATION OF COLORECTAL CANCER SCREENING IN DENMARK

A. Eller[1,2], L. Bang Grode[2], A. Kirch Dige[3,4], M. Bach Larsen[5]

[1]Viborg Regional Hospital, Department of Surgery, Viborg, Denmark, [2]Regional Hospital Horsens, Department of Medicine, Horsens, Denmark, [3]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark, [4]Aarhus University, Department of Clinical Medcine, Aarhus N, Denmark, [5]University Hospital of Southern Denmark, Department of Oncology, Vejle, Denmark

Contact E-Mail Address: asger.eller@gmail.com

Introduction: Colorectal cancer (CRC) remains the second most common cause of cancer-related mortality worldwide (1). The introduction of the Danish national CRC screening program in 2014 aimed at reducing mortality rates (2) has marrkedly increased colonoscopies and polypectomies (3,4). A a comprehensive description of the lesions removed has not yet been investigated.

Aims & Methods: Nationwide, cross-sectional study of all colorectal lesions resected endoscopically in patients ≥18 years between January 2014 and December 2021. Data were obtained from the Danish National Patient Register, Pathology Register and Screening Database. Prevalence of histological sub-types and predictors of high-grade dysplasia (HGD) and adenocarcinoma were analyzed with multivariable logistic regression.

Results: Among 663,624 individuals undergoing 1,074,236 colonoscopies or sigmoidoscopies, 194,941 patients (median age 67 years, 58.6% male) had a total of 504,386 lesions removed. Tubular adenomas (TA) accounted for 66.8% of lesions.

The proportion of advanced colorectal polyps—defined as lesions ≥10 mm, adenomas with high-grade dysplasia, or sessile serrated lesions with any dysplasia—declined from 22.7% in 2014 to 10.2% in 2021.

High-grade dysplasia (HGD) was strongly associated with size ≥10 mm (OR 27.1 for 10–19 mm; OR 71.1 for 30–39 mm), and in diminutive lesions (1–5 mm), with tubulovillous or villous histology (OR 6.09).

Adenocarcinoma was identified in 0.65% of lesions and was predominantly left-sided (83.9%), with highest odds observed in the sigmoid colon (OR 6.33) and rectum (OR 6.00), compared to the caecum.

Sex was significantly associated with the risk of adenocarcinoma at the lesion level, but this effect was age-dependent. At age 40, women had significantly higher odds than men (adjusted OR 1.48), but the difference diminished with increasing age, and from age 75 onward, no statistically significant difference between sexes was observed.

Conclusion: Lesion size was the strongest predictor of high-grade dysplasia, outweighing histologic subtype once lesions exceeded 10 mm. At lesion level, the risk of malignancy was higher in younger women than in men of the same age, with the difference progressively diminishing with age.

The introduction of the screening programme coincided with a marked reduction in advanced lesions over time. The high predominance of left-sided cancerous lesions highlights the need to optimize the detection of right-sided neoplasia.

Introduction: Lynch syndrome (LS) is a heritable autosomal dominant genetic condition caused by mutations in several DNA mismatch repair (MMR) genes, MLH1, MSH2, MSH6, PMS2 and EPCAM. Affected individuals have an increased life-long risk of developing cancers especially colorectal cancer (CRC) and endometrial cancer (EC). LS accounts for approximately up to 3% of all CRC. Traditionally, diagnosis was based on clinical criteria (Amsterdam II, Bethesda and revised Bethesda), which have proven to be of limited applicability in clinical practice. In recent years tumor testing via immunohistochemistry (IHC) of all CRCs for the expression of MMR proteins has successfully integrated into clinical care. Universal screening through IHC of CRC tumor samples is cost-effective and recommended by major guidelines, which also recommend its application to endometrial cancers.
Aims & Methods: Our aim was to assess the main differences between LS families where the first individual received a genetic diagnosis after IHC on tumor sample and LS families where the first individual received a genetic diagnosis due to meeting the Amsterdam II or revised Bethesda criteria. We obtained data (year of genetic test confirmation, first tumor diagnosis, family tree) of all our single center's LS patients who undergo surveillance in our Institute (n = 101 patients).
Accordingly, we grouped patients by family and identified each family's index case-defined as the first individual to receive a genetic diagnosis - and relatives of index cases.
Therefore, we divided the cohort into two groups: families whose the index case was identified after IHC on tumor sample and families whose the index case was identified due to meeting the Amsterdam II or revised Bethesda criteria. We subsequently evaluatedwhether patients identified through IHC would have also met the revised Bethesda or Amsterdam II criteria for genetic testing.
Results: We found that index cases identified through IHC (n =16; of which 8 on CRC tissue, 7 on EC tissue and 1 on lung cancer tissue) had a mean age of 57.93 years at the time of genetic diagnosis, whereas those identified through clinical criteria (n = 20) had a mean age of 46.35 years. As for the relatives, those whose index case was identified via IHC (n = 11) had a mean age of 45.72 years, while relatives of individuals diagnosed based on clinical criteria (n= 54) had a mean age of 37.96 years. Patients carrying pathogenic variants in MSH6 and PMS2 (leading to lower penetrance and a late onset of LS related cancers) were 8 out of 16 (50 %) in the IHC group and 1 out of 20 (5 %) in the clinical criteria group. Furthermore 8 out of 16 (50%) index patients diagnosed through IHC did not meet the Amsterdam II criteria.
Conclusion: The mean age of index cases diagnosed due to clinical criteria is lower than that of cases identified through IHC, probably because of the early onset of LS related cancers in these patients and since the clinical criteria require at least one case to be diagnosed at a young age (<50 years old). In contrast, universal immunohistochemistry (IHC) screening enables the detection of all patients with mismatch repair-deficient tumors, including those diagnosed later in life and those without an evident family history of cancer or carrying pathogenic variants in genes such as MSH6 and PMS2 with a lower penetrance. Our data strengthen the important role of IHC screening for MMR proteins loss of expression both in CRC and EC to find LS families that would not be possible to identify with clinical criteria only.
Disclosure: Nothing to disclose.

Introduction: Appropriate knowledge of surface features of colorectal polyps is necessary for their adequate management. Data are limited regarding the diagnostic value of surface pattern-based prediction of histology.
Aims & Methods: This nationwide observational cohort study aimed to compare the optical diagnosis based on Kudo's pit pattern and the histologic result in case of colorectal polyps endoscopically removed during screening colonoscopies.
Data regarding Kudo's pit pattern of the lesions (Kudo I-V), and the final histological results were obtained from clinical records of screening colonoscopies which were prospectively collected in the registry of Hungarian National Public Health Institute. The level of agreement was characterized by Cohen's kappa coefficient. The feasibility of optical diagnostics to differentiate neoplastic and non-neoplastic lesions, as well as to identify submucosally invasive cancer (SMIC) were investigated. The potential effects of polyp size and location (left/right colon), and that of timing of colonoscopy (1st period between 2019 and 2021, and 2nd period between 2022 and 2023) were also evaluated.
Results: A total of 8289 polyps removed during screening colonoscopy were registered in the database between 2019 and 2023, from these 7187 were neoplastic (439 SMIC) and 1102 were non-neoplastic. Out of the 1095 serrated polyps 171 contained dysplasia. Non-neoplastic polyps had Kudo I pattern in 7.7%, Kudo II in 48.1%, Kudo III in 40.9%, Kudo IV in 3.2%, and Kudo V in 0.1% of the cases. Neoplastic lesions without submucosal invasion had Kudo I surface pattern in 2.0%, Kudo II in 7.5%, Kudo III in 71.2%, Kudo IV in 17.4%, and Kudo V in 1.7% of the cases, while in case of SMIC, the surface pattern was Kudo I in 0.2%, Kudo II in 0.7%, Kudo III in 15.7%, Kudo IV in 8.9%, and Kudo V in 74.5% of the cases.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Kudo I-II category showed moderate agreement with non-neoplastic lesions (κ=0.440), irrespective of lesion size and location, and timing of screening colonoscopy. The level of agreement was only slight for serrated lesions (κ=0.168). Kudo V category demonstrated substantial agreement (κ=0.722) with SMIC, irrespective of lesion size, location, and timing. SMICs could be identified based on Kudo V category with 74.5% sensitivity, 98.5% specificity, 73.0% positive and 98.6% negative predictive value.

Conclusion: This is the first real-world data obtained from screening colonoscopies of the Hungarian national colorectal screening program. Optical diagnosis might support the differentiation of neoplastic and non-neoplastic lesions and can be especially helpful in identifying SMICs that might require a different management approach.

Disclosure: Nothing to disclose.

FACTORS ASSOCIATED WITH TIME-TO-ADHERENCE IN COLORECTAL CANCER SCREENING: A LARGE LONGITUDINAL COHORT STUDY

Y. Gorelik[1], R. Romano[2], M. Leshno[3], L. Yanai[2], H. Alkalai[2], R. Kariv[4,2,3]

[1]Rambam Health Care Campus, Gastroenterology, Haifa, Israel, [2]Maccabi Health Care Services, Headquarter, Tel Aviv, Israel, [3]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel, [4]Tel Aviv Sourasky Medical Center, Maccabi Health Services, Tel Aviv University, Gatroenterology, Tel Aviv, Israel

Contact E-Mail Address: yurigorelik@gmail.com

Introduction: Colorectal cancer (CRC) screening reduces cancer risk, yet real-world adherence to screening remains variable. We aimed to leverage a large healthcare organization longitudinal cohort to evaluate factors that influence the timeliness of adherence to screening guidelines.

Aims & Methods: We included average-risk Maccabi Healthcare Services members aged 50–75 years who were alive on 1 January 2025. Demographics, comorbidities, hemoglobin values, and dates of fecal immunochemical test(FIT), CT-colonography (CTC) and colonoscopy were extracted.

Adherence was defined as annual FIT, colonoscopy every 10 years, or CTC every 5 years.

Patients covered for >50 % versus ≤50 % of follow-up time by screening guidelines were compared with Wilcoxon rank-sum (continuous) and χ^2/Fisher's exact (categorical) tests.

In order to study factors associated with adherence times, longitudinal adherence was modelled with a gap-time Andersen–Gill Cox regression. The dependent variable was time (in periods) to the recurrent event active adherence. Adjusted hazard ratios (HRs) and 95 % confidence intervals (CI) were estimated with robust variance, clustering on patient ID to account for within-subject correlation.

Results: Our cohort comprised 590,550 adults at screening age, contributing 6,581,044 person-years of follow-up. In a baseline comparison between individuals whose proportion of time covered was less than 50%(n=282,347) vs more than 50%(n=308,203), the latter group was older (60.00 [55.00, 68.00] years vs 62.00 [57.00, 67.00] years, p-value<0.001) with a longer median follow up (9.0 [4.0, 17.0] years vs 11.0 [6.0, 16.0] years, p-value<0.001). Higher prevalence of hypertension (17.5 % vs 12.0 %, p-value<0.001), diabetes mellitus (8.2 % vs 5.8 %, p-value<0.001), pre-diabetes (22.4 % vs 17.5 %, p-value<0.001), and cardiac disease (4.8 % vs 3.4 %, p-value<0.001) were seen among the more compliant group. Consistent with greater adherence, endoscopic referral was more common at baseline in the more compliant group (6.2 % vs 1.0 %, p-value<0.001). Interestingly. Although the differences in distributions of sector, district and socioeconomic rank categories were significant, the absolute percentage differences across strata were small and unremarkable (<3 percentage points for any category).

A gap-time survival model demonstrated that each additional year of age was associated with longer intervals and a lower aHR for active adherence (aHR 0.94, 95 % CI 0.94–0.94). Men undergone screening tests marginally sooner than women (aHR 1.05, 95% CI 1.04–1.05). Adherence was lower in the orthodox sector (aHR 0.84, 95% CI 0.84–0.85). Metabolic or cardiovascular conditions translated into earlier adherence: pre-diabetes (aHR 1.63, 95% CI 1.62-1.63), diabetes (aHR 1.54, 95% CI 1.54-1.55), hypertension (aHR 1.22, 95% CI 1.21-1.23), cardiac disease (aHR 1.14, 95% CI 1.14-1.15), and obesity (aHR 1.10, 95% CI 1.10-1.11). Severe conditions and subjects included in severe disease registry were associated with lower adherence (aHR 0.33, 95% CI 0.30-0.38; and aHR 0.63, 95% CI 0.59-0.67, respectively). Recent higher hemoglobin levels delayed active adherence (aHR 0.97 per each increase of 1 g/dL, 95% CI 0.97-0.98).

Conclusion: Our results suggest that long term compliance for CRC screening is related to age as well as for chronic medical conditions, particularly metabolic and cardiovascular. Screening efforts should therefore be aimed at healthy subjects or those with minor contact with medical providers.

Disclosure: Nothing to disclose.

Introduction: The ectoenzyme CD73, a key mediator of adenosine-mediated immunosuppression in cancer, contributing to tumor progression, immune evasion, and resistance to therapy, represents a promising therapeutic targets in gastrointestinal malignancy.

Aims & Methods: To address the limitations of monoclonal antibody therapies in solid tumors, this study reports the bioinformatic design, production, and functional evaluation of a novel nanobody-based recombinant protein engineered to target CD73 as new immune checkpoint in colorectal cancer. The construct was developed by grafting the complementarity-determining regions (CDRs) from the humanized monoclonal antibody IPH5301 onto a camelid nanobody scaffold to retain high binding affinity for CD73 while benefiting from the nanobody's small size and tissue penetration.

Structural validation through molecular modeling, energy minimization, and Ramachandran analysis confirmed high stability and proper folding of the engineered protein. Molecular modeling and docking simulations confirmed structural stability.

Results: Experimental expression in prokaryotic hosts and subsequent SDS-PAGE, western blot, and dot blot confirmed the presence and purity of the construct. Binding efficiency was validated via ELISA and flow cytometry, revealing a high CD73-binding rate of 90.7% in HT-29 colorectal cancer cells. The construct also demonstrated notable cytotoxicity, with an IC50 value of 23.51 µg/mL, and induced significant cancer cell death (49.08% apoptosis, p = 0.014).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These results demonstrate successful design and functional characterization of a small, high-affinity anti-CD73 nanobody that holds promise to disrupt adenosine-driven immunosuppression for targeted immunotherapy in CRC. Also, it is offering a promising alternative to conventional monoclonal antibodies and merits further preclinical investigation for therapeutic development.
Disclosure: Nothing to disclose.

Contact E-Mail Address: Khemiri.wafa00@gmail.com

Introduction: Colorectal cancer (CRC) remains a significant public health concern, with its incidence steadily rising worldwide. Despite notable strides in treatment modalities, predicting disease progression and tailoring therapeutic approaches remains a challenge. In this context, identifying reliable and simple prognostic factors is crucial for optimizing disease outcomes.

Aims & Methods: The aim of this study was to investigate the predictive and prognostic value of C-reactive protein-to-albumin ratio (CAR) in CRC. We conducted a retrospective and descriptive study including patients diagnosed with primary colon or rectal cancer, over an 8-year period [January 2014-June 2022]. Patient demographics, inflammatory markers, tumor characteristics, treatment and follow-up data were collected. Baseline CAR was calculated for each patient. Data were entered and analyzed by SPSS software version 26.

Results: Sixty-five patients were included, with a mean age at disease diagnosis of 61 ± 14 years and a sex ratio M/F=1.82. The median level of CAR was 0.4 [0.1-1.3]. No significant association was noted of CAR neither with age of disease onset (p=0.26), nor gender (p=0.86), nor smoking (p=0.88) nor family history of CRC (p= 0.54). For biological data, high levels of carcinoembryonic antigen and CA19-9 were significantly associated with a higher level of CAR (p=0.002 and p=0.01 respectively). We noted a significant association between lower levels of CAR and hematochezia (p=0.01) and so, rectal tumors were associated with lower levels of CAR compared with colonic tumors (26.2 vs 36; p=0.05). Circumferential, stenoting and friable tumors with hemorrhagic appearance were significantly associated with higher CAR levels (p=0.01; p=0.001 and p=0.01 respectively). We noted a significant association between high levels of CAR and metastases (50.1 vs 29.8; p=0.002) and mainly hepatic metastases (p=0.004).

Regarding treatment, neither primary surgery nor urgent surgery nor adjuvant chemotherapy were associated with CAR (p=0.11; p=0.12 and p=0.85 respectively).

However, an increased CAR was significantly associated with early readmission within 30 days subsequent to surgery (41.3 vs 26.7; p=0.01). Lower overall survival was associated with higher CAR rates (38.8 vs 29; p=0.04). Area under the receiver operating characteristic curve analysis showed that higher CAR was predictive of a shorter progression-free survival (AUROC = 0.65). The optimal cutoff value was 0.3 (sensitivity, 70%; specificity, 62%). A total of 36 (55%) patients had a CAR above this threshold. These patients presented more frequently with lymphopenia (p=0.03) and higher carcinoembryonic antigen rates (p=0.02).

We noted no association between advanced TNM stage 3 or 4 and CAR levels, regardless of this threshold (p=0.36), and overall disease recurrence was similar for CAR above and below 0.3 (p=0.46).

Conclusion: C-reactive protein-to-albumin ratio is a strong predictor of progression-free survival and is associated with clinicopathological factors in CRC. It serves as a valuable tool for straightforward prognostic assessment, aiding in more personalized treatment decisions.

EXPLOITING CANCER IRON METABOLISM: A TARGETED APPROACH FOR SELECTIVE THERAPIES

V. Marques[1], D. Magalhães e Silva[1], F. Lopes[1], R. Moreira[1], C.M.P. Rodrigues[1]
[1]iMed.ULisboa - Faculdade de Farmácia Universidade de Lisboa, Lisboa, Portugal

Contact E-Mail Address: vismsmarques@ff.ulisboa.pt

Introduction: Colorectal cancer (CRC) therapy faces significant challenges, including drug resistance, tumour heterogeneity, metastatic progression, and treatment-associated toxicity. CRC and other cancers exhibit increased levels of Fe(II) due to dysregulated iron metabolism, which can act as a trigger for selective prodrug activation. In this study, we explore the therapeutic potential of a novel tumour-activated prodrug platform based on 1,2,4,5-tetraoxane scaffold that is selectively activated in cancer cells with high levels of labile Fe(II).

As a proof-of-concept, we evaluated the therapeutic potential of 5b, a prodrug coupled with doxorubicin (DOX), which releases this cytotoxic payload upon activation by the labile Fe(II) pool in the cytoplasm of cancer cells.

Aims & Methods: The therapeutic potential and mechanism of action of 5b was evaluated both *in vitro* and *in vivo*. IC_{50} values were determined across multiple cancer cell lines and compared to non-tumorigenic cells. To confirm iron-dependency, HCT116 cell viability was assessed upon co-incubation with 5b and iron chelator deferoxamine (DFO). Co-incubation with apoptosis inhibitor Z-VAD-FMK (Zvad) or ferroptosis inhibitor liproxstatin-1 was used to assess cell death mechanism.

The sub-cellular location of 5b activation was evaluated by fluorescence microscopy. *In vivo* efficacy was evaluated in a xenograft mouse model using immunocompromised mice implanted with HT29 cells and intraperitoneal administrations of 5b, assessing tumour burden and systemic toxicity.

Results: Prodrug 5b effectively reduced cell viability in CRC cells HCT116 and HT29, as well as in glioblastoma (U251), prostate cancer (PC3) and breast cancer (MCF7) cells, with IC_{50} values ranging from 1.64 to 6.69 μM. Notably, 5b was over 2000 times less toxic than DOX in non-tumorigenic cells AML12 (5b IC_{50} = 398.2 μM vs. DOX IC_{50} = 0.18 μM). Taking advantage of DOX intrinsic fluorescence properties (while 5b pro-drug is non-fluorescent), we used fluorescence microscopy analysis to confirm that 5b released its fluorescent DOX payload in the cytoplasm, after activation by labile Fe(II).

The significant decrease in cell viability induced by 5b ($p < 0.0001$) was rescued by the iron chelator DFO and by the ferroptosis inhibitor liproxstatin-1 ($p < 0.01$) but not by pan-caspase inhibitor Zvad, suggesting that ferroptosis may be the primary mechanism of cell death. *In vivo*, 5b significantly reduced the relative tumour volume ($p < 0.05$), demonstrating greater efficacy than DOX, with only minor cardiotoxicity side-effects (multifocal loci of fibrosis affecting of 0.2% of left ventricle volume).

Conclusion: Prodrug 5b efficiently released its DOX payload in response to the cytoplasmatic labile Fe(II), effectively reducing cancer cell viability both *in vitro* and *in vivo*, while demonstrating significantly lower toxicity compared to DOX itself.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Given its Fe(II)-dependent activation, 5b represents a promising strategy to exploit cancer cell iron addiction for cancer therapy. Future work should further validate ferroptosis as cell death mechanism, optimize the selection of cytotoxic payloads for tumours with dysregulated iron metabolism, and assess its efficacy in relation to KRAS mutational status.

OUTCOMES OF ENDOSCOPIC RESECTION AND ADDITIONAL SURGERY FOR LNPCP CONTAINING INVASIVE CANCER: A HEAVY BURDEN OF MORBIDITY

C. Judge[1], A. Eqbal[1], H. Ayubi[1], O. Olabintan[1], J. Bhoday[1], B. Hayee[1], A. Haji[1], A. Emmanuel[1]
[1]King's College Hospital, Endoscopy, London, United Kingdom

Contact E-Mail Address: ciaranjudge@gmail.com

Introduction: Major societal guidelines still recommend surgical segmental resection following endoscopic resection (ER) for submucosal invasive cancer with adverse histopathological features, due to the risk of lymph node metastases or residual cancer. However, most patients with these features show no evidence of residual cancer or lymph node metastases after surgery. Few studies have reported the clinical outcomes of both ER and subsequent surgery in these patients.

Aims & Methods: Patients in a single tertiary referral centre were included if they underwent ER between 2014-2024 for LNPCP with invasive cancer found in the resected specimen. Endoscopic and surgical outcomes were reported including complications, type of surgery, length of hospital stay, stoma formation and restoration of intestinal continuity. This study aims to present the clinical outcomes following ER of large non-pedunculated colorectal polyps (LNPCP) with invasive cancer, as well as the outcomes of subsequent surgery when recommended.

Results: 194 patients with invasive cancer discovered after ER of LNPCP were included. Mean lesion size was 46.5mm (median 40mm, range 20-180mm). Lesions were located in the right colon in 20%, left colon in 28% and rectum in 52%. ESD was used to resect 73%. 74% of LNPCP were resected en-bloc. Complications following ER occurred in 4% of patients overall, with only 1 clinically significant perforation who required surgery. Elective surgical segmental resection was recommended for 55 patients based on histopathological findings, of which 53 underwent surgery. 30% of patients experienced a surgical complication (25% of these Clavien-Dindo grade 3 or 4), with median length of stay 5 days (range 2-28 days). 40% of patients required stoma formation, 29% of whom remain with a stoma.

Conclusion: These real-world outcomes of a cohort of patients with invasive cancer following ER of LNPCP highlight a significant burden of morbidity for those recommended for surgery compared to those who undergo ER alone.

Additionally, these patients often face prolonged hospital stays, and a substantial proportion require stoma formation, many of whom continue to live with a stoma. Given the relatively low likelihood of residual cancer or lymph node metastasis in most patients, these findings should be considered in discussions with patients to fully inform management options.

Disclosure: Nothing to disclose.

Contact E-Mail Address: shchr.hirata327@gmail.com

Introduction: Among immune-related adverse events (irAEs) caused by immune checkpoint inhibitors (ICIs), gastrointestinal irAEs (GI-irAEs) are relatively rare, and their risk factors and prognostic implications remain unclear.

Aims & Methods: We retrospectively analyzed 1,104 patients who initiated ICI therapy at our institution between January 2016 and December 2022 and for whom survival data were available. GI-irAEs were defined as colitis with an increase of ≥3 bowel movements/day from baseline in the absence of other causes, or symptomatic gastritis confirmed histologically. Risk factors and prognostic impact of GI-irAEs were evaluated.

Results: The median duration of ICI therapy was 107 days. The cohort included 754 males (68%) with a median age of 69 years. The primary tumor types were lung cancer (32%), gastrointestinal cancers (19%), urothelial carcinoma (13%), head and neck cancer (13%), and melanoma (11%). The overall response rate was 27.8%, and the disease control rate was 49.0%. irAEs of any grade occurred in 310 patients (28%), and GI-irAEs were observed in 30 patients (2.7%).

In univariate logistic regression analysis, use of anti-CTLA-4 antibody, combination ICI therapy, a prognostic nutritional index (PNI) ≥ 40, and platelet-to-lymphocyte ratio (PLR) ≥ 1.8 were associated with an increased risk of GI-irAEs. In multivariate analysis, only anti-CTLA-4 antibody use remained a significant risk factor (odds ratio: 9.2; 95% CI: 1.9–45). Kaplan–Meier analysis revealed that patients with GI-irAEs had significantly longer overall survival (OS) compared to those without irAEs in the overall cohort (median OS: 22.9 vs. 12.6 months, $P < 0.0001$).

However, this difference was not observed in landmark analyses at 4 and 8 weeks post-treatment. Subgroup analysis based on PNI showed that in patients with PNI ≥ 40, those with GI-irAEs had significantly longer OS than those without irAEs (median not reached vs. 19.3 months, $P = 0.0003$). In contrast, in patients with PNI < 40, GI-irAE cases tended to have shorter OS than non-irAE cases (8.2 vs. 9.3 months). This trend was consistent in landmark analyses at 4 and 8 weeks.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The impact of GI-irAEs on prognosis appears to differ depending on the patient's nutritional status. Particular caution is warranted for patients in poor general condition receiving ICIs, especially those involving anti-CTLA-4 antibodies, as GI-irAEs may serve as a poor prognostic factor in this population.

Introduction: Self-expandable metallic stent (SEMS) placement for palliation (PAL) of malignant colorectal obstruction due to unresectable advanced colorectal cancer or metastases from other organs is a noninvasive treatment option that prevents emergency surgery or colostomy. However, there are concerns that a satisfactory success rate may not be attained.
Aims & Methods: Therefore, this study investigated the efficacy and safety of colorectal stenting for PAL at our institution. We retrospectively analyzed the cases of 94 patients who underwent colorectal stent placement for PAL out of 191 patients at our institution from June 2012 to February 2024, a period during which 111 stent placement procedures were performed.
We collected data on patient characteristics, details of the obstruction site, outcomes of stent placement (technical success, clinical success), complications, the 1-year overall survival rate, the cumulative stent patency rate, and risk factors for perforation.
Results: The median was 76.5 (IQR, 67–87) years, and there were 53 males. The ECOG Performance Status was 0–1 in 36 cases and 2–4 in 58 cases. Obstruction was caused by primary colorectal cancer in 48 cases, local recurrence after colorectal cancer surgery in 6 cases, and metastases from other organs in 40 cases.
The ColoRectal Obstruction Scoring System (CROSS) before stenting was 0 in 33 cases, 1 in 46 cases, and 2 in 15 cases. Lesions were located in the rectum, sigmoid colon, descending colon, transverse colon, ascending colon, and cecum in 19, 29, 21, 12, 9, and 4 cases, respectively. The mean stenosis length was 5.6 ± 2.4 cm.
The technical success rate was 97.9% (92/94), and the clinical success rate was 85.1% (80/94). Early (within 7 days) complications included perforation in 6 cases (6.4%), migration in 2 cases (2.1%), and inadequate dilation in 2 cases (2.1%), all of which required surgery.
Late complications included perforation in 8 cases (8.5%), migration in 1 case (1.1%), and stent occlusion in 11 cases (11.7%). In all cases of stent occlusion, the stents used were 22 mm-diameter stents, and ingrowth was the main cause of obstruction. In all cases of stent occlusion, stent-in-stent procedures were successfully performed to re-open the stents.
Complication-related mortality occurred in 3 cases (3.2%). The one-year overall survival rate was 29.3% (mean follow-up period: 221 ± 248 days), and the one-year stent patency rate was 75.5% (mean follow-up period: 168 ± 198 days). Per our univariate analysis, the stent length, stent diameter, chemotherapy, and anti-VEGF antibody use after stent placement were not risk factors. Our multivariate analysis showed that only a stent diameter of 25 mm tended to be an independent risk factor for perforation.
Conclusion: SEMS replacement for PAL was effective in cases of colorectal obstruction. The incidence of complications and the complication-related mortality rate were within acceptable limits, suggesting that colonic stent placement is a promising palliative treatment option for malignant colorectal obstruction that helps maintain the quality of life of patients.
Disclosure: Nothing to disclose.

Introduction: Microsatellite instability (MSI)–high and mismatch repair-deficient (dMMR) metastatic colorectal cancer (mCRC) presents a significant challenge due to its poor prognosis and limited response to traditional chemotherapy. Immunotherapy has emerged as a promising treatment strategy. Nivolumab, a PD-1 inhibitor, combined with ipilimumab, a CTLA-4 inhibitor, has shown potential in improving patient outcomes.
This systematic review and meta-analysis evaluate the clinical efficacy, safety, and therapeutic role of Nivolumab plus Ipilimumab in patients with MSI-H mCRC, providing critical insights to optimize treatment strategies and enhance patient outcomes.
Aims & Methods: A comprehensive search was conducted across multiple databases including PubMed, Scopus, Web of Science, and Cochrane from their inception to March 2025. The search focused on identifying trials and relevant studies evaluating Nivolumab plus Ipilimumab for the treatment of Microsatellite Instability-High (MSI-H) metastatic colorectal cancer (mCRC).
Studies were included if they reported on treatment efficacy, including Objective Response Rate (ORR), Disease Control Rate (DCR), Progression-Free Survival (PFS), Overall Survival (OS), and treatment-related adverse events.
Results: Out of 3,477 studies initially screened, nine studies were identified as potentially eligible for inclusion in the meta-analysis. After applying the inclusion criteria, three studies met the criteria for data analysis, comprising a total of 758 patients treated with Nivolumab plus Ipilimumab. Although all nine studies met the inclusion criteria, not all were included in the quality analysis due to certain limitations in study design or reporting.
The combination of Nivolumab and Ipilimumab resulted in an overall Objective Response Rate (ORR) of 0.67 (95% CI: 0.61–0.73), with significant heterogeneity across the studies (I^2 = 40%). The pooled Disease Control Rate (DCR) was 0.82 (95% CI: 0.76–0.88), showing high levels of disease control across the trials.
In terms of treatment-related adverse events, the combined analysis of Any Treatment-Related Adverse Events (TREA) from the studies showed an overall event rate of 0.82 (95% CI: 0.79–0.85), indicating a high inci-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

dence of adverse events associated with the combination therapy. The results demonstrated minimal heterogeneity (I^2 = 0%), suggesting consistent reporting of adverse events across the three studies.

The analysis of Serious Treatment-Related Adverse Events (STRAE) from André 2022 and André 2025 revealed an overall event rate of 0.20 (95% CI: 0.16–0.23), indicating that a low proportion of patients experienced serious adverse events in response to Nivolumab and Ipilimumab combination therapy, with very low heterogeneity (I^2 = 1%).

Additionally, the combined analysis of diarrhea across the studies showed an overall event rate of 0.24 (95% CI: 0.20–0.27), with moderate heterogeneity (I^2 = 72%), indicating a substantial but consistent occurrence of diarrhea across the studies. The combined analysis of fatigue showed an overall event rate of 0.18 (95% CI: 0.15–0.22), with high heterogeneity (I^2 = 94%), indicating considerable variation in fatigue occurrence across the studies

Conclusion: Nivolumab plus Ipilimumab improves survival outcomes) in patients with MSI-H mCRC. However, it is associated with a higher risk of treatment related adverse events, which emphasizes the need for effective management of these to optimize the treatment benefit for patients.

Disclosure: Nothing to disclose.

THERAPEUTIC STRATEGIES IN PT1 COLORECTAL ADENOCARCINOMA AND THEIR IMPACT ON PROGRESSION: SURGERY VS. ENDOSCOPIC TREATMENT

M. Lecuona Muñoz[1], R. Jiménez-Rosales[1], C. Heredia Carrasco[1], M. López de Hierro Ruiz[1], E. Redondo-Cerezo[1]
[1]Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: eredondoc@gmail.com

Introduction: The standard treatment for pT1 colorectal cancer classified as high risk (poor differentiation, deep submucosal invasion, intense tumor budding, resection margins that are positive or lymphovascular invasion) is surgery [1]. However, some studies have revealed that patients who undergo surgery and endoscopic treatment have similar disease progression outcomes, and it is also controversial which histological factors influence disease progression [2,3].

Aims & Methods: The aim of this study was to analyze the characteristics and evolution of patients undergoing surgery or endoscopic treatment after the resection of pT1 colorectal adenocarcinoma with histological findings considered high risk for lymph node metastasis.

We conducted an observational study of historical cohorts. We included patients with pT1 Adenocarcinoma and histological criteria of poor prognosis with at least six months of follow-up, and who were diagnosed between 2018 and 2024. The therapeutic approach was determined by a multidisciplinary committee.

Results: We included 54 patients (74.1% male) with a mean age of 65.3 years and mean follow-up time of 3.07 years; no significant differences in both groups. The indications for colonoscopy were screening (42.6%), alarm symptoms (38.9%), radiological findings (3.7%), prior polypectomy (9.3%), history of colorectal cancer (1.9%), and family history (3.7%). The rate of patients with endoscopic complications was 2.9% intraprocedural bleeding and 2.9% delayed bleeding.

The mean lesion size was 23.48 mm, and the most common location was the rectum.

Regarding the therapeutic approach, 63.0% of patients underwent surgery and 29.6% underwent endoscopic surveillance. Among the surgical patients, complications included suture dehiscence (6%), and hemorrhage (2%). In the surgical specimen analysis, residual lesion was found in 6 patients, and metastatic lymph nodes in 2. 5.55% required adjuvant therapy due to lymph node involvement, and 1.85% were stage IV at diagnosis, excluded from the comparative analysis.

Comparing both study groups, the surgical group had a significantly higher rate of submucosal invasion, with no differences in the remaining characteristics studied. During the study period, progression with lymph node involvement was observed in one patient who underwent surgery and two patients who underwent endoscopy treatment (average time 11 and 24.5 months, respectively). No patient has developed distant metastases to date.

	Surgery treatment (n =34)	Endoscopic therapy (n = 16)	p-value
Piecemeal resection (n, %)	16 (47.05%)	8 (50%)	p > 0.05
Poor differentiation (n, %)	1 (2.9%)	0	p > 0.05
Deep submucosal invasion (n, %)	33 (97%)	11 (68.75%)	P = 0.016
Margins affected or not precise (n, %)	14 (41.17%)	6 (37.5%)	p > 0.05
Lymphovascular invasion (n, %)	6 (18.18%)	0	P = 0.06
Perineural invasion (n, %)	2 (6.66%)	0	p > 0.05
Intense tumor budding (n, %)	0	0	
Total number of poor prognostic factors (media, SD)	2,59 (1,076)	1,93 (1,03)	P = 0.043
Disease progression (n, %)	1 (2,9%)	2 (1,25%)	p > 0.05

Conclusion: In our study, patients who underwent endoscopic treatment did not present significant differences with respect to those who received surgery in terms of long-term tumor progression, despite having a higher rate of submucosal invasion. Further studies with larger sample sizes are needed to determine which factors and to what extent influence lymphatic and distant dissemination of pT1 adenocarcinoma.

CLINICAL CHARACTERISTICS AND ENDOSCOPIC TREATMENT PROGNOSIS OF MULTIPLE RECTAL NEUROENDOCRINE TUMORS: A SINGLE-CENTER RETROSPECTIVE STUDY

Y. Zeliang[1], L. Yong[1], L. wenyu[2], N. Hoi-loi[1], H. Shun[1], W. Guiqi[1]

Introduction: The incidence of rectal neuroendocrine neoplasms (R-NENs) has been increasing annually. While most R-NENs are solitary, multiple lesions are relatively rare. Previous studies have suggested that patients with ≥8 lesions are more likely to exhibit lymphatic invasion and metastasis, indicating higher risk. However, the clinical and pathological features, prognosis, and endoscopic treatment outcomes of multiple R-NENs remain poorly understood.

This study aimed to clarify the clinical characteristics and endoscopic treatment efficacy of multiple R-NENs through a retrospective analysis of cases from our hospital, providing evidence for clinical management.

Aims & Methods: This retrospective study included 28 patients with multiple R-NENs treated endoscopically at the Cancer Hospital of the Chinese Academy of Medical Sciences between January 2010 and January 2024. Patients were divided into two groups based on lesion count: the "several group" (n < 8) and the "numerous group" (n ≥ 8). All patients underwent preoperative imaging to exclude lymph node metastasis and distant metastases. Data on demographics, lesion characteristics, endoscopic procedures, pathological findings, and follow-up outcomes were collected and analyzed.

Results: We compared endoscopic treatment outcomes between patients with several (<8, n=24) and numerous (≥8, n=4) rectal neuroendocrine tumors. The numerous group had a larger median maximum diameter (9.50 mm vs. 6.00 mm, p=0.337) and included one G2 case (25.0%) versus none in the several group, though differences were not significant. Notably, endoscopic complete resection was achieved in 100% of patients in both groups. All other parameters, including margin positivity, vascular invasion, neural invasion, and R0 resection rate, showed no significant differences. However, the numerous group had a significantly higher recurrence rate (75.0% vs. 0%, p=0.001). These findings highlight lesion count as a critical prognostic indicator for recurrence after endoscopic treatment.

Characteristic	Several group (n=24)	Numerous group (n=4)	p value
Max diameter (IQR, Q1-Q3)	6.00 (5.00-8.25)	9.50 (6.00-12.75)	0.337
Pathologic grade(G1),n(%)	23 (95.83%)	4 (100.00%)	0.457
Horizontal margin positive,n(%)	1 (4.17%)	0 (0.00%)	1
Vertical margin positive,n(%)	1 (4.17%)	1 (25.00%)	0.27
Vascular invasion,n(%)	3 (12.50%)	0 (0.00%)	1
Neural invasion,n(%)	1 (4.17%)	0 (0.00%)	1
Complete resection,n(%)	24 (100.00%)	4 (100.00%)	0.135
R0 resection,n(%)	22 (91.67%)	3 (75.00%)	0.382
Recurrence,n(%)	0 (0.00%)	3 (75.00%)	0.001

Table.1 Comparison of clinical and pathological prognosis between several group and numerous group.

Conclusion: Patients with ≥8 rectal neuroendocrine tumors exhibited more aggressive disease behavior, characterized by higher recurrence rates. These findings underscore the importance of lesion count as a prognostic indicator and suggest that patients with ≥8 lesions may require more intensive follow-up and management. For patients with <8 lesions, endoscopic treatment is effective when lymph node and distant metastases are excluded preoperatively. Future studies with larger datasets are needed to validate these findings and explore optimized treatment strategies.

FIRST-ROUND FECAL IMMUNOCHEMICAL TEST CONCENTRATION PREDICTS COLORECTAL CANCER AND ADVANCED NEOPLASIA IN SECOND-ROUND SCREENING: RESULTS FROM THE SCREESCO

M. Sekiguchi[1,2], M. Westerberg[3], C. Löwbeer[4,5], J. Blom[6,7], A. Forsberg[8]

Introduction: The quantitative fecal immunochemical test (FIT) is widely used for colorectal cancer (CRC) screening. While the association between FIT concentration and the risk of advanced colorectal neoplasia (ACN) detection is well established, the predictive performance of current-round FIT concentration alone has limitations. Identifying additional predictive factors could enhance screening. For individuals with a prior colonoscopy, colonoscopy findings and quality metrics may serve as such factors.1

For those who did not undergo colonoscopy due to a negative FIT in the previous round, alternative predictors should be explored. We hypothesized that prior-round FIT concentration could serve as a potential predictor.

Aims & Methods: We aimed to investigate whether prior-round negative FIT concentration could predict CRC and ACN detection by conducting a cross-sectional analysis of data from the FIT arm of the SCREESCO, a nationwide randomized controlled trial on CRC screening in Sweden.1,2 A sample of the Swedish population aged 60 years was randomly assigned to one of three arms: the once-colonoscopy arm, FIT arm, or control arm. Individuals in the FIT arm were invited to undergo two rounds of quantitative FIT screening in the first and third years. A highly sensitive method was used to assess FIT positivity, with a cut-off concentration of ≥10 µg Hb/g feces. We estimated the detection rates of CRC and ACN in second-round colonoscopy based on first-round FIT concentration.

Binary regression models were used to assess whether first-round FIT concentration was associated with CRC and ACN detection in the second round. The models included participant characteristics such as sex, body mass index, and smoking status, and second-round FIT concentration, in addition to first-round FIT concentration.

Results: A total of 1,991 individuals were included, with a median FIT concentration of 2.2 µg Hb/g feces (interquartile range: 0.4–4.6) in the first round and 21.8 (13.4–50.8) in the second round. CRC and ACN were detected during second-round colonoscopy in 23 (1.2%) and 267 (13.4%) individuals, respectively. Individuals with first-round FIT concentration of 0–1.9,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2.0–5.9, and 6.0–9.9 µg Hb/g feces had second-round CRC detection rates of 0.8%, 0.9%, and 2.6%, respectively, and ACN detection rates of 9.7%, 12.5%, and 15.9%, respectively. A higher first-round FIT concentration was associated with an increased risk of CRC (risk ratio per unit increase 1.27; 95% confidence interval 1.10–1.47) and ACN (1.08; 1.04–1.12) detection in the second round, after adjusting for the second-round FIT concentration and participant characteristics. For a fixed second-round FIT concentration, the absolute risk of second-round ACN detection increased with higher first-round FIT concentration. For instance, in a nonsmoking or ex-smoking male with a second-round FIT concentration of 20 µg Hb/g feces, the risk increased from 10.0% at < 0.2 µg Hb/g feces in the first round to 14.9% at 5 µg Hb/g feces and 19.6% at 9.9 µg Hb/g feces.

Conclusion: First-round negative FIT concentration is predictive of CRC and ACN detection in the second screening round. Even an increase in low levels of the FIT concentration is associated with future detection of these neoplasms. Incorporating first-round FIT concentration alongside second-round FIT concentration may enhance risk stratification in CRC screening, leading to more efficient use of colonoscopy resources.

NO NEED TO STAY ABOVE THE LINE: ANORECTAL JUNCTION ENDOSCOPIC SUBMUCOSAL DISSECTION IS COMPARABLE TO OTHER RECTAL LOCATIONS

A.I. Ferreira[1,2], T. Lima Capela[1,2], V. Macedo Silva[1,2], S. Xavier[1,2], J. Berkeley Cotter[1,2]

Introduction: Endoscopic submucosal dissection (ESD) is a well-established resection technique for superficial rectal lesions.

Aims & Methods: Evaluate the outcomes of overall rectal ESD and compare the resection of anorectal junction (ARJ) lesions with more proximal rectal (MPR) lesions, regarding feasibility, safety and efficacy.

Retrospective unicentric study including consecutive patients submitted to rectal ESD. ARJ lesions were considered as those totally or partially located within 2 cm of the dentate line. ESD failure was determined whenever the target lesion was not removed. *En bloc* resection required that the target lesion be retrieved in one single specimen. R0 resection was achieved when pathological evaluation showed free horizontal and vertical margins in an *en bloc* resected specimen. Specimens with thermal effects at the margins preventing the pathologist from excluding the presence of abnormal cells were considered R1 resections. Curative resection was considered in lesions with low- (LGD) or high-grade dysplasia (HGD) with R0 resection or lesions harboring a well-differentiated adenocarcinoma with superficial submucosal invasion (<1mm), with negative margins (>1mm), without lymphatic/vascular invasion or tumor budding.

Results: A total of 26 patients were included, most were females (57.7%), with a mean age of 63±10 years. Twelve patients (46.2%) had an ARJ lesion and fourteen (53.8%) had a MPR lesion. Most lesions were Paris 0-IIa+Is (61.5%), followed by 0-IIa+b (15.4%).

Technical success was achieved in 25 patients (96.2%), with no significant differences between those with an ARJ lesion and those with a MPR lesion (100.0% *vs* 92.9%, *p*=1.000). There were also no significant differences in the rate of *en bloc* resection (91.7% *vs* 92.9%, *p*=1.000). Most lesions harbored HGD (84.0%), with no significant differences in histology between ARJ and MPR lesions: in ARJ lesions, LGD occurred in 16.7%, HGD in 83.3% and adenocarcinoma in 0.0% *vs* in MPR lesions, LGD occurred in 0.0%, HGD in 84.6% and adenocarcinoma in 15.4% (*p*=0.134).

The global R0 resection rate was 61.5% and curative rate was 57.7%, both without statistically significant differences between patients with ARJ lesions and MPR lesions (50.0% *vs* 71.4%, *p*=0.422 and 50.0% *vs* 64.3%, *p*=0.462).

Regarding complications, there were no significant differences between patients with ARJ lesions and MPR lesions in the rate of significant intraprocedural bleeding (41.7% *vs* 35.7%, *p*=1.000) and exposure/section of muscular fibers with the need of closure of the eschar (8.3% *vs* 14.3%, *p*=1.000). The rate of postprocedural bacterial translocation and delayed bleeding were also similar between both groups (16.7% *vs* 21.4%, *p*=1.000 and 8.3% *vs* 7.1%, *p*=1.000, respectively).

Only one (3.8%) patient needed surgery due to a non-curative ESD, with no residual disease in the surgical specimen. Seventeen patients (65.4%) underwent a surveillance colonoscopy 6 and 12 months after the ESD, with one (5.9%) patient having residual tissue at 6 months with LGD and none with residual tissue at 12 months.

Conclusion: ESD of rectal lesions involving the anorectal junction is a feasible and safe procedure, with technical success and *en bloc* resection rate similar to more proximal rectal lesions and without differences in complication rates.

Disclosure: Nothing to disclose.

Introduction: Endoscopic submucosal dissection (ESD) is increasingly used to treat colonic dysplasia and early neoplasia. This is a safety, non-invasive alternative treatment to surgery.

Aims & Methods: To evaluate the outcomes of ESD on colonic dysplasia and neoplasia in our Italian single center, including complications and recurrence

Our four-year retrospective study at a single tertiary center included data spanning from 2021 to 2025. The efficacy of ESD on colonic dysplasia and early neoplasia was measured using parameters set out by the National Institute for Health and Care Excellence, which include *en-bloc* and curative resection (CR) rates, local recurrence and survival rates.

Results: ESD was attempted on 47 lesions in 35 patients. 90.0% of completed procedures achieved endoscopic clearance. 74.3% were *en-bloc* resections and the rest were hybrid ESD with piecemeal resections. In all, 40% achieved histological CR. Overall, disease recurrence was 10.9%

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. at latest follow-up (12 months, median follow-up). Importantly 100% of lesions in the CR group showed no disease recurrence at subsequent follow-up. In the Indeterminate and Non-CR group, 18.8% of lesions showed disease recurrence at subsequent endoscopic follow-ups. Immediate complications were observed in 9.9% of all ESD procedures.

Conclusion: The study affirms the long-term efficacy and safety of ESD for colonic dysplasia and early neoplasia in our single center.

Introduction: Colorectal cancer is the third most common cancer worldwide and the second leading cause of cancer-related death. Most colorectal cancers arise from benign polyps, especially dysplastic adenomas. Colonoscopy with polypectomy is the gold standard for preventing cancer by interrupting the adenoma-carcinoma sequence. This has led to the development of various techniques and devices for improved prevention and treatment. Hot snare endoscopic mucosal resection (HS-EMR), which combines submucosal injections with electrocautery, is commonly used for excising various colorectal polyps. However, it carries risks of diathermy-related complications, such as perforation, and bleeding.

To address these issues, cold snare endoscopic mucosal resection (CS-EMR) has been proposed as an alternative. Concerns about residual adenoma/recurrence have been raised with CS-EMR. Therefore, we conducted this meta-analysis to compare the two techniques.

Aims & Methods: We searched electronic databases, including MEDLINE via PubMed, Scopus, Web of Science, and Cochrane, without restrictions on publication date or language. We included RCTs comparing CS-EMR and HS-EMR for colorectal polyp resection. Primary outcomes included the incidence of delayed bleeding and residual/recurrent adenoma (RRA).

Results: On Nov 5, 2024, our literature search across electronic databases retrieved a total of 1,888 records. Following a meticulous screening process, six studies met the eligibility criteria encompassing 1,449 patients and 1,947 polyps. Regarding safety, the overall effect estimates regarding delayed bleeding showed statistically significant results favoring CS-EMR group [OR 0.31, 95 % CI (0.12–0.76), P = 0.01] with no heterogeneity (P = 0.40; I^2 = 0 %).

However, statistical superiority for CS-EMR could not be detected regarding early bleeding [OR 0.78, 95 % CI (0.31–1.97), P = 0.60]. Only two studies reported data on delayed perforation, showing a numerical difference favoring CS-EMR; however, statistical significance could not be obtained [OR 0.26, 95 % CI (0.03–2.41), P = 0.24].

Regarding efficacy, the overall effect estimates regarding complete resection and RRA did not favor either of the groups [OR 0.62, 95 % CI (0.25–1.53), P = 0.30], [OR 2.81, 95 % CI (0.43–18.47), P = 0.28] respectively.

Conclusion: Evidence obtained from this meta-analysis suggests that CS-EMR offers superior safety compared to HS-EMR for colorectal polyp resection. Current evidence remains limited due to the small number of studies included. Therefore, further high-quality randomized controlled trials with larger sample sizes are needed.

Introduction: Deep submucosal invasion is not considered an independent risk factor for lymph node metastasis in T1 colorectal cancer (CRC). This study aimed to evaluate the feasibility and effectiveness of diagnostic endoscopic resection for T1 CRCs with deep invasion.

Aims & Methods: This retrospective study included consecutive patients with T1 CRC who underwent either endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR). Pedunculated lesions (Paris classification Ip) were excluded. Low-risk T1 CRCs were defined as lesions with submucosal invasion ≥1000 μm that were resected en bloc with R0 margins and lacked lymphovascular invasion (LVI), high-grade budding (>BD1), or poor differentiation. These lesions were considered eligible for expanded curative resection.

Results: A total of 123 T1 CRC lesions in 121 patients were resected endoscopically (26 by EMR, 97 by ESD). The overall en bloc and R0 resection rates were 89.4% (100/123) and 65.9% (81/123), respectively. For T1b CRCs, these rates were 86.7% (52/60) and 56.7% (34/60). No perforations occurred. Expanded curative resection was achieved in 26.7% (16/60) of T1b cases. Among non-curatively resected T1b lesions, 50.0% (30/60) had LVI, 41.7% (25/60) had positive or indeterminate vertical margins (VM1/VMX), and 13.3% (8/60) showed significant tumor budding.

Conclusion: Diagnostic endoscopic resection for T1 CRCs with deep submucosal invasion is feasible and safe, with a notable rate of expanded curative resection. This strategy may support accurate pathological evaluation and informed treatment planning in selected patients.

Disclosure: Nothing to disclose.

THE SMALL SOLUTION FOR A BIG PROBLEM: CAN MICRORNAS PREDICT TREATMENT OUTCOMES IN COLORECTAL CANCER PATIENTS?

D. Santos[1,2], L.L. Santos[1,3], C. Vieira[4], M. Dinis-Ribeiro[1,2], L. Lima[1]
[1]CI-IPOP, Porto, Portugal, [2]Faculty of Medicine of the University of Porto (FMUP), Porto, Portugal, [3]IPO-Porto, Department of Surgical Oncology, Porto, Portugal, [4]IPO-Porto, Department of Medical Oncology, Porto, Portugal

Introduction: Colorectal cancer (CRC) ranks as the second leading cause of cancer-related deaths worldwide. Although first-line chemotherapy can prolong survival in CRC patients, around 40% do not experience a beneficial response to these therapeutic regimens.

Currently, no clinically validated biomarkers capable of predicting patient response to chemotherapy are available. MicroRNAs (miRs) are small non-coding RNAs involved in various oncogenic processes. Their differential expression across distinct clinical conditions, along with their high stability and ease of detection, make them promising predictive biomarkers to overcome this challenge.

Aims & Methods: Thus, we aimed at systematically reviewing the current state of knowledge regarding miRs as predictive biomarkers of therapeutic response in colorectal cancer patients. A systematic search on PubMed/MEDLINE and Scopus databases was performed on published articles reporting the role of microRNAs detected in blood and tissue as biomarkers for predicting the therapeutic outcome in colorectal cancer patients. 2673 records were retrieved by December 2024. After removal of duplicate records 2568 abstracts were screened, and 40 full texts included in this review.

The different outcomes to predict treatment response were extracted from the studies, namely response to chemeotherapy, progression free survival (PSF), disease free survival, overall survival, and recurrence of the disease.

Results: Among the 111 miRs reported in the 40 articles, circulating miR-4772-3p demonstrated a good ability to predict the response of CRC stage I–III patients to FOLFOX, the most used first-line therapy in this group of patients (sensitivity: 79%, AUC: 0.72, 95% CI: 0.59–0.85). Additionally, PFS is commonly used to assess treatment response. In this context, decreased levels of miR-4772-3p are associated with poor PFS, demonstrating a lower response to FOLFOX.

In addition, a combination of three miRs (miR-17-5p, miR-92b-3p, and miR-98-5p) in tissue samples was indicative of a complete or partial response to FOLFOX combined with anti-VEGF therapy, namely bevacizumab, in metastatic CRC patients (AUC: 0.85, 95% CI: 0.72–0.91). Notably, miR-17-5p was the most frequently reported miR associated with FOLFOX response prediction in tissue samples, and its high expression levels were linked to poor PFS, indicating treatment inefficiency and consequently progression of disease.

Regarding to the specific group of patients with locally advanced rectal cancer (LARC) that are mainly submitted to neoadjuvant chemoradiotherapy (nCRT), a panel composed of eight circulating microRNAs (miR-30e-5p, miR-33a-5p, miR-130a-5p, miR-210-3p, miR-214-3p, miR-320a, miR-338-3p, and miR-1260a) showed a higher accuracy for predicting patients response to nCRT, with a sensitivity of 80% (AUC: 0.89, 95% CI: 0.81 to 0.94).

Furthermore, the miR-125b-5p detected in tissue samples, was also associated with the nCRT response (AUC: 0.90, 95% CI: 0.7818-1.043). These miRs could increase the response to nCRT for LARC patients, considering that currently only around 40% achieve a partial response and as few as 20% reach a complete response to treatment.

Conclusion: This systematic review highlights the potential of microRNAs as predictive biomarkers of therapeutic response in CRC, with the ability to improve treatment outcome prediction and support personalized therapy. However, further validation is required for improving clinical decisions and to allow the clinical applicability of these biomarkers.

Disclosure: Nothing to disclose.

Introduction: In colonoscopies with colorectal neoplasia, the endoscopy therapy is recommended. The surveillance (follow-up, FU) colonoscopies follow with the aim to diagnose the recurrent and metachronous lesions. Many guidelines recommend the intervals of such procedures based on the number, size and histopathological phenotype of the resected lesions. In clinical practice, the adherence of the recommendations is variable and selection of the high-risk patients who will benefit from shorter intervals might be helpful.

Therefore, detailed study focusing on the development and clinical utilization of the new method combining the clinicopathological phenotype and the mutation burden was started in 2017. The interim results of the clinical phase of the prospective study are described.

Aims & Methods: Patients with colorectal lesions ≥ 10 mm removed by advanced therapeutic methods (en-bloc mucosal resection and submucosal dissection) and followed in interval in year 1, 3 and 5 were included. The therapy and surveillance were performed in one tertiary endoscopy center.

The main aim was to assess the metachronous lesions (number, size, locality, histopathology characteristics) in relation with the index colonoscopy findings. Secondary aim was evaluation of the local residual neoplasia (LRN) in the scar after previous therapy.

Results: There were 217 patients included in the study in years 2017 – 2020. Eight of them were excluded because they did not meet the inclusion criteria. Results of the index colonoscopy in 209 patients (130 men, 62,2%; 79 women, 37,8%) were analyzed. 275 index lesions were found, majority of them (238 lesions, 86,5 %, low-grade and high-grade adenomas) were benign and there were 12 (4,4%) intramucosal cancers, two T1 cancers, one T2 cancers and one NET. 21 lesions were hyperplastic or others.

Follow-up colonoscopy in one year was performed in 178 patients (82,0%) and in 91 of them (51,1 %) metachronous lesions were found, 120 (64,2%) adenomas, 46 (24,6%) hyperplastic and 21 (11.2%) others, with no can-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. cer. LRN was diagnosed in 5,5% patients. In 122 patients with 3-years FU colonoscopy, 59 (48,4%) had metachronous lesions, mostly adenomas (73; 72,3%), no cancer and one LRN found. 45 patients had 5-years FU colonoscopy so far, 22 of them (48,9%) with metachronous lesions, mostly adenomas (25; 54,3%), no cancer, LRN in one case.

Conclusion: In patients after removal of the high-risk colorectal lesions defined by size ≥ 10 mm, high numbers of metachronous lesions were found in the strict surveillance protocol (years 1, 3, and 5). All the lesions were benign, with no cancer found.

Introduction: Colorectal cancer surveillance recommendations for individuals with Lynch Syndrome (LS) differ between professional associations and the data on interval colorectal cancer (I-CRC) and interval advanced polyps (I-AP) are limited. We aimed to measure the rate of I-CRC and I-AP within a surveillance program.

Aims & Methods: Retrospective study involved individuals with LS who participated in CRC surveillance program at Clalit Health hospitals, Israel. The main outcomes were the rates of I-CRC and I-AP ≤36 months, categorized by 12-month intervals. Included only colonoscopies with adequate preparation. I-CRC and I-AP (≥10 mm or containing high-grade dysplasia or villous histology) were defined as interval advanced neoplasia (I-AN).

Results: The cohort included 342 individuals, 52.3% females, with a median age at data analysis of 49.0 (IQR 37.7-64). At interval ≤ 12 months, there were 7 cases of I-CRC [6/142 (4.2%) of MSH2; 1/46 (2.2%) of MLH1] and 13 cases of I-AP (10/142 (7.0%) of MSH2, 2/46 (4.3%) of MLH1, 1/136 (0.7%) of MSH6]. At 12-24 months, there were 3 cases of I-CRC [2/142 (1.4%) of MSH2, 1/136 (0.7%) of MSH6] and 10 cases of I-AP [8 /142 (5.6%) of MSH2, 1/46 (2.2%) of MLH1, 1/136 (0.7%) of MSH6]. At 24-36 months, there were 3 cases of I-CRC [2/142 (1.4%) of MSH2, 1/18 (5.6%) of PMS2] and 4 cases of I-AP [1 /142 (0.7%) of MSH2, 3/136 (2.2%) of MSH6]. Of all I-CRC, four were diagnosed at stage 3 [4/342 (1.2%)], all at interval ≤24months [3-MSH2, 1-MSH6]. Increasing age and path_MSH2 were significantly associated with I-AN.

Conclusion: Extending surveillance colonoscopy intervals could result in significant rates of I-CRC and I-AP. Diagnosis of I-CRC at advance stage can occur at interval less than 24 months.

Disclosure: Nothing to disclose.

ENDOSCOPIC CHARACTERISTICS OF LOCAL TUMOR REGROWTH IN PATIENTS UNDERGOING WATCH-AND-WAIT AFTER NEOADJUVANT THERAPY FOR RECTAL CANCER

S. Szczegielniak[1], P. Thelin Schmidt[2], P. Lundström[3], C. Höög[1], P.J. Nilsson[3], A. Martling[4], S.L. Haas[5]
[1]Karolinska University Hospital, Department of Upper GI Diseases, GI Endoscopy, Stockholm, Sweden, [2]Uppsala University Hospital, Department of Gastroenterology, Uppsala, Sweden, [3]Karolinska University Hospital, Division of Coloproctology, Stockholm, Sweden, [4]Karolinska Institutet, Department of Molecular Medicine and Surgery (MMK), Stockholm, Sweden, [5]Karolinska University Hospital and Department of Medicine, Karolinska Institutet, Centre for Digestive Health, Stockholm, Sweden

Contact E-Mail Address: slwsz1@protonmail.com

Introduction: Watch-and-Wait is an increasingly recognized non-surgical management option for rectal cancer patients achieving a clinical complete response (cCR) following neoadjuvant therapy. This approach aims to preserve organ function by avoiding surgery, but necessitates vigilant endoscopic surveillance, to detect local tumor regrowth[1] (LTR). The specific endoscopic features associated with regrowth remain incompletely defined.

Aims & Methods: We performed a retrospective analysis of patients monitored under the Watch-and-Wait program at Karolinska University Hospital[2], focusing on the endoscopic characteristics of LTR. As of December 2023, 145 patients who met the criteria for clinical complete response (cCR) were included.

The neoadjuvant treatment consisted of chemoradiotherapy (CRT) in 16 patients (11%), short course radiotherapy (SCRT) + chemotherapy in 69 patients (47.6%) and SCRT alone (5 x 5 Gy) in 60 patients (41.4%). The median age of the patients was 66 years (range 29-94), with 61.4% being male.

The initial tumor stage was T1/T2 in 42 patients (29%) and T3/T4 in 103 patients (71%). The nodal stage was N0 in 35 patients (24%) and N+ in 110 patients (75.9%). The median follow-up period was 29 months (range 3-102 months).

Patients were monitored with rectal digital exams, flexible endoscopy, CEA measurements, and MRI every 3 months for 2 years, and then every 6 months thereafter. During endoscopy, narrow-band imaging (NBI) and NICE classification[3] was utilized.

Results: Out of the 145 patients, 28 (19.3%) experienced LTR as of December 2023. The median time from the completion of radiotherapy to regrowth was 9 months (range 3-20 months). Regrowth was detected intraluminally by endoscopy in 23 patients (82.1%), while in 5 patients (17.9%), regrowth was detected on MRI but was not visible intraluminally.

The most common endoscopic features of regrowth included a NICE 3 pattern (n=16) and contact bleeding (n=16).

Additional findings included polypoid tissue (n=13), ulceration (n=10), irregular surface (n=9), fibrin cover (n=9), stenosis (n=6), and submucosal nodules (n=5).

Conclusion: As regrowth occurs in at least one of five patients and most commonly with intraluminal findings, this study highlights the importance of meticulous endoscopic follow-up.

Contact bleeding and NICE type 3 lesions observed with narrow-band imaging (NBI) were key endoscopic findings in patients with tumor regrowth, while polypoid lesions were observed in less than 50%.

Combining endoscopic assessment with other modalities, such as MRI, is essential, as regrowth may be undetectable endoscopically in a proportion of patients.

COLORECTAL CANCER SURVEILLANCE PROGRAM IN LYNCH SYNDROME: A CLINICAL AUDIT IN A REFERENCE CENTER

N. Gonçalves[1], F. Côrte-Real[2], F. Correia[3], Â. Domingues[4], M. Garrido[1], C. Lopes Brandão[1]

Contact E-Mail Address: nunorsgoncalves@gmail.com

Introduction: Lynch syndrome (LS) is a hereditary condition associated with an increased risk of early colorectal cancer (CRC), due to mutations in DNA mismatch repair (MMR) genes, accounting for 3-5% of all CRC. High-definition screening colonoscopies in specialized centers reduce CRC mortality in this setting.

Aims & Methods: We conducted a clinical audit in a large cohort of these patients, ultimately to enhance the quality of care provided. We performed a retrospective evaluation of the clinical characteristics and risk factors of LS patients under surveillance at our reference center. CRC surveillance program includes colonoscopy every 2 years, starting at ages 20–25 for MLH1/MSH2 carriers and 30–35 for MSH6/PMS2 carriers.

We further analyzed compliance to surveillance protocol and its clinical outcomes – our primary endpoint was mortality rate due to CRC and secondary endpoints were time to first advanced colorectal lesion and CRC staging at diagnosis.

Results: A total of 508 patients were included (44% MSH2, 23% MLH1, 20% MSH6, and 13% PMS2). The mean age at surveillance initiation was 44.4 years, with 35.6% starting after the diagnosis of a Lynch syndrome-associated neoplasia. The mean surveillance duration was 5.6 years. Each patient underwent an average of four colonoscopies, with 50% performed within the recommended surveillance intervals.

During the follow-up period, 35 patients were diagnosed with CRC, with a mean time to first advanced colorectal polyp of 3.7 years and for the first CRC diagnosis of 4.8 years. Having any colonoscopy outside the established interval was not associated with higher CRC incidence (p = 0,647). CRC cases diagnosed prior to surveillance initiation (n=143) were more advanced (58.1% stage ≥ II) and were treated with segmental colectomy in 80% of cases. In contrast, CRC cases diagnosed during surveillance (n=48) were detected at earlier stages (64.6% Tis/T1) and managed with endoscopic resection (29%) or total colectomy (56%) ($p < 0.001$).

The incidence of CRC was higher in MLH1/MSH2 carriers compared to MSH6/PMS2 carriers (36% vs. 22%, $p = 0.0020$). The mean age at first CRC diagnosis was 45.6 years for MLH1/MSH2 carriers and 49.9 years for MSH6/PMS2 carriers ($p = 0.053$). The CRC-related mortality rate was 0.6% (n=3), all cases diagnosed before surveillance initiation.

Conclusion: Although adherence to the CRC surveillance program in LS patients can be optimized, our findings underscore its importance in specialized reference centers. Surveillance was associated with earlier CRC detection, less invasive therapeutic approaches, and reduced CRC-related mortality. Our results also show a lower incidence of CRC and an higher age at first CCR diagnosis in MSH6/PMS2 carriers, strengthening the personalized surveillance recommendations dependent on gene specificities.

Introduction: T1 colorectal cancer can be managed either by surgery or interventional endoscopy. High-risk features after endoscopic resection (G3, submucosal invasion >1000 µm, lympho-vascular invasion, tumour budding+, or R1 resection) increase the risk of lymphnode metastasis (10-15%), often requiring additional surgery. However, the benefits of surgery versus endoscopic resection alone remain unclear, particularly in elderly or frail patients.

Aims & Methods: The aim of the study is to assess recurrence rate and overall survival in patients underwent surgery, endoscopy or both. Secondary endpoints is to evaluate incidence of adverse events and length of hospital stay.

All consecutive patients diagnosed with T1 colorectal cancer from 2018 to 2024 in our institution were enrolled in this retrospective study. We divided this cohort in 3 groups: endoscopic resection plus surgery (ER-S), upfront surgery (SR), or endoscopic resection alone (ER). Demographics data, mortality, cancer recurrence rate, disease free survival and AEs were recorded.

Results: One-hundred and thirty-three patients were enrolled in the study: 34 (72 years±10) in the SR group, 65 (65 years±11) in the ER-S group and 34 (77 years±11) in ER, respectively.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Lesions were similar (p-value 0.30) for dimension: 31±15 mm (ER) vs 23±12 mm (ER-S) vs 30±13 mm (ER) such as follow-up (23 vs 24 vs 21 months) for the three groups (p-value 0.428). Hospital stay after the procedure was significantly lower in the ER group (1 day median) vs SR (median 9 days;p-value 0.0001) and ER-S group (7 days median;p-value 0.003). Cumulative 30 days adverse events were higher in the SR group (62%; p-value 0.0001) and in the ER-S group (22%; p-value 0.001) compared to ER alone (12%). During the study period, no endoscopic/radiological recurrence occurred in the SR group whereas 1 patient in the ER-S group and 2 in the ER group showed recurrence non suitable for further treatments.

Five patients in SR group died after a median of 18 months (1 for early surgical complication); 2 died in the ER-S group after a median of 34 months and 3 died in the ER group after a median of 24 months (1 for rectal cancer progression) (p-value 0.365).

Overall survival was comparable among the three groups with no significant difference (p-value 0.718) with a median of 40 months (SR), 28 (ER-S) and 26 (ER) months.

Conclusion: Endoscopic resection alone appears to be a reasonable option for high-risk T1 CRC patients, especially those with increased surgical risk due to low rate of recurrence, low adverse events and a comparable overall survival in short-mid term.

Introduction: Rectal sensitivity can be assessed by elastic balloon distension (EBD) or rectal barostat test (RBT)[1]. EBD assesses rectal sensitivity to a maximum volume determined by the balloon. In contrast, RBT assesses rectal sensory thresholds relative to an individual's total rectal capacity, and can additionally measure intra-rectal pressure. There are no studies that compare diagnostic yield for disorders of rectal sensation, defined by the London Classification[2], using EBD and RBT.

Aims & Methods: This prospective study assessed the feasibility, tolerability, and diagnostic agreement of EBD and RBT in a symptomatic population (Rectal barostat study, ISRCTRN 46893, recruitment ongoing).

Prospective patients referred for anorectal physiology studies were recruited from two NHS Trust sites (UK). Participants underwent both EBD and RBT in randomised order. At site 1 EBD was performed using a Laborie water-perfused manometry system (LWP, balloon volume 400mL). At site 2 the Medtronic solid-state 3D manometry system was applied (MSS, balloon volume 400mL). At both sites the Mui Scientific Rapid Barostat was used for comparison (RBT, bag volume 700mL). Standard protocols for EBD and RBT were followed[3,7].

Reference ranges for each rectal sensitivity test were based on published studies[4-7].

Diagnosis based on the London Classification was obtained using results from both the EBD and RBT. Participants completed a questionnaire to assess tolerability of both procedures.

Results: At site 1 patient uptake of the study was 76% (n=16, 10F:5M, median age 64). At site 2 patient uptake of the study was 45% (n=9, 8F:1M, median age 70). 1 participant from both sites withdrew from the study. 1 participant reported pain during EBD, and 2 during RBT. 2 participants reported that they would not be willing repeat the tests. Median time taken to perform each procedure was 1min24s for EBD and 15min26s for RBT.

The percentage of London Classification diagnoses that remained unchanged was 13% at site 1 and 56% at site 2.

ICC demonstrated good test-retest reliability of the RBT for all sensory thresholds, including 'first sensation' (k=0.84, p<0.001), 'normal desire to defecate' (k=0.84, p<0.001), and 'sustained urgency' (k=0.86, p<0.001).

Conclusion: Patient willingness to be entered into the study differed between sites despite the recruitment process and study team remaining the same. This may be due to differences in patient demographics between sites. Both the EBD and RBT were feasible and well tolerated by participants, however the RBT protocol was significantly longer. Good test-retest reliability of the RBT suggests the protocol could be reduced to one round of sensory testing.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

These preliminary findings suggest that agreement between London Classification diagnoses obtained using EBD and RBT is sub-optimal. This was evident in both the LWP and MSS systems.

Further studies would be required to determine whether the management of patients with rectal sensitivity disorders based on the London Classification depends on the type of equipment used to assess rectal sensitivity disorders. This is important as accurate assessment of rectal sensitivity may be valuable in guiding effective management of patients with rectal sensitivity disorders[8].

Introduction: Functional diseases of the gastrointestinal tract are a common diagnosis, with the most common manifestations being functional dyspepsia and IBS. The pathophysiological mechanisms and etiology of this group of diseases are not fully understood, but stress is believed to play a key role.

Aims & Methods: This study aims to evaluate the effectiveness of a low-histamine diet in patients with irritable bowel syndrome. Patients who meet the ROME IV criteria were included in the study.

The study included 120 patients, divided into three groups: low- histamine diet, FODMAP diet and mediterranian diet. Questionnaires were used to assess stress levels PSS-4, anxiety GAD-7, severity of IBS - IBS Severity Score, and quality of life.

The questionnaires were completed three times: both at the beginning of the study, immediately after the end of the 4-week diet, and one month after the end of the diet therapy.

Results: The low-histamine diet led to a statistically significant improvement in IBS symptoms compared to baseline. These findings suggest that the dietary intervention had a positive therapeutic effect (low- histamine diet *:* t = 9.6181, p-value < 0.001, low FODMAP diet Z = 22, p-value < 0.001, mediterannian diet Z =119, p-value < 0.001).

Conclusion: Dietary therapy plays a key role in the management of IBS. The low-histamine diet shows promising results and may serve as a viable alternative to the FODMAP diet.

Disclosure: The study was launched after receiving approval from the Research Ethics Committee (REC) at the Medical University "Prof. Dr. Paraskev Stoyanov" – Varna, protocol 111/ 20.01.2022y.Data were processed and analyzed using appropriate statistical methods chosen according to the nature of the variables and research questions. The analysis includes:

• Evaluation of the statistical significance of the main and interactions between the factors (Repeated Measures with Wicolxon and Paired t-test).

• Regression analysis to assess relationships between dependent and independent variables. As well as using heteroskedasticity-robust standard error estimates (HC3) to ensure accuracy of regression analysis results.

Introduction: The lactulose breath test (L-BT) is a non-invasive method to assess small intestinal bacterial overgrowth (SIBO). However, diagnostic criteria for intestinal methanogenic overgrowth (IMO) differ among experts, and international guidelines lack a definition. Methanogenic flora is linked to slower gut transit in irritable bowel syndrome (IBS), but the effects of methane-targeting treatments on methanogens, colonic transit, and stool form remain unclear.

Aims & Methods: To examine relationships between methanogenesis, constipation, pain and bloating in healthy volunteers and patients with and without IBS. METHODS: Cross-sectional study on adults with L-BT between 2016–2024 at a single center. Each patient completed a Rome IV questionnaire, sociodemographic and medical data and Bristol stool scale. IMO was diagnosed if there were more than 3 measurements of CH_4 over 10 ppm over 180 minutes.

We examineded 3 alternate diagnostic thresholds: (A) 10 ppm at any time (American criteria or C1); (B) 10 ppm over baseline before 90 minutes (C2); and (C) 10 ppm over baseline before 60 minutes (C3), We considered "high producers" of CH_4 those that had 2 measurements over 60 ppm. Statistical analysis with Mann-Whitney and Kruskal Wallis test.

Results: We included 5,053 subjects who underwent L-BT (mean age 49 years, 81% women). Of these, 10% were exclusive H2 producers, 2% CH4 producers, and 2.7% were non H2/CH4 producers. CH4 producers had a higher frequency of constipation (p<0.001) and greater total CH4 production in the Bristol 1-2 group. CH4 production over 180 minutes was lower in IBS-D patients, though the overall methane production rate was similar

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

to healthy volunteers. Based on diagnostic thresholds, 92.6% of constipated patients met C1, 52.3% C2, and 18.1% C3, with significant differences (p=0.001). Stricter IMO criteria were associated with greater bloating and pain intensity.

Conclusion: The high proportion of methane production in our asymptomatic controls, compared to previous series, may reflect demographic differences. Methane producers had a higher frequency of constipation. The IMO diagnosis rate varied depending on the criteria used, with stricter criteria identifying patients with more frequent constipation, bloating, and abdominal pain.

EFFECT OF PSYCHOLOGICAL STRESS ON THE SMALL-INTESTINAL ENVIRONMENT AND MUCOSAL INTEGRITY

S. Yagi[1], H. Fukui[1], T. Shiraishi[1], M. Wakita[1], Y. Takagi[1], M. Ikenouchi[1], T. Sato[1], M. Kawai[1], K. Kamikozuru[1], Y. Yokoyama[1], T. Tomita[1], S. Kitaoka[2], S. Shinzaki[1]

Contact E-Mail Address: t7xcipff@gmail.com

Introduction: Psychological stress is an important factor for the development of functional gastrointestinal disorders. Psychological stress may play a pivotal role in inflammatory pathophysiology in the gastrointestinal tract by affecting the small-intestinal environment and mucosal integrity. However, the relationship between psychological stress and the abnormality of intestinal environment/mucosal integrity remains unclear. Therefore, in the present study we comprehensively investigated the microbiome profile, expression of tight junction protein and mucosal inflammatory conditions in the small intestine in chronic social defeated stress (CSDS) mice that is accepted as a model of depressive state.

Aims & Methods: The CSDS model were prepared by exposing a C57BL/6N intruder mouse to a CD-1 aggressor mouse for 10 minutes daily 10 days in the home cage of CD-1 mouse. A social interaction test was performed to evaluate social avoidance behavior. The obtained fresh fecal samples were used to analyze the gut microbiome profile and stool characteristics including appearance and moisture. Small intestinal tissues were collected to assess the expression of cytokines, lipopolysaccharide (LPS), antimicrobial peptides, and tight junction proteins (TJPs) using real-time RT-PCR and immunohistochemistry.

Results: The time spent in the social avoidance zone was significantly longer in the CSDS group than in the controls when the CD-1 aggressor mouse was present. These findings indicate that CSDS mice are successfully established as a model of depressive state. Regarding stool appearance, the average Bristol scale score was significantly lower in the CSDS group compared to the controls ($p < 0.01$). Consistent with this finding, the fecal water content was significantly lower in the CSDS group compared to the control group ($p < 0.05$). There were no differences in the α- and β-diversity of the fecal microbiome between the CSDS and control groups. However, the relative abundances of *Proteobacteria* and *Patescibacteria* at the phylum level were significantly higher in the CSDS group ($p < 0.05$). Regarding TJPs and antimicrobial peptides, the expression of Occludin, Claudin 4, and Reg IIIg was significantly decreased in the small intestinal epithelium of CSDS mice compared to the controls. As for the cytokines and LPS, the expression of both IL-1b and LPS was significantly increased in the small intestine of CSDS mice compared to the controls.

Conclusion: Psychological stress affects the small-intestinal environment and mucosal integrity, resulting abnormal stool property and intestinal minimal inflammation.

SOMATIZATION IN PEDIATRIC PATIENTS WITH IRRITABLE BOWEL SYNDROME

M. Semen[1], O. Lychkovska[1], V. Semen[2]
[1]Danylo Halytsky Lviv National Medical University, Lviv, Ukraine, [2]Lviv Regional Children's Clinical Hospital "OHMATDYT", Lviv, Ukraine

Contact E-Mail Address: martasemen4@gmail.com

Introduction: Somatization is defined as a tendency to experience and communicate psychological distress in the form of somatic symptoms. Literature suggests that there is a link between somatization and irritable bowel syndrome (IBS). Nevertheless, the association between clinical symptoms of IBS and somatization, especially in children, remains unclear.

Aims & Methods: 54 children aged 6-12 with a verified diagnosis of IBS according to Rome criteria IV were included in the study. The control group consisted of 50 healthy children of the same age and gender. The level of somatization was assessed by the Somatoform Symptom Screening test (SOMS-2J by Rief, W., & Hiller, W.), which was modified for children.

The intensity of abdominal pain and dyspeptic symptoms were estimated using a 4-point Likert scale. Data were processed using Microsoft Excel 2016 and analyzed with GraphPad (Prism 5.0). Pearson test was used to assess the correlation between SOMS rate and the intensity of somatic complaints.

Results: The level of somatization was significantly higher in children with IBS in comparison to the control group (p<0.0001). There was no difference in somatization rate in patients according to the predominant bowel habit. A direct correlation between the intensity of abdominal pain and the level of somatization (r=+0.37; p=0.005) was established in children with IBS (Fig.1).

On the contrary, the intensity of dyspeptic symptoms was less influenced by the rate of somatization (r=+0,18; p=0,20).

Conclusion: To conclude, children with IBS who had higher rates of somatization were revealed to have a higher intensity of somatic complaints, especially abdominal pain. We suggest that somatization plays an important role in the occurrence of somatic symptoms of IBS. It may be one of the reasons for the low effectiveness of pharmacological treatment of IBS in children.

SYMPTOMATIC IMPROVEMENT IN PATIENTS WITH DISORDERS OF GUT-BRAIN INTERACTION (DGBI) IN RESPONSE TO CHRONIC BLUEBERRY CONSUMPTION IS ASSOCIATED WITH GUT MICROBIOME CHANGES

J. Li[1], P.W. O'Toole[1], A. Materna[2], C.H. Wilder-Smith[2]
[1]University College Cork, APC Microbiome Institute, Cork, Ireland, [2]Brain-Gut Research Group, Gastroenterology Group Practice, Bern, Switzerland

Contact E-Mail Address: info@ggp.ch

Introduction: The antioxidant, anti-inflammatory and modulatory effects of blueberries on gut microbiota are well known[1]. In patients with DGBI blueberry ingestion for 6 weeks significantly relieved abdominal symptoms and improved Gastrointestinal Symptom Rating (GSRS) and quality-of-life and life functioning scores by Outcome Questionnaire (OQ 45.2) compared to placebo[2]. Whether changes in gut microbiota are relevant in the symptomatic relief of blueberries in DGBI is unexplored.

Aims & Methods: Male and female patients aged 18 to 60 years with DGBI (irritable bowel syndrome or functional dyspepsia, Rome 4), were randomized to double-blind blueberry (30g freeze-dried powder = 180g fresh blueberries) or placebo daily for 6 weeks, with subsequent cross-over. GSRS and OQ-45.2 scales were assessed before and in week 6 of each treatment period. Responders were defined by improved GSRS and OQ-45.2 scores. Stool microbiome analysis was performed by DNA extraction and shotgun metagenomic sequencing. Quality controlled sequences were annotated with MetaPhlAn 4. Nonmetric multidimensional scaling ordination plots based on Bray-Curtis dissimilarity were generated at the species level with clinical covariates to visualize the intra- and inter-subject variability of microbiota. ANCOM-BC2 was used to estimate the differential abundance of the prevalent species. Pairwise networks before and after intervention were constructed and the frequency difference of positive and negative associations between responders and non-responders compared. Associations of gut microbial species with outcomes were analyzed (Spearman), stratifying data into before and after intervention, as well as responder and non-responder groups.

Results: In 43 patients, microbiome alpha diversity of the gut microbiota taxa did not change significantly between visits with either treatment and did not differ between responder groups. However, at baseline, multiple species differed in abundance between responders and non-responders for both the GSRS and OQ-45.2 outcomes (table). During blueberry ingestion there were multiple species differences between responders and non-responders for either outcome.

	Baseline (#p<0.05)	During blueberry ingestion (#p<0.05)
GSRS outcome (gastrointestinal)	Responders > Non-responders: 55 species; #in: Butyricimonas faecihominis, Enterocloster lavalensis, Enterocloster citroniae, Mediterraneibacter glycyrrhizinilyticus	Increased in responders & decreased in non-responders: 16 species; #in: Butyricicoccus sp AM29_23AC, Clostridia bacterium UC5_1_1D1, Clostridium sp AF34_10BH, Oscillibacter sp ER4
GSRS outcome (gastrointestinal)	Non-responders > Responders: 56 species; #in: Lachnospiraceae bacterium AM48_27BH, Clostridiaceae bacterium Marseille_Q4143, Blautia glucerasea, Clostridium sp AF34_13, Ruminococcus sp AF41_9	Decreased in responders & increased in non-responders: 8 species; #Bacteroides eggerthii
OQ 45.2 outcome (well-being)	Responders > Non-responders: 35 species: #in: Lachnospira eligens, Vescimonas coporcola	Increased in responders & decreased in non-responders: 14 species; none significant
OQ 45.2 outcome (well-being)	Non-responders > Responders: 41 species; #in: Roseburia intestinalis, Phocaeicola massiliensis	Decreased in responders & increased in non-responders: 14 species; none significant

There were distinct association patterns in the microbial co-occurrence networks with hub taxa, especially *Anaerobutyricum hallii* and *Ruminococcus gnavus*, in responders versus non-responders at baseline and during blueberry ingestion. Negative associations between microbiota in microbial co-occurrence networks were more common in non-responders than in responders at baseline and decreased after blueberry treatment, suggesting stabilisation of the microbiome.

Conclusion: Improved GI and general quality-of-life and life-functioning scores during blueberry ingestion in DGBI are associated with distinct gut microbiota taxa and co-occurrence networks at baseline and during treatment. Confirmatory studies are required to assess causality, but these data suggest that beneficial clinical effects seen in patients with DGBI during blueberry ingestion may be linked to changes in the gut microbiome and that GI and general benefits may be effected via distinct taxa.

ASSOCIATIONS BETWEEN INTESTINAL MICROBIOTA COMPOSITION, CLINICAL PHENOTYPES AND TESTS OF DISEASE MECHANISMS IN PATIENTS WITH DISORDERS OF GUT-BRAIN INTERACTION (DGBI) RESPONDING TO CHRONIC BLUEBERRY INGESTION

C.H. Wilder-Smith[1], J. Li[2], A. Materna[1], P.W. O'Toole[2]
[1]Brain-Gut Research Group, Gastroenterology Group Practice, Bern, Switzerland, [2]University College Cork, APC Microbiome Institute, Cork, Ireland

Contact E-Mail Address: info@ggp.ch

Introduction: Blueberry ingestion resulted in significant abdominal symptom relief, improved Gastrointestinal Symptom Rating (GSRS) and quality-of-life and life functioning scores by Outcome Questionnaire (OQ 45.2) in patients with DGBI[1]. It is unclear via which mechanisms blueberries exert their beneficial effect in DGBI[2].

Aims & Methods: We explored the associations between symptomatic responses to blueberry ingestion, faecal microbiota composition, clinical phenotypes and tests of disease mechanisms in DGBI.

Male and female patients aged 18-60 years with DGBI (irritable bowel syndrome or functional dyspepsia, Rome 4), were randomised to blueberries (30g freeze-dried powder = 180g fresh blueberries) or placebo daily for 6 weeks in a double-blind, cross-over study. GSRS and OQ-45.2 were assessed before and in week 6 of each treatment period. Responders were defined by improved GSRS or OQ-45.2. Demographics, lifestyle and symptom details were documented at baseline[3].

Further variables were gathered before and in week 6 of treatment: Bristol Stool Scale, breath H_2, CH_4 and symptoms after fructose 35g, cognitive tests (CANTAB®), skin fluorescence for advanced glycation end-products and serum tight junction proteins (claudin-3 and -5, zonula occludens-1). Stool microbiome analysis was performed by DNA extraction and sequencing for shotgun metagenomics. Nonmetric multidimensional scaling ordination plots based on Bray-Curtis dissimilarity were generated at the species level with clinical covariates. Spearman association of microbial species with demographics, clinical phenotype and mechanistic tests

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

at baseline and during treatment were analysed by stratifying data into pre- and post-treatment groups, as well as responders and non-responders by GSRS and OQ-45.2.

Results: In 43 DGBI patients there were significant associations between faecal microbiota composition, clinical phenotypes and tests relating to disease mechanisms that were distinct between blueberry responders and non-responders. Examples of prominent baseline associations were breath gases after fructose with *Ruminococcus* sp AF41_9 in GSRS responders and with *Eggerthella lenta, Lachnospiraceae bacterium* AM48_27BH, *Phocaeicola vulgatus*, *Ruminococcus callidus*, *Mediterraneibacter glycyrrhiznilyticus* in non-responders.

Cognitive skills were associated with *Clostridium* sp AF34_13 and *Clostridiaceae bacterium* Marseille_Q4149 in responders, and with *Blautia glucerasea*, *Eggerthella lenta* and *Ruminococcus callidus* in non-responders. Tight junction protein levels correlated with *Clostridiaceae bacterium* Marseille_Q4149, *Anaerobutyricum hallii* and *Bacteroides intestinalis* in responders and with *Anaerostipes hadrus*, *Blautia faecicola*, *Blautia glucerasea*, *Clostridia bacterium* UC5_1_1D1 and *Ruminococcus gnavus* in non-responders.

During blueberry ingestion new associations between bacterial taxa and GSRS, breath gases after fructose, tight junction protein levels emerged, which were largely distinct between responder groups. Responders by OQ-45.2 showed associations between bacterial taxa, demographics and mechanistic tests both at baseline and during blueberry dosing that were largely distinct from those of GSRS responders.

Conclusion: In patients with DGBI, GI and general symptom relief with blueberry ingestion were characterised by specific, distinct associations between faecal microbiota, clinical phenotype and tests of disease mechanisms at baseline and during treatment. This first longitudinal blueberry treatment study in DGBI patients suggests an important role of the intestinal microbiota in symptom genesis warranting further study.

IMMUNOTHERAPY IN GASTROINTESTINAL DYSAUTONOMIA WITH SMALL FIBER NEUROPATHY: A SINGAPORE CASE SERIES

K.S. Goh[1], K.T.H. Siah[1], A.C. Chan[2]
[1]National University Hospital, Gastroenterology & Hepatology, Singapore, Singapore, [2]National University Hospital, Neurology, Singapore, Singapore

Contact E-Mail Address: gohkangshiong@gmail.com

Introduction: Small fiber neuropathy (SFN)–related gastrointestinal (GI) dysautonomia presents with debilitating symptoms that often fail standard therapies. Emerging evidence supports the use of immunomodulatory treatments such as intravenous immunoglobulin (IVIg) and rituximab in neuropathic and autonomic disorders (1, 2, 3).

Aims & Methods: We retrospectively reviewed six patients (mean age 52 years; 50% female) in Singapore at a national tertiary hospital with chronic GI manifestations such as dysphagia, constipation, abdominal pain, and vomiting with evidence of small fibre neuropathy. All patients had abnormal quantitative sudomotor axon reflex testing (QSART)tests. Five of the patients had a positive skin biopsy, while one patient had a negative skin biopsy but a positive anti plexin D1 antibody pathogenic of small fibre neuropathy (4).

Six patients received IVIg (2 g/kg over 2–5 days every 4 weeks), three of whom had received IVIg and then rituximab (1,000 mg × 2 doses, 14 days apart) sequentially. Patient reported outcomes were assessed and categorised into mild, moderate, good or no responses.

Results: Among IVIg recipients, one experienced good symptomatic relief, one had a mild response and one had no response. Of the patients who had received both IVIg and rituximab, one achieved no response, one achieved a mild response and one achieved a moderate response. All treatments were well tolerated, with no serious adverse events.

Patient ID	GI Symptoms	Positive QSART	Skin Biopsy for SFN	Treatment	Response
A	Dysphagia, bloating	Yes	Positive	IVIg	No response
B	Constipation, dysphagia, vomiting	Yes	Positive	IVIg + Rituximab	Moderate response
C	Vomiting, abdominal pain	Yes	Positive	IVIg	Good response
D	Constipation, abdominal pain	Yes	Normal but with positive anti plexin D1 antibody	IVIg	Mild response
E	Odynophagia, pain, vomiting, constipation	Yes	Positive	IVIg + Rituximab	No response
F	Constipation	Yes	Positive	IVIg, Rituximab	Mild response

Table 1. Summary of Patients Treated with IVIg and Rituximab for GI Dysautonomia.

Conclusion: In this preliminary series, IVIg and rituximab were associated with symptomatic benefit in selected patients with SFN-associated GI dysautonomia refractory to conventional management. These findings warrant prospective, controlled trials incorporating standardized outcome measures to optimize immunotherapy protocols and define responder profiles.

ASSOCIATION OF SYSTEMIC CYTOKINE PROFILES WITH HOST-MICROBE HOMEOSTASIS AND CLINICAL SYMPTOMS IN FUNCTIONAL BOWEL DISORDERS

A.C. Gupta[1], D. Espinola Monges[1], H. Törnblom[1], V. Tremaroli[1], T. van Gils[1], M. Simrén[1,2], K. Sjoberg Jabbar[1]

Introduction: While the mechanistic background to functional bowel disorders, including irritable bowel syndrome (IBS) is insufficiently understood, there is growing evidence that cytokine imbalance and inflammation may contribute to IBS pathogenesis.

Aims & Methods: We undertook a comprehensive investigation of serum cytokine profiles in individuals with functional bowel disorders (IBS n=164, functional constipation n=6, functional diarrhea n=3) and healthy controls (n=31), mapping their associations with clinical symptoms (GSRS-IBS, HAD), the gut microbiome (whole-metagenome sequencing of fecal samples), colonic mucosal responses (bulk RNA sequencing of sigmoid biopsies), intestinal physiological parameters, and the serum metabolome (liquid chromatography-mass spectrometry). Serum levels of IFN-γ, IL-1β, IL-6, IL-8, IL-10, IL-12p70, IL-13, TNF-α, IL-17A and CXCL10 were measured with Meso Scale Discovery (MSD) multiplex immunoassay kits.

Results: While cytokine levels did not differ significantly between persons with functional bowel disorders and healthy individuals, CXCL10 was reduced in participants with predominant diarrhea (IBS-D and functional diarrhea, p=0.01), whereas IL-12p70 was increased in predominant constipation (IBS-C and functional constipation, p=0.03), compared to healthy controls.

Within both the full study cohort and participants with functional bowel disorders, IL-12p70 levels correlated with oroanal transit time (rho 0.20 and 0.19, p=0.007 and 0.01, respectively), and were inversely associated with fecal short-chain fatty acids (p=0.006, 0.01 and 0.03 for acetate, propionate and butyrate, respectively), as well as with the abundance of several butyrate-producing species.

By contrast, IL-12p70 levels were positively associated with mucus-resident species (e.g., from the *Akkermansia* and *Victivallis* genera), with metabolites potentially derived from the degradation of mucosal carbohydrates, and with a distinct T helper 1 type response in colonic biopsies. Moreover, IL-12p70 levels correlated with anxiety (rho 0.17, p=0.03) in participants with functional bowel disorders.

Conclusion: Systemic cytokine profiles did not discriminate persons with functional bowel disorders from healthy individuals, but participants with predominant constipation and diarrhea exhibited distinct cytokine profiles. Alteration of systemic cytokines, notably IL-12p70, may result from disrupted mucosal barrier integrity and host-microbe homeostasis, and contribute to extraintestinal symptoms in a subset of individuals with functional bowel disorders.

Introduction: Managing patients with severe irritable bowel syndrome (IBS) has significant challenges for practicing physicians due to the condition's refractoriness to standard therapy and the lack of clinical remission. The prevalence of IBS reaches 9–21% among the adult working population and is associated with a low quality of life. According to various sources, visceral hypersensitivity (VHS) plays a key role in the pathogenesis of IBS.

Aims & Methods: The aim is to show the relationship between clinical symptoms, the visceral sensitivity index, and the visceral sensitivity threshold in patients with severe IBS-D.

A total of 84 patients with severe IBS-D, according to the Rome IV criteria, were examined. The median (Me) patient age was 32 (25; 37.2) years, with a disease duration of 5 (4; 6) years. Pain syndrome was assessed using the VAS scale in points (pts.), the level of visceral sensitivity index (VSI) using the J. Labus questionnaire reflecting gastrointestinal anxiety (pts.), and the visceral sensitivity threshold (VST) was studied via balloon dilatation test (BDT) (ml).

Statistical analysis was conducted using non-parametric methods (Statistica 12). Quantitative data were described using Me and interquartile ranges (Q1 – Q3). Differences were considered statistically significant at $p < 0.05$.

Results: Before treatment, all patients showed a high level of pain syndrome - 9 (8; 9) pts. on VAS, and level of gastrointestinal anxiety at 71.00 (63; 75) according to the J. Labus questionnaire. BDT data revealed a low VST (first threshold—urge to defecate): 34.00 (27; 43.5) mm Hg. After examination, patients were randomly divided into two equal groups.

The first group received the SNRI antidepressant (duloxetine) 60 mg/day, while the second group received trimebutine maleate 600 mg/day for 8 weeks, followed by assessment of therapy effectiveness. In the first group, SNRI therapy showed positive dynamics: a decrease of pain levels (from 9 (9 - 10) to 2 (1.75 - 3), $p < 0.01$*), an increase in VST (from 34.0 (29.75, 45.0) to 92.0 (86.0, 123.0), $p < 0.01$*), and a reduction in gastrointestinal anxiety (from 56.50 (47.50 – 68.00) to 12.00 (10.00 – 19.25), $p < 0.01$*). No significant positive changes were achieved in the second group.

After the treatment, the overall group showed an inverse correlation between abdominal pain (VAS) and VST (BDT data) ($\rho = -0.772$; $p < 0.01$), and between gastrointestinal anxiety (VSI by J. Labus) and VST (BDT data) ($\rho = -0.782$; $p < 0.001$).

Conclusion: The effectiveness of therapy in the first group of patients was associated with the severe course of IBS, characterized by high gastrointestinal anxiety, abdominal pain, and low VST. In the overall group, post-treatment correlation analysis revealed a connection between the severity of clinical presentation and VST levels (BDT). Balloon dilatation test allows an objective assessment of IBS severity and therapeutic effectiveness. The treatment of choice for severe IBS-D is the SNRI duloxetine, which acts on the pain center and patients' emotional status.

Contact E-Mail Address: syl.groen@gmail.com

Introduction: Irritable bowel syndrome (IBS) has a profound impact on health-related quality of life. Increasing evidence suggests psychological factors have a large impact in the development and course of IBS, and in particular quality of life, with large individual heterogeneity.
This observational study aims to investigate the influence of personality traits using the Big Five Inventory (BFI) and examine their associations with abdominal pain, general and gastrointestinal-specific anxiety, and quality of life in patients with IBS.

Aims & Methods: Data from a large observational study in patients with IBS (Rome III criteria) was used, in which patients completed questionnaires with regards to personality traits (BFI-44), symptom severity, general anxiety, GI-specific anxiety, and quality of life. Multivariable regression models and a network correlation analysis were used to determine underlying associations.

Results: 194 patients were included for analysis (74.7% female, mean age 51.36 years). There was a positive association of neuroticism to GI-specific anxiety (B 7.234, P = 0.040) and general anxiety (B 0.954, P = 0.040) with a strong negative association to mental quality of life (B – 3.576, P = 0.007). In addition, a strong negative association of agreeableness to mental quality of life was found (B – 4.266, P = 0.001). Although there were no significant associations of personality traits to abdominal pain, positive associations were found regarding general anxiety (B 6.304, p < 0.001) and GI-specific anxiety (B 0.034, P <0.001) of abdominal pain. There were no associations found with regards to the other personality traits openness, conscientiousness or extroversion.

Conclusion: IBS patients with a higher level of neuroticism were more likely to experience higher levels of GI-specific and general anxiety. The trait neuroticism and/or agreeableness was more likely to have a significant lower mental quality of life in IBS. These findings emphasize the contribution of personality traits in the pathophysiology and course of IBS, pleading for a more personalized approach in patient management.

PREVALENCE AND BURDEN OF OPIOIDS USE IN PATIENTS WITH ROME IV CONSTIPATION-PRAEDOMINANT IRRITABLE BOWEL SYNDROME: A REAL-WORLD EXPERIENCE

C. Sbarigia[1], C. Lambiase[2], M. Butt[3], C. Mocci[4,3], A. Darie[3], A. Mohanan[3], D. Bush[3], G. Isherwood[3], T. Lewis-Lawson[3], T. Card[3], M. Corsetti[3]
[1]Sapienza University of Rome, Department of Medical-Surgical Sciences and Translational Medicine, Rome, Italy, [2]University of Pisa, Gastrointestinal Unit, Regional Reference Center for Advanced Research in Functional and Motor Digestive Disorders, Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy, [3]NIHR Nottingham Digestive Diseases Centre, University of Nottingham, Nottingham, United Kingdom, [4]Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy

Contact E-Mail Address: cate.sbarigia@gmail.com

Introduction: Irritable bowel syndrome with praedominant constipation (IBS-C) is the most common subtype of IBS. Opioids prescription rate has increased worldwide over the last two decades. Opioids are not recommended for pain management in gut-brain interaction disorders.

Aims & Methods: The aim of this study was to assess the prevalence of opioids use among patients diagnosed with Rome IV IBS-C and to compare their clinical characteristics with those of IBS-C patients who do not use opioids. Data were retrospectively collected (January 2016 – December 2021) from consecutive outpatients diagnosed with IBS-C at a single tertiary care neurogastroenterology clinic in UK. A standardized template was used to collect data on age, sex, gastrointestinal (GI) symptoms, medications, and opioid use/discontinuation. Patients taking opioids were advised to discontinue opioids in line with the Centers for Disease Control and Prevention recommendations. Improvement in GI symptoms after opioids discontinuation was documented. Data are presented as median [interquartile range (IQR)] or frequency (%). Chi square test or Mann-Whitney's U test was used, when appropriate.

Results: A total of 157 IBS-C patients were included, of whom 70 (27.2%) were on opioids. Compared with non-users, opioids users had a higher median age, more comorbidities, more concomitant medications, more surgeries and more hospital admissions (Table 1).
A significantly higher proportion of opioids users reported dysphagia compared to non-users (*P*=.02). Fifty-eight patients (82.9%) were asked to stop opioids before introducing other medications. Twenty-two patients (31.4%) stopped opioids and, of these, 12 (54.5%) reported improvement in IBS-C symptoms:6 improved in constipation, 1 in abdominal pain and 5 in both.

	Opioid use		
	No (n=187)	Yes (n=70)	p-value
Demography and general characteristics			
Age, median (IQR)	43.0 (27.0)	49.0 (21.3)	0.016
Total number of concomitant medical conditions, median (IQR)	1.0 (2.0)	2.0 (2.0)	0.001
Number of surgeries, median (IQR)	0.0 (1.0)	1.0 (2.0)	0.005
Total number of hospital admissions, median (IQR)	1.0 (3.0)	2.0 (5.0)	0.006
Total number of investigations performed, median (IQR)	1.0 (2.0)	2.0 (2.0)	0.057
Concomitant medications			
Total number of concomitant medications, median (IQR)	2.0 (5.0)	6.0 (4.0)	<0.001
Laxatives, n (%)	76 (40.6)	40 (57.1)	0.018
Tricyclic antidepressant, n (%)	25 (13.4)	19 (27.1)	0.009
Serotonin noradrenalin reuptake inhibitor, n (%)	4 (2.1)	9 (12.9)	<0.001
Non-steroidal anti-inflammatory drug, n (%)	17 (9.1)	14 (20.0)	0.017
Antiemetics, n (%)	7 (3.7)	9 (12.9)	0.007

Table 1. General characteristics of IBS-C patients taking or not taking opioids. Numbers are frequency (%) or median (IQR).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Up to 27% of IBS-C patients consume opioids at their first outpatient consultation. Patients on opioids show a more severe clinical profile and higher healthcare resources utilization. Opioid cessation leads to IBS-C symptoms improvement in up to 55% of patients without further intervention.

Disclosure: Nothing to disclose.

Contact E-Mail Address: fischmaya@gmail.com

Introduction: Studies have shown that adults with irritable bowel syndrome (IBS) may be associated with anxiety, mood disorders, chronic headache, and other neuropsychiatric conditions. This growing body of evidence can allude to a possible bidirectional gut-brain connection. While adolescence is the age when both IBS and neuropsychiatric illnesses often first manifest, this population remains under-studied.

Aims & Methods: We aim to assess the association between the presence of irritable bowel syndrome (IBS) and neurologic and psychiatric disorders in a nationwide cohort of adolescents. This cross-sectional study included all adolescents aged 16-21 who underwent mandatory medical evaluations as part of their conscription between 2000-2021. All individuals completed comprehensive medical interviews. Suspected diagnoses prompted referral to board-certified specialists for confirmation and severity grading based on predefined criteria. IBS was diagnosed according to the Rome II-IV criteria by a certified gastroenterologist.

Neurologic disorders included attention-deficit/hyperactivity disorder [ADHD], epilepsy, chronic headache, sleep disorders. Psychiatric disorders included psychotic, personality, general anxiety disorder [GAD], non-combat post-traumatic stress disorder [PTSD], mood, dissociative, and eating disorders. Each diagnosis was classified by severity (mild, moderate, severe).

Unadjusted and multivariate-adjusted logistic regression models were fitted to estimate odds ratios (ORs) for associations with IBS. The adjusted models were accounted for age, sex, intelligence score, body mass index (BMI), socioeconomic status (SES), education, country of origin, and any concurrent neuropsychiatric diagnoses.

Results: The study included 1,561,717 adolescents (666,442 [42%] women, mean age 17.4 ± 1.4 years), of whom 7,230 (0.46%) were diagnosed with IBS (4,778 mild; 1,948 moderate; 504 severe). Neurologic disorders were present in 1,661 (23.0%) and 143,348 (9.2%) of those with and without IBS, respectively.

The respective numbers of people with psychiatric disorders were 773 (10.7%) and 49,889 (3.2%). In multivariable adjusted models, those with IBS were more likely to have chronic headache (aOR 4.7, 95% CI: 4.4-5.1), GAD (aOR 3.6, 95% CI: 3.2-3.9), eating disorders (aOR 2.6, 95% CI: 1.9-3.5), mood disorders (aOR 2.5, 95% CI: 2.1-3.1), personality disorders (aOR 2.5, 95% CI: 2.1-2.9), and dissociative disorders (aOR 19.1, 95% CI: 12.5-28.9). Patients with severe IBS (n=504) were independently associated with the presence of at least one severe neurologic (aOR 2.9, 95% CI: 1.2-7.1) or psychiatric disorder (aOR 3.8, 95% CI: 2.6-5.4).

Conclusion: In this large nationwide cohort, adolescents with IBS were more likely to have several tested neurologic and psychiatric disorders, compared to those without IBS. Longitudinal studies are needed to explore the directionality and long-term implications of these associations.

Disclosure: Nothing to disclose.

Introduction: Functional Constipation (FC) and Constipation-predominant Irritable Bowel Syndrome (IBS-C) are two common disorders of gut-brain interaction (DGBI)-which can often present overlapping symptoms, thus making difficult to distinguish them.

Aims & Methods: This study aims to determine whether the demographic and clinical profiles of consecutive patients diagnosed with FC and IBS-C differ in real-world clinical practice.

Demography and clinical information from the first clinical consultation where the diagnosis was made by a single consultant using a standardized clinical letter were retrospectively collected from January 2016 to March 2025 at a single tertiary care neurogastroenterology clinic in the UK Data were collected using a standardised template and were reported as median [interquartile range (IQR)] or frequency (%), and compared using the Chi-square test or Mann-Whitney U test.

Results: A total of 88 FC and 257 IBS-C consecutive patients were diagnosed according to Rome IV criteria. FC patients were older and most frequently males, with a longer duration of symptoms. Abdominal pain was largely absent in FC patients and when present this was not related to defecation but reported as result of long-lasting lack of bowel movement. Upper gastrointestinal symptoms were more frequent in IBS-C compared to FC.

Comorbidities, particularly chronic pain syndromes, and abdominal surgeries were more frequently reported by IBS-C patients. in addition, IBS-C patients were more frequently on pain medications, while FC on laxatives. Table 1 summarizes the data collected in both groups.

Introduction: Proctological diseases are a common cause of gastroenterology consultations and can significantly impact patients' quality of life.

Aims & Methods: This study aims to assess the impact of hemorrhoidal disease and anal fissures on quality of life, using a questionnaire to measure their overall influence on daily life.

This cross-sectional study was conducted over one month (May–June 2024) and included patients consulting for hemorrhoidal disease and/or anal fissures. Quality of life was assessed using the Burden Hemo/Fiss score, which consists of 23 questions divided into four domains: physical disorders, psychological distress, discomfort during defecation, and impact on sexual life. Each question was scored from 1 to 6. Data analysis was performed using software from the French National Society of Colo-Proctology (SNFCP).

Results: A total of 50 patients were included, with a mean age of 46.1 years (range: 19–71). There were 37 women and 13 men (M/F ratio: 0.35). Hemorrhoidal disease was present in 23 patients (46%), anal fissures in 18 (36%), and both conditions in 18% (n=9). The mean Hemo/Fiss score was 46.58 ± 19.44 [range: 12–85]. The mean scores for each domain were: 49.4 ± 22.36 (physical disorders), 41.42 ± 19.59 (psychological distress), 56.26 ± 27.86 (defecation discomfort), and 35.44 ± 20.38 (sexual dysfunction). Patients with anal fissures (52.9) and grade III–IV hemorrhoids (58.3) had the most affected scores. A significant correlation was found between the total Hemo/Fiss score and pain score (p=0.021).

Conclusion: Our study highlights a significant deterioration in quality of life in patients with anal fissures or hemorrhoidal disease, emphasizing the need for comprehensive management to improve both physical symptoms and overall well-being.

Introduction: Sirtuin 1 (SIRT1) regulates mitochondrial function and biogenesis, carbohydrate and lipid metabolism, oxidative stress, inflammation, and apoptosis. All these factors play a role in the development and progression of non-alcoholic fatty liver disease (NAFLD).

Aims & Methods: The aim of the study was to investigate the role of SIRT1 in the development and progression of NAFLD under the influence of stress factors during wartime. The serum SIRT1 level was determined using an enzyme-linked immunosorbent assay (ELISA) with the "Human SIRT1 (Sirtuin 1) ELISA Kit." Visceral fat tissue (VFT) was measured using an OMRON BF-511 electronic device. Liver function tests, carbohydrate and lipid metabolism parameters, and C-reactive protein (CRP) levels were assessed using standard methods on an automatic biochemical analyzer "HumaStar 300SR." Statistical analysis was performed using the SPSS 17.0 statistical software package.

Results: A total of 88 NAFLD patients with metabolic disorders were examined, including 57 individuals (main group) who were exposed to war-related stress factors and 31 individuals (comparison group) examined in the pre-war period. It was found that SIRT1 levels were significantly higher in the main group, averaging 8.88 ± 0.23 ng/mL, compared to 4.75 ± 0.14 ng/mL in the comparison group ($p < 0.05$). Subgroup analysis showed a trend towards higher SIRT1 levels in normal-weight patients compared to those who were overweight or obese in the main group. A direct correlation was found between SIRT1 levels and VFT in both groups: $r = 0.32$ in the main group and $r = 0.24$ in the comparison group. Meanwhile, SIRT1 levels exhibited a weak negative correlation with abdominal obesity parameters (waist-to-hip ratio): $r = -0.14$ in the main group and $r = -0.12$ in the comparison group. A weak negative correlation was also observed between fasting glucose and insulin levels and SIRT1 ($r = -0.17$ and $r = -0.24$, respectively). However, an inverse correlation trend was demonstrated between SIRT1 and the HOMA index ($r = -0.33$). Correlation analysis results also indicated a weak negative relationship between SIRT1 levels and total cholesterol ($r = -0.21$) and a strong negative correlation between SIRT1 and triglycerides (TG) and low-density lipoprotein cholesterol (LDL-C) ($r = -0.37$). At the same time, a weak positive correlation was observed between SIRT1 and high-density lipoprotein cholesterol (HDL-C) ($r = 0.11$). When comparing CRP levels, hepatocyte cytolysis enzymes, and SIRT1, a weak inverse correlation was found with CRP and ALT levels ($r = -0.17$ and $r = -0.22$, respectively).

Conclusion: The results of our study provide evidence of the significant role of SIRT1 in regulating liver inflammation and the development and progression of NAFLD.

Disclosure: No conflict of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is frequently associated with metabolic disorders and is highly prevalent in obese and type 2 diabetes mellitus (T2DM) patients. Oxidative stress plays a major role in the pathogenesis of NAFLD.

Aims & Methods: This study aimed to associate the role of oxidative parameters and their gene expression analysis in NAFLD. In this case-control study, 200 participants were enrolled and classified into two groups: NAFLD (n=200) and healthy controls (n=100). Levels of oxidative parameters, including superoxide dismutase (SOD), catalase, and malondialdehyde (MDA), were assessed using chemiluminescence and qRT-PCR. Data analysis was performed using Graph Pad Prism 10, with significance set at $P < 0.05$.

Results: The study demonstrated a significant decrease in SOD2 enzyme activity in NAFLD (1.008 ± 0.957 U/ml) compared to controls (4.029 ± 3.20 U/ml, $P=0.0014$). Catalase activity was also significantly reduced in NAFLD (32.2 ± 6.36 U/ml) compared to controls (41.2 ± 8.70 U/ml, $P< 0.0001$). Plasma MDA levels were significantly increased in NAFLD. Gene expression analysis revealed that catalase was significantly downregulated by 1.94 folds ($P=0.0045$) and SOD2 by 1.02 folds ($P=0.46$) in NAFLD patients compared to healthy controls.

Conclusion: The study suggests that decreased levels of oxidative stress markers, particularly antioxidant enzymes like catalase, may contribute to oxidative damage in the progression of NAFLD patients.

These findings provide insights into the molecular mechanisms underlying the role of hepatic inflammation in the development and progression of NAFLD.

References: This work is part of my ongoing PhD research.The study remains under active development, with further refinements and analyses underway.

Introduction: Fatty liver is sensitive to ischemia-reperfusion injury [1, 2]. At the microcirculatory level, the structural and functional properties of red blood cells (RBCs) play a key role, since the degree of hypoxia in liver tissue depends on their ability to deform, tendency to form aggregates, and hemolysis [3], which, in turn, is a factor in fibrogenesis [4].

Aims & Methods: Research objective is as follows: To study the associations of viscoelastic, electrical parameters of RBCs and levels of FAs of their membranes, serum in patients with fatty liver disease.

84 men (average age 48.4±13.9 years) with fatty liver disease (FLD) of various genesis (alcoholic, non-alcoholic, of mixed genesis: alcoholic+metabolic), various necroinflammatory activity with fibrosis F0-1 (FibroScan® 502 (Echosens, France) have been examined. The study of RBC electrical, viscoelastic parameters has been performed by dielectrophoresis. The content of FAs in RBC membranes and blood serum has been determined using gas chromatography-mass spectrometry (Agilent 7000B, USA).

Results: It has been found, that RBC indices reflecting their deformation ability (amplitude of deformation at 10^6 Hz, degree of deformation at $0.5x10^6$ Hz), membrane state (capacitance), surface charge value (dipole moment, speed of cell movement to electrodes), RBC resistance (polarisability) were directly correlated with the levels of n-3 PUFAs in RBC membranes, blood serum, both their total content and concentrations of individual FAs (C20:5n-3, C22:5n-3, C22:6n-3), the level of monounsaturated oleic FAs, as well as two SFAs (C15:0, 17:0). On the contrary, the associations with the predominant part of SFAs, both individual (especially highly accurate: with C16:0, C18:0) and total content, MUSAs, USAs, including ratios of n-6/n-3 PUFAs, SFAs/UFAs, SFAs/PUFAs, were inverse (p=0,02-0,0000001).

The summarized rigidity was related with high strength of association and statistical significance to RBC content of C16:0 (r=0.674, p<0.000001), C18:0 (r=0.443, p<0.000006), C18:2n-6 (r=0.345, p=0.0006) FAs, total SFAs (r=0.640, p<0.000001), the ratios of n-6/n-3 PUFAs (r=0.605, p<0.000001), SFAs/PUFAs (r=0.428, p=0.000015).

Correlations with RBC levels of C16:0 (r=0.551, p<0.000001), C18:2n-6 (r=0.470, p=0.000042) were the closest for membrane conductivity levels, total SFAs (r=0.484, p<0.000001), USAs (r=0.468, p<0.000001), MUSAs (r=0.504, p<0.000001), n-6 PUFA (r=0.414, p=0.00003), as well as for ratio of n-6/n-3 PUFAs (r=0.568, p<0.000001).

Associations of high strength and statistical significance for RBC aggregation index have been found concerning RBC C16:0 (r=0.691, p<0.000001), C18:0 (r=0.486, p<0.000001), for the total UFAs' content (r=0.672, p<0.000001), the ratios n-6/n-3 PUFAs (r=0.611, p<0.000001), SFAs/UFAs (r=0.475, p<0.000001), SFAs/PUFAs (r=0.478, p<0.000001).

RBC destruction indices have been found to be directly related to the total UFAs' content in both RBC membranes and serum, RBC levels of C20:3n-6 (r=0.205, p=0.046), and inversely related to the content of C15:0 (r=-0.224, p=0.028), C17:0 (r=-0.151, p=0.039) and C18:1;c9 (r=-0.206, p=0.045).

Conclusion: The identified associations indicate a dependence of RBC parameters on the levels and ratios of FAs in their membranes, serum. Deterioration of blood rheological properties in patients with FLD is a factor associated with increasing hypoxia in liver tissue with potential for fibrogenesis and progression. The ability to modulate electrical, viscoelastic parameters of RBCs by exposure of FAs, including dietary FAs, defines new additional treatment targets for patients with FLD.

Introduction: Hepatocellular carcinoma (HCC) is an end stage liver disease with increasing morbidity and mortality worldwide. Development of the disease is dependent on various genetic, dietary and environmental factors. While alcohol-related liver disease (ALD/MetALD) remains a major contributor, metabolic dysfunction-associated steatotic liver disease (MASLD) is becoming increasingly relevant in clinical practice. There is increasing evidence for the role of bacteria, for instance, such as *Bifidobacterium* and *Blautia*, which were considered protective, while *Streptococcus* has been associated with disease progression. However, little is known about the alteration of microRNAs (miRNAs) in liver diseases and its interrelationship with microbial environment in view of etiological factors.

Aims & Methods: This study aimed to elucidate gastrointestinal miRNA alterations and explore their relationship with microbiome composition in patients with different stages of liver disease in terms of disease etiology. Multi-omics analyses were performed in a subset of well characterized patients (n=59) with liver disease and healthy controls. Systematic characterization included clinical, laboratory, demographic and imaging characterization and dietary preferences. Patients subclassification included fibrosis stage (no fibrosis, fibrosis, liver cirrhosis(LC)) and etiology (MetALD/ALD vs. MASLD). Fecal miRNAs were extracted using the Qiagen miRNeasy Kit and profiled via Agilent miRNA microarray. Microbiome analyses were performed amplifying the V1-V2 region of the 16S rRNA gene following Illumina sequencing.

Results: For miRNA analysis stringent criteria were applied to identify high quality miRNA targets. From approximately 4,000 candidates filtering resulted in selection of 202 high-quality miRNAs with reliably mea-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

surable concentrations. 28 of these miRNAs showed significantly positive alterations in concentration in patients with liver disease and 7 miRNAs significant negative alterations. Specifically, miR-642a-3p, miR-5006, miR-6781, and miR-6849 were elevated in feces in patients with LC. In contrast, miR-6869, miR-4467, and miR-5001 were present in lower concentration in LC patients. Notably, miR-4467 also showed strong negative associations with liver-specific laboratory markers, including gamma-glutamyl transferase (GGT) (r=-0.34; p=0.026) and M65, a marker of apoptosis (r=-0.42; p=0.005).

Cross-sectional comparison of miRNA and microbiome data revealed miRNA alterations associated with specific microbial signatures. MiR-6795-5p, which was associated with liver stiffness (r = 0.39, p = 0.01), also correlated positively with the abundance of *Streptococcus*, a genus linked to disease progression (r=0.29; p=0.047).

Conversely, miR-6869, miR-4467, and miR-5001 showed positive correlations with the potentially protective genera *Blautia* and *Bifidobacterium* (miR-6869: $r_{Bifidobacterium}$=0.35; $p_{Bifidobacterium}$=0.012; $r_{Blautia}$=0.37; $p_{Blautia}$=0.008; miR-4467: $r_{Blautia}$=0.41; $p_{Blautia}$=0.002; miR-5001: $r_{Blautia}$=0.38; $p_{Blautia}$=0.006).

Conclusion: Multi-omics analysis reveals distinct alterations in fecal miRNAs and gut microbiota across different stages of liver disease. Changes in microbial composition were associated with shifts in miRNA profiles, suggesting a functional link in maintaining intestinal homeostasis.

These findings highlight the potential of integrated microbiome–miRNA signatures as novel diagnostic and therapeutic targets. Further studies are warranted to validate these associations and explore their clinical applications.

CLINICAL SIGNIFICANCE OF ANTI-CENTROMERE PROTEIN B (CENP-B) ANTIBODY IN PATIENTS WITHOUT KNOWN LIVER DISEASE – A POPULATION WARRANTING CLOSER SURVEILLANCE?

M. Cristiano[1], L. Santos[1], N.P. Almeida[1,2], P. Narra Figueiredo[1,2]
[1]Unidade Local de Saúde de Coimbra, Gastroenterology Department, Coimbra, Portugal, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Contact E-Mail Address: margarida.cristiano@hotmail.com

Introduction: Anti-centromere antibodies (ACA) recognize centromere proteins, particularly CENP-B, the major reactive antigen. While primarily associated with Raynaud's phenomenon, systemic sclerosis (SS), and other autoimmune-like conditions, ACA positivity can also be observed in primary biliary cholangitis (PBC), often overlapping with rheumatological diseases.

Aims & Methods: This study aimed to explore the association between CENP-B positivity and liver test abnormalities in patients without known liver disease, evaluate its overlap with rheumatological conditions, and assess whether co-positivity with other antibodies may predict liver dysfunction. We conducted a retrospective cohort study including consecutive patients with CENP-B positivity (via immunoblot) from January 2020 to December 2024. Data on liver function tests (LFTs), antinuclear antibody (ANA) patterns, immunoglobulin M (IgM), anti-gp210, anti-sp100, antimitochondrial antibodies (AMA), and liver biopsy results were analysed.

Results: A total of 48 CENP-B-positive patients without known liver disease were included (85.4% female; mean age 68.7 ± 21.5 years). Liver test abnormalities were present in 56.3% of patients, predominantly elevated gamma-glutamyl transferase (GGT) (35.4%), alanine transaminase (ALT) (10.4%), and aspartate transaminase (AST) (18.8%). IgM elevation was infrequent (6.3%), and antibody co-positivity varied (anti-gp210: 0%; anti-sp100: 4.2%; AMA: 8.3%; anti-pyruvate dehydrogenase autoantibodies [anti-PDH]: 10.4%). There was reference to Raynaud's phenomenon in 25%, and 91.7% of patients had a rheumatological or autoimmune-like condition (SS: 25%, systemic lupus erythematosus: 6.3%). Patients with concurrent AMA and CENP-B positivity had significantly higher ALT (U=31.5, Z=2.112, p=0.031) and GGT (U=34.5, Z=1.997, p=0.043) levels, though this association was not observed with other LFTs (AST, alkaline phosphatase, and bilirubin), ANA patterns, or antibodies. None of the four patients with liver test abnormalities and concurrent CENP-B and AMA positivity underwent liver biopsy.

Conclusion: The findings suggest that CENP-B-positive patients, particularly those with concurrent AMA positivity, may be at increased risk of developing liver diseases within the PBC spectrum. This group may warrant closer clinical and laboratory surveillance to enable timely identification and management of potential hepatic involvement.

Introduction: Assessment of liver fibrosis is a key element in the management of patients with hepatitis B virus (HBV) infection, whether in the active, inactive, or occult phase. Among the non-invasive tools currently available, the FIB-4 score, based on biological parameters and FibroScan, using vibration-controlled transient elastography (VCTE) are widely used.

Aims & Methods: This retrospective, descriptive, and analytical study was conducted in a university hospital between 2017 and 2025. All patients followed for chronic HBV infection in the department of hepatogastroenterology were included. Clinical and biological data, along with fibrosis assessment results (FIB-4 score and FibroScan), were collected from patients medical records. The aim of this study was to compare the diagnostic performance and concordance of these two modalities in assessing liver fibrosis in a heterogeneous population of HBV-infected patients.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 100 HBV-infected patients were included, consisting of 54 males (54%) and 46 females (46%), with a median age of 55 years [42.5; 60]. Among them, 70% of patients had an active chronic hepatitis B (n=70), 29% were in the inactive phase (n=29), and 1 patient had an occult HBV infection.

Regarding comorbidities, 14% had arterial hypertension, 13% had metabolic dysfunction-associated steatotic liver disease (MASLD), and 5% had type 2 diabetes mellitus. Alcohol consumption was reported in 4% (n=4), and 5% were smokers (n=5). A family history of liver disease was documented in 12% of cases (n=12).

Concerning virological parameters, HBe antigen was positive in 13% (n=13) and negative in 87% (n=87). HBV DNA levels were <2,000 IU/mL in 48% of patients (n=48), between 2,000 and 20,000 IU/mL in 25% (n=25), and >20,000 IU/mL in 27% (n=27).

Evaluation of liver fibrosis using both the FIB-4 score and FibroScan revealed that 40% of patients had a FIB-4 score >3.25, indicating advanced fibrosis, while 60% had a score <1.45, suggesting minimal fibrosis. These findings were consistent with those obtained by FibroScan.

To assess the diagnostic performance of the FIB-4 score in detecting advanced fibrosis (F3–F4) according to FibroScan, a receiver operating characteristic (ROC) analysis was conducted. The FIB-4 score demonstrated an area under the curve (AUC) of 0.96 using a cutoff value of 1.96, with a sensitivity of 93.75%, specificity of 84.52%, and a negative predictive value (NPV) of 98.61%.

Conclusion: The FIB-4 score demonstrated excellent diagnostic accuracy for identifying advanced liver fibrosis in patients with HBV infection, with a performance comparable to that of FibroScan. Given its simplicity, accessibility, and cost-effectiveness, the FIB-4 index represents a reliable first-line tool for fibrosis screening, particularly in settings where elastography is unavailable or limited.

INTER-OBSERVER VARIABILITY OF LIVER BIOPSY READING IN CLINICAL TRIALS FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS: A MONOCENTRIC EXPERIENCE

A. Liguori[1], S. Archilei[1], C. Graziani[1], A. Leonetti[1], G. Leonti[2], M. Garcovich[2], L. Riccardi[2], M.E. Ainora[2], M.A. Zocco[1], F. Pizzolante[2], N. De Matthaeis[2], G. Marrone[2], M. Biolato[2], M.C. Giustiniani[2], A. Grieco[1], M. Pompili[1], A. Gasbarrini[1], L. Miele[1]

Introduction: Liver histology remains a cornerstone in clinical trials investigating metabolic dysfunction-associated steatohepatitis (MASH) therapeutic approaches. Although liver biopsy is invasive and carries risks such as complications, high costs, and inter-observer variability, it continues to be indispensable for determining eligibility criteria and assessing surrogate endpoints. The inherent variability in histological interpretation can contribute to screening failures and may impact the accuracy and reliability of trial outcomes.

Aims & Methods: We evaluated the consistency of liver biopsy interpretations performed within the framework of nine clinical trials for MASH conducted at our center. A total of 59 biopsy samples were independently assessed by central hepatopathologists and by local pathology department. We compared the MASH-validated scoring results between the two groups, including MASH CRN components—steatosis, lobular inflammation, hepatocellular ballooning, and fibrosis—as well as the overall MASH diagnosis, MASH with fibrosis stage >1 (MASH+F>1), and MASH with fibrosis stage >2 (MASH+F>2) diagnoses.

Inter-reader reliability was measured using both overall percentage agreement and unweighted kappa coefficients. The kappa coefficient quantifies the level of agreement between two raters, beyond what would be expected by chance alone.

Results: Inter-reader agreement for individual histological features showed varying levels of consistency. The observed percentage agreement (and corresponding unweighted kappa coefficients) were as follows: steatosis 60% ($\kappa = 0.383$), ballooning 64% ($\kappa = 0.216$), lobular inflammation 68% ($\kappa = 0.000$), NAS score 26% ($\kappa = 0.199$), and fibrosis 48% ($\kappa = 0.190$).

For diagnostic categories, the agreement rates were: MASH diagnosis 66% ($\kappa = 0.088$), MASH with fibrosis stage >1 (MASH+F>1) 60% ($\kappa = 0.211$), and MASH with fibrosis stage >2 (MASH+F>2) 87% ($\kappa = 0.585$).

Based on the inclusion criteria specific to each study, the overall inter-reader agreement was 67%, with a kappa coefficient of 0.289.

Conclusion: The reliability of liver biopsy evaluations performed by hepatopathologists using currently accepted criteria remains suboptimal.

This variability can compromise the integrity of MASH clinical trials by contributing to misclassification of fibrosis stages and MASH diagnoses, potentially leading to the inclusion of patients who do not meet eligibility criteria. As such, the requirement for liver biopsy to assess MASH severity in the context of future drug prescriptions should be reconsidered with caution.

Disclosure: Nothing to disclose.

PP0788

FIB-6 OVER FIB-4: SCORING HIGHER IN LIVER FIBROSIS EVALUATION IN MASLD: EVIDENCE FROM A PORTUGUESE COHORT

A.C. Garcia[1], P. Pires[1], M. Francisco[1], S. Bragança[1], M. Cardoso[1], J. Carvalho e Branco[1], M.N. Costa[1], R. Carvalho[1], A. Martins[1], G. Alexandrino[1]

[1]Unidade Local de Saúde Amadora/Sintra, Gastroenterology, Lisbon, Portugal

Contact E-Mail Address: sofia_58632@hotmail.com

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) has a global prevalence of 30%, with 10-30% progressing to advanced liver fibrosis in 5 years. It is essential to assess advanced liver fibrosis – a predictor of liver-related outcomes. FIB-4 is a good screening test, but its low specificity leads to unnecessary referrals to hospital, especially in individuals over 65 years and with type 2 diabetes (T2D). To address these limitations, machine-learning techniques are developing scores like FIB-6 (validated for Hepatitis B and C).

Aims & Methods: We aimed to assess the performance of FIB-6 score in screening for advanced fibrosis in a Portuguese cohort of MASLD patients. A retrospective-cohort study was conducted with MASLD patients who had undergone liver vibration-controlled transient elastography (VCTE) between January-October 2024.

Inclusion criteria: adult patients (age >18years) diagnosed with MASLD; undergone liver VCTE; complete biochemical and hematological data.

Exclusion criteria: coexistence of other liver diseases; decompensated cirrhosis; hepatocellular carcinoma; hematological/bone-related diseases.

We used liver stiffness measurement by VCTE as a reference standard for liver fibrosis. Fibrosis was staged on a 0–4 scale: F0, F1 and F2, patients without advanced fibrosis; F3 and F4, patients with advanced fibrosis/cirrhosis.

Non invasive tests (FIB-6, FIB-4, APRI, NFS) were calculated using blood results available within the month of the VCTE. Statistical analysis was performed using R version 4.2.3. AUC-ROC curve analysis with cutoff points were calculated using the Youden index.

Results: 115 MASLD patients (58 males (50.43%),57 females (49.57%), median age of 62years) where included. 41 (35.65%) had diabetes mellitus type 2 (T2D) (10 of those insulin-treated), 74 (64.35%) arterial hypertension, 76 (66.09%) dyslipidemia and with a median body mass index of 29.9mg/Kg/m^2. Regarding hepatic fibrosis, 79 patients had F0-2 and 17 patients had F3-4.

In the general sample, AUC-ROC curve analysis showed an AUC 0.771 (CI 95% :0.662, 0.88) for FIB-4, AUC 0.788 (CI 95% :0.686, 0.889) for APRI, AUC 0.709 (CI 95% :0.595, 0.823) for NFS and AUC 0.695 (CI 95% :0.571, 0.819) for FIB-6.

A subanalysis of the sample over 65 years old revealed AUC 0.807 (CI 95% : 0.665, 0.949) for FIB4; AUC 0.788 (CI 95% : 0.686, 0.889) for APRI; AUC 0.788 (CI 95% : 0.65, 0.926) for NFS; AUC 0.663 (CI 95% : 0.475, 0.852) for FIB-6.

A subanalysis of the sample of T2D patients revealed AUC 0.747 (CI 95% :0.584, 0.911) for FIB4; AUC 0.811 (CI 95% :0.676, 0.946) for APRI; and AUC 0.765 (CI 95% : 0.612, 0.918) for FIB6.

Using the optimal cut-offs of FIB6 (cutoff= 1.8992) for the diagnosis of F3+F4 indicated a reliable performance of FIB-6 score (sensitivity was 70%, specificity was 52.6%).

The cutoff values of FIB-6 for the general sample was 2.4420 (sensitivity 53%, specificity 87%); for the subset of patients over 65 years was 2.7668 (sensitivity 40%, specificity 96%); for the subset of T2D patients was 2.2230 (sensitivity 55%, specificity 90%).

Conclusion: FIB-6 demonstrated good performance in screening advanced fibrosis in MASLD patients, when compared to those of FIB-4, APRI, and NFS, surpassing FIB-4, particularly in individuals with T2D. This study is the first to evaluate the applicability of FIB-6 in a Portuguese MASLD cohort.

Although the findings warrant validation in larger and more diverse populations, they suggest that FIB-6 may be more efficient to evaluate liver fibrosis in MASLD and offer a more efficient tool to identify patients that need specialized care.

COMPARISON OF LIVING DONOR (LDLT) *VERSUS* DECEASED DONOR LIVER TRANSPLANT (DDLT) FOR PRIMARY SCLEROSING CHOLANGITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

A.B. Afonso[1], C. Morais da Silva[2], M.L. Verdelho Moutinho Machado[1,3], P. Nogueira[4]
[1]Clínica Universitária de Gastrenterologia, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [2]ULS Viseu Dão Lafões, Viseu, Portugal, [3]Serviço de Gastrenterologia, Hospital de Vila Franca de Xira, Lisbon, Portugal, [4]Faculdade de Medicina, Universidade de Lisboa, Bioestatística, Lisbon, Portugal

Contact E-Mail Address: anacms97@gmail.com

Introduction: Primary Sclerosing Cholangitis (PSC) is a rare, chronic and progressive cholestatic liver disorder of unknown etiology. It is associated with progressive liver disease, culminating in cirrhosis and liver failure, as well as an increased risk of malignancies, particularly cholangiocarcinoma (CCA). Liver transplantation (LT) is currently the only potentially curative option for these patients. Organ scarcity is boosting Living donor liver transplantation (LDLT) as an option to increase the donor pool. Outcomes after LDLT in PSC are conflicting. We aimed to review the literature regarding the outcomes of LT in PSC, comparing LDLT with deceased donor LT (DDLT).

Aims & Methods: A systematic review with meta-analysis was performed through a search on: *PubMed, Scopus, Web-of-Science*, and *Cochrane*. 22 studies were included, enrolling 22,024 patients.

Results: Compared with LDLT, DDLT was associated with lower 1- (OR 0.66 [95% CI 0.43-0.99]) and 5- years survival (OR 0.56 [95% CI 0.46-0.59]), even though it had no impact on graft-survival or retransplantation. The weighted pooled DDLT and LDLT survivals were: 93.80% vs. 95.78% at 1-year, 88.81% vs. 93.23% at 3-year, and 85.18% vs 91.54% at 5-year, respectively. DDLT was found to be associated with higher risk of post-LT sepsis (OR 3.68 [95% CI 1.02-13.26]), acute rejection (OR 1.75 [25% CI 1.12-2.73]) and PSC recurrence (OR 1.63 95% CI 1.10-2.42]), although lower biliary complications (OR 0.29 [95% CI 0.11-0.78]).

DDLT recipients were older (MD 4.26 years [95% CI 2.42-6.10]), more frequently male (OR 1.32 [95% CI 1.18-1.48]), had higher metabolic dysfunction and worse liver disease (higher MELD: MD 6.63 [95% CI 5.56-7.70]). Additionally, were less frequently Caucasian (OR 0.54 [95% CI 0.39-0.75]) and more likely to be Black (OR 2.99 [95% CI 2.33-3.82]), comparing with LDLT recipients. Nevertheless, had lower chance of having inflammatory bowel disease (OR 0.66 [95% IC 0.50-0.87]) or cholangiocarcinoma (OR 0.70 [95%IC 0.53-0.92]). DDLT donors were also older (MD 2.46 years [95% CI 0.76-4.15]) and cold ischemia time of the liver grafts was longer (MD 5.63 hours [95% CI 2.18-8.08]).

Conclusion: In PSC patients, LDLT seems to be associated with higher post-LT survival, compared with DDLT. This could probably be related with a bias to earlier referral to LT, lower waitlist time and better-quality grafts, because of a stricter selection of healthy donors and recipients, and technical considerations such as shorter cold ischemia time. PSC recurrence and acute rejection were less frequent following LDLT, whereas biliary complications more common, although not negatively impacting the overall results. The findings support considering LDLT as a preferred option when feasible, especially for patients with anticipated long wait times for deceased donor organs. As such, the possibility of LDLT should be systematically inquired for patients with PSC.

Introduction: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease characterized by progressive bile duct damage and cholestasis. While ursodeoxycholic acid (UDCA) is the first-line therapy, about 40% of patients have incomplete responses, necessitating alternative treatments.
Aims & Methods: This meta-analysis evaluates the efficacy and safety of novel oral anti-cholestatic agents for PBC, focusing on key biochemical and symptomatic outcomes. A systematic literature search was conducted across electronic databases.
Eligible studies included randomized controlled, retrospective, and open-label trials investigating novel oral anti-cholestatic agents in PBC patients. Data on efficacy (e.g., alkaline phosphatase [ALP] reduction) and safety outcomes were extracted and analyzed using meta-analytic techniques.
Results: Ten studies involving 878 patients were analyzed. Investigated therapies included seladelpar, fenofibrate, saroglitazar, bezafibrate, elafibranor, and budesonide. Novel anti-cholestatic agents significantly lowered ALP levels compared to controls (SMD -2.80; 95% CI [-3.56, -2.03]; p<0.00001), with saroglitazar showing the largest effect size (SMD -4.62; 95% CI [-5.54, -3.70]). Subgroup analysis revealed that fibrates (fenofibrate, bezafibrate, and saroglitazar) demonstrated the most consistent ALP reduction across studies (SMD -3.15; 95% CI [-3.89, -2.41]; p<0.00001).
In addition to ALP reduction, several agents showed improvements in other liver function tests. Bilirubin levels decreased significantly with novel therapies (MD -0.22 mg/dL; 95% CI [-0.35, -0.09]; p=0.001). Gamma-glutamyl transferase (GGT) also showed substantial reduction (SMD -1.98; 95% CI [-2.56, -1.40]; p<0.00001).
Symptomatic improvements were observed, particularly for pruritus. Bezafibrate and seladelpar demonstrated the most promising results, with mean reductions in visual analog scale scores for pruritus of 30% and 35%, respectively. Fatigue scores also improved, though to a lesser extent (SMD -0.42; 95% CI [-0.68, -0.16]; p=0.002).
Safety profiles were comparable to controls, with no significant increase in serious adverse events (OR 1.21; 95% CI [0.81, 1.83]; p=0.35). The most common adverse events were mild gastrointestinal symptoms (10-15% of patients) and transient elevations in creatinine (5-8% of patients). No significant hepatotoxicity was observed across the studies.
Conclusion: Novel oral anti-cholestatic agents show promise in managing PBC patients with suboptimal UDCA responses, demonstrating significant improvements in biochemical markers and some symptomatic relief. However, study heterogeneity, small sample sizes, and limited follow-up durations restrict direct comparisons and generalizability. Further research is needed to confirm long-term efficacy and safety.

THE ROLE OF VITAMIN D DEFICIENCY IN THE PROGRESSION AND OUTCOMES OF PRIMARY SCLEROSING CHOLANGITIS: A PRELIMINARY ANALYSIS

V. Affatato[1], F. Savino[1], D. Forastiere[1], A. Iannone[1], A. Castellaneta[1], M.R.D. Principi[1]

Introduction: Primary sclerosing cholangitis (PSC) is a progressive and debilitating liver disease involving chronic inflammation and fibrosis of bile ducts. Vitamin D plays a critical role in anti-inflammatory and anti-fibrotic pathways, yet its impact on PSC progression remains insufficiently explored.
Aims & Methods: This study investigates the relationship between vitamin D deficiency and key outcomes in PSC patients, including biliary damage, hepatic decompensation, and survival. Sixteen PSC patients from a

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tertiary care outpatient clinic were included. Vitamin D status was determined via serum 25-hydroxyvitamin D3 levels, with deficiency defined as <30 ng/mL. Patients were categorized into deficient and normal vitamin D groups.

Outcomes assessed included alkaline phosphatase (ALP) levels, PREsTo score for hepatic decompensation risk, and 4-year survival using the revised Mayo Risk Score (rMRS). Statistical analyses included t-tests, Mann-Whitney tests, Fisher's exact test, and Spearman's correlation.

Results: The cohort had a mean age of 55.8±13.1 years, with equal gender distribution. Vitamin D deficiency was observed in 56.25% of patients. No significant differences were found between deficient and normal groups for ALP (106 vs. 100 U/L, p=0.71), PREsTo score (5% vs. 5%, p=0.31), or rMRS (0.2±1.1 vs. -0.2±0.6, p=0.42). Furthermore, no meaningful correlation was identified between vitamin D levels and ALP (Spearman's rho = -0.18, p=0.56).

Conclusion: While vitamin D deficiency is prevalent among PSC patients, this preliminary analysis did not reveal a significant impact on disease progression or prognosis.

These findings suggest that vitamin D's roles in inflammation and fibrosis may not translate into measurable clinical effects within this study's scope. Further research with larger cohorts, extended follow-up, and interventional studies on vitamin D supplementation is warranted.

Disclosure: Nothing to disclose.

Introduction: Primary biliary cholangitis (PBC) is a rare, chronic autoimmune liver disease characterized by progressive destruction of small intrahepatic bile ducts, leading to cholestasis and end-stage liver disease. Liver transplantation (LT) remains the definitive treatment, with excellent long-term outcomes. However, a subset of patients experiences disease recurrence (rPBC), which may impact prognosis. Due to the rarity of the condition, risk factors for rPBC remain poorly defined.

Aims & Methods: This study aims to determine the prevalence of rPBC after LT and identify potential risk factors associated with recurrence. A systematic search was conducted in MEDLINE, Embase, and Cochrane CENTRAL using a predefined strategy.

We included full-text studies reporting the number of PBC patients who developed rPBC post-LT. Abstracts and studies lacking clear data on prevalence or risk factors were excluded. Prevalence estimates were pooled using a two-step approach with logit transformation and generalized linear mixed models. Hazard ratios (HRs) and 95% confidence intervals (CIs) were synthesized using a random-effects model with restricted maximum likelihood estimation. All analyses were performed using R Studio.

Results: Fifty-five studies met inclusion criteria, most conducted in Europe, followed by North America, Asia, and Australia; two studies were multi-continental. A total of 5,715 patients with PBC who underwent LT were included, with 9.98% being male. Reported prevalence of rPBC ranged from 0% to 50%, with a pooled prevalence of 15% (95% CI: 12%-19%). Significant risk factors for rPBC included younger age at LT (HR = 0.97, 95% CI: 0.96-0.98) and use of tacrolimus in maintenance immunosuppression (HR = 1.79, 95% CI: 1.09-2.95).

Protective factors included cyclosporine-based maintenance immunosuppression (HR = 0.50, 95% CI: 0.28-0.87) and post-LT prophylactic use of ursodeoxycholic acid (HR = 0.42, 95% CI: 0.30-0.58). Donor age, donor-recipient sex mismatch, cold ischemia time, and use of tacrolimus, cyclosporine, or azathioprine in initial immunosuppression, as well as maintenance azathioprine or occurrence of acute cellular rejection, were not significantly associated with rPBC.

Conclusion: This is the largest meta-analysis to date evaluating rPBC, including 5,715 liver transplant recipients with PBC. The overall recurrence rate was 15%. Younger age at transplantation and tacrolimus-based immunosuppression were associated with higher recurrence risk, while cyclosporine and post-LT ursodeoxycholic acid appeared protective.

These findings may inform risk stratification and guide post-transplant management in PBC. Prospective studies are needed to validate these associations and refine strategies to prevent rPBC.

Disclosure: RVM has received funding from PSC Support. GGLC has received a research grant from IPSEN.

CHOLECYSTECTOMY IN PRIMARY SCLEROSING CHOLANGITIS (PSC): IMPACT ON BILE COMPOSITION, DISEASE PROGRESSION AND OUTCOME

M.A. Färkkilä[1], A. Tenca[2], J. Jokelainen[2], H. Kautiainen[3]
[1]Helsinki University Hospital and University of Helsinki, Gastroenterology, Helsinki, Finland, [2]Helsinki University Hospital, Gastroenterology, Helsinki, Finland, [3]University of Eastern Finland, Institute of Public Health and Clinical Nutrition, Kuopio, Finland

Introduction: PSC is chronic infammatory disease of bile ducts leading to strictures of bile duct and eventually to liver cirrhosis. Chronic inflammation is associated with markedly increased risk of cholangiocancer (CCA). In addition, gall bladder abnormalities are common in patients with PSC[1] such as cholecystitis, gallstones, polys and gallbladder carcinoma (GBCA). Increased fasting gallbladder volume has been reported with normal gallbladder emptying[2]. Due to the increased risk of GBCA[3] cholecystectomy is recommended in PSC with gallbladder polyps ≥8 mm and smaller polyps growing[4].

However, cholecystectomy has been associated with impaired PSC outcome. A study consisting of 11 PSC patients with cholecystectomy suggested protective role of gallbladder based on MRCP changes and elevated AST levels in patients with cholecystectomy. No significant difference in serum bile acids was observed in patients with or w/o cholecystectomy[5].

Another small study including five PSC patients with cholecystectomy showed that cholecystectomy was associated with worse Mayo scores and an elevated FIB4[6]. More than 50% of PSC have enlarged gallbladder

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

which is suspected to be caused by hyperpressure in the biliary tract[5]. Cholecystectomy may thus eliminate this reserve function and lead to progression of bile duct strictures.

Aims & Methods: To evaluate the impact of cholecystectomy on liver enzyme levels, biliary bile acid composition, bile duct disease progression, and overall outcomes in a large PSC patient cohort, we analyzed data from 1,009 individuals enrolled in the prospective Helsinki PSC registry. Of these, 114 patients (11.3%) had undergone cholecystectomy—34 prior to and 80 following the PSC diagnosis. Patients with gallbladder cancer were excluded. Clinical and laboratory parameters were collected, along with data on disease progression based on sequential ERC examinations scored by the Helsinki ERC score[7]. Additionally, bile composition was analyzed in a subgroup of 157 patients receiving UDCA therapy, 32 of whom had undergone cholecystectomy.

Results: Demographics, liver function tests, and outcomes stratified by cholecystectomy, are presented in the table. We found no differences between the three groups (no cholecystectomy, cholecystectomy done prior or after PSC dg) regarding the progression of bile duct disease or its severity, liver function tests, development of biliary dysplasia or need for dilatation, Mayo- and MELD-scores. The cumulative incidence of the composite end point (= transplantation, liver related death, HCC or CCA) did not differ between groups. The molar-% of phospholipids were lower and cholic acid and deoxycholic acid (mg) elevated in bile in patients with cholecystectomy, whereas no differences were found in UDCA content.

Variable	No cholecystectomy, n=895	Cholecystectomy before PSC dg, n=34	Cholecystectomy after PSC dg, n=80	P-value**
Men, n(%)	537(60)	12(35)	39(49)	0.003
Age, mean (SD)	37(13)	46(12)	43(13)	<0.001
BMI, mean(SD)	25.6(4.5)	26.5(4.2)	26.4(4.5)	0.22
ERC-score, mean (SD)	5.8(3.5)	6.4(3.7)	6.4(3.5)	0.16
Need for dilatation	398(44)	18(53)	42(53)	0.26
P-AST, U/l, median (IQR)	36(25,58)	37(28,52)	34(26,51)	0.83

Introduction: Anti-mitochondrial antibodies (AMA) are commonly associated with Primary Biliary Cholangitis (PBC), a progressive liver disease. However, the clinical significance of AMA positivity in patients with normal liver enzymes remains poorly understood. Despite the presence of AMA, many patients maintain normal liver function, raising the question of whether these individuals are at risk for developing liver-related complications.

Aims & Methods: This study aims to evaluate the natural history, prognostic implications, and potential risk factors for disease progression in AMA-positive patients with normal liver enzymes.

A retrospective cohort study was conducted using a national healthcare database to identify patients (aged>18) with a positive AMA and normal liver enzymes between 2002 and 2023. Demographics, biochemical parameters, and liver-related complications were analyzed. Multivariate regression models assessed predictors of disease progression.

Results: Among 1,018 patients, 76 (7.5 %) developed Primary biliary cholangitis (PBC), and 30 (2.9%) progressed to cirrhosis over a median follow-up of 6.3 years. Liver-related complications were rare, with esophageal varices in 1.1%, ascites in 1.8%, hepatocellular carcinoma in 0.2%, and liver transplantation in 0.1%. Notably, higher AMA titers were strongly associated with increased risk of developing PBC, cirrhosis and liver-related complications, demonstrating a clear titer-dependent pattern.

Conclusion: Most AMA-positive patients with normal liver enzymes do not develop clinically significant liver disease. However, higher AMA titers identify a high-risk subgroup that warrants closer monitoring. These findings underscore the need for risk-stratified follow-up strategies and may influence future clinical guidelines.

*L*ACTOBACILLUS PLANTARUM ALLEVIATES CHOLESTATIC LIVER INJURY BY ENHANCING TRYPTOPHAN METABOLISM

C. Zhu[1], S. Dong[1], C. Xuan[1], S. Zhou[1], L. Guo[1], L. Zhou[1]
[1]Tianjin Medical University General Hospital, Department of Gastroenterology and Hepatology, Tianjin, China

Contact E-Mail Address: norm_seanzhu@outlook.com

Introduction: *L*actobacillus plantarum is a probiotic with known therapeutic potential in various diseases, including liver diseases. However, the therapeutic effects and underlying mechanisms of *L*actobacillus plantarum in cholestatic liver injury remain poorly understood.

Aims & Methods: This study aims to investigate the therapeutic role and mechanism of Lactobacillus plantarum in cholestatic liver injury. Cholestatic liver injury was induced in mice using either a 0.1% 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC) diet or α-naphthyl isothiocyanate (ANIT) gavage. Mice were then treated with Lactobacillus plantarum. Therapeutic

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

effects were evaluated using histopathology, 16S rRNA sequencing, untargeted metabolomics, RNA sequencing, whole-genome sequencing, and immunohistochemistry.

Results: *L*actobacillus plantarum treatment markedly reduced liver inflammation, fibrosis, and ductular proliferation. Multi-omics analysis revealed enhanced tryptophan biosynthesis in the Lactobacillus plantarum treatment group. Tryptophan levels were significantly elevated in both liver and serum following treatment. Exogenous administration of tryptophan alone was sufficient to alleviate liver injury in the cholestasis models. RNA-seq data suggested that tryptophan acts by activating the AHR signaling pathway, and the therapeutic effect of tryptophan was diminished after the use of AHR inhibitors.

Conclusion: In summary, our findings suggest that Lactobacillus plantarum alleviates cholestatic liver injury by increasing circulating tryptophan, which may represent a potential therapeutic strategy for cholestatic liver injury.

Disclosure: Nothing to disclose.

HEPATIC SARCOIDOSIS: CLINICAL PROFILE AND UDCA THERAPEUTIC OUTCOMES: A MOROCCAN RETROSPECTIVE STUDY

H. Himmi[1], M. Borahma[1], F.-Z. Chabib[2], N. Lagdali[1], F.Z. Ajana[3], M. Kadiri[4]
[1]Mohammed the Vth University, Ibn Sina Hospital, Gastroenterology C, Rabat, Morocco, [2]Ibn Sina University Hospital, Medical Unit C, Seclin, France, [3]CHU Ibn Sina, SMMAD, Moroccan Society of Digestif Diseases, Rabat, Morocco, [4]Ibn Sina Hospital, Rabat, Morocco

Contact E-Mail Address: hanaehimmi@gmail.com

Introduction: Hepatic sarcoidosis, a rare manifestation of systemic sarcoidosis, is characterized by the development of non-caseating granulomas in the liver parenchyma. Diagnosis requires a combination of clinical, biological, and histopathological assessment, while treatment commonly includes ursodeoxycholic acid (UDCA) and corticosteroids as key therapeutic options.

Aims & Methods: This study focuses on exploring the clinical spectrum, diagnosis features, and treatment responses in a Moroccan cohort.

This retrospective descriptive study reviewed 16 patients diagnosed with hepatic sarcoidosis treated at Ibn Sina Hospital's Gastroenterology department (Rabat, Morocco) between 2010 and 2024. All the patients included were aged over 30 years at diagnosis.

Results: The cohort comprised exclusively female patients (n=16) with an average age of 53 years (range 32-75). Diabetes was the predominant comorbidity (37.5%). The most frequent presenting symptoms were asthenia (37.5%), pruritus (31.25%) and anemia (18.75%). Physical examination revealed splenomegaly in 37.5% of cases and hepatomegaly in 43.75%. Cutaneous venous collaterals were present in 19% of patients while 25% had unremarkable findings.

Biological analysis identified cytolytic (31.25%) and cholestatic (68.75%) patterns, with no evidence of hepatocellular failure. On imaging evaluation, all patients underwent abdominal ultrasound, revealing features of chronic liver disease in 62.5% and portal hypertension signs in 31.25%. Esophagogastroduodenoscopy, performed on 14 patients, revealed portal hypertension manifestations (esophageal varices / hypertensive gastropathy) in 9 cases while findings were normal in 5.

The diagnosis of hepatic sarcoidosis was histologically confirmed through liver biopsy demonstrating characteristic non-caseating granulomatous hepatitis, after excluding alternative granuloma etiologies (notably primary biliary cirrhosis and hepatitis C virus infection). All patients underwent evaluation for extra hepatic involvement, revealing isolated hepatic disease in 25% of cases (n=4) and pulmonary manifestations as the most common concurrent finding.

Regarding therapeutic management, 11 patients received ursodeoxycholic acid (UDCA): as mono-therapy (n=4), combined with corticosteroids (n=6), and with anti-epileptics in one case of neurological involvement. Three patients were treated with corticosteroids alone. Overall, 81.25% of the cohort achieved satisfactory treatment outcomes.

Conclusion: In summary, our findings revealed that hepatic sarcoidosis predominantly affected women (mean age 53 years) in our cohort. The disease manifested as either isolated hepatic involvement or combined with pulmonary pathology. UDCA-based regimens constituted the primary treatment approach and were associated with favorable clinical outcomes in 81% of cases, reinforcing their role as first-line therapy.

Disclosure: Nothing to disclose.

Introduction: The non-invasive assessment of liver fibrosis in primary biliary cholangitis (PBC) is primarily based on transient elastography. The objective of this study was to evaluate the diagnostic performance of simple fibrosis scores in patients with PBC.

Aims & Methods: This was a retrospective, single-center study including all patients followed for PBC in a gastroenterology department between January 2001 and December 2023. Demographic, clinical, biological, and histological data were collected. Histological staging was performed according to the Scheuer classification, with stage 4 corresponding to cirrhosis. The following non-invasive fibrosis scores were calculated using validated online formulas and calculators: APRI (AST to Platelet Ratio Index), FIB-4, AST/ALT ratio (AAR), and GGT to Platelet Ratio (GPR).

Multivariate logistic regression analysis was used to identify independent predictors of cirrhosis. Diagnostic performance was assessed using receiver operating characteristic (ROC) curve analysis and area under the ROC curve (AUROC) with a 95% confidence interval (CI).

Results: Fifty-seven patients were included, of whom 54 were women. The mean age was 59 years (range: 20–96 years). Liver biopsy was performed in 29 patients (50.9%).

Histological staging according to the Scheuer classification was as follows: stage 1 (8 patients, 27.6%), stage 2 (6 patients, 20.7%), stage 3 (8 patients, 27.6%), and stage 4/cirrhosis (7 patients, 20.1%).

Multivariate logistic regression analysis identified FIB-4 as the only inde-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pendent predictor of cirrhosis (p = 0.011). The FIB-4 score demonstrated an AUROC of 0.818 (p = 0.011). At a cut-off value of 2.92, FIB-4 had a sensitivity of 100% and a specificity of 63% for the diagnosis of cirrhosis.

Conclusion: Among the simple fibrosis scores evaluated, only the FIB-4 score showed adequate diagnostic performance for predicting cirrhosis in patients with primary biliary cholangitis. These findings suggest its potential role as a non-invasive screening tool in clinical practice.

Disclosure: Nothing to disclose.

PP0798

DOES THE ALP-A SCORE PREDICT BIOCHEMICAL RESPONSE TO URSODEOXYCHOLIC ACID AFTER ONE YEAR OF TREATMENT IN PRIMARY BILIARY CHOLANGITIS?

I. Lassoued[1], M. Yakoubi[2], A. Ben Mohamed[3], R. Limam[2], G. Gharbi[3], M. Moufida[4], A. Khsiba[5], M. Medhioub[4], M.L. Hamzaoui[3]

Introduction: Biochemical response to ursodeoxycholic acid (UDCA) is a major prognostic factor in primary biliary cholangitis (PBC). This response is typically assessed using the Paris criteria. The aim of this study was to evaluate the performance of the ALP-A score in predicting biochemical response to UDCA after one year of treatment.

Aims & Methods: This was a retrospective, single-center study including all patients followed for PBC in a gastroenterology department between January 2001 and December 2023. Demographic, clinical, biological, and histological data were collected.

The ALP-A score was calculated using the following formula:

Age at diagnosis / (alkaline phosphatase at diagnosis / upper limit of normal [ULN])

The diagnostic performance of the score was assessed using receiver operating characteristic (ROC) curve analysis, with the area under the ROC curve (AUROC) and a 95% confidence interval (CI).

Results: Fifty-seven patients were included, with a mean age of 59 years (range: 20–96 years), and a strong female predominance (n = 54). At diagnosis, 21 patients (36.84%) had cirrhosis.All patients received UDCA at a dose of 13–15 mg/kg/day. After one year of treatment, a biochemical response according to the Paris criteria was observed in 27 patients (47.7%). The mean ALP-A score was 28.62 (range: 0.65–71). The ALP-A score showed an AUROC of 0.723 (p = 0.004). At a cut-off value of 22, the score yielded a sensitivity of 73% and a specificity of 63%.

Conclusion: The ALP-A score may help identify patients who are less likely to respond to UDCA, allowing for early consideration of second-line therapies. Its use could be valuable in optimizing treatment strategies in PBC.

Disclosure: Nothing to disclose.

PP0799

ROLE OF THE MEAN PLATELET VOLUME-TO-PLATELET COUNT RATIO IN PREDICTING LIVER FIBROSIS IN PRIMARY BILIARY CHOLANGITIS

I. Lassoued[1], M. Yakoubi[2], A. Ben Mohamed[3], R. Limam[2], G. Gharbi[1], M. Moufida[1], A. Khsiba[4], M. Medhioub[5], M.L. Hamzaoui[1]
[1]Mohamed Taher Maamouri, Gastroenterology, Nabeul, Tunisia, [2]Faculty of Medicine of Tunis, Gastroenterology, Tunis, Tunisia, [3]Mohamed Taher Maamouri Hospital, Gastroenterology, Tunis, Tunisia, [4]Faculté de Medecine de Tunis, Mohamed Taher Maamouri Hospital, Gastroenterology and Hepatology, Nabeul, Tunisia, [5]Mohamed Taher Maamouri Hospital, Gastroenterology, Nabeul, Tunisia

Contact E-Mail Address: lasswediness@gmail.com

Introduction: The mean platelet volume (MPV)-to-platelet count (PLT) ratio is an emerging biomarker in various inflammatory and neoplastic diseases. In chronic liver disease, thrombocytopenia and elevated MPV—frequently observed in hepatic fibrosis and portal hypertension—suggest the potential value of this ratio.

The aim of this study was to evaluate the MPV/PLT ratio as a marker of disease severity in patients with primary biliary cholangitis (PBC).

Aims & Methods: This retrospective, single-center study included all patients with biopsy-proven PBC followed over a 16-year period.Demographic, clinical, biochemical, and histological data were collected. Liver fibrosis was staged using the Scheuer classification.

Patients were categorized into two groups: early-stage disease (Scheuer stages 1–2) and advanced-stage disease (Scheuer stages 3–4). Variables were compared using Pearson's chi-squared test, with a significance level set at $p < 0.05$.

Results: A total of 29 PBC patients underwent liver biopsy. Fourteen patients (48.3%) had early-stage disease, while fifteen (51.7%) had advanced-stage disease. There were no significant differences between the two groups in terms of hematological parameters (white blood cell count, platelet count, hemoglobin) or biochemical markers (AST, ALT, GGT, alkaline phosphatase, total bilirubin, albumin) ($p > 0.05$). Likewise, no significant difference was found in the MPV/PLT ratio between early and advanced fibrosis groups (p = 0.4 and 0.52, respectively); However, the MPV/PLT ratio was significantly higher in patients with cirrhosis (0.68 vs. 0.5; p = 0.021). The AUROC for the MPV/PLT ratio in predicting cirrhosis was 0.792. A cut-off value of 0.059 yielded a sensitivity of 73% and a specificity of 63%.

Conclusion: The MPV/PLT ratio may serve as a simple and non-invasive biomarker for identifying advanced fibrosis in patients with PBC.

PREDICTION OF ESOPHAGEAL VARICES IN PRIMARY BILIARY CHOLANGITIS: WHAT ROLE OF THE E-LIFT SCORE?

I. Qarch[1], M. Borahma[1], F.-Z. Chabib[1], N. Lagdali[1], F.Z. Ajana[1], M. Kadiri[1]
[1]Ibn Sina University Hospital Center, Faculty of Medicine and Pharmacy, Mohammed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ismail.qarch@gmail.com

Introduction: Screening for esophageal varices (EV) in patients with primary biliary cholangitis (PBC) can effectively reduce the morbidity and mortality associated with gastrointestinal bleeding. Current research focuses on using non-invasive tests to minimize unnecessary endoscopic screenings.

The e-LIFT score, a non-invasive method used primarily for the detection of advanced liver fibrosis in chronic liver disease, however, the use of this score for predicting varices, has been evaluated in only one study.

Aims & Methods: This was a retrospective, descriptive, and analytical monocentric study conducted in a gastroenterology department over a 7-year period (2017–2024). It included patients with PBC who underwent upper gastrointestinal endoscopy. Data were collected from patient records. All patients underwent esophagogastroduodenoscopy (EOGD) to detect esophageal varices. The sensitivity (Se) and specificity (Sp) of the e-LIFT score were assessed using the ROC curve.

The objective of our study was to assess the correlation between endoscopic findings and the e-LIFT test.

Results: A total of 67 PBC patients were included. The mean age was 50 ± 14.2 years, with a marked female predominance (80.6%, 54 patients) and a female-to-male ratio of 4.15.

EOGD revealed the presence of EV in 41.4% (24 patients), among whom 12.5% (3), 41.6% (10), and 45.8% (11) had grade I, grade II, and grade III varices, respectively.

The area under the ROC curve for the e-LIFT score in predicting the presence of EV was 0.745. The optimal discriminative threshold for this score was 13, with a sensitivity of 82.14% and a specificity of 61.51%. The negative predictive value (NPV) was 82.76%.

Conclusion: The e-LIFT score is a simple and reliable serum marker for screening esophageal varices in PBC. Thus, upper gastrointestinal endoscopy can be avoided in 82.76% of patients with a score < 13. However, a larger-scale study is needed to confirm the results of our study.

Disclosure: Nothing to disclose.

Introduction: Intrahepatic cholestasis of pregnancy (ICP) is a liver disorder unique to pregnancy, with complex pathogenesis influenced by genetic factors. Polymorphisms in the *ABCB4* and *ABCB11* genes have been implicated in the pathogenesis of ICP and specifically the ABCB4 rs2109505, ABCB11 rs3815676 and ABCB11 rs7577650 single nucleotide polymorphisms (SNPs). Data from Greece regarding these SNPs are limited.

Aims & Methods: The aim of the study was to investigate the frequency of the three common SNPs in a cohort of Caucasian pregnant women and to evaluate their potential associations with the clinical and laboratory presentation of ICP.

Prospective study during 2020-2024 recruiting Caucasian pregnant women of white eastern European origin with ICP diagnosis. Demographic and laboratory data were recorded. Pregnant women with concomitant history of liver disease (viral hepatitis, autoimmune hepatitis, primary biliary cholangitis etc) were excluded. Peripheral blood samples were collected, and genetic material (DNA) was isolated from whole blood using the commercially available PureLink Genomic DNA Kit, which allows for rapid and efficient DNA isolation. Polymerase Chain Reaction (PCR) was applied to the samples using sequence specific primers to amplify the gene of interest. The PCR products were subjected to agarose electrophoresis to confirm gene amplification, and the samples were subsequently sequenced using an automated analyzer to reveal the presence of the following polymorphisms: ABCB4 rs2109505, ABCB11 rs3815676 and ABCB11 rs7577650.

A square root transformation was applied to achieve normality in skewed variables. Linear and logistic regression models were used to examine the effect of mutated genes on relevant variables, where appropriate. The present study was sponsored by the Hellenic Society of Gastroenterology.

Results: The mean age of the 66 participants was 33.05 ± 7.29 years. Pruritus was reported by 39 (59.09%) of them. A personal history of ICP was noted in 7 (10.61%) women, and a family history in 5 (7.58%). Sixteen (24.24%) participants had gestational diabetes.

First parity was observed in 43 (65.15%), while twin pregnancies were detected in 9 (13.64%) women. The median serum bile salt concentration was 20 mg/L (IQR: 11–49), and the median ALT level was 185 U/L (IQR: 69–428). The ABCB4 rs2109505 SNP was detected in 6 (9.09%) cases, ABCB11 rs3815676 in 2 (3.03%), and ABCB11 rs7577650 in 27 (40.91%).

Women carrying the ABCB11 rs7577650 SNP exhibited a significantly greater weight gain during pregnancy compared to those with the wild-type gene (mean difference: 4.09 kg, 95% CI: 0.19–7.98, p = 0.04). The

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

wild-type ABCB11 genotype was associated with higher ALT levels, with a mean difference of 4.56 in the square root of ALT (95% CI: 0.14–8.98, p = 0.04).

The presence of the ABCB11 rs7577650 SNP showed a trend toward association with lower bile salt levels and more frequent diagnosis of gestational diabetes (p = 0.08 and p = 0.07, respectively). No statistically significant associations were detected between ABCB4 rs2109505, ABCB11 rs3815676 SNPs and the other variables.

Conclusion:

1. Overall polymorphisms of the ABCB4 or ABCB11 genes were observed in 53% of the study population of Caucasian women with ICP.
2. The most frequently observed polymorphism was the ABCB11 rs7577650.
3. Women with ICP and the ABCB11 rs7577650 polymorphism tend to gain more weight during pregnancy and present with higher ALT levels.

Disclosure: The present study was sponsored by the Hellenic Society of Gastroenterology.

Introduction: Primary biliary cholangitis (PBC) is a chronic autoimmune inflammatory disease of the intrahepatic bile ducts. It is characterized by chronic cholestasis, the presence of specific auto immune antibodies, and distinctive histological lesions. PBC is frequently associated with other autoimmune diseases.

Aims & Methods: This study aims to describe the clinical, biological, morphological, and histological characteristics of PBC patients with associated autoimmune diseases, as well as the therapeutic approaches used.

This was a descriptive retrospective study conducted in the Medicine C of Hepatogastroenterology Department at Ibn Sina Hospital in Rabat, including 62 patients with PBC and associated autoimmune diseases between 2010 and 2025

Results: Among 130 patients with PBC, 62 had an associated autoimmune disease, representing a prevalence of 47%. The mean age was 47 years, with a sex ratio of 1M/9F. The most frequent symptoms were jaundice in 45.2% (n=28) of cases, asthenia in 41.9% (n=26), and pruritus in 35.5% (n=22). Clinical examination revealed signs of portal hypertension in 48.4% (n=30) of patients, jaundice in 51.6% (n=32), and scratch lesions in 19.4% (n=12).

Abdominal ultrasound showed liver with features of chronic liver disease in 71% (n=44) of patients, splenomegaly in 41.9% (n=26), ascites in 37.1% (n=23), and collateral venous circulation in 32.3% (n=20).

Biological abnormalities included cytolysis in 71% (n=44) of cases, cholestasis in 38.7% (n=24), and hepatocellular insufficiency in 22.6% (n=14). Regarding the autoimmune profile, 62.9% of PBC cases were seropositive, with anti-mitochondrial antibodies type 2 detected in 45% (n=28), anti-Sp100 antibodies in 19% (n=12), and anti-Gp210 antibodies in 16% (n=10) of patients.

Liver biopsy was performed in 40 patients and the Scheuer stages were classified as follows: stage 1 in 12.9% (n=8), stage 2 in 29% (n=18), stage 3 in 19.4% (n=12) and stage 4 in 3.2% (n=2) of cases.

Fibrosis assessment was carried out in 53 patients, using transient elastography (FibroScan) in 13 cases and liver biopsy in 40 cases. The fibrosis stage distribution was as follows: F3 in 38.7% (n=24), F2 in 25.8% (n=16), F4 in 11.2% (n=7), F1 in 8% (n=5), and F0 in 1.6% (n=1) of cases.

The main associated autoimmune diseases were autoimmune hepatitis in 40.3% (n=25) of cases and autoimmune thyroiditis in 40.3% (n=25), followed by Sjögren's syndrome in 21% (n=13), type 1 diabetes in 8.1% (n=5), and celiac disease in 4.8% (n=3). Less frequent associations included juvenile polyarthritis, Graves' disease, and vitiligo (each in 3.2% (n=2) of cases), as well as scleroderma and Addison's disease (each in 1.6% (n=1) of cases). Among these patients, 29% (n=18) had two associated autoimmune diseases, and 6.5% (n=4) had three.

All patients received ursodeoxycholic acid (UDCA) at doses of 13-15 mg/day, along with specific treatments for concomitant autoimmune diseases.

Treatment response assessment using the Paris II score showed a good response in 62% (n=38) of patients and a partial response in 38% (n=24) of patients.

Conclusion: This study confirms the high prevalence of autoimmune diseases associated with PBC, particularly autoimmune hepatitis and thyroiditis, with a strong female predominance. The most frequent stages of fibrosis were F2 and F3, highlighting the moderate to advanced disease progression at diagnosis in many patients. It emphasizes the importance of systematic screening for these comorbidities to ensure optimal management.

PRIMARY BILIARY CHOLANGITIS AND NON-RESPONSE TO URSODEOXYCHOLIC ACID: PREDICTING PROGNOSIS FROM DIAGNOSIS

O. Trabelsi[1], S. Mrabet[1], E. Mourali[2], R. Harbi[3], I. Akkari[4], E. Benjazia[2]

[1]Farhat Hached University Hospital, Gastroenterology, Sousse, Tunisia, [2]Farhat Hached University Hospital, Sousse, Tunisia, [3]Faculté de Medecine Ibn Al Jazzar de Sousse, Sousse, Tunisia, [4]Farhat Hached Hospital Sousse, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: trabelsioussama28@gmail.com

Introduction: The response to ursodeoxycholic acid (UDCA) in primary biliary cholangitis (PBC) varies widely. Identifying patients at risk for non-response early in the disease course is crucial for anticipating the need for second-line therapies.

Aims & Methods: This monocentric retrospective study included 83 patients with PBC who were treated with ursodeoxycholic acid (13–15 mg/kg/day). Therapeutic response was assessed after one year using the Paris II criteria. The primary objective was to identify factors associated with non-response to UDCA.

Results: The mean age at diagnosis was 55.6 years (range: 27–82), with a clear female predominance. The most common clinical presentations were fatigue (34.9%) and pruritus (22.9%). Additionally, 25 patients (30.1%) had cirrhosis at diagnosis. Autoimmune diseases were observed in 60.2% of cases, primarily autoimmune thyroiditis. At one year, 30.1% of

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients were classified as non-responders to UDCA treatment. Non-responders were older at diagnosis (p = 0.026), more frequently had cirrhosis (p < 0.01), and exhibited a more severe biological profile at diagnosis, including elevated total bilirubin (p = 0.013), hypoalbuminemia (p < 0.01), thrombocytopenia (p = 0.016), and a decreased prothrombin time (p = 0.022). However, initial clinical symptoms (fatigue, pruritus, arthralgia) and autoimmune profiles (specific antibodies, associated autoimmune diseases) were not associated with treatment response.

A statistically significant positive correlation was found between non-response to UDCA and continuous prognostic scores (GLOBE, UK-PBC, Mayo Risk; p < 0.01), as well as non-invasive fibrosis markers (FIB-4: p = 0.032; FibroIndex: p = 0.015; GPR: p = 0.015).

Conclusion: In PBC, the factors driving non-response to UDCA do not appear to be related to clinical symptoms or autoimmune profiles, but rather to an early biological signature. A combined approach, incorporating prognostic scores and non-invasive fibrosis markers, could help identify at-risk patients sooner and guide treatment decisions.

EXTRAHEPATIC AUTOIMMUNE COMORBIDITIES IN PRIMARY BILIARY CHOLANGITIS: REFLECTION OF AN IMMUNOLOGICAL PHENOTYPE WITH NO PROGNOSTIC IMPACT?

O. Trabelsi[1], S. Mrabet[1], E. Mourali[2], R. Harbi[3], I. Akkari[4], E. Ben Jazia[4]

Introduction: Primary biliary cholangitis (PBC) is often associated with extrahepatic autoimmune diseases (EAIDs) such as Sjögren's syndrome, autoimmune thyroiditis, and connective tissue disorders. While this association suggests a shared immunological predisposition, its effect on disease prognosis remains unclear.

Aims & Methods: This retrospective study included 69 patients diagnosed with PBC, excluding those with overlap syndromes involving autoimmune hepatitis. Patients were divided into two groups: isolated PBC (n = 35) and PBC associated with EAIDs (n = 34). The two groups were compared based on clinical, immunological, elastometric characteristics, disease progression, and prognostic scores (Paris I, Paris II, Rotterdam, Barcelona, Rochester, GLOBE, UK-PBC). Statistical analysis was conducted using appropriate tests, with a significance threshold set at p < 0.05.

Results: The average age at diagnosis was 55.6 years. The disease was initially suspected based on functional symptoms in 39% of cases (fatigue, pruritus, arthralgia), biological cholestasis in 33.3%, and decompensated cirrhosis in 20.3%. The most common associated autoimmune diseases were Sjögren's syndrome (17.4%), thyroid disorders (13%), and systemic lupus erythematosus (10.1%). All patients received treatment with ursodeoxycholic acid at 13-15 mg/kg/day. No significant differences were found between the two groups regarding functional symptoms, biological markers (bilirubin, albumin, prothrombin time), autoantibodies (AMA, Anti-GP210, anti-SP100, anti-PML), non-invasive fibrosis scores (Fib4, Fibroindex, Fibroscan, S-index), or hepatic complications (HDH, cirrhosis, hepatic encephalopathy, liver-related death). Prognostic scores were also comparable between both groups: Paris I (p = 0.468), Paris II (p = 0.519), GLOBE score (p = 0.6), UK-PBC (p = 0.49), Rotterdam (p = 0.897), Barcelona (p = 0.181), Rochester (p = 0.727).

Conclusion: The presence of extrahepatic autoimmune diseases in PBC does not appear to affect the clinical, biological, or prognostic profiles of patients. Despite their frequency, these comorbidities do not seem to influence the progression of PBC.

Disclosure: None.

Introduction: Cirrhosis secondary to autoimmune hepatitis (AIH) presents a unique clinical challenge, with limited data available on its presentation and management.

Aims & Methods: This study aimed to assess the clinical spectrum and evaluate real-world treatment outcomes, particularly the efficacy and safety of low-dose steroid therapy, in patients with AIH-related cirrhosis.

Results: Of 102 AIH patients, 73 (71.6%) had cirrhosis: 40 (54.8%) were compensated, 17 (23.3%) presented with decompensated cirrhosis, and 16 (21.9%) with acute-on-chronic liver failure (ACLF). The majority were female (84.9%) with a significantly higher median age at presentation compared to males (54 vs. 39 years, p = 0.046).

The most common presenting symptom was jaundice (65.8%), followed by anorexia (45.2%), abdominal pain (32.9%), fatigue (23.3%), fever (19.7%), weight loss (13.7%), pruritus (5.5%). 8.5% patients had HE on presentation. Concomitant autoimmune diseases were noted in 21.9% of patients.

Liver biopsy was performed in 48 patients, revealing lymphoplasmacytic infiltrates (100%), portal inflammation (100%), interface hepatitis (97.9%), centrilobular necrosis (70.8%), rosette formation (52.1%), ballooning degeneration (52.1%), biliary changes (31.3%), cholestasis (20.8%), emporipolesis (18.8%) and steatosis (8.3%).. Autoantibody-negative AIH was identified in 11 patients. Median follow-up was 47 months. Five patients (6.8%) died within 6 months of diagnosis, including 4 with ACLF.

A total of 70 patients (95.8%) received steroid therapy. Among 29 patients with decompensated cirrhosis or ACLF who survived beyond 6 months, recompensation was achieved in 8/17 (47.1%) and 11/12 (91.7%) patients, respectively (p = 0.019). Low-dose steroid therapy (≤20 mg/day) was associated with significantly better recompensation rates in decompensated cirrhosis compared to high-dose therapy (80% vs. 0%, p = 0.015), without an increased risk of infections or complications.

Conclusion: AIH presenting with decompensated cirrhosis or ACLF is not uncommon and can be managed successfully with low-dose corticosteroids in selected patients. This approach appears to balance efficacy with safety, offering a viable treatment option in settings where transplant access is limited.

BRIDGING THE GAP: AN ASIAN PERSPECTIVE ON ADHERENCE TO QUALITY INDICATORS IN THE MANAGEMENT OF PRIMARY BILIARY CHOLANGITIS (PBC)

A. Sim[1], I.Y. Liew[1], Z.W. Kong[1]
[1]Tan Tock Seng Hospital, Gastroenterology and Hepatology, Singapore, Singapore

Contact E-Mail Address: ianyang.liew@mohh.com.sg
Introduction: Primary biliary cholangitis (PBC) is an autoimmune, cholestatic liver disease which results in significant morbidity and mortality. As PBC progresses, it is accompanied by a spectrum of symptoms that can be burdensome. The British Society of Gastroenterology (BSG) has described standards for the management of PBC which address disease progression and symptom burden: adequate dosing of ursodeoxycholic acid (UDCA) 13-15mg/kg/day, timely initiation of second line therapy in those with inadequate response to UDCA, evaluation of symptoms, risk assessment for osteoporosis and identifying high risk patients (bilirubin>50umol/L/ decompensated liver disease) for liver transplant referral. It remains a rare disease worldwide, particularly in Asia, where there is lack of structured care models. We evaluated our hospital's adherence to these recommended guidelines.
Aims & Methods: The primary aim was to evaluate our overall performance against the BSG recommended service standards for the management of PBC. We retrospectively reviewed all patients diagnosed with PBC at our tertiary centre from 1 January 2015-31 December 2023. We included all adult patients with an International Classification of Diseases (ICD-10) code for PBC (K74.3) and/or PBC-specific autoantibodies: antimitochondrial antibody (AMA) or antimitochondrial-2 (anti-M2) who had a follow-up duration ^{3}12 months. Data was captured on baseline demographics, details about diagnosis and follow-up, treatment, symptom and osteoporosis risk assessment, presence of decompensation and discussion regarding transplant for high-risk patients. Inadequate response to UDCA was defined as ALP>1.67x upper limit of normal (ULN) after 1 year of UDCA.
Results: Of the 175 patients analysed,146 (83.4%) were females, mean age 67(±13.3). 96% had a positive AMA. Mean follow-up was 48 months, baseline ALP level was 254U/L and Bilirubin 19umol/L. Of these, 10 patients (5.7%) were diagnosed with an overlap syndrome with autoimmune hepatitis (AIH) after liver biopsy. We noted good adherence to UDCA initiation within 6 months of diagnosis (96.6%) receiving optimal UDCA dose of 13-15mg/kg. Remnant suboptimal dosing was due to intolerance from gastrointestinal (GI) side effects. 77.7% patients were assessed for symptoms in the last 2 years, but interestingly only 2.3% and 3.4% of patients reported pruritus and fatigue respectively. Although most (86%) responded to UDCA, in the remnant 14.3% of non-responders, only 7.4% were prescribed fibrates as second line therapy. None received obeticholic acid. Risk assessment for osteoporosis was done in 56.6% of patients. At baseline, 41 (23.4%) of patients had cirrhosis with decompensation noted in 6.9% (defined as development of ascites, variceal bleeding or hepatic encephalopathy), although less than 10% had liver transplant discussion documented.
Conclusion: Our findings highlight suboptimal performance in adherence to recommended guidelines when measured across most domains. As PBC is rarer in Asia compared to western populations we face challenges in delivering effective therapy using structured models of care. Although larger, more representative studies are required, we will implement a PBC care bundle, followed by re-evaluation as an effort to improve on these shortfalls for better adherence to these key standards to improve quality of care for our PBC patients.

Introduction: Autoimmune hepatitis (AIH) is a rare cause of liver disease, early detection and treatment with immunosuppressive drugs is life saving. Diagnosing AIH involves laboratory tests, liver tissue examination, and ruling out other liver diseases. In 2008, the International Autoimmune Hepatitis Group (IAIHG) introduced simplified diagnostic criteria, which include four factors: autoantibodies, serum immunoglobulin (IgG) levels, results for chronic viral hepatitis, and liver biopsy findings. In line with simplified criteria, each variable is evaluated on a scale of 0 to 2 points. An overall score of 6 is categorized as 'probable AIH,' whereas a score of 7 is classified as 'definite AIH'.
Liver tissue examination is essential for diagnosing AIH, especially when serological markers are missing. The simplified criteria identify portal lymphocytic infiltrates, emperipolesis, and hepatic rosette formation as characteristic features.
Few studies have assessed these simplified histological criteria. In 2022, the AIH-Pathology Group proposed new criteria that classify histological features as likely, possible, or unlikely. In 2021, the IAIHG revised the

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

methodology for immunoserological testing, raising the positive threshold for antinuclear autoantibodies (ANA) when evaluated on HEp-2 cells. The new serological criteria wasn't externally validated yet.

Aims & Methods: We conducted a retrospective analysis of data from 179 patients, with 111 diagnosed with AIH, 33 with primary biliary cirrhosis (PBC), and 35 with drug-induced liver injury (DILI), collected from three centers in Türkiye between January 2013 and March 2021. Initially, we assessed the diagnostic accuracy of both the new histological criteria and the older simplified histological criteria. Subsequently, we revised the simplified criteria by integrating findings from the new histological criteria and immunoserological testing, and then evaluated its diagnostic accuracy.

Results: The new histological criteria and the simplified histological criteria demonstrated sensitivities of 95% and 88%, respectively, for diagnosing possible/probable AIH, with specificities of 75% and 32%. The new histological criteria demonstrated a sensitivity of 60% and a specificity of 97% for likely AIH, whereas the simplified histological criteria had a sensitivity of 42% and a specificity of 94% for definitive AIH. The area under the curve (AUC) for diagnosing AIH was higher with the new histological criteria compared to the simplified histological criteria (0.913 vs 0.714). The updated simplified score demonstrated similar sensitivity to the original simplified score (88% vs 87%) but exhibited higher specificity (91% vs 74%) for probable AIH. For definitive AIH, the specificity was slightly reduced (57% vs 63%), while specificity was enhanced (96% vs 85%). The AUC for AIH diagnosis was higher in the updated simplified score than in the simplified score (0.942 vs 0.856).

Conclusion: The new histological criteria demonstrated greater sensitivity and specificity compared to the simplified criteria for diagnosing AIH. Updating the simplified criteria further enhanced the accuracy for the diagnosis of AIH. Our findings suggest that upgrading the current simplified criteria both serologically and histologically would improve diagnosis in AIH patients.

Introduction: The current universal standard of care in primary biliary cholangitis (PBC) is ursodeoxycholic acid (UDCA), although its clinical benefit in PBC has never been reported in absolute measures.

Aims & Methods: This cohort aimed to assess the prevalence of incomplete response to UDCA and determine non-response predictors.

Patients with PBC as main diagnosis were included from the hospital's centralized electronic medical records system, over a 10-year period. Overlap syndromes (PBC-Auto-Immune Hepatitis) were also included. Main endpoints included incomplete response to UDCA treatment according to Paris I, Paris II criteria, and Globe score.

Results: A total of 50 patients were included in this study. The mean age at diagnosis was 52.74 years (24-73 years) and 92% females. Only one patient was asymptomatic at onset and 82% had positive anti-mitochondrial antibodies. All patients were treated with ursodeoxycholic acid (UDCA). Corticosteroids and immunosuppressive therapies were associated in 26% of cases. Incomplete response to UDCA was observed in 28% and 34% of patients according to Paris I and II criteria, respectively. Non-response predictors were poor therapeutic adherence, Overlap syndrome and hepatocellular carcinoma in 14%, 6% and 4% respectively.

Five patients were lost to follow-up and five cases died from cirrhosis 'complications. The median ΔGLOBE score was 0.42 (IQR: -1.58 to 3.92). The 5, 10 and 15 years liver transplantation-free survival (median) was: +10%, +7.38% and +5% respectively. Liver transplantation (LT) was considered in one patient with excellent outcomes at last follow-up.

Conclusion: A considerable proportion of patients showed incomplete response to UDCA treatment according to Paris II criteria. Early identification of patients at risk of incomplete response could improve patient management and overall disease prognosis.

ENHANCED PLATELET AGGREGATION WITH TRAP-6 IN PLATELET AGGREGOMETRY IN PATIENTS WITH ACUTE-ON CHRONIC LIVER FAILURE

I. Girleanu[1], C. Ioana[1], C.M. Muzica[1], L. Huiban[1], S. Zenovia[1], A.M. Singeap[1], R. Avram[1], L. Oloeru[1], O. Georgeta[1], F. Anastasia[1], I. Buzincu[2], T. Cristina[3], C. Diana[2], A.-V. Trifan[1]

Contact E-Mail Address: icovaliu4@yahoo.com

Introduction: Patients with acute-on-chronic liver failure (ACLF) have traditionally been considered with a tendecy for bleeding however, they frequently display a paradoxical prothrombotic state. ACLF is characterized systemic inflammation and an increased risk of both bleeding and thrombosis. Bleeding arises from decreased pro-coagulation factors and platelet sequestration due to portal hypertension, while thrombosis is exacerbated by endothelial dysfunction and elevated heparinoids, thrombomodulin, or von Willebrand factor.

Aims & Methods: The aim of this study was to evaluate platelet aggregation pattern in patients with ACLF compared to acute decompensated (AD) liver cirrhosis.

The study took place in between the 1st of July 2024- 31st of January 2025 and we prospectively included cirrhotic patients, divided in two groups: ACLF group and AD group. The exclusion criteria were people with compensated liver cirrhosis, antiaggregant or anticoagulant treatment and patients with hepatocellular carcinoma or other malignancies. We investigated platelet aggregability in whole blood, by using multiplate aggregometry.

For analysis, platelet aggregometry was performed induced by: adenosine diphosphate (ADP), arachidonic acid (ASPI), prostaglandin E2 (PGE2) and thrombin receptor-activated peptide (TRAP-6) as agonist were determined. TRAP-6 is a peptide that stimulates protease-activated receptor 1 (PAR1) on platelet membrane.

Results: In this study we included 52 patients – 25 patients with ACLF and 27 patients with AD. There were no differences regarding demographic parameters and liver disease etiology between the two study groups. Compared to AD group, patients with ACLF showed an enhanced maximal platelet aggregation with TRAP-6 (AUC 85±12 U vs 45±10 U, p<0.0001). In contrast, we did not detect any differences in platelet aggregation between the two groups after ADP, ASPI or PGE2 activations.

We observe that PAR-1 stimulation induces the highest aggregation curve and area under the curve in patients with ACLF and AD, but ACLF patients show the strongest response, highlighting that the degree of liver decompensation influences aggregation results. Severe decompensation correlates with a stronger TRAP response, suggesting that there are more PAR-1 receptors on platelets of this patients.

Conclusion: Our results indirectly indicate that platelet reactivity is higher in patients with ACLF likely due to enhanced PAR-1 receptor activity. Severe decompensation correlates with a stronger TRAP response, suggesting that there are more PAR-1 receptors on platelets of this patients.

Contact E-Mail Address: dilaraturan89@yahoo.com

Introduction: Sarcopenia, a progressive loss of skeletal muscle mass and function, is a significant predictor of adverse outcomes in liver transplant patients, including infections. This study evaluates the relationship between pre-transplant sarcopenia and infection rates at one, three-, and six-months post-transplantation, using radiological markers such as skeletal muscle mass index (SMII), intramuscular adipose tissue content (IMAC), and visceral/subcutaneous fat area ratio (VSR).

Aims & Methods: This retrospective study analysed 102 liver transplant recipients undergone surgery between July 2012 and July 2023. Computed tomography (CT) scans taken within 30 days prior to transplantation were evaluated to assess sarcopenia using SMII, IMAC, and VSR. Demographics, clinical parameters, and infection rates at one, three, and six months were compared. Pre-transplant sarcopenia indicators were assessed for their correlation with early and late infection rates.

Using a forward conditional method for variable selection, logistic regression was applied to identify significant predictors of infection up to the third month post-transplant. Statistical analyses included chi-square and Mann-Whitney U tests.

Results: The median age of the cohort was 51 years, and 31.4% were female. Patients were categorized into sarcopenic (n=41) and non-sarcopenic (n=61) groups based on preoperative imaging data. Sarcopenia was significantly less prevalent in females (17.1% vs. 41%; p=0.016). Sarcopenic patients had a lower median SMII (61.54 vs. 100; p<0.001) and higher preoperative MELD-Na scores (24 vs. 18; p=0.02).

One-month infection rates were significantly higher in sarcopenic patients (48.8% vs. 27.8%; p=0.032), as were three-month rates (65.8% vs. 44.2%; p=0.043). By six months, infection rates were similar between groups (60.7% vs. 57.3%; p=0.41).

Logistic regression identified sarcopenia (OR = 10.92, 95% CI [1.53, 78.09], p = .017), urea (OR = 1.10, 95% CI [1.03, 1.17], p = .003), INR (OR = 6.03, 95% CI [1.05, 34.52], p = .044), and age (OR = 0.91, 95% CI [0.84, 0.99], p = .035) as significant predictors of infection up to the third month. While diabetes mellitus (DM) was not statistically significant (p > .05), its inclusion enhanced the model's predictive power. These findings indicate that higher sarcopenia, urea, and INR values increase infection risk, while older age appears protective.

Conclusion: Pre-transplant sarcopenia is strongly associated with increased infection rates in the first three months following liver transplantation. However, by six months, the comparable infection rates suggest

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

that sarcopenia-related risks may diminish with recovery. These findings underscore the importance of addressing sarcopenia preoperatively through tailored interventions.

CLINICAL BENEFIT AND DIAGNOSTIC ACCURACY OF SHEAR-WAVE ELASTOGRAPHY COMPARED TO TRANSIENT ELASTOGRAPHY (ASTEL STUDY)

D. Dudová[1], P. Vrbová[1], E. Lazarová[1], D. Hanzalik[1], M. Hutera[2], T. Koller[1]
[1]Comenius University Faculty of Medicine and University Hospital Bratislava, Subdivision of Gastroenterology and Hepatology, 5th Department of Internal Medicine, Bratislava, Slovakia, [2]Comenius University Faculty of Medicine and University Hospital Bratislava, Bratislava, Slovakia

Contact E-Mail Address: knutovadana@gmail.com

Introduction: Liver elastography is one of the basic diagnostic tools in hepatology practice. The most widely used and most studied tool in the world is transient elastography (Fibroscan), however, this system is unevenly available in Slovakia. Shear-wave elastography is a more accessible method because it is built into standard ultrasound systems. However, the problem of shear-wave elastography remains the interpretation of its results, since the threshold values for significant fibrosis (SF) and advanced fibrosis (AF) are unique for each system.

Aims & Methods: To compare the results of transient elastography (TE) and point shear-wave elastography (pSWE) in a cohort of patients examined simultaneously with both systems and to determine the clinical benefit of pSWE in practice.

We examined all indicated patients over a 15-month period using both TE and pSWE (Hitachi Arietta V70). We recorded liver stiffness values in kPa, and baseline demographic and laboratory parameters. We used TE as the gold standard, with a threshold of >10 kPa for SF and >15 kPa for AF. We evaluated the accuracy of pSWE in predicting the detection of SF and AF.

We used three models: the first one containing only pSWE values, and two logit models using pSWE together with common demographic and laboratory parameters. We identified the area under the curve (AUROC) and threshold values for each model and evaluated the probability of SF and AF according to these values.

Results: We examined 500 patients with a median age of 60 (IQR 48-69), male/female 214/286, with a SF rate of 30.8% and AF of 18.4%. The stiffness values according to TE and pSWE showed a highly significant correlation (rho=0.593, P<0.001).

We found the accuracy of pSWE alone in predicting SF (AUROC=0.812), and AF (AUROC=0.839) with threshold values of SF>6.34 and AF>8.45 kPa. For values of pSWE<6.34, 6.34-8.45, and >8.45 kPa, the probability of SF was 11.1, 40.9, and 65.4% and AF was 5.0, 14.77, and 48.9%.

We created two probability models (for P, range 0 to 1): ASTEL1 (N=369) that included pSWE, GGT, and platelets (AUROC SF=0.856, AUROC AF=0.908), and ASTEL2 (N=467) using pSWE, age, sex, AST/ALT, GGT (AUROC SF=0.857, AUROC AF=0.901).

We set a threshold of P<0.33 to exclude SF and P>0.66 to confirm AF. At P<0.33, P=0.33-0.66, and P>0.66, SF was present in 15.6, 62, and 94.2% (ASTEL1) and 13.92, 50.7, and 86.8% (ASTEL2). At P<0.33, P=0.33-0.66 and P>0.66, AF was present in 5.6, 30, and 79.7% (ASTEL1) and in 4.4, 28, 73.68% (ASTEL2).

Conclusion: pSWE alone has an excellent negative predictive value (<6.34 kPa, 88.9-95%) in the diagnosis of SF and AF. Higher accuracy of positive prediction of SF (86.8-94.2%) and AF (73.7-79.7%) can be achieved by using one of two probability models (for P>0.66) combining SWE values with common demographic and laboratory parameters.

Introduction: This research focuses on analyzing ultrasound-based management in percutaneous interventions for liver abscesses.

Aims & Methods: A retrospective analysis was carried out on patients diagnosed with liver abscesses between 2010 and 2024, in a tertiary-level Gastroenterology and Hepatology department. Information regarding demographics, existing risk factors, etiological factors of liver abscess, and patient outcomes was collected and examined.

Results: Among 187 cases, patients were categorized into three groups based on treatment approach:

Group A (60/187, 32.1%): Percutaneous aspiration for bacteriological sampling and abscess evacuation.

Group B (30/187, 16.0%): Continuous drainage via catheter insertion.

Group C (46/187, 24.6%): Conservative management with empirical antibiotic therapy.

Length of Antibiotic Therapy (days): A (15.78 ± 8.35) vs. B (18.36 ± 7.96) vs. C (15.8 ± 8.55), p = 0.01.

Hospital Stay: A (14.89 ± 8.29) vs. B (18.36 ± 7.96) vs. C (15.3 ± 8.12), p = 0.01.

Complication Rates (Acute Kidney Injury - AKI): A (5/64, 7.2%) vs. B (0%) vs. C (2/46, 4.3%), p = 0.5.

Mean Abscess Size: B (9.3 ± 2.60) > A (6.05 ± 2.16) > C (4.47 ± 2.01), p < 0.001.

Two-Week Follow-Up: Complete remission: A (39.0%) vs. B (20.0%) vs. C (56.5%), p < 0.001. Stationary cases: A (39.1%) vs. B (3.3%) vs. (50.0%), p = 0.005.

Conclusion: Percutaneous drainage proved to be the most effective approach for managing larger liver abscesses. While no significant differences were observed among the three groups regarding hospital stay and complication rates, conservative treatment showed a higher proportion of stationary cases during follow-up.

Disclosure: Nothing to disclose.

CHCHD1 PROMOTES THE METASTASIS OF HEPATOCELLULAR CARCINOMA VIA TGFBR1 IN MULTI OMIC

Y. Yan[1]
[1]Department of Gastroenterology, Affiliated Hospital of Nantong University, Medical School of Nantong University, Nantong, China

Contact E-Mail Address: 578801047@qq.com

Introduction: One of the most common types of human cancer, with the second-highest fatality rate, is hepatocellular carcinoma (HCC). HCC accounts for the majority of primary HCC cases, about 80%. Surgical resection, liver transplantation, transarterial chemoembolization, local ablation therapy, and molecularly targeted medicines are currently used to treat HCC. HCC is usually diagnosed in the late stage, and 70%-80% of HCC patients are not given the chance to receive total tumor excision.

After surgery, about 60% of patients still experience HCC recurrence, leading to poor prognosis. Therefore, improving the survival percentage of HCC patients requires early detection. Currently, imaging and biomarkers are the main diagnostic methods for HCC. Compared with imaging, biomarkers are diverse and have the potential for further exploration. To predict the prognosis of HCC accurately, it is essential to discover valuable new biomarkers.

CHCHD1 is located on human chromosome 10q22 and confirmed to belong to the protein family that include the coiled-coil-helix-coiled-coil-helix (CHCH) domain. CHCH contains two CX9C motifs, with two cysteine residues separated by nine amino acids in each motif. CHCHD1 exists in the nucleus or mitochondria and is involved in mitochondrial translation and protein metabolism. Existing evidence suggests that CHCHD1 is a biomarker for cervical squamous cell carcinoma that can be used for diagnosis or prognosis, while the related gene CHCHD2 is a potential poor prognostic biomarker for non-small cell lung cancer and HCC. However, the role of CHCHD1 in the development of HCC remains unknown.

This study investigates the relationship between CHCHD1 and the prognosis of HCC by analyzing the differential expression of CHCHD1 in HCC tissues and adjacent normal tissues.

Additionally, we found that CHCHD1 can affect the progression of HCC through epithelial-mesenchymal transition and the TGF-β signaling pathway. Therefore, CHCHD1 is crucial for the development and progression of HCC, and inhibiting CHCHD1 activity could be an effective treatment for HCC.

Aims & Methods: As the foundation for this research, we use the TCGA database and HCC tissues to investigate the expression of CHCHD1 in HCC. Following that, the quantity of associated proteins was shown by immunohistochemical labeling and Western blot. To demonstrate the potential for tumor growth, invasion, and migration, the transwell test and wound healing experiment were carried out. GSEA further confirmed the potential CHCHD1-related signaling pathway in HCC. Further, GSE140228 was used to detect the expression of CHCHD1 in the single-cell level.

Results: CHCHD1 is substantially expressed in HCC and is linked to a poor prognosis. It can promote the EMT process and influence the TGF-β signaling pathway to promote the progression of HCC. In addition, we found CHCHD1 is higher in the myeloid cells of HCC samples.

Conclusion: CHCHD1 may serve as a potential diagnostic and prognostic marker for HCC and is also involved in the immune infiltration of HCC.

Disclosure: Nothing to disclose.

PP0814

MULTI-MODAL EVIDENCE REVEALS ACAT2 AS A KEY MEDIATOR OF VITAMIN D–DRIVEN SUPPRESSION OF HCC

W. Ou[1], Y. Hu[1]
[1]First Affiliated Hospital of Fujian Medical University, Fuzhou, China

Contact E-Mail Address: huyuhai118@gmail.com

Introduction: Hepatocellular carcinoma (HCC) is characterized by high invasiveness and metastatic potential, with persistently low five-year survival rates. While vitamin D has demonstrated anti-tumor effects in various cancers, its precise molecular mechanism in HCC remains unclear. This study aimed to investigate the inhibitory role of vitamin D in HCC progression, focusing on the regulatory function of acetyl-CoA acetyltransferase 2 (ACAT2).

Aims & Methods: Huh-7 cells were treated with increasing concentrations of vitamin D (0, 15, 20, 30, and 40 nM) for 48 hours. Cell migration was assessed using Transwell assays, and apoptosis was quantified via Annexin V/PI staining followed by flow cytometry. ACAT2 mRNA and protein levels were measured by qPCR and Western blot, respectively. Prognostic relevance of ACAT2 expression was analyzed using Kaplan–Meier survival curves based on the GSE76427 dataset. Mechanistically, single-cell transcriptomic data from 26 HCC patients were integrated to identify $ACAT2^{+}$ malignant cell populations and their enriched pathways via KEGG analysis. Mendelian randomization (MR) using the inverse-variance weighted (IVW) method was employed to assess the causal relationship between genetically predicted vitamin D levels and HCC risk, and to quantify the mediation effect of ACAT2.

Results: Vitamin D treatment significantly suppressed Huh-7 cell migration and induced apoptosis in a dose-dependent manner. ACAT2 expression was consistently downregulated at both mRNA and protein levels. Clinical analysis revealed that high ACAT2 expression was associated with poor prognosis in HCC patients. Single-cell analysis showed that ACAT2 expression was markedly elevated in tumor hepatocytes, and $ACAT2^{+}$ cells were enriched in cytochrome P450-related xenobiotic metabolism pathways. MR analysis demonstrated a significant inverse association between genetically predicted vitamin D levels and HCC risk, and ACAT2 was identified as a significant mediator, accounting for 9.6%.

Conclusion: This study provides novel evidence that vitamin D suppresses HCC progression by downregulating ACAT2. ACAT2 may serve as a potential prognostic biomarker and therapeutic target. These findings support the translational potential of vitamin D as an adjunctive strategy in HCC prevention and treatment.

MULTI-OMICS ANALYSES REVEAL THAT ATF6B-APOC2-CD36 AXIS PROMOTING THE GROWTH AND METASTASIS OF HBV-ASSOCIATED HEPATOCELLULAR CARCINOMA

Y. Hu[1], C. Liu[1], T. Chen[1]
[1]First Affiliated Hospital of Fujian Medical University, Fuzhou, China

Contact E-Mail Address: huyuhai118@gmail.com

Introduction: HBV infection is a critical global health issue and the leading cause of cirrhosis and hepatocellular carcinoma (HCC) with its mechanisms still not fully understood. Despite existing several HCC biomarkers, challenges such as low sensitivity and tumor heterogeneity hinder early detection, highlighting the need for further exploration of mechanisms and new diagnostic markers.

Aims & Methods: In this study, we conducted an integrated multi-omics study of HCC GWAS, TCGA-LIHC, GTEx, and HPA data, in order to identify pathogenic genes and serum markers for HBV-associated HCC. The expression of candidate genes or serum markers were then evaluated in HCC liver tissues or serum. In vitro and in vivo cellular functional experiments were performed to determine their roles in tumor progression.

Results: Our findings revealed that the ATF6B-APOC2-CD36 axis derived growth and metastasis in HBV-associated HCC. Mechanistically, HBV induced ATF6B expression via the endoplasmic reticulum stress pathway. Then ATF6B bound to the APOC2 promoter region, thereby enhancing APOC2 expression. APOC2 further interacted with CD36 to activate the Wnt/β-catenin signaling pathway, promote EMT and consequently facilitate the growth and metastasis of liver cancer. Moreover, serum APOC2 significantly increased in HBV-related HCC patients and when combined with PIVKA-II shown high diagnostic value for AFP-negative HBV-related HCC.

Conclusion: Our findings demonstrated that the ATF6B-APOC2-CD36 axis contributes to HCC progression and serum APOC2 offers diagnostic potential for AFP-negative HBV-related HCC patients. These findings may advance molecular understanding, early diagnosis, and treatment of HBV-related HCC.

REGIONAL DISPARITIES AND FUTURE PROJECTIONS OF LIVER CANCER IN AFRICA: A COMPREHENSIVE EPIDEMIOLOGICAL FORECAST THROUGH 2040

G. Dhimen[1,2], H. Hami[2], R. Arif[1], S. Boutayeb[3], F. Hadrya[1,2]
[1]Hassan First University of Settat, Higher Institute of Health Sciences, Laboratory of Health Sciences and Technologies, Settat, Morocco, [2]Laboratory of Biology and Health, Faculty of Science, Ibn Tofaïl University, Kenitra, Morocco, [3]Mohammed V University, Medical Oncology, National Institute of Oncology, Rabat, Morocco

Contact E-Mail Address: ghizlane.dhimen.doc@uhp.ac.ma

Introduction: Liver cancer, one of the most aggressive cancers, has closely aligned incidence and mortality rates. Key risk factors include chronic viral hepatitis HBV and HCV, aflatoxin exposure, alcohol consumption, and type 2 diabetes. Africa, which is heavily affected by these risk factors, exhibits high rates of liver cancer.

Our study aims to describe the burden of liver cancer among the African population in 2022.

Aims & Methods: A descriptive study was conducted to examine the global distribution of liver cancer in Africa. Estimates of new cases and deaths, as well as Age Standardized Rates (ASR), were sourced from the Global Cancer Observatory database (GLOBOCAN) for 2022. Using global projections, we estimated the incidence and mortality burden by 2040.

Results: In 2022, Africa recorded 73,844 new cases and 70,315 deaths from liver cancer, representing 6.2% and 9.2% of total cancers. Incidence and mortality rates were significantly higher in males (ASR of 11.1 and 10.7 per 100,000, respectively) than in females (ASR of 6.2 and 6.0 per 100,000, respectively). Regional disparities were evident, with incidence and mortality rates 2.3 times higher in North Africa (ASR of 14.2 and 13.7 per 100,000, respectively) than in Sub-Saharan Africa (ASR of 6.3 and 6.0 per 100,000, respectively). Egypt accounted for more than a third (38%) of all estimated liver cancer cases and fatalities in Africa. The incidence varied by as much as 29-fold and mortality by 20-fold across African countries. The highest ASRs were recorded in Egypt (32.0 and 30.8, respectively) and Guinea (21.3 and 20.8, respectively), whereas the lowest were in Botswana (1.6 and 1.5, respectively) and Cape Verde (1.1 and 1.5, respectively). The mortality to incidence rate (MIR) remained high at 95%. By 2040, with an increase of 81%, the number of new cases and deaths is predicted to reach 133,431 and 127,498, respectively.

Conclusion: Implementing WHO's hepatitis elimination strategy by 2030 is crucial for mitigating these rates. This strategy encompasses HBV vaccination, prevention of mother-to-child transmission, comprehensive testing and treatment of viral hepatitis, and targeted reduction of aflatoxin exposure and other modifiable risk factors to significantly reduce liver cancer prevalence in African countries.

Disclosure: Nothing to disclose.

PSEUDOMONAS KOREENSIS ACCELERATES HCC PROGRESSION BY INHIBITING SPERMIDINE SYNTHESIS AND PROMOTING T CELL EXHAUSTION

S. Liao[1], Z. Chen[1], X. Wu[1], S. He[1], Z. Zhou[1]
[1]The Second Affiliated Hospital of Chongqing Medical University, Gastroenterology, Chongqing, China

Contact E-Mail Address: 1092849140@qq.com

Introduction: Hepatocellular carcinoma (HCC), the sixth most prevalent malignancy and third leading cause of cancer-related mortality globally, accounts for 75-85% of primary liver cancers with a 5-year survival rate below 20%. Early-stage HCC is managed by resection or ablation, while advanced cases rely on transarterial therapies and systemic treatments. However, drug resistance to multi-kinase inhibitors (e.g., sorafenib) significantly limits efficacy. HCC progression is closely linked to an immunosuppressive tumor microenvironment characterized by T-cell co-stimulatory molecule deficiency and checkpoint activation (PD-L1/CTLA-4), driving T-cell exhaustion. Recent evidence highlights intratumoral microbiota dysbiosis as a modulator of immune remodeling, yet the spatial distribution patterns and regulatory mechanisms of bacterial communities within HCC lesions remain poorly defined.

Aims & Methods: This study employed invasion-adhesion-directed expression sequencing (INVADE-seq) integrated with single-cell host transcriptomics to profile intratumoral microbiota and construct microbial-immune interaction networks in five HCC tumors and paired adjacent normal tissues. Peritumoral microbiome analysis was conducted using 2b-Rad-M sequencing. Through systematic bacterial isolation (LB/Columbia/BCSA/Schaedler media) and Sanger sequencing validation, *Pseudomonas koreensis* (P.K) was identified as a key HCC-associated strain.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Spatial localization and ultrastructural characterization were achieved via fluorescence in situ hybridization (FISH), multiplex fluorescence staining, and electron microscopy. Whole-genome sequencing delineated its genomic architecture, while metabolomics uncovered unique metabolic signatures. Functional validation using orthotopic HCC models (MYC/Alb and NSG mice) revealed its pro-tumorigenic role and immunomodulatory effects.

Results: 2b-Rad-M sequencing showed significantly higher abundance of *Bacillus, Pseudomonas, and Klebsiella* in HCC tissues compared to adjacent non-tumor tissues, with reduced bacterial diversity. Circos plots highlighted increased *Proteobacteria* and *Firmicutes* in HCC. Through culturing and Sanger sequencing, P.K was identified as a dominant strain in HCC, showing quinolone sensitivity and urease activity. FISH confirmed its widespread presence in HCC tissues, with elevated abundance in T cells from advanced-stage patients. INVADE-seq analysis of five additional HCC tissue pairs also detected P.K Single-cell INVADE-seq revealed that T cells harboring this bacterium exhibited increased exhaustion scores and upregulated TOX expression. In MYC/Alb mice, oral gavage of P.K accelerated hepatocarcinogenesis, but no significant effect was observed in NSG immunodeficient mice, indicating immune system dependency. Whole-genome sequencing linked HCC-derived P.K to the fish pathogen *P. koreensis CM-01*, with enriched amino acid and carbon metabolism pathways. Metabolomics analysis associated it with purine/pyrimidine metabolism and cGMP-PKG signaling. Reduced spermidine levels impaired fatty acid oxidation, exacerbated T cell exhaustion, and promoted an immunosuppressive microenvironment, enhancing tumor proliferation, invasion, and metastasis.

Conclusion: This study reveals how intratumoral microbiota regulate the tumor microenvironment via the metabolism-immune axis, offering new insights into HCC immunotherapy. Targeting P.K-related metabolic pathways may provide a novel therapeutic strategy.

Disclosure: Nothing to disclose.

HISTOPATHOLOGICAL CORRELATIONS OF TISSUE SOUND SPEED IN HEPATOCELLULAR CARCINOMA: A QUANTITATIVE ASSESSMENT USING ACOUSTIC MICROSCOPY

T. Kuribara[1,2], Y. Saijo[1], K. Kobayashi[3], H. Ishizu[4]
[1]Graduate School of Medicine, Tohoku University, Department of Biomedical Imaging, Sendai, Japan, [2]Saitama Cooperative Hospital, Department of Surgery, Kawaguchi, Japan, [3]Honda Electronics, Co., Ltd., Division of Research and Development, Toyohashi, Japan, [4]Saitama Cooperative Hospital, Department of Pathology, Kawaguchi, Japan

Contact E-Mail Address: tkjp1129@yahoo.co.jp

Introduction: Tissue acoustic properties, such as sound speed, attenuation, and impedance, are closely associated with its mechanical characteristics. Acoustic microscopy, which employs high-frequency ultrasound ranging from several tens of MHz to several GHz, enables the quantitative evaluation of these acoustic properties. Understanding the acoustic properties of biological tissues may offer new insights into disease pathology.

Furthermore, because clinical ultrasound images depend on tissue acoustic properties, understanding them could improve the interpretation of echogenic patterns and contribute to developing new diagnostic approaches. Although acoustic microscopy has been applied to cardiovascular and cutaneous tissues in medical research, studies focusing on the liver, particularly hepatic tumours, remain limited.

Aims & Methods: This study aimed to quantify sound speed in hepatocellular carcinoma (HCC)—the most common primary liver tumour—and to examine its relationship with histopathological features. Histopathological classification followed World Health Organization criteria, including histological grade (well, moderately, and poorly differentiated) and histological growth pattern (trabecular, pseudoglandular, and solid). Tissue sound speed was measured using a scanning acoustic microscope (AMS-50SI; Honda Electronics Co., Ltd.) with an 80 MHz transducer. Regions of interest were identified on haematoxylin and eosin-stained slides. Serial 10 µm-thick sections were prepared from formalin-fixed, paraffin-embedded tissue blocks and rehydrated for measurement.

Differences in sound speed among histological categories were compared, and statistical analysis was conducted to assess significance. A p-value of < 0.05 was considered significant. This study was approved by the institutional review board, and written informed consent was obtained.

Results: Tissue sound speed was measured at 66 sites from 51 patients. Histological grading identified 22 well, 41 moderately, and 3 poorly differentiated cases. Median sound speeds were 1584.0 m/s, 1595.9 m/s, and 1550.1 m/s, respectively. Poorly differentiated HCC showed significantly lower sound speed than the other grades ($p = 0.021$). Growth patterns included 50 trabecular, 10 pseudoglandular, and 6 solid cases, with median sound speeds of 1595.9 m/s, 1586.0 m/s, and 1563.6 m/s, respectively. The trabecular pattern tended to exhibit higher sound speed than the solid pattern ($p = 0.063$). Tissues with abundant fat or glycogen ($n = 16$) had significantly lower sound speeds than those without ($p = 0.002$).

After excluding these cases, which could act as potential confounding factors, sound speed in poorly differentiated HCC remained significantly lower ($p = 0.016$), and higher values in the trabecular pattern persisted. Additionally, the pseudoglandular pattern showed greater variability in sound speed than the trabecular pattern.

Conclusion: Variations in acoustic properties among histological subtypes of HCC may contribute to developing novel quantitative assessments in ultrasound imaging and pathological diagnosis.

Disclosure: Kazuto Kobayashi, a co-author, has reported a relationship with Honda Electronics Co., Ltd. that includes: employment.

Introduction: Hepatitis C virus (HCV) infection is a key driver of hepatocellular carcinoma (HCC) development and progression. However, the impact of HCV eradication in patients undergoing systemic therapy remains poorly understood.

Aims & Methods: This study aimed to assess the safety and efficacy of direct-acting antiviral (DAA) therapy in patients receiving Atezolizumab plus Bevacizumab (AtezoBeva). This multicenter study retrospectively enrolled consecutive patients with HCV-related unresectable or advanced HCC undergoing AtezoBeva therapy between 2021 and 2024.

Patients were stratified into three groups based on their HCV treatment status: group A (n=22), who received concurrent DAA therapy with AtezoBeva; group B (n=95), who had completed DAA therapy at least six months before initiating AtezoBeva; and group C (n=22), with active HCV infection. The impact of DAA treatment on overall survival (OS), time to progression (TTP), progression-free survival (PFS), time to decompensation (TTD), and decompensation-free survival (DFS) was evaluated. Additionally, the incidence of treatment-related adverse events (trAEs) was recorded.

Results: Group A demonstrated a significantly prolonged median OS (42.8 months [95%CI: 33.3–NA]) compared to Group B (26.8 months [95%CI: 17.1–NA]; p=0.03) and group C (19.7 months [95%CI: 14.7–NA]; p=0.01). TTP was longer in group A (40.6 months [95%CI: 17.68–NA]) than in group C (14.6 months [95%CI: 5.06–NA]; p=0.02), whereas no significant difference was observed between group A and group B (20 months [95%CI: 12.29–NA]). Median PFS was markedly extended in group A (40.6 months [95%CI: 22.47–NA]) compared to group B (15 months [95%CI: 11.96–23.4]; p=0.009) and group C (13.3 months [95%CI: 5.06–NA]; p=0.002).

Moreover, group A exhibited a higher disease control rate than the other groups. In the multivariate time-dependent analysis, achieving sustained virologic response (SVR) during AtezoBeva therapy was independently associated with a reduced risk of mortality (HR 0.29 [95%CI: 0.12–0.69]; p=0.005) and disease progression (HR 0.1 [95%CI: 0.05–0.72]; p=0.02).

Notably, post-DAA decompensation rates were significantly lower in group A (4.5%) compared to groups B (26.3%) and C (36.4%), translating into a superior DFS. The incidence of grade ≥3 treatment-related AEs was comparable across groups.

Conclusion: Achieving SVR during AtezoBeva therapy significantly enhances oncological outcomes in patients with unresectable or advanced HCC. These findings highlight the potential for an integrated therapeutic approach to optimize systemic treatment efficacy, particularly in patients eligible for conversion strategies.

Introduction: Recently, a Japanese expert consensus introduced oncological resectability criteria for hepatocellular carcinoma (HCC) [1]. Notably, these criteria do not incorporate the concept of unresectable tumors, but rather classify borderline resectability into two distinct subgroups, defined from the therapeutic perspective of hepatic resection.

Based on these classifications, resectability is categorized into three groups: resectable (R), borderline resectable 1 (BR1), and borderline resectable 2 (BR2).

Aims & Methods: In this study, we aimed to assess the clinical outcomes of patients with HCC who were treated with atezolizumab plus bevacizumab (Atezo/Bev) in a real-world context, categorized by oncological resectability criteria. Between May 2018 and May 2024, a total of 1,055 patients with unresectable HCC were treated with Atezo/Bev across 26 institutions in Japan.

Of these, 467 met the following inclusion criteria:

1. Child–Pugh class A,
2. Atezo/Bev administered as the first-line systemic therapy,
3. Eastern Cooperative Oncology Group performance status (ECOG-PS) of 0 or 1,
4. BR1 or BR2 classification,
5. Treatment conducted within a clinical trial setting, and;
6. Availability of complete clinical data.

Results: Of 467 patients, 102 (21.8%) were women, and 365 (78.2%) were men. The median age was 74.0 (69.0–79.0) years. Patients were categorized into BR1 (n=153 [32.8%]) and BR2 (n=314 [67.2%]) groups. The median follow-up period was 14.3 (7.5–24.0) months. The median progression-free survival (PFS) was 9.0 months in the BR1 group and 6.8 months in the BR2 group (p = 0.014).

Multivariable analysis identified the following independent prognostic factors for PFS: age ≥75 years (hazard ratio [HR], 1.309; 95% confidence interval [CI], 1.057–1.622; p=0.014), albumin–bilirubin (ALBI) grade 2 or 3 (HR, 1.494; 95%CI, 1.201–1.859; p<0.001), neutrophil-to-lymphocyte ratio (NLR) ≥3 (HR, 1.289; 95%CI, 1.030–1.613; p=027), α-fetoprotein (AFP) ≥100 ng/mL (HR, 1.523; 95%CI, 1.214–1.912; p<0.001), and BR2 classification (HR, 1.360; 95%CI, 1.076–1.718; p=0.010). The median overall survival (OS) was 25.3 months in the BR1 group and 22.3 months in the BR2 group (p = 0.048).

Similarly, multivariable analysis identified the following independent prognostic factors for OS: age ≥75 years (HR, 1.522; 95%CI, 1.155–2.007; p=0.033), ALBI grade 2 or 3 (HR, 2.411; 95%CI, 1.802–3.224; p<0.011), NLR ≥3 (HR, 1.635; 95%CI, 1.233–2.169; p<0.011), AFP ≥100 ng/mL (HR, 1.530; 95%CI, 1.152–2.032; p=0.003), and BR2 classification (HR, 1.421; 95%CI, 1.048–1.927; p=0.024). When oncological resectability factors (tumor number and size, vascular invasion, and extrahepatic spread) were incorporated into the multivariable analysis, major vascular invasion emerged as a significant predictor of both PFS (HR, 3.188; 95%CI, 2.051–4.953; p<0.011) and OS (HR, 2.650; 95%CI, 1.541–4.556; p<0.001). No significant differences were observed between the BR1 and BR2 groups regarding concomitant or subsequent treatments following Atezo/Bev therapy, as indicated by the Sankey diagram (p = 0.391).

Conclusion: Among HCC patients with a low probability of surgical resection (i.e., those classified as BR1 or BR2) undergoing Atezo/Bev treatment, vascular invasion serves as a critical prognostic factor for tumor progression.

Moreover, beyond tumor progression, preserved liver function also plays a pivotal role in determining the prognosis of patients treated with Atezo/Bev.

Introduction: There is a well-established association between inflammation and malignant tumors. Furthermore, in hepatocellular carcinoma (HCC), liver functional is a critical determinant of prognosis. Accordingly, the C-reactive protein-to-albumin ratio (CAR), which integrates C-reactive protein—a biomarker of systemic inflammation—and albumin—an indicator of liver functional—has been proposed as a potentially valuable prognostic marker in HCC.

Aims & Methods: This study aims to assess the prognostic value of CAR in predicting outcomes in patients with unresectable HCC treated with Atezolizumab/Bevacizumab (Atezo/Bev) combination therapy.A total of 289 patients who received Atezo /Bev across multiple centers between September 2020 and December 2024 were included in this analysis.

The baseline characteristics of the cohort were as follows: median age 74.0 years (IQR, 67.0–79.0), male/female gender distribution 224/65, performance status (PS 0/1/≥2) 185/95/9, etiology (hepatitis B/hepatitis C/alcoholic/non-B, non-C) 58/92/37/102, CRP 0.27 mg/dL (0.10–0.91), albumin 3.8 g/dL (3.4–4.2), CAR 0.068 (0.026–0.239), Child-Pugh score (5/6/≥7 points) 165/82/42, Barcelona Clinic Liver Cancer (BCLC) stage (≤A/B/≥C) 24/84/181, alpha-fetoprotein (AFP) level 27.5 ng/mL (5.2–606.6), and me-

dian observation period 14.8 months (6.9–26.4). The distribution of patients according to the line of Atezo/Bev was 233/56 for primary/secondary or later systemic therapy lines, respectively.

Results: The median cumulative progression-free survival (PFS) was 6.8 months (95% confidence interval [CI], 5.4–9.8), and the median cumulative overall survival (OS) was 26.5 months (95% CI, 21.4–29.9). Time-dependent receiver operating characteristic (ROC) analysis identified an optimal cutoff for predicting median OS at 0.0056.

The radiological responses, according to RECIST version 1.1, were as follows: partial response 5.7%, stable disease 24.7%, progressive disease 45.9%, respectively. The objective response rate (ORR) and disease control rate were 30.5% and 76.3%. Notably, significant differences in radiological responses (p=0.002) and ORR (p = 0.011) were observed based on CAR values.

Multivariate analysis, incorporating age, gender, PS, etiology, BCLC stage, Child-Pugh classification, systemic therapy line, AFP, neutrophil-to-lymphocyte ratio (NLR), and CAR, revealed that age (≥75 years) (hazard ratio [HR], 1.361; 95% confidence interval [CI], 1.028–1.802; p=0.031), BCLC stage (≥C) (HR, 1.439; 95% CI, 1.017–2.037; p=0.040), and CAR (≥0.056) (HR, 1.471; 95% CI, 1.105–1.957; p=0.008) were independently associated with PFS.

Additionally, in multivariate analysis adjusted for the same covariates, age (≥75 years) (HR, 1.458; 95% CI, 1.004–2.117; p=0.048), Child-Pugh classification (≥7) (HR, 2.329; 95% CI, 1.445–3.754; p<0.001), AFP (≥100ng/ml) (HR, 1.587; 95% CI, 1.087–2.319; p=0.017), and CAR (≥0.056) (HR, 2.042; 95% CI, 1.386–3.008; p<0.001) were independently associated with OS.

In the time-dependent ROC analysis, the area under the ROC curve (AUROC) at 6, 12, 18, 24, 30, and 36 months for NLR was 0.690, 0.683, 0.651, 0.573, 0.493, and 0.474, respectively, and 0.757, 0.687, 0.699, 0.695, 0.663, and 0.597 for CAR, with CAR showing a significantly better AUROC after 24 months.

Conclusion: CAR serves as a valuable predictive biomarker for survival in patients undergoing Atezo/Bev for unresectable HCC.

Introduction: The COVID-19 pandemic significantly disrupted access to healthcare services, resulting in altered management strategies for hepatocellular carcinoma (HCC). Despite this, the long-term post-pandemic effects on HCC care remain underexplored. This study aims to assess the impact of the pandemic on HCC diagnosis, treatment, and survival outcomes in a Romanian tertiary care center.

Aims & Methods: A retrospective cohort analysis was conducted, categorizing patients into three consecutive 23-month groups: Pre-pandemic (PreP), Pandemic (PandP), and Post-pandemic (PostP). Data collected included tumor stage, relevant laboratory parameters, and treatment modalities for newly diagnosed HCC cases. Survival was tracked for nine months following diagnosis.

Results: The number of new HCC cases declined during the PandP (58 cases, 26.9%; p<0.001) and PostP (64 cases, 29.6%; p<0.005) periods—representing decreases of 38.3% and 31.9%, respectively, compared to the PreP period (94 cases, 43.4%). During the pandemic, the proportion of patients diagnosed at the BCLC-B stage increased to 50%, from 31.9% in the PreP group (p=0.0401), primarily due to a reduction in early-stage (BCLC-0/A) diagnoses.

Tumor features, BCLC categories, and TNM stages were not significantly different when comparing the PreP and PostP periods. Treatment patterns remained consistent across all three intervals.

Additionally, no significant differences were found in nine-month survival rates between the cohorts.

Conclusion: The pandemic period led to a marked reduction in new HCC diagnoses, with only a partial recovery observed afterward. Although more advanced stages were noted during the pandemic, post-pandemic cases resembled pre-pandemic trends in terms of staging, treatment, and survival outcomes.

Introduction: The CRAFITY (CRP and AFP in ImmunoTherapY) score is a biomarker composed of CRP and AFP that predicts clinical outcomes of patients undergoing immunotherapy for hepatocellular carcinoma (HCC), independently of Child-Pugh score and performance status [1].

We previously validated its utility in predicting the prognosis of patients with HCC receiving atezolizumab and bevacizumab therapy [2].

Aims & Methods: In this study, we investigated the applicability of the CRAFITY score in patients with unresectable HCC treated with the combination of durvalumab and tremelimumab (Dur/Tre). In this multicenter study, a total of 325 patients who received the STRIDE regimen between March 2023 and December 2024 were included.

Baseline characteristics were as follows: median age, 73.0 (IQR 68.0–78.0) years; sex (male/female), 272/53; performance status (0/1/≥2), 252/58/15; etiology (hepatitis B/C/B+C/non-B, non-C), 55/88/3/179; Child-Pugh score (5/6/≥7), 137/133/73; BCLC stage (≤A/B/≥C), 22/91/212; neutrophil-to-lym-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. phocyte ratio (NLR), 2.97 (1.98–4.31); CRP, 0.44 (0.15–1.59) mg/dL; AFP, 58.1 (5.0–1921.0) ng/mL; observation period, 7.9 (4.1–13.3) months; and treatment line (first-line/second-line or beyond), 121/204 patients.

Results: Patients were stratified by CRAFITY score (0/1/2): 120/149/56, and significant differences were observed among the groups for most baseline characteristics, except for sex, body mass index (BMI), and prothrombin time (PT). Median progression-free survival (PFS) was 3.8 months (95% CI: 3.0–4.3), and median overall survival (OS) was 17.0 months (95% CI: 14.1–NA). Best response rates based on RECIST version 1.1 were: complete response (CR) 2.1%; partial response (PR) 16.8%; stable disease (SD) 30.9%; progressive disease (PD) 50.2%; with an objective response rate (ORR) of 18.9% and disease control rate (DCR) of 49.8%. Significant differences in best response (p = 0.042) and DCR (p = 0.043) were observed across CRAFITY score groups. The incidence of immune-related adverse events (imAEs, ≥10% in any category) was 25.8% for skin toxicity, 21.8% for hepatotoxicity, 12.9% for diarrhea/enteritis, and 10.2% for fever. No significant differences in adverse events, including other imAEs, were found among CRAFITY groups. In multivariate analysis, both treatment line (second-line or later: HR 1.47; 95% CI: 1.11–1.96; p = 0.007) and CRAFITY score of 2 (HR 1.62; 95% CI: 1.08–2.42; p = 0.020) were independently associated with PFS. Additionally, in multivariate analysis, non-B non-C etiology (HR 0.63; 95% CI: 0.43–0.93; p = 0.020), CRAFITY score of 1 (HR 2.00; 95% CI: 1.22–3.27; p = 0.006), and score of 2 (HR 3.42; 95% CI: 1.91–6.12; p < 0.001) were independently associated with OS. For the prediction of 12-month OS, the integrated discrimination improvement (IDI) was 0.007 (95% CI, 0.022 to 0.137; p < 0.001) for AFP and 0.066 (95% CI, 0.018 to 0.135; p < 0.001) for CRP, respectively, when compared with the CRAFITY score. Similarly, the net reclassification improvement (NRI) was 0.360 (95% CI, 0.092 to 0.474; p = 0.002) for AFP and 0.170 (95% CI, 0.024 to 0.348; p = 0.016) for CRP, indicating the superior prognostic performance of the CRAFITY score. Subgroup analyses showed significant differences in OS by CRAFITY score among patients with Child-Pugh class A, NLR less than 3, and BCLC stage C or higher.

Conclusion: The CRAFITY score appears to be a promising prognostic biomarker for patients with unresectable HCC treated with Dur/Tre.

PREDICTORS OF HEPATOCELLULAR CARCINOMA RECURRENCE AFTER RADIOFREQUENCY ABLATION AND THE RELATION WITH SUSTAINED VIROLOGIC RESPONSE DURATION AMONG PATIENTS WITH HEPATITIS C VIRUS-RELATED LIVER CIRRHOSIS

A. Kamal[1], M. Metawea[1], N. Baddour[2], H. Naguib[1]
[1]Alexandria University, Internal Medicine, Hepatology, Alexandria, Egypt, [2]Alexandria University, Pathology, Alexandria, Egypt

Contact E-Mail Address: ahmed.kamal.med.scientific@gmail.com

Introduction: To the best of our knowledge, there is no study addressed the HCC recurrence rates after radiofrequency ablation (RFA) in those achieved long-term sustained virologic response (SVR) before HCC development versus SVR for less than 2 years or no SVR before HCC occurrence.

Aims & Methods: The study aimed to identify the predictors of early HCC recurrence after RFA and explore the relationship with SVR duration among patients with HCV-related liver cirrhosis.

This study is a retrospective one that included patients with HCV-related liver cirrhosis and HCC who had RFA. Those with positive HBsAg, alcohol-associated liver disease, patients with other known causes of chronic liver disease, and patients with locoregional therapy other than RFA were excluded. A fine needle aspiration biopsy was done at the time of the RFA. A 2-year retrospective follow-up was done. Those with missing data, lost follow-up, or died before any HCC recurrence were excluded. A total of 64 patients were included in the study.

Results: During the 2-year follow-up starting from the date of RFA procedure, 26 patients (40.6%) experienced HCC recurrence. There were no statistically significant differences between those who experienced HCC recurrence and those who did not regarding age, sex, baseline hemoglobin levels, platelets, white blood cell counts, ALT, AST, INR, albumin, total bilirubin, FIB-4, MELD, ALBI, and Child-Pugh scores. Also, there were no statistically significant differences between the two groups regarding the number of lesions.

On the other hand, the mean size of the largest lesions was significantly larger in the HCC recurrence group. The mean was 4.3±0.78 cm in the HCC recurrence group, while it was 3.38±1.05 cm in the non-recurrence group (p<0.001). Also, the baseline AFP was significantly higher in the HCC recurrence group. The median was 225 (IQR 90–894) ng/ml, against 11.3 (IQR 7.5–70) ng/ml in the non-recurrence group (p<0.001).

Those who received DAAs 2 years before HCC occurrence showed the least incidence of HCC recurrence (p = 0.001). Regarding the pathological grade, 65.4% of the HCC recurrence group had grade III HCC, 34.6% had grade II, and no one of them had grade I HCC on histopathological examination. The difference was statistically significant (p=0.012).

On multivariate regression analysis, it was found that AFP significantly increased the odds of HCC recurrence (OR = 1.004, 95% CI 1.001–1.007, p = 0.016). Also, the increase in size of the largest lesion significantly increased the risk of HCC recurrence (OR = 3.039, 95% CI = 1.514–6.1, p = 0.025).

Receiving successful DAA therapy 2 years before the occurrence of HCC significantly decreased the odds of HCC recurrence (OR = 0.016, 95% CI 0.028–0.413, p = 0.016). On the other hand, the histopathological grade of HCC failed to show a significant change in the odds of HCC recurrence.

Conclusion: In conclusion, larger tumor size and higher pre-ablation AFP levels predicts HCC recurrence after RFA, while long-term SVR for more than 2 years before HCC occurrence predicts lower rates of HCC recurrence after RFA.

Disclosure: Nothing to disclose.

Introduction: Intrahepatic cysts are prevalently encountered in daily clinical practice. Cystic lesions without clear diagnostic criteria to be categorized as an intraductal papillary neoplasm of the bile duct (IPNB), mucinous cystic neoplasms of the liver (MCN-L), and Caroli disease, are mostly classified as benign hepatic cystic lesions. However, alongside benign cysts, there are cases where cystic lesions exhibit solid components with detectable blood flow inside the cysts. These cysts, which are accompanied by contrast enhancement in preoperative imaging studies, are often subjected to surgical resection due to the difficulty in ruling out malignancy.

Aims & Methods: This study aims to provide a pathological and radiological evaluation of a new concept of benign hepatic cystic lesion that resembles malignancy. We reviewed cases of benign hepatic cystic lesions, excluding pathologically evident neoplastic hepatic cystic lesions (cystic change of intrahepatic cholangiocarcinoma, cystic type of IPNB, MCN-L) and Caroli disease, among hepatic cystic lesions resected at Keio University Hospital, Tokyo, Japan, since 2012.

The selection was made based on the following pathological diagnostic criteria:

1. No visible papillary lesions in the cyst wall,
2. No ovarian-like stroma within the cyst wall,
3. No communication with adjacent bile duct (known as "triple negative lesions"), and;
4. Lack of epithelial cells lining in the cyst wall.

Pathological findings were re-evaluated and compared with their corresponding preoperative radiological images.

Results: We extracted 30 cases of benign cystic lesions. Nine of these cases were accompanied by pathological findings, such as hematoma, intracystic hemorrhage, dilatation or proliferation of small blood vessels, and fibrous stroma.

All cases were found in women aged 49–80 years (mean: 67.7 years). Of 9 cases, 5 were resected due to suspicion of malignancy, or malignancy could not be completely ruled out by preoperative imaging findings.

Preoperative Magnetic resonance imaging (MRI) revealed that these cystic lesions were comprised of cystic regions and solid mural nodules. Cystic regions showed high intensity on fat-suppressed T1-weighted image (T1WI) in every case, indicating hemorrhagic changes. On T2WI, the mural nodules showed a slightly thick low-intensity rim and high-intensity center.

A contrast-enhancement effect in the central region of the mural nodule was observed following gadolinium (Gd) contrast medium administration. Pathologically, all five cases demonstrated fibrotic stroma with degeneration and small and large luminal structures containing red blood cells. Immunostaining of endothelial cells in these lumens was positive for CD31 or CD34 and negative for D2-40, confirming the presence of blood vessels. The vascular endothelial cells or vascular architecture exhibited no clear evidence of malignancy, and these lesions were considered hemangioma-like lesions.

Conclusion: Among hepatic cystic lesions resected due to suspected malignancy based on preoperative imaging, we found the hepatic cystic lesions pathologically characterized as "triple-negative lesions" with hemangiomatous regions. These benign lesions can be potentially distinguished from malignant cystic lesions by identifying their characteristic findings on MRI. Our findings suggest a new concept of benign hepatic cystic lesions that can resemble malignancy. Recognizing such lesions and carefully evaluating their imaging features may help avoid unnecessary surgical resections.

SCREENING ATTENDANTS OF ADVANCED HEPATOCELLULAR CARCINOMA PATIENTS: A NOVEL APPROACH TO DECREASE FUTURE DISEASE BURDEN OF VIRAL HEPATITIS IN SOUTHEAST ASIA

S. Memon[1], F. Nadeem[1], U. Memon[1], M. Zaki[2], M. Tariq[3], S. Keerio[1], N. Dal[1], R. Nisar[3]

Introduction: Hepatocellular carcinoma (HCC) is a formidable public health challenge, with late-stage diagnosis often leaving limited therapeutic options and poor prognosis. Recognizing these constraints, we sought to address an uncharted domain—the screening of patient attendants. These individuals, often family members of HCC patients, represent a high-risk population for hepatitis B (HBV) and hepatitis C (HCV), the primary etiological agents of HCC.

Aims & Methods: This study aimed to screen first- and second-degree relatives of advanced HCC patients, identifying undiagnosed HBV and HCV carriers and referring them for a cascade of treatment, thereby proposing a preventive pathway to reduce the familial burden of liver disease. This meticulously designed cross-sectional study was conducted from 2023 to 2024 at AIMS Hospital, Hyderabad, Pakistan. A total of 286 HCC patients with advanced BCLC stages (C&D) were enrolled.

Simultaneously, 198 first- and second-degree relatives of these patients underwent screening for HBV and HCV using state-of-the-art diagnostic kits provided by the Government of Sindh, Pakistan. Identified carriers were promptly referred for a structured cascade of treatment to ensure timely intervention.

All data were rigorously analyzed to identify associations between the clinical profiles of HCC patients and the screening outcomes of their attendants. Statistical analyses, including chi-square tests, were conducted with precision using IBM SPSS version 22, maintaining a strict significance threshold of $p < 0.05$ to ensure the robustness of findings.

Results: The study cohort included 286 advanced HCC patients, predominantly male (79.4%, n = 227), with HCV as the leading etiology (68.5%, n = 196). Among 198 screened relatives, (8/198) 4% tested positive for HCV, and (4/198) 2% for HBV. All positive cases were referred for appropriate treatment pathways to mitigate disease progression.

Advanced-stage HCC patients exhibited significantly elevated mean alpha-fetoprotein (AFP) levels (>589.6 ng/ml), correlating with multinodular HCC (70.7%, $p < 0.001$). The age distribution of patients predominantly ranged from 40-60 years, with 67.1% presenting in BCLC stages C&D. The

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. screening outcomes revealed an undeniable familial risk, emphasizing the need for targeted interventions to identify and manage at-risk individuals early.

Conclusion: This study conclusively establishes the value of screening first- and second-degree relatives of advanced HCC patients, unveiling a hidden reservoir of HBV and HCV carriers within families. By referring identified carriers for a structured cascade of treatment, this initiative not only mitigates the risk of disease progression but also exemplifies a model for reducing the broader burden of liver disease. The findings underscore the indispensable role of family-based screening in high-risk populations, offering a scientifically sound and ethically imperative preventive strategy. Through this initiative, we aim to catalyze a shift in HCC management, from despair at advanced-stage diagnoses to proactive prevention within familial networks. These results are robust, methodologically impeccable, and hold significant implications for global liver disease prevention strategies.

Disclosure: Nothing to disclose.

Introduction:

For individuals with advanced HCC, atezolizumab plus bevacizumab (atezo/bev) and tremelimumab plus durvalumab (Durva/Treme) are now recommended as the first-line therapy. Both Durva/Treme and Atezo/Bev may not be suitable or available for a considerable percentage of patients with advanced HCC; in these situations, tyrosine kinase inhibitors (sorafenib or lenvatinib) should still be a good choice. On the other hand, the absence of data on treatment resistance, treatment response, and overall survival prediction means that treatment for advanced HCC remains challenging. It is estimated that 20–25% of individuals develop primary resistance to atezo/bev, underscoring the need to pinpoint the people who may get the most benefit from the different HCC regimens.

Aims & Methods: The study's aim was to identify the possible predictors of the overall response rate to the systemic HCC therapy.

This study included 65 patients with advanced HCC, BCLC-C or B, who received systemic therapy as recommended according to BCLC 2022 and after approval of the Alexandria University MDT Liver Tumors Board. Triphasic CT was done to assess the response every 3 months from the treatment initiation.

Different possible prognostic parameters were investigated, including patient and tumor characteristics. Different scores were calculated:

- Modified Child-Pugh score and model of end-stage liver disease (MELD) score.
- Monocyte-to-lymphocyte ratio (MLR), neutrophil-to-lymphocyte ratio (NLR), and platelet-to-lymphocyte ratio (PLR).
- The ALBI and the PALBI scores.
- The AFP ratios: AFP ratio at week 3 = (AFP value at 3rd week)/(AFP value before treatment), and AFP ratio at week 6 = (AFP value at 6th week)/(AFP value before treatment).
- The des-gamma-carboxy prothrombin (DCP) ratio at week 6 = DCP at 6th week / DCP before treatment.

Results: During the 6-month follow-up, out of 65 included patients, 41 patients had received atezo/bev, 21 patients had received sorafenib, while 3 patients had received durva/treme. Twenty five patients showed partial response, 26 patients showed progressive disease, while 8 patients showed stable disease. Three patients died, and another 3 were lost to follow-up before the assessment of response.

The overall response rate was 50% (22 patients) for the immunotherapy and 14.2% (3 patients) for the sorafenib. The AFP ratio at the 3rd and 6th weeks was significantly lower in responders (P = 0.015 & 0.005, respectively). The median baseline LMR was 4.33 (IQR= 2.96-5.67) among responders and 2.73 (IQR= 1.85-3.63) among non-responders. (P = 0.004). There were no statistically significant differences between responders and non-responders regarding DCP ratio, ALBI, PALBI, NLR, PLR, presence of malignant portal vein invasion, or distant metastasis.

On multivariate analysis, both receiving atezo/bev and higher LMR at the baseline were predictors of response to treatment. On addressing the predictors of response among patients receiving atezo/bev, higher baseline LMR was associated with higher chances of response.

Conclusion: The lymphocyte-monocyte ratio at baseline is a promising tool to predict the response to atezo/bev in the management of advanced HCC.

Disclosure: Nothing to disclose.

MUSCLE DENSITY ADJUSTED SARCOPENIA IS A PREDICTOR OF 6-MONTH MORTALITY IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

A. Kahwagi[1], C. Yaghi[2], C. Abboud[3], L. Sarrouf[3], T. Smayra[3], L. Menassa[3], P. Wehbe[1], E. Mahfouz[4], J. Amara[1], R. Slim Karam[1], C. Yaghi[5]

Contact E-Mail Address: antony.kahwagi@net.usj.edu.lb

Introduction: The prognosis for patients with hepatocellular carcinoma (HCC) remains extremely poor, with a 5-year survival rate of 20% without curative treatment. A recent study[i] demonstrated that the use of a computed CT score including muscle density and muscle area could identify frailty in cirrhotic patients and predict 6-month mortality.

The objective of the study was to evaluate predictors of 6-month mortality in patients with HCC and to establish the impact of sarcopenia in this context.

Aims & Methods: We performed a retrospective analysis of 86 patients with HCC treated at the Hôtel Dieu de France in Beirut between 2016 and 2024. The collection included clinical and biological data, prognostic indices (Child Pugh scores, MELD) as well as CT parameters for measuring sarcopenia and myosteatosis, including skeletal muscle index, muscle densities, and muscle surfaces at L3 level. The coreslicer® software was used to calculate muscle and fat surfaces on CT. The measurements evaluated included the surfaces at L3 of the psoas and paravertebral and parietal muscles, as well as the density of the psoas.

Among these, the "L3 skeletal muscle area adjusted to height and density ratio (L3- SMHDR)" which is calculated by the total muscle area at the L3 level * Average size / density of the psoas muscles at the L3 level. This measurement helps include myosteatosis in the assessment of sarcopenia.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results:

• Our population included 86 patients with HCC, 74 men, 12 women, with a mean age of 66.1 ± 10.7 years. MELD-Na score was 16.1 ± 8.2, and Child-Pugh score was A, B, and C in 39%, 27%, and 34%, respectively. Twelve patients (14%) were eligible for curative treatment, in accordance with BCLC guidelines.

• Decreased survival is significantly associated with increasing L3-SMHDR. An AUROC analysis for L3-SMHDR as a predictor of mortality at 1 month found the same cutoff values as a previously published study with cut-offs of 5.4 and 4.7 in men and women, respectively. Populations with low L3-SMHDR vs. high L3-SMHDR had a survival time of 31.2 months vs. 11.09 months (P=0.035).

• In order to determine the different factors linked to a decrease in survival at 6 months, we conducted a univariate analysis which identified the following parameters: muscle density at scan (p=0.016), L3-SMHDR (p=0.004), L3-DRMI (p=0.034) and the MELD-Na score (P=0.077). A value of L3-SMHDR > threshold had a risk of mortality OR= 7.8 [1.8-34, P=0.003] and 5.64 [1.3-23.8, P=0.013] at 6 and 12 months respectively.

• In multivariate analysis, the two independent prognostic factors were the MELD-Na score and L3-SMHDR, which allowed us to arrive at the following equation:

• Probability = 0.112* MELDNa + 2.518* L3-SMHDR – 3.11.

• This analysis allowed us to classify patients according to the above function categories, and to estimate the risk of mortality at 6 and 12 months at respectively OR = 10 [2-50, P=0.003] and 11.4 [2.2-58.6, P=0.002].

Conclusion: The 6-month prognosis of patients with HCC depends primarily on liver function and the severity of sarcopenia and myosteatosis, not tumor stage. This should provide additional prioritization for patients eligible for liver transplantation. Confirmation of these results should be considered in a larger-scale study.

Introduction: Hepatocellular Carcinoma is One of the highest incidence among all hepatic malignancies. Most HCC cases occur in patients with underlying liver disease. HCC is the second most frequent cancer in men and the sixth most frequent cancer in women in Egypt where post HCV-related cirrhosis is the most common cause.

Aims & Methods: This is a retrospective record-based analysis of prospectively collected data done in the Tropical Medicine Department, Mansoura University Hospital, Egypt covering the 10 years period. It included all HCC patients who received treatment during the period from 2011 to2020. Patients with hepatic tumor other than HCC, or missed follow up were excluded.

A total of 202 out of 715 HCC patients (28.3%) were included in the study-was elgible for Loco regional treatment according to Barcelona clinic of liver cancer in the form of Radiofrequency (RF), tranansarterialchemoembolization(TACE)and Microwaveablation (MWA). Modified Response Evaluation Criteria In Solid Tumors(mRIST) and Hepatoma Arterial-embolisation Prognostic (HAP) Score were applied in this study

Results: This study included 202 patients with age ranging from 42 to 81 years with a mean of 58.8 ± 7.1 years. The duration of follow-up ranged from 11 to 132 months with a mean 37.9 ± 15.6 months and a median of 36 months. All cases was post HCV related cirrhosis. At the start of the study 33.7% received no locoregional treatment, while 41.5%, 41.6%, 0.03,%, 0.05% and 15.34% undergo TACE,MWA,RF,and multiple interventions respectively while at the end of the study 70.3%,19.3% and 10.4% undergo TACE, MWA and RF respectively

According to mRIST the complete response, partial response, stationary and progressive course accounted for 48.5%, 46.0%, 0.99% and 4.45%; respectively.

The overall complete response was 48.5%. The complete response is significantly higher in females (CRR=2.0), CHILD A5 (CRR=2.4), BCBC (CRR=4.2), single nodule (CRR=5.1), nodule size of <2 and 2 to <3 (CRR=6.1 and 8.1; respectively), AFP <400 (CRR=6.3), HAP score 1and treated HCV (CRR=3.2 and 4.4; respectively)and treatment with MWA and RF (CRR=6.1 and 11.0; respectively).

The independent predictors of complete response are BCLC of 0 & A (ARR=2.6), Single nodule (ARR=3.8), nodule size of <2 and 2-<3 (ARR=4.7 and 8.0; respectively), AFP<400 (ARR=7.7) and cured past hepatitis (ARR=4.4).(NB:CRR= crude relative risk ,ARR= adjusted relative risk)

the overall mean survival is 49.9 months. The mean overall survival is significantly longer in age ≤60 years, males, BCLC of 0 & A, single node affection, AFP <400, Previous treatment with MWA and HAPscore (0 & 1) *P*< 0.001).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The overall mean progression free survival (PFS) is 19.4 months. The mean PFS is significantly longer in BCLC of B & C ,HAP (0&1) and single node affection P<0.005).

The cox regression analysis revealed that the independent predictors of overall survival are age >60 years (HR=0.6), BCLC B&C (HR=2.3) and multiple nodes affection (HR=0.1) while the independent predictor of PFS is multiple nodes affection (HR=0.4).

Conclusion: The complete response and the over all survival (mean49.4 months) were significantly higher in younger age .early child score, early staging, HAP score (0&1) AFP<400 and treatment with MWA. The overall mean progression free survival (PFS) is 19.4 months. The mean PFS is significantly longer in BCLC of B & C, HAP (0&1) and single node affection.

Introduction: Hepatocellular carcinoma (HCC) is a global health problem and the fourth leading cause of cancer-related deaths worldwide. The carcinogenic role of methylation, a critical epigenetic modification, is well known in HCC.

Aims & Methods: Thus, in this study, we aimed to assess the role of plasma level of methylated RASSF1A in post hepatitis C virus, (HCV) cirrhotic patients as a non- invasive diagnostic marker for HCC.

The levels of methylated RASSF1A were determined in plasma of 120 participants who were classified to three groups (40 participants each); HCC patients on top of chronic HCV infection, post hepatitis C cirrhotic patients without HCC in addition to healthy matched age and sex control group. Methylation-sensitive restriction enzyme digestion and real-time quantitative polymerase chain reaction method was employed to measure the expression level of RASSF1A.

Results: Patients with HCC exhibited significantly higher levels of circulating hypermethylated RASSF1A than post hepatitis C patients and control groups. In addition, a statistically significant correlation between RASSF1A and the different clinico-pathological parameters was observed. The receiver operating characteristic curves plotted showed that plasma RASSF1A helped in significant differentiation between HCC and cirrhotic patients.

Test characteristics	HCC versus cirrhosis		
	RASSF1A (copies/µL)	AFP (ng/mL)	Combined measurement
Best cutoff value	≤ 0.40	≤ 22.14	at 0.40 (RASSF1A) and 22.14(AFP)
AUC	0.81	0.73	0.87
P-value	<0.001	<0.001	<0.001
Sensitivity %	80.0	62.5	82.5
Specificity %	75.0	77.5	70.0
PPV %	76.2	73.5	73.3
NPV %	78.9	67.4	80.0
Accuracy %	77.5	70.0	76.3

Table. Diagnostic performance of RASSF1A (copies/µL) for discrimination between cirrhosis and HCC groups.

Conclusion: Circulating hypermethylated RASSF1A could be a non- invasive diagnostic marker for discriminating HCC among post HCV cirrhotic patients and characterizing their progression.

Contact E-Mail Address: ericauholanda@gmail.com

Introduction: Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer-related mortality worldwide. Patients with cirrhosis have a cumulative incidence of HCC ranging from 1.5% to 6% per year. Nodule screening, as well as early diagnosis of this cancer are crucial for prognosis.

Aims & Methods: The aim of the present study was to compare the diagnosis of HCC by imaging with anatomopathological findings in the explanted liver (AP). A cross-sectional study including patients over 18 years old with a radiological diagnosis of HCC undergoing liver transplantation from 04/2018 to 12/2020. Patients were excluded if the last imaging examination (CT or MRI) was performed more than 6 months before transplantation or if they underwent imaging at an external facility.

An experienced radiologist, blinded to clinical data, reviewed the latest examination and classified nodules according to LI-RADS classification. The explanted liver was evaluated for the detection of macronodules, and on microscopy, nodules were classified as regenerative macronodules,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

low or high-grade dysplastic, or HCC. The presence of vascular microinvasion and satellite nodules was also assessed by a liver pathologist blinded to the imaging examination. A significance level of $p < 0.05$ was considered for statistical analysis.

Results: 77 patients were included, and a total of 225 nodules were identified. Of these,19 was visualized only in imaging, 151 in both (imaging and AP), and 55 only in AP. The correlation between the number of nodules in imaging and AP was moderate (coefficient 0.693). Satellite nodules were identified in 6.12% (9/147) and microvascular invasion in 8.84% (13/147) of HCC nodules of explanted liver. There was a correlation between the size of nodules in the explanted liver and the presence of satellite nodules (p 0.024). HCC diagnosis was confirmed by AP in 147/206 nodules (71.4%). The correlation between the number of LI-RADS 5 nodules on imaging and in the explanted liver was moderate (coefficient 0.543), as well as the correlation between patients meeting Milan criteria on imaging and AP (kappa 0.437). Thirty-one nodules classified as HCC on AP were not identified on imaging (21.08%). Among those identified, 48/90 (53.3%) were classified as LI-RADS 5; eighteen (20%) as LI-RADS 4, and twenty-four (26.7%) as LI-RADS 3.

Conclusion: The present study highlights the need for prompt radiological follow-up in patients with LI-RADS 3 nodules, as well as reinforces the indication of liver transplantation as the treatment of choice in eligible patients.

RETHINKING VARICEAL SCREENING IN HEPATOCELLULAR CARCINOMA COMPLICATED CIRRHOSIS: THE ALBI-PLT SCORE ADVANTAGE

E. Slama[1], H. Elloumi[1], S. Ben Hamida[1], I. Cheikh[1]
[1]Bizerte Universitary Hospital, Gastroenterology, Bizerte, Tunisia

Contact E-Mail Address: eya.slama@etudiant-fmt.utm.tn

Introduction: Clinically significant portal hypertension (CSPH) is a major prognostic factor in patients with hepatocellular carcinoma (HCC) complicated by cirrhosis, influencing both survival and treatment outcomes. Esophageal variceal hemorrhage, a severe complication of CSPH, is associated with a poor prognosis. The gold standard for diagnosing CSPH involves invasive procedures like hepatic venous pressure gradient (HVPG) measurement; however, these methods are not always feasible in clinical practice. The Baveno VII consensus recommends non-invasive strategies for variceal screening, but their applicability in HCC patients remains uncertain due to the potential confounding effects of HCC on liver stiffness measurements (LSM).

Aims & Methods: The primary objectives were to determine the prevalence and risk factors of varices in HCC patients, validate the predictive ability of the ALBI-PLT score for variceal screening in compensated cirrhosis, and identify a subgroup of patients who could safely forgo endoscopic variceal screening.

This single-center, retrospective, cross-sectional study was conducted at the Department of Gastroenterology and Hepatology, Habib Bougatfa University Hospital, Tunisia, over six months (July 2024 - January 2025). A total of 50 patients with cirrhosis complicated by HCC were included. The ALBI score, ALBI grade, and ALBI-PLT score were calculated, and esophageal varices were assessed by esophagogastroduodenoscopy (EGD). The exclusion criteria were as follows:

1. Patients with incomplete information regarding HCC etiology, CTP score, cancer stage, treatment, or mortality,
2. Patients who did not undergo endoscopic screening of esophageal varices within three months of HCC diagnosis,
3. Patients who had undergone splenectomy or partial splenic arterial embolization, as these interventions could affect the ALBI-PLT score, and;
4. Decompensated patients, defined as those with ascites, varices, hepatic encephalopathy, jaundice, or a CTP score >6. Statistical analysis was performed using SPSS v26, with p-values ≤ 0.05 considered statistically significant.

Results: The cohort had a mean age of 67.5 ± 12.20 years, with a male predominance (62%). Hepatitis C was the leading etiology (44%). Esophageal varices were present in 82% of patients, with 18% having no varices, 4% with grade I, 44% with grade II, and 34% with grade III varices.

A statistically significant association was found between the ALBI-PLT score and the presence of high-risk varices (HRV) (Pearson Chi-square = 43.677, df = 4, $p < 0.001$), indicating that higher ALBI-PLT scores were associated with an increased risk of varices.ROC curve analysis yielded an area under the curve (AUC) of 0.908 (95% CI: 0.736–1.000, $p < 0.001$), indicating excellent discriminative ability.

The optimal cutoff for the ALBI-PLT score was identified as ≥ 1.5, based on the Youden Index. At this threshold, the score demonstrated a sensitivity of 100% and a specificity of 88.9%, with a Youden Index of 0.889.

This suggests that patients with an ALBI-PLT score below 1.5 are very unlikely to have varices and could potentially avoid unnecessary endoscopic screening. Logistic regression confirmed the ALBI-PLT score as an independent predictor of high-risk varices (OR = 6.35, p = 0.002), reinforcing its clinical utility for non-invasive screening.

Conclusion: The ALBI-PLT score provides a reliable, non-invasive tool for identifying HCC patients with compensated cirrhosis who are at low risk for varices and may safely avoid routine endoscopic screening. Further validation of this score in larger cohorts is warranted.

Disclosure: We declare no Conflict of interest.

Introduction: Calcineurin inhibitors (CNIs), such as tacrolimus and cyclosporine, have revolutionized immunosuppression in solid organ transplantation by significantly reducing acute rejection rates and improving graft survival. However, their long-term use is associated with an increased risk of de novo malignancies (DNMs), a leading cause of morbidity and mortality in transplant recipients.

Aims & Methods: The aim of this study is to systematically assess the relationship between CNIs and DNM incidence, investigate potential mechanisms, and evaluate risk-reduction strategies. This systematic review synthesizes evidence from nine studies (comprising 6,829 liver transplant

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

recipients) sourced from PubMed, MEDLINE, and the Cochrane Library to evaluate the association between CNIs and DNM incidence, explore underlying mechanisms, and assess risk-mitigation strategies.

Results: Our analysis of 47 studies revealed compelling statistical evidence linking CNI exposure to increased malignancy risk. A meta-analysis of 12 studies showed a pooled relative risk (RR) of 1.65 (95% CI: 1.39-1.96, p<0.001) for de novo malignancies in high CNI exposure groups compared to low exposure groups. Dose-dependent effects were observed in 78% of studies, with a median 2.3-fold increase in malignancy risk for every 100 ng/mL increase in tacrolimus trough levels (IQR: 1.8-2.9, p<0.01). Risk factor analysis identified age >60 years (OR: 2.1, 95% CI: 1.7-2.6), male gender (OR: 1.4, 95% CI: 1.2-1.7), and smoking history (OR: 1.8, 95% CI: 1.5-2.2) as significant predictors of malignancy development. Time since transplantation showed a positive correlation with malignancy risk (r = 0.68, p<0.001). Evaluation of CNI minimization strategies revealed promising outcomes. Early withdrawal protocols reduced malignancy incidence by 35% (95% CI: 25-45%, p<0.001) compared to standard regimens. Combination therapy with mTOR inhibitors demonstrated a 42% reduction in malignancy risk (HR: 0.58, 95% CI: 0.46-0.73, p<0.001). Subgroup analyses indicated varying malignancy risks across cancer types, with skin cancers showing the highest incidence (38.5 per 1000 person-years, 95% CI: 32.1-45.9), followed by lymphoproliferative disorders (12.7 per 1000 person-years, 95% CI: 9.8-16.4).

Conclusion: Higher tacrolimus levels, particularly in the early post-transplant period, were consistently linked to greater cancer incidence. CNI minimization strategies showed promise in reducing malignancy risk, with up to 84% risk reduction observed with conversion to MMF monotherapy. Patient-specific factors, especially smoking, significantly modified risk. These findings support adopting personalized immunosuppression approaches that consider individual risk profiles and emphasize early CNI optimization.

HIGH PREVALENCE OF STEATOTIC LIVER DISEASE AND FIBROSIS IN SCREENING COLONOSCOPY PATIENTS: A MISSED OPPORTUNITY FOR EARLY DETECTION?

M.MK. Qasem[1], O. Bednar[1], V. Procházka[1], D. Hegyi[1], K. Dvorak[2,1]
[1]Regional Hospital Liberec, Department of Gastroenterology and Hepatology, Liberec, Czech Republic, [2]4th Department of Internal Medicine, General Teaching Hospital, First Faculty of Medicine, Charles University, Prague, Czech Republic

Contact E-Mail Address: Marwan-qasem@outlook.com

Introduction: Steatotic liver disease (SLD) encompasses a spectrum of conditions, including metabolic dysfunction-associated SLD (MASLD), alcohol-related liver disease (ALD), and the overlapping category of MetALD. SLD affects more than a third of adults globally, but the majority remain undiagnosed, partially due to its lack of symptoms and limited awareness among patients and physicians. Adults undergoing screening colonoscopy, typically aged ≥50 years, represent a key population for targeted SLD detection, as they have a higher prevalence of cardiometabolic risk factors and is already engaged with preventive healthcare.

Aims & Methods: We examined 610 consecutive individuals aged ≥50 years with no known history of chronic liver disease who were referred for a colonoscopy for colorectal cancer screening. The protocol included sonographic assessment of liver steatosis and point shear wave elastography (pSWE) for liver fibrosis quantification, anthropometric measurements, biochemistry, medical history and alcohol intake evaluation. From the collected data, non-invasive fibrosis scores were calculated and used for aetiological and risk stratification.

Results: A total of 543 patients were included in the final analysis, after excluding patients with an invalid pSWE measurement (5.3%, n=29) and then excluding patients with incomplete results (n=38). The median age was 64 years (IQR 57-70) and 54.0% were male. The median BMI was 28.7 kg/m^2 (IQR 25.8–31.4) in males and 28.3 kg/m^2 (IQR 24.2-31.5) in females. SLD was identified in 63.4 % (n=344) of participants. Elevated liver stiffness (pSWE ≥ 1.30 m/s) was found in 26.9 % (n=146), and 4.8% (n=26) had values ≥1.70 m/s, suggestive of compensated advanced chronic liver disease. Among patients with pSWE ≥ 1.30 m/s, MASLD was the predominant aetiology (69.9%, n=102), followed by MetALD (15.8%, n=23), ALD (1.4%, n=2), cryptogenic (11.6%, n=17) and other etiologies (1.4%, n=2).

Preselection using EASL-EASD-EASO criteria (i.e. presence of type 2 diabetes or central obesity plus ≥1 cardiometabolic risk factor and elevated liver enzymes) would have detected 365 at-risk individuals (67.2% of the cohort) of whom 55.9% (n=204) had a FIB-4 index ≥1.30. This approach would have identified only 30.4% (n=38) of all the patients with MASLD/MetALD with elevated liver stiffness (n=125).

Conclusion: Opportunistic screening for SLD in patients undergoing screening colonoscopy could be a useful strategy for detecting asymptomatic and potentially progressive liver disease. This approach identified a high prevalence of SLD (63.4%) and elevated liver stiffness (26.9%) in this population, primarily due to MASLD and MetALD. The integration of ultrasound and elastography added minimal burden to the existing workflow while enabling early risk stratification without the need for additional patient visits or referrals.

IMPACT OF MATERIAL DEPRIVATION ON CLINICAL OUTCOMES OF PATIENTS WITH CIRRHOSIS

A. Pasta[1], D.M. Rossi[1], S. Labanca[2], S. Marenco[2], G. Pieri[2], M.C. Plaz Torres[3], E. Giannini[1]
[1]University of Genoa, Genoa, Italy, [2]San Martino Hospital IRCCS, Genova, Italy, [3]University of Genoa, Dept. of Internal Medicine, Genova, Italy

Contact E-Mail Address: andrea.pasta@edu.unige.it

Introduction: Material deprivation (MD) is a social determinant of health, and the Genoa Deprivation Index (GDI) describes its distribution in Genoa based on unemployment, education level, housing ownership, and overcrowding.

Aims & Methods: This study assessed the impact of MD on the outcome of patients with cirrhosis. We retrospectively analysed medical records of patients with cirrhosis in Genoa followed at the Gastroenterology Unit (2016–2022). We evaluated demographic, clinical, and outcome data, assessing their relationship with MD. The MD class was determined by residential address using GDI. Participants were classified into low and high MD categories based on the median value. Endpoints included diagnosis modality, disease stage, adherence to follow-up, hepatic decompensation requiring hospitalisation, and overall survival (OS).

Results: We studied a total of 368 patients (68.5% males, median age 63 years, IQR 57 - 71). The majority of patients had compensated liver disease (n=213, 57.9%). Patients with low MD were older (64 years, IQR 58-73 vs. 62 years, IQR 56-70; p<0.0001), more frequently received a diagnosis through screening (106, 58.6% vs. 27, 14.4%; p<0.001), and showed greater adherence to follow-up [patients lost to follow-up: 15 (8.3%) vs. 29 (15.5%); p<0.0001] compared to those with high MD.

During follow-up, the hospitalisation rate for hepatic decompensation was lower in patients with low MD than in those with high MD (1/100 vs. 2.1/100 patients/year; IRR: 1.95, CI 1.29-2.99; p=0.001). OS from diagnosis was longer in patients with low MD compared to those with high MD (93.7 months, CI 83.5–103.5 vs 66.2 months, CI 59.6–72.7; p=0.007); this difference was confirmed in the sub-analyses of compensated patients and after excluding liver transplant recipients.

Conclusion: MD has a significant impact on the clinical management and prognosis of patients with cirrhosis. It would be beneficial to seek ways to reduce the socioeconomic barriers underlying this inequality.

Introduction: Traditionally, liver surgery has been dominated by open surgical approaches. However, with the increasing application of robotic surgical systems, a potential paradigm shift is emerging.

Aims & Methods: A historical comparison of open vs. robot-assisted liver surgery with the primary endpoint being the complication rate according to Clavien-Dindo grades I to IV.

Secondary endpoints included operative time, intraoperative blood loss, length of hospital stay and resection outcomes.

A single-center, retrospective analysis of a patient cohort that underwent liver resection procedures for benign or malignant liver disease between 2010 and 2024. Statistical methods included descriptive statistics with median and interquartile ranges (IQR), as well as interferential statistics using analysis of variance (ANOVA), Chi-square test or Fisher's exact test, Wilcoxon test, and effect size calculation. Additionally, regression analysis and subgroup analysis for the major resection group were performed.

Results: A total of 185 patients were included (open surgery: n = 86, robotic: n = 99).

Robot-assisted liver surgery was associated with significantly reduced blood loss, shorter intensive care unit stays, and shorter total hospital stays. (Table 1)

The major complication rates according to Clavien-Dindo were significantly lower with moderate effect sizes (OLR vs. RLR, p = 0.011, d_{Cohen} = 0.4203).

Regression analysis demonstrated that the surgical approach was the best predictor of complication occurrence (OLR vs. RLR, p = 0.004).

Subgroup analysis of major resections showed significantly shorter ICU stays (OLR: 2 days vs. RLR: 1 day, p = 0.002), total hospital stays (OLR: 14 days vs. RLR: 10.5 days, p = 0.027), and lower blood loss (EBL OLR: 650 ml vs. RLR: 300 ml, p = 0.008).

	OLR	RLR	P-value[A]
n[B]	86	99	0.917
Minor/Major-Resection	52/34	60/38	0.917
EBL (ml)	400	200	0.013
ICU (days)	1.0 [2.3][C]	1.0 [1.0][C]	< 0.001
LOS (days)	13.0 [14.0][C]	9.0 [8.0][C]	< 0.001
R-Status (R0)	79 (91.9%)	85 (89.5%)	0.990

Table 1. Results.
[A]P < 0.05: statistical significance
[B]n= sample
[C]Median [Interquartile range]
Abbrevations:
OLR: open liver resection; RLR: robotic liver resection; EBL: estimated blood loos; ICU: intensive care unit; LOS: length of stay;

Conclusion: Robot-assisted liver surgery, compared to conventional open liver surgery, offers equivalent resection quality with reduced complication rates, lower intraoperative blood loss, and shorter ICU and hospital stays. Prospective randomized studies are necessary to validate these retrospective findings.

Disclosure: Nothing to disclose.

FECAL MICROBIOTA TRANSPLANTATION FOR CHILDREN WITH AUTISM SPECTRUM DISORDER AND THE CORE FUNCTIONAL STRAIN IDENTIFICATION: A COHORT STUDY

D. Dai[1], Z. Zhu[2], Y. Zou[1], Z. Li[1], B. Lin[1], M. Luo[3], H. Zhou[3]
[1]Shenzhen Children's Hospital, International Medical Center, Endoscopy Center and Gastroenterology Department, Shenzhen, China, [2]Shenzhen Children's Hospital, Shenzhen, China, [3]Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China

Contact E-Mail Address: daidong3529@sina.com

Introduction: Autism Spectrum Disorder (ASD) is closely associated with gut-brain axis dysfunction[1]. Fecal microbiota transplantation (FMT) may alleviate gastrointestinal and behavioral symptoms in ASD children by remodeling gut microbiota[2], yet the key functional bacterial strains underlying FMT-mediated neurobehavioral regulation remain unidentified.

Aims & Methods: This study aims to systematically evaluate FMT efficacy through a cohort study, combined with metagenomic analysis to investigate the dynamic patterns of microbiota colonization in ASD children. We will thoroughly identify core bacterial strains and analyze the relationship between their colonization patterns and therapeutic outcomes. The children aged 0-18 years meeting the diagnostic criteria for ASD were included in this study. The clinical data of recipients was collected before FMT, alongside questionnaire surveys and fecal sample collection. Pre-FMT assessments were conducted by pediatric psychologists using standardized scales. Donor feces were extracted via standardized protocols, and 100 mL of donor microbiota suspension was administered into the jejunum or ileum via colonoscopy or nasojejunal tube once every other day, total three sessions.

Post-FMT fecal samples were collected from recipients at 1, 2, 4, 12, and 24 weeks for metagenomic analysis at species and strain levels. At 12 and 24 weeks post-FMT, the same psychologists reevaluated recipients using assessment scales, while parents completed follow-up questionnaires to document clinical outcomes.

Finally, correlation analysis was conducted between laboratory data and clinical outcomes.

Results: A total of age-matched healthy pediatric donors (86 fecal samples) and 52 ASD children (351 fecal samples) were included. Results revealed that 69.2% of ASD children exhibited gastrointestinal (GI) symptoms (e.g., constipation or diarrhea), 58.3% had one or more food protein allergies, and 78.5% experienced sleep disturbances (<8 hours/day).

Post-FMT, GI symptoms improved most significantly: 80% of recipients showed at least one grade reduction in Gastrointestinal Symptom Rating Scale (GSRS) scores, while 60% demonstrated improvements in autism-related behavioral traits, including reduced emotional dysregulation/negativity and enhanced sensory responsiveness.

Clinical improvements became more pronounced over time. Metagenomic analysis demonstrated a significant increase in gut microbiota diversity and structural remodeling in recipients, with microbial profiles converging toward donor compositions. Correlation analysis identified donor-derived Bacteroidetes and Bacillota phyla as closely associated with clinical improvements.

Conclusion: FMT can significantly and ‚long-term' reconstruct the gut microbiota of children with autism, effectively alleviating concurrent symptoms such as gastrointestinal disorders. Successful colonization of Bacteroidetes and Bacillota from donor sources is closely related to clinical improvement.

NONALCOHOLIC FATTY LIVER DISEASE, HISTAMINE PRODUCING GUT BACTERIA AND NEWLY ONSET HEART FAILURE

D. Georgescu[1], D.-F. Lighezan[1], C.I. Rosca[1], N. Basa[1], O.E. Ancusa[1], P. Ciubotaru[1], I. Suceava[1], M. Ionita[1], R. Buzas[1]
[1]"V Babes" University of Medicine and Pharmacy, Department of Internal Medicine I, Timisoara, Romania

Contact E-Mail Address: doina.georgescu@umft.ro

Introduction: Nonalcoholic fatty liver disease (NAFLD) represents a risk factor for development of cardio-vascular conditions.

Aims & Methods: The aim of this study was to explore whether there is a relationship between inflammation associated to gut dysbiosis in patients with NAFLD and newly onset heart failure (HF).

Patients and methods 150 research participants, 69 men, 81 women, age range :46- 85 years, 50 patients with NAFLD and no signs of HF, 50 patients with NAFLD and newly onset HF with preserved left ventricular ejection fraction (LVEF) and 50 healthy controls joined this observational study.

Several diseases and conditions have been ruled out.

Research participants underwent thoroughly clinical examination, lab work-ups, including stool microbiota assessment, thorax radiology, 12 channels ECG, abdominal and cardiac ultrasonography and liver elastography.

Results: No significant differences were noted related to age, gender and several conditions, such as: type 2 diabetes mellitus, dyslipidemia, hypertension.

Significant differences were however recorded in HF group, in relation to fatty liver index (FLI), liver fibrosis, C reactive protein (CRP), dysbiosis severity, chronic kidney disease, relative wall thickness (RWT) and E/A ratio.76% of patients with HF displayed *Bacteroides spp.* and *Prevotella spp.* dominant enterotypes. Increased amount of LPS (+) bacteria was noted in 72% and augmentation of the amount of histamine (H) producing bacteria was observed in 62% of patients from the HF group.

Decreased amount of acetate/propionate producing bacteria and mucosa protective bacteria such as *Akkermansia muciniphila* were noted in 56% of HF patients Among several imbalanced gut microbiota, noted in HF group, H producing bacteria positively correlated to FLI, CRP and negatively correlated to E/A ratio.

Conclusion: Patients with NAFLD and newly onset HF displayed significant elevation of FLI, CRP and more severe liver fibrosis and gut dysbiosis. Imbalanced microbiota with H (+) bacteria was linked to inflammation and diastolic dysfunction in patients with NAFLD and newly onset HF.

DIETARY INULIN SUPPRESSES METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE-RELATED HEPATOCELLULAR CARCINOMA BY MODULATING GUT MICROBIOTA AND METABOLITES

W. Wei[1], Y. Pan[1], C.C. Wong[1], X. Zhang[1], J. Yu[1]
[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong

Contact E-Mail Address: 1155136015@link.cuhk.edu.hk

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a rapidly growing cause of hepatocellular carcinoma (HCC) worldwide. Emerging evidence implies that dietary modification could modulate the pathogenesis of MASLD-HCC.

Aims & Methods: In this study, we aim to elucidate the roles of the fermentable fiber inulin and non-fermentable fiber cellulose in MASLD-HCC progression and its underlying mechanisms by modulating gut microbiota and metabolites. Two MASLD-HCC models were established: C57BL/6 mice (2-3 weeks) were injected with Diethylnitrosamine (DEN) (25mg/kg) and fed with high fat, high cholesterol diet (HFHCD) or choline deficient, high fat diet (CDHFD) for 6 months. Meanwhile, 10% fermentable fiber inulin or non-fermentable fiber cellulose was added to respective diets. To track the *in vivo* incorporation of inulin into gut microbiota and metabolites, samples from mice labeled with ^{13}C-inulin were analyzed with shotgun metagenome sequencing, non-targeted metabolomics and targeted metabolomics. The functional metabolite and its interacting protein in MASLD-HCC cells were identified by cellular thermal shift assay and mass spectrometry, and confirmed by surface plasmon resonance (SPR) and molecular docking. Human MASLD-HCC cell lines (HKCI2 and HKCI10) were used for functional validation of the candidate metabolites and its interacting protein.

Results: Inulin administration, but not cellulose, consistently suppressed MASLD-HCC in DEN-injected mice fed HFHCD with significantly decreased tumor number and tumor load. The tumor inhibitory effect of inulin was validated in a second MASLD-HCC mouse model induced by DEN plus CDHFD. We utilized stable isotope probing to trace the incorporation of ^{13}C-inulin into gut bacterial genomes and metabolites during MASLD-HCC progression. Shotgun metagenome sequencing revealed that the commensal *Bacteroides cellulosilyticus* was enriched by ^{13}C-inulin. Integration of ^{13}C-inulin labeled metagenome and metabolome revealed that *B. cellulosilyticus* assimilated inulin to produce propionic acid, leading to the enrichment of this metabolite in stool and portal vein serum of inulin-fed mice. This was validated in *B. cellulosilyticus* monocolonized, inulin-fed germ-free mice. Functional work demonstrated that *B. cellulosilyticus* or its metabolite propionic acid was protective against MASLD-HCC formation in DEN plus HFHCD model. Mechanistically, *B. cellulosilyticus*-derived propionic acid suppressed the viability of MASLD-HCC cells by interacting with anti-apoptotic protein BIRC5, which triggers its ubiquitination and subsequent degradation via proteasomal pathway. This led to cell apoptosis, cell cycle arrest and inactivated MAPK signaling pathway. Consistent with this, BIRC5 knockdown or pharmacological inhibition abolished the effect of propanoic acid in inhibiting MASLD-HCC cell growth *in vitro* and *in vivo*.

Conclusion: We demonstrated the preventive effect of inulin in suppressing MASLD-HCC by enriching gut commensal *B. cellulosilyticus* and its metabolite propionic acid, which in turn promotes ubiquitination-mediated degradation of BIRC5, thereby triggering apoptosis and cell cycle arrest in MASLD-HCC.

Introduction: Pemafibrate, the first clinically available selective peroxisome proliferator-activated receptor alpha (PPARα) modulator for improving hypertriglyceridemia (HTG), has been reported to enhance liver function and reduce liver stiffness (LS) without reducing liver fat content in patients with metabolic dysfunction-associated steatotic liver disease (MASLD) [1].

In contrast, sodium-glucose cotransporter-2 (SGLT2) inhibitors primarily target glucose metabolism and body weight, indirectly improving liver fat content and liver enzyme levels [2]. Therefore, the combination of these agents may comprehensively address the multifactorial pathogenesis of MASLD.

Aims & Methods: This study aimed to investigate the effects of combination therapy with pemafibrate and an SGLT2 inhibitor on MASLD in real-world clinical practice. We analyzed 53 patients with MASLD complicated by HTG and type 2 diabetes mellitus (T2DM), who had been treated with either pemafibrate or an SGLT2 inhibitor for more than three months, and who showed no improvement in alanine aminotransferase (ALT) levels in the two most recent measurements taken at least two months apart prior to initiating combination therapy. Of these, 23 patients were initially treated with an SGLT2 inhibitor, followed by the addition of pemafibrate (Pemafibrate add-on group), while the remaining 30 patients were first treated with pemafibrate, followed by the addition of an SGLT2 inhibitor (SGLT2 inhibitor add-on group). Patients received pemafibrate at a dose of 0.2 mg daily for 96 weeks. Clinical data from both groups were retrospectively analyzed.

Results: After 96 weeks of combination therapy, both the pemafibrate add-on and SGLT2 inhibitor add-on groups demonstrated significant reductions in aspartate aminotransferase (AST) (32.0 to 25.6 U/L, $p = 0.025$; 28.8 to 21.5 U/L, $p = 0.032$, respectively) and ALT levels (42.7 to 29.0 U/L, $p = 0.007$; 34.4 to 20.5 U/L, $p = 0.046$, respectively).

In the pemafibrate add-on group, γ-glutamyl transpeptidase (GGT) and triglyceride (TG) levels significantly decreased (GGT: 83.0 to 53.2 U/L, $p = 0.039$; TG: 644.3 to 369.0 mg/dL, $p = 0.012$), while body weight remained unchanged. Among patients with a baseline FIB-4 index ≥ 1.3, the FIB-4 index significantly improved (1.69 to 1.36, $p = 0.022$).

In contrast, the SGLT2 inhibitor add-on group showed no significant changes in GGT or TG levels; however, body weight significantly decreased (84.1 to 79.2 kg, $p = 0.006$).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In the pemafibrate add-on group, one patient underwent magnetic resonance elastography (MRE) and MRI-proton density fat fraction (MRI-PDFF) measurements, revealing a decrease in LS (MRE: 3.03 to 2.40 kPa) without a corresponding reduction in liver fat content (MRI-PDFF: 21.9% to 23.5%).

Another patient showed a decrease in LS (SWE: 6.6 to 4.9 kPa) as assessed by shear wave elastography (SWE), while liver fat content measured by attenuation imaging (ATI) remained unchanged.

In the SGLT2 inhibitor add-on group, one patient demonstrated reductions in both LS and liver fat content (MRE: 4.30 to 2.83 kPa; MRI-PDFF: 22.5% to 11.05%). Another patient showed decreased LS (SWE: 10.2 to 5.2 kPa) and liver fat content (ATI: 0.98 to 0.69 dB/cm/MHz).

Conclusion: Combination therapy with pemafibrate and an SGLT2 inhibitor improved liver function in patients with MASLD, HTG and T2DM compared to monotherapy. These findings suggest that combination therapy may offer synergistic benefits in managing the complex pathophysiology of MASLD.

GILBERT'S SYNDROME IN PATIENTS WITH METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE (MASLD):FRIEND OR FOE?

A.P. De Silva[1], K. Prabagar[1], W.A. Sewwandi[1], A.A. Wanniarachchi[1], D.S. Ediriweera[2], M. Niriella[1], H.J. De Silva[1]

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a growing public health concern, with projections indicating that over half of the global population could be affected by 2040. MASLD is strongly linked to cardiometabolic risk factors and can progress to advanced liver diseases such as fibrosis, cirrhosis, and hepatocellular carcinoma. It is characterized by lipid accumulation within hepatocytes, leading to oxidative stress and inflammation.

Gilbert's syndrome (GS), a benign hereditary condition marked by elevated unconjugated bilirubin, is known for its antioxidant and anti-inflammatory properties. These properties have been associated with a reduced risk of several cardiometabolic conditions, raising the question of whether GS may influence the progression or severity of liver disease in MASLD.

Aims & Methods: This study aimed to investigate the potential relationship between GS and MASLD, focusing specifically on the impact of bilirubin's effects on liver fibrosis and disease severity. A retrospective cohort study was conducted at Nawaloka Hospital, Colombo, Sri Lanka. Medical records from January 2022 to December 2024 were reviewed to extract sociodemographic, anthropometric, and biochemical data. Liver fibrosis was assessed using Fibro Scan® 502. Data analysis was performed using SPSS version 28, employing univariate analyses including t-tests, chi-square tests, and simple linear regression. A P-value <0.05 was considered statistically significant.

Results: A total of 180 patients with MASLD were included, of whom 36 were identified as having GS (defined by total bilirubin >1 mg/dL with elevated unconjugated bilirubin) and 144 without. No statistically significant difference in liver stiffness measurements (LSM) was observed between patients with and without GS (P = 0.8919). GS was not significantly associated with the presence or severity of liver fibrosis. Increasing age (P = 0.0278), body mass index (BMI) (P = 0.0330), and blood sugar levels (P = 0.0257) were positively associated with liver fibrosis. Demographic and clinical characteristics of the participants are summarized in Table 1.

Variable	Gilbert's Syndrome (N=36)	Controls (N=144)
Age(years)	48.39(9.73)	47.03(10.85)
Gender	33(91.67%/3(8.33%)	115(79.86%)/29(20.14%)
BMI(kg/m²)	29.13(5.37)	30.74(5.94)
FBS(mg/dL)	115.97(38.10)	114.79(33.60)
Total Cholesterol(mg/dL)	202.58(47.83)	196.47(42.53)
Total Bilirubin(mg/dL)	1.50(0.52)	0.58(0.20)
CAP score(dB/m)	308.06(41.38)	314.97(38.16)
Liver Stiffness(kPa)	10.53(8.43)	10.33(7.61)
Fib-4	1.28(1.19)	1.07(0.59)

Table 1: Demographic and clinical characteristics of the participants.

Conclusion: There was no difference in the presence of fibrosis in MASLD patients with GS without GS in our population. This is in keeping with the view that GS is a benign condition. The significant associations of age, BMI, and blood sugar with increased fibrosis are well documented.

Disclosure: Nothing to disclose.

Contact E-Mail Address: marcello.dallio@gmail.com

Introduction: Two years after the Delphi consensus-proposed revolution in the nomenclature and diagnosis of Steatotic Liver Disease (SLD), the potential benefits of adopting Metabolic dysfunction-associated steatotic liver disease (MASLD) rather than Metabolic dysfunction-associated fatty liver disease (MAFLD) diagnostic criteria in defining the disease progression risk of SLD patients have never been systematically and longitudinally evaluated in real-life.

Aims & Methods: The present study aimed to compare MASLD and MAFLD criteria in estimating the 3-year risk of advanced fibrosis (AF) progression and Acute Cardiovascular Event (ACE) occurrence in not-lean (NL) and lean (L) SLD patients.

For this purpose, we retrospectively analyzed the anthropometrical, biochemical, clinical, and Liver Stiffness Measurement (LSM - FibroScan) data stored in the University Hospital (UH)-official Health Documents Digitization Archive of 931 SLD patients admitted to UH "Luigi Vanvitelli" (between January 2016 and May 2021), and followed up for 3 years. Based on baseline Body Mass Index (BMI), patients were subdivided into "L" (BMI <25 kg/m2) (n:134) and "NL" (n:797) and, subsequently, by ap-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

plying MAFLD and MASLD criteria, in NL-MASLD (n:206), NL-MASLD/MAFLD (n:481), NL-MAFLD (n:110), and L-MASLD (n:39), L-MASLD/MAFLD (n:68), L-MAFLD (n:27). The following validated LSM cut-offs were used to identify the different liver fibrosis stages according to the Metavir score: (a) F0-F2 ≤ 9.6 kPa; (b) F3: 9.7 - 13.5 kPa; (c) F4 ≥ 13.6 kPa. AF (F3-F4) was defined by LSM values > 9.7 kPa. The transition from F0-F2 to F3-F4 defined AF progression. Retrospectively collected and documented ACEs were: (1) Acute Myocardial Infarction (IMA), (2) Acute Coronary Syndrome (ACS), (3) Ictus cerebri (IC), and (4) Transient Ischemic Attack (TIA).

Results: MASLD and MAFLD criteria similarly estimated [MASLD: OR: 2.334, C.I.95%: 1.878 - 3.028, MAFLD: OR: 2.469, C.I.95%: 1.892 - 3.668, p < 0.0001; positive predictive value (PPV), MASLD: 0.800, C.I. 95%: 0.641-0.89 vs MAFLD: 0.785, C.I. 95%: 0.604-0.897, p: 0.076)] the overall 3-year risk of AF progression in NL-SLD, whereas in L-SLD, MAFLD criteria better estimated the overall 3-year risk of AF progression [PPV, MASLD: 0.571, C.I. 95%: 0.405-0.841 vs MAFLD: 0.714, C.I. 95%: 0.558-0.794, p: 0.006].

Compared to MASLD, MAFLD diagnostic criteria better estimated the 3-year risk of ACEs occurrence in NL [HR: 1.104, C.I..95%: 0.024-1.293, p:0.025], and not in L [HR: 1.260, C.I..95%: 0.665-2.101, p:0.071] patients. Multivariate competing risk analysis (adjusted for sex, age, diabetes, steatosis, and fibrosis severity) revealed diabetes (aHR: 2.113, C.I. 95%: 1.981-2.434, p:0.001), high-sensitivity-C-reactive protein (aHR: 1.441; C.I. 95%: 1.232-1.775; p:0.02) and Homeostatic-model-assessment-for-insulin-resistance (aHR: 1.228; C.I. 95%: 1.152-1.893; p:0.03) as associated with ACE occurrence in NL-MAFLD patients.

Conclusion: MAFLD criteria better estimate the 3-year AF progression and the ACE occurrence risk in L-SLD and NL-SLD patients, respectively.

Introduction: Patients with diabetes mellitus (DM) are at increased risk of developing cardiovascular disease (CVD). Hepatic fibrosis is common among patients with DM and is associated with liver-related events. However, its impact on CVD risk remains unclear.

Aims & Methods: This study aimed to prospectively assess the association between hepatic fibrosis and CVD risk in patients with DM.

A total of 323 patients with DM were prospectively enrolled from January 2022, excluding those with viral hepatitis, overt cirrhosis, or cancer. Clinical measurements and CVD history were recorded. The following parameters were assessed: body weight (BW), body mass index (BMI), waist circumference (WC), laboratory data [aspartate aminotransferase, alanine aminotransferase (ALT), gamma-glutamyl transferase, platelet count, hemoglobin A1C, cholesterol, and triglycerides], presence of hypertension (HTN), dyslipidemia, alcohol consumption, smoking status, liver steatosis measured by the controlled attenuation parameter (CAP) using FibroScan®, and current anti-DM medications. Hepatic fibrosis was quantified by liver stiffness measurement (LSM) using FibroScan®, assessed at baseline and after two years. CVD was defined as ischemic heart disease or ischemic/hemorrhagic stroke.

Results: A total of 277 patients completed the two-year follow-up and underwent repeat LSM. The mean age was 57±12 years, and 56.3% were male. The baseline mean LSM was 6.9±3.7 kPa. A history of CVD was present in 86 (31%) patients, while 6 (3.2%) developed new CVD events during follow-up. Among the new CVD cases, 3 were cardiac events, and 3 were neurovascular events. LSM decreased in 157 patients (d-LSM group) and increased in 120 patients (i-LSM group). The mean LSM change was -1.7±2 kPa in the d-LSM group and +1.5±1.3 kPa in the i-LSM group. The d-LSM group had significantly higher baseline ALT (39±30 vs. 32±21 IU/L, p=0.018), CAP (281±51 vs. 264±49 dB/m, p=0.005), and LSM (7.9±4.2 vs. 5.7±2.3 kPa, p<0.001) than the i-LSM group.

Alcohol consumption was more prevalent in the i-LSM group (30.8% vs. 17.8%., p=0.011). There were no significant differences between the two groups in mean age (57±13 vs. 57±10 years, p=0.738), male proportion (51.6% vs. 62.5%, p=0.07), BW (72±16 vs. 72±14 kg, p=0.93), BMI (26.7±4.7 vs. 26.1±4.1 kg/m^2, p=0.233), WC (90±12 vs. 89±10 cm, p=0.816), HTN (58% vs. 48.3%, p=0.111), dyslipidemia (68.2% vs. 62.5%, p=0.326), laboratory results excluding ALT, or smoking status (45.2% vs. 49.2%, p=0.515). The use of metformin (91.1% vs. 95.8%, p=0.121), pioglitazone (1.9% vs. 2.5%, p=1.0), and insulin (7% vs. 9.2%, p=0.51) did not differ significantly between the two groups. When stratified by LSM change, the incidence of new CVD was 2% (1/49) in patients with a decrease LSM of ≤-2 kPa, 2% (4/198) in those with changes between -2 and +2 kPa, and 3.3% (1/30) in those with an increase of ≥+2 kPa (p=0.897).

Conclusion: Hepatic fibrosis, as measured by LSM, can change dynamically in patients with DM. Although this was an observational study, a decrease in LSM was not associated with a reduced risk of CVD. Therefore, LSM monitoring may have limited value in assessing CVD risk in this population.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a significant public health concern. Social media (SoMe) is increasingly popular in lower-middle-income countries and can potentially influence perceptions and understanding of illness. Approximately one-third of Sri Lanka's population uses SoMe for health information. We assessed the quality of NAFLD-related content on SoMe.

Aims & Methods: This observational, cross-sectional study aimed to assess the accuracy, completeness and quality of SoMe content relating to NAFLD across Facebook, YouTube, TikTok, Instagram and X (Twitter) from Sri Lanka, in Sinhala, English, and Tamil languages. Posts containing keywords related to NAFLD published between January 2005 to December 2024 were evaluated. Specialist gastroenterologists independently reviewed the content using standardized scales for accuracy (0-3), completeness (0-5), and global quality score (GQS) (0-5). Posts were categorized by source profile [healthcare institution (HI), healthcare professional (HP), alternative healthcare professionals (AHP), non-healthcare person (NHP), or undisclosed identity (UI)] and content type [health education (HEd), health promotion (HProm), HEd and HProm or product endorsement]. User interactions (likes, shares, views) were also analyzed and correlated with reviewer scores.

Results: The analysis included 289 SoMe posts [158 (54.7%) YouTube, 101 (34.9%) Facebook, 14 (4.8%) TikTok, 11 (3.8%) X, 5 (1.7%) Instagram] relating to NAFLD in three languages [214 (74.0%) Sinhala, 54 (18.7%) Tamil, 21 (7.3%) English]. Posts from UI (36.0%) and NHP (26.0%) comprised the majority of content sources. HP (22.1%), AHP (14.2%), and HI (1.7%) represented the remainder. HProm (61.9%) was the predominant content type followed by HEd and HProm (17.6%), HEd alone (11.8%), and product endorsement (8.7%).

The mean accuracy score was 1.78/3 (59.3%), with significant differences between sources (HP: 2.35/3 (78.5%), AHP: 1.53/3 (51.0%), NHP:1.65/3 (55.1%), UI: 1.63/3 (54.3); p<0.001).

Completeness scores averaged 2.1/5 (42%), with content in English scoring higher [2.52/5(50.4%)] than Sinhala [2.05/5 (40.97%)] and Tamil [2.17/5 (43.33%)]. GQS averaged 2.4/5 (48.4%). 82% of posts were classified as "Rotten" (<60% composite reviewer score for accuracy, completeness, and global quality).

Content quality by platform was compared using ANOVA (mean) and Kruskal-Wallis (median) tests. Posts on Facebook and YouTube showed significantly higher completeness and GQS compared to other platforms (p<0.05).

User interaction analysis was conducted using both Pearson's and Spearman's correlation tests. There were no significant correlations observed between accuracy, completeness, or GQS and views or likes. Inter-reviewer variation was assessed using ANOVA and non-parametric tests. There was no statistically significant inter-reviewer variation in scoring patterns, indicating consistency within reviewer groups.

Conclusion: The majority of the SoMe content was from NHP sources. HP delivered the most accurate content. Facebook and YouTube emerged as platforms with relatively higher-quality content compared to others. Overall accuracy, completeness and GQS remained suboptimal across platforms. Most posts (82%) failed to meet adequate quality standards. Notably, user engagement metrics did not correlate with content quality. These findings highlight the need for improved quality control measures and health literacy initiatives to enhance the reliability of information regarding NAFLD on SoMe platforms.

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is one of the main causes of chronic liver disease. Although liver biopsy is still the gold standard to assess disease severity, noninvasive tests are often used. The fibrosis-4 (FIB-4) index is one of the most useful tools to estimate liver fibrosis. In this study, we evaluated how reliable FIB-4 is as a noninvasive test in predicting liver fibrosis and (Liver related events (LREs). We also tested whether combining FIB-4 with body mass index (BMI) could better predict liver-related complications.

Aims & Methods: This was retrospective, descriptive and analytical study conducted in a gastroenterology department over 8 years including patients diagnosed with MASLD. The data normality test for this study was conducted using the Shapiro-Wilk test. Comparaison between medians was conducted using Mann-Whitney test. The discriminatory ability of FIB-4 and FIB-4×BMI (a preliminary score obtained by multiplying FIB-4 by BMI) to predict fibrosis and LREs (event of decompensation, HCC, transplantation, or liver-related death) was evaluated using AUROC curve.

Results: 114 patients we enrolled in this study, mean age was 48.1±15 years. Sex ratio W/M was 1.92. Hypertension was found in 13(11.4%), diabetes occurs in 58(50.8%) and dyslipidemia was found in 5(4.3%). Mean BMI was 26.9±6.25, 61(54.5%) were obese and 51(45.5%) were lean. Cardiometabolic syndrome was found in 65(57%) of the cases.

Concerning biologic findings, Cytolysis was observed in 12.2%(14), cholestasis in 21(18.4%), and cytolysis with cholestasis was found in 15.7%(18).

For fibrosis and steatosis assessment, 64(56.14%) patients underwent Vibration-Controlled Transient Elastography and 50(43.8%) a liver biopsy. For fibrosis, 9(9.1%)were F0, 60(60.9%)F1,22(22.2%) F2, 6(6.1%) F3 and 2(2%) F4. For steatosis, 32(33.1%) were S1, 36(37.5%) S2 and 28(29.2%) S3.

Median FIB4 for all patients was 1.29[0.67;1.76], with significant difference between lean and obese patients (1.42 vs 0.76, p<0.001). Median FIB4*BMI score was 27[13.7;47.7], with significant difference between lean and obese patients (42.9 vs 16.1, p<0.001)

LREs occurs in (13)11.4%;9(7.8%) had portal hypertension,6(5.2%) variceal bleeding, 3(2.6%) had ascites, 1(0.8%) had hepatorenal syndrome and 1(0.8%) a hepatocellular carcinoma.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The FIB-4 index showed strong predictive ability for both liver fibrosis and liver-related events. Its discriminatory performance for detecting LREs was demonstrated by an AUROC of 0.873 with a sensitivity of 77.7% and a specificity of 88.3%. The FIB-4–BMI combined score further improved diagnostic accuracy for liver-related complications, yielding an AUROC of 0.883. Using a cutoff value of 56, it reached a sensitivity of 88.8% and a specificity of 86.4%. For the prediction of severe fibrosis (F3–F4), the AUROC values for FIB-4 and the FIB-4×BMI combined score was 0.967 and 0.952, respectively. FIB4 showed a sensitivity of 100% and a specificity of 84% at a cutoff of 1.78, while the FIB4×BMI score had a sensitivity of 100% and a specificity of 81.5% at a cutoff of 54.7.

Conclusion: Non-invasive testing plays a key role in the management of MASLD, providing reliable tools for assessing fibrosis and predicting liver-related outcomes while avoiding the risks of invasive procedures. In this context, both FIB-4 and the FIB-4–BMI combined score were evaluated for their predictive value. In our study, FIB-4 alone showed good performance, but the FIB-4–BMI score demonstrated superior accuracy in predicting advanced fibrosis and liver-related complications.

"WHAT HAPPENS IN THE GREY ZONE" - FIB-4 VARIATION IN THE PROGRESSION OF INTERMEDIATE RISK MASLD

P. Gomes[1], I. Caetano[1], D. Simas[1], A. Gonçalves[1], A.G. Antunes[1], I. Cotrim[1], H. Vasconcelos[1]
[1]Unidade Local de Saúde da Região de Leiria, Leiria, Portugal

Introduction: Metabolic associated steatotic liver disease (MASLD) represents the most common cause of chronic liver disease (CLD) globally. The Fibrosis-4 Index for Liver Fibrosis (FIB-4) is an accessible and widely used tool for stratifying the risk of fibrosis. However, its correlation with clinical progression in intermediate risk patients is not fully understood.

The aim is therefore to assess: whether the variation in FIB-4 can be a tool for early identification of patients at risk of progression to Advanced Chronic Liver Disease (ACLD); and whether the reassessment of FIB-4 at 12 months for intermediate risk patients referred to in the recommendations of the European Association for the Study of the Liver 2024 is appropriate.

Aims & Methods: Retrospective analysis of a cohort of patients with MASLD with intermediate risk FIB-4 index, with at least 1 year of follow-up, in a single centre. Patients with other concomitant liver disease; a history of alcohol consumption; age under 35 years and over 65 years were excluded. Calculation of the variation in FIB-4 between 0 and 12 months of follow-up.

Analysis of the relative risk associated with an increase of any magnitude in FIB-4 for developing ACLD in 5 years (presence of compensated ACLD; variceal rupture, ascites; encephalopathy; hepatocarcinoma). In a secondary analysis, the ROC curve of the variation in FIB-4 in relation to progression to ACLD was studied.

Results: 68 patients were included (male-42.6%; mean age-55.4±6.8 years; mean follow-up time-64±38.9 months; presence of hypertension-64.7%; type II diabetes mellitus-42.6%; dyslipidaemia-70.6%; overweight/obesity-88.2%; mean BMI-31.6±5.8 kg/m2; FIB-4 at admission-1.72±0.38). The development of ACLD at 5 years was 14.6%.

The variation in FIB-4 in the group with disease progression (median=0.34; [-0.29;2.85]) was significantly higher than in the group without progression (median=-0.09; [-0.5;0.2]), (U=79.5; p=0.003). FIB-4 at admission was not associated with disease progression at 5 years (U=148.5; p=0.353).

The risk of progression to ACLD at 5 years was 1.23 times higher (RR=1.23; p<0.05) in patients with an increase in FIB-4 at 12 months of any magnitude versus no increase. The variation in FIB-4 at 12 months showed good discriminatory capacity (AUC=0.767; p<0.05), with the cut-off point with the best accuracy in predicting ACLD at 5 years being an increase in FIB-4≥0.56 (sensitivity-66.7% and specificity-80.0%).

Conclusion: In patients with intermediate-risk MASLD, an increase in FIB-4 over 12 months was associated with an increased risk of disease progression, regardless of the magnitude of FIB-4 on admission. Patients with an increase ≥0.56 in 1 year seem to benefit from long-term specialised follow-up, due to the increased risk of developing ACLD in 5 years.

ASSESSMENT OF THE QUALITY OF LIFE IN PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS IN COMBINATION WITH CORONARY HEART DISEASE WITH STABLE ANGINA PECTORIS AFTER TREATMENT WITH USING COMPLEX THERAPY

I. Chopey[1], K. Chubirko[1], Y. Ihnatko[1], T. Griadil[1], M. Hechko[1]
[1]Uzhhorod National University / Faculty of Postgraduate Education, Therapy and Family Medicine, Uzhhorod, Ukraine

Contact E-Mail Address: ivchopey@gmail.com

Introduction: Curent studies have proven that non-alcoholic fatty liver disease (NAFLD) impacts an important role in the development of risk factors for cardiovascular diseases. Comorbidities are a risk of a complicated course of coronary heart disease (CHD). The criteria for the effectiveness of treatment in medical practice are the duration and quality of life (QoL) of patients. The main tool for assessing quality of life in curent clinical research is questionnaires. The most common questionnaires widely used by scientists are the Medical Outcomes Study 36-Item Short-Form Health Status (SF-36) and EuroQoL-5D (EQ-5D).

Aims & Methods: The aim: To evaluate the indicators of QoL in patients with non-alcoholic steatohepatitis with coronary heart disease with stable angina pectoris in combination after complex therapy including ezetimibe and ursodeoxycholic acid.

Materials and methods: The prospective study included 145 patients with a verified diagnosis of CHD with stable angina pectoris II functional class combined with nonalcoholic steatohepatitis (NASH) and 100 patients with CHD without NASH. All 245 patients received basic CHD therapy: acetylsalicylic acid 100 mg once a day, ramipril 2.5 mg once a day, bisoprolol 2.5 mg once a day, and rosuvastatin - 20 mg once a day. To achieve the aim, 3 groups of patients were formed depending on the available metabolic factors (MFR): group 1-a (n=75) – patients had CHD+ NASH + MFR (arterial hypertension (AH), dyslipidemia, increased body weight or obesity) and

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

group 1-b (n=70) – CHD+ NASH + AH, as well as group 2 (n=100) – CHD without NASH. Group 1-a patients received the basic therapy of CHD and ezetimibe 10 mg/1 time per day and UDCA 15 mg/kg/day 2 hours before bedtime, for 6 months, against the background of recommendations for lifestyle modification (LM). Group 1-b received basic therapy of CHD and UDHC 15 mg/kg/day 2 hours before bedtime, for 6 months, against the background of recommendations for LM (weight loss, hypocaloric diet). Group 2 patients received only the basic therapy of CHD.

Results: As the obtained results show, positive clinical dynamics from treatment were noted in patients of group 1-a who received complex therapy with the addition of ezetimibe and UDCA at p<0.05. Regarding the QoL indicators according to the SF-36 questionnaire after treatment, a tendency to improve most of its indicators was revealed, which is more clearly observed in patients of group 1-a.

Analyzing the integrated indicators of physical and mental components of health on all scales of SF-36 revealed reliable positive dynamics on all scales of the questionnaire, which are best expressed in patients of group 1-a in comparison with group 1-b at p<0.05. The following indicators were most significantly affected: social functioning increased by 40.6 points in group 1-a, respectively, by 27.6 points in group 1-b at p<0.05; the value of the role of emotional problems increased by 55.7 points in group 1-a, respectively, by 40.3 points in group 1-b at p<0.05; general health increased by 56.9 points in group 1-a, respectively, by 45 points in group 1-b at p<0.05.

Conclusion: Complex therapy including ezetimibe and UDCA in patients with CHD combined with NASH is more effective compared to basic CHD therapy, as it reliably reduces the frequency of attacks of stable angina and the need for nitroglycerin.

The effectiveness of the treatment of CHD combined with NASH is increased by the inclusion of ezetimibe and UDCA in the basic therapy and has a positive effect on the clinical course of CHD, QoL of patients and the patient's attitude to his own disease.

RISK OF AUTOIMMUNE DISEASE IN OFFSPRING OF MOTHERS WITH BIOPSY-PROVEN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD). A NATIONWIDE COHORT STUDY

C. Marxer[1], F. Ebrahimi[1,2], D. Bergman[1], J. Sun[1], H. Hagström[3,4], M. Thuresson[5,1], O. Stephansson[6,7], J.F Ludvigsson[8,1]

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent and associated with an increased risk of adverse pregnancy and birth outcomes,[1,2] but the risk of adverse clinical outcomes beyond the perinatal period are under investigated. Recent studies suggest an overlap in clinical and immunological features between MASLD and autoimmune diseases,[3,4] but whether fetal exposure to MASLD is associated with a higher risk of offspring autoimmune diseases remains unclear.

Aims & Methods: In this nationwide cohort study, we included all singleton live born offspring with fetal exposure to maternal biopsy-proven MASLD diagnosed in Sweden between 1992 and 2017. We stratified maternal MASLD in simple steatosis versus severe MASLD (defined as either steatohepatitis, any stage of liver fibrosis, or cirrhosis). We matched the 239 identified MASLD offspring with ≤5 reference offspring (n=1,131) of mothers without known MASLD. Matching factors were maternal age at delivery, calendar year of delivery, and parity. We used multivariable Cox proportional hazard models to estimate adjusted hazard ratios (aHRs).

The endpoint was any incident autoimmune disease up until December 31, 2023. We performed a sibling-controlled analysis comparing the risk of autoimmune disease in offspring of sisters of women with biopsy-proven MASLD to investigate if early environmental and intrafamilial factors play a role.

Results: During a median of 18.4 years of follow-up (interquartile range [IQR] 13.2-23.8), 15 exposed offspring (incidence rate [IR] 3.4/1000 person-years) vs. 40 reference offspring (IR 1.9/1000 person-years) were diagnosed with autoimmune disease. This corresponded to an aHR of 1.20 (95% CI 0.57-2.53). The median age at incident autoimmune disease was higher among offspring of mothers with MASLD (14.7 years, IQR 5.5-17.5) compared to reference offspring (8.1 years, IQR 4.1-14.1).

The sibling analysis yielded a similar risk magnitude (aHR 1.14, 95% CI 0.28-4.63), indicating that early environmental and intrafamilial factors likely do not substantially contribute to the risk of early-onset autoimmune disease.

Among MASLD offspring, inflammatory bowel disease was the most frequent autoimmune disease during follow-up (26.7% [n=4] vs. 7.5% [n=3] among reference offspring), followed by type 1 diabetes (20%, n=3), and celiac disease (13.3%, n=2).

Among reference offspring, celiac disease was the most common autoimmune disease (32.5%, n=13), followed by type 1 diabetes (27.5%, n=11) and psoriasis (15%, n=6). The risk of autoimmune disease remained unchanged among 175 offspring born to mothers with simple steatosis alone

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. (aHR 0.84, 95% CI 0.29-2.45). However, we saw a positive association in 64 offspring of mothers with severe MASLD, but the risk estimate failed to attain statistical significance possibly due to small sample size (aHR 1.98, 95% CI 0.67-5.84).

Conclusion: Fetal exposure to maternal MASLD does not seem to be associated with increased risk of autoimmune disease in the offspring up until early adulthood. Further, studies with longer follow-up are needed to investigate the long-term risk of autoimmune disease after fetal exposure to MASLD.

INDICES OF THE LIVER FUNCTIONAL STATE, BLOOD LIPID SPECTRUM IN PATIENTS WITH METABOLIC DISFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH), MODERN APPROACHES TO COMPLEX TREATMENT

V. Kulaiets[1], N. Kulaiets[2,2]

[1]Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine, [2]Ivano-Frankivsk National Medical University, Department of Internal Medicine and Nursing, Ivano-Frankivsk, Ukraine

Contact E-Mail Address: virakulaiets@gmail.com

Introduction: Metabolic disfunction-associated Liver Disease (MASLD) and Metabolic disfunction-Associated Steatohepatitis (MASH) are conditions that are significantly influences by lifestyle factors. Actual problem today is the significant spread of MASLD among people of socially active age, high costs for diagnosis and treatment, and a decrease in the quality of life and work capacity of such patients.

Aims & Methods: The aim of the research is to study the dynamics of indicators of the functional state of the liver, the lipid spectrum of the blood, to evaluate the cardiovascular risk according to the SCORE-2 scale under the influence of complex pathogenetic treatment of the identified disorders in patients with steatohepatitis associated with metabolic dysfunction in combination with obesity. 46 outpatients with a diagnosis MASH were examined: 29 (63.1 %) men and 17 (36.9 %) women aged 32-55 years. There were patients divided into two groups.

The first (main) group with a diagnosis MASH were 19 (41.3 %) people who received atorvastatini: 20 mg per day, 90 days.

The second group (comparison) – 27 (58.7%) of patients who were prescribed ursodeoxycholic acid preparations in combination with atorvastatini: 250 mg (15 mg/kg of body weight) for 90 days. The healthy group consisted of 12 people of the appropriate age. The anthropometric criterion of obesity was the Quetelet index (BMI = body weight (kg)/height (m^2)). Phenotypic variant of obesity was determined by the ratio of waist circumference / hip circumference (WC/HC). Visceral obesity was observed in all examined patients. Among the patients of the main group, there were 9 (47.4 %) people with type I obesity degree (BMI = 32.6 ± 2.2 kg/m2), 6 (31.5 %) – II degree (BMI = 35.8 ± 3.6 kg/m2), and 4 (21.1 %) – III degree (BMI = 40.0 ± 2.1kg/m2), in the comparison group – 17 (62.9 %), 6 (22.3 %) and 4, respectively (14.8 %). This indicated that the patients had an abdominal type obesity.

For assessment biochemical indicators of the functional state of the disease were studied using unified methods (general level bilirubin and its fractions (direct and indirect), activity of serum aminotransferases ALT and AST, alkaline phosphatase (AP), total cholesterol (CHD) content in serum blood, high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), very-low-density lipoprotein cholesterol (VLDL), triglycerides.

Results: In most patients suffering from MASH there was found a reliable increase of the direct bilirubin level in the blood, of the activity of alanine aminotransferase (ALT, ALT) and alkaline phosphatase (ALP), and of the blood lipid spectrum (p<0,05). According to the body mass index (BMI) most of the examined patients had visceral obesity.

After the course of the combined therapy there were marked the positive dynamics in biochemical indices of the blood (p < 0,05): decrease of the direct bilirubin level, aminotransferase (ALT, ALT), blood phosphatase. The indices of blood lipid spectrum approached to the normal indexes (p < 0,05).

Conclusion: the addition of ursodeoxycholic acid to statin therapy results in a statistically significant reduction in overall cardiovascular risk, as measured by SCORE-2, compared with atorvastatin monotherapy. All

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. patients were recommended to continue the course treatment - a combination of atorvastatini and ursodeoxycholic acid for 2-3 months. This indicates the almost complete recovery of the liver functional activity and achievement of the consistent biochemical of MASH.

STEATOTIC LIVER DISEASE IN NON-OBESE INDIVIDUALS: A STATISTICAL ANALYSIS OF ASSOCIATED FACTORS AND TREATMENT RESPONSE

S. Belhaj[1], M. Borahma[2], F.-Z. Chabib[3], N. Lagdali[4], F.Z. Ajana[5], M. Kadiri[6]

[1]Ibn Sina University Hospital, Faculty of Medicine and Pharmacy, Mohamed the Vth University, Gastroenterology C, Rabat, Morocco, [2]Mohammed the Vth University, Ibn Sina Hospital, Gastroenterology C, Rabat, Morocco, [3]Ibn Sina University Hospital, Rabat, Medical Unit C, Seclin, France, [4]University Hospital Ibn Sina, Faculty of Medicine and Pharmacy, Mohamed V University, Gastroenterology, Medicine C, Rabat, Morocco, [5]CHU Ibn Sina, SMMAD, Moroccan Society of Digestif Diseases, Rabat, Morocco, [6]Ibn Sina Hospital, Rabat, Morocco

Contact E-Mail Address: soukaina.belhaj@hotmail.com

Introduction: Steatotic liver disease (SLD) in non-obese individuals (body mass index -BMI- <25) is an increasingly recognized clinical entity, distinct from the classic metabolic-associated fatty liver disease typically linked to obesity. Despite growing awareness, the characteristics, associated conditions, and treatment response of this phenotype remain poorly understood. This study aimed to evaluate clinical, biochemical, and histological characteristics in this population and to assess the impact of targeted interventions on liver-related outcomes.

Aims & Methods: We conducted a retrospective monocentric analytical study including 50 non-obese patients (BMI <25) diagnosed with SLD by ultrasound. Patients were stratified based on associated comorbidities, including coeliac disease, inflammatory bowel disease (IBD), type 2 diabetes, and hypertension. Comparative statistical analysis was performed using chi-square and Student's t-test; p-values <0.05 were considered statistically significant.

Results: Out of 162 patients followed for SLD, 30.86% (n=50) were classified as non-obese, among which 22% (n=11) were underweight. The mean age was 40.6, with a slight female predominance and a sex ratio M/F of 0.81. SLD was MASLD in 26% of patients (n=13), among which 9 patients had type 2 diabetes, and 4 patients had arterial hypertension. MASH was diagnosed in 7 patients of this group.

SLD was secondary to other causes of steatosis in 74% of cases (n=37): 38% had coeliac disease (n=19), 30% had inflammatory bowel disease (n=15), 4% had thyroid dysfunction (n=2), and 2% had LPAC syndrome (n=1).

Liver function abnormalities were found in 58% (n=29) of patients.

Patients with coeliac disease who underwent liver biopsy showed significantly higher rates of steatohepatitis (grade 2-3) compared to non-coeliac patients (68.4% vs 40%, p=0.03).

After one year of follow-up, liver enzyme normalization was observed in 75% of patients who received targeted treatment (gluten-free diet or optimized management of comorbidities) along with adapted physical activity and a weight loss goal of 3-5%, compared to 33.3% in untreated patients (p=0.01).

Histological improvement (≥1 grade regression of steatohepatitis) was documented in 44.4% of biopsied patients post-intervention, with a statistically significant association between adherence to gluten-free diet and histological regression in coeliac patients (p=0.02).

No significant association was found between presence of diabetes or hypertension and severity of liver histology (p>0.05).

Evaluation of liver fibrosis showed F0-F1 in 70% (n=35) and F2 in 12% of patients (n=6). Fibroscan stages remained stable in all these patients during follow-up, with no progression beyond F2.

Conclusion: In non-obese individuals, SLD is frequently associated with immune-mediated comorbidities, particularly coeliac disease and IBD, and characterized by mild fibrosis. Targeted treatment strategies, particularly in coeliac patients, significantly improve liver biochemistry and histological status. These findings support the need for systematic etiological screening and personalized therapeutic approaches in non-obese patients with hepatic steatosis.

Disclosure: Nothing to disclose.

Contact E-Mail Address: azzouzidriss.ad@gmail.com

Introduction: The prevalence of metabolic associated fatty liver disease (MASLD) is increasing worldwide and it increases their risk of chronic liver disease and cardiometabolic complications. While traditionally associated with obesity, hepatic steatosis can also develop in lean individuals, for whom the underlying mechanisms remain poorly understood.

Aims & Methods: This is a prospective monocentric and analytical study including all patients followed for hepatic steatosis in the hepato-gastro-enterology department over a 6-months period from September 2024 to March 2025. Diagnosis of metabolic steatosis is based on abdomino-pelvic ultrasound. We compared 2 categories of patients: lean (BMI< 25kg/m2) vs not lean patients (BMI>25 kg/m2) with hepatic steatosis.

Statistical analysis was carried out using t-tests and chi-square tests, with a significance level of p<0.05.The aim of our work is to compare lean and not lean patients with hepatic steatosis, their cardiometabolic profile, the risk factors and to study the outcome these patients.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The study included 100 patients, divided into two groups of 50 each. In group A (non-lean patients), the mean age was 46.3 ± 8.2 years, and in group B (lean patients), 44.1 ± 7.6 years (p = 0.12). Group A had a male predominance (70%) compared to 50% in group B, a statistically significant difference (p = 0.03).

The mean body weight index was 29.2 ± 4.5 kilograms per square meter in group A and 19.5 ± 1.2 in group B (p < 0.001). Metabolic syndrome was present in 84% of group A versus 34% in group B, indicating a significant difference in metabolic profiles (p < 0.001).

All patients in both groups had hepatic steatosis confirmed by ultrasound. Liver function was altered in 60% of group A: 24% had isolated cytolysis, 20% cytolysis with cholestasis, and 16% isolated cholestasis. In group B, 48% had abnormal tests: 28% with cytolysis, 20% with cholestasis. These abnormalities were significantly more frequent in group A (p < 0.05).

Fibrosis was assessed by liver biopsy or elastography in 42 patients from group A and 44 from group B. In group A, 76.2% were stage F0-F1, 14.3% F2, and 9.5% (n=4) had advanced fibrosis (F3-F4). In group B, 86.4% were F0-F1 and 13.6% F2; no F3-F4 stages were observed (p < 0.05).

Autoimmune diseases were significantly more prevalent in lean patients (group B): 30% had celiac disease, 16% Crohn's disease, and 4% ulcerative colitis. In group A, 14% had primary biliary cholangitis, 12% autoimmune thyroiditis, and 4% Crohn's disease (p < 0.001).

After multidisciplinary management, 36% of group A patients with initial abnormalities normalized their liver function tests, while 4% progressed to cirrhosis. In group B, 40% normalized liver tests. Two patients with celiac disease on gluten-free diet showed marked histological improvement, with one achieving complete regression of steatohepatitis.

Conclusion: Although lean individuals with steatosis generally showed a healthier metabolic profile and a lower degree of liver fibrosis compared to non-lean patients, both groups exhibited a significant proportion of metabolic derangements. Our study also highlighted a significantly higher prevalence of autoimmune diseases in lean patients (p < 0.001).

Management combining treatment of underlying conditions with lifestyle measures led to notable improvements in liver function, imaging and histology. These findings underline the importance of tailored strategies based on patient phenotype, including autoimmune screening in lean individuals.

WAR-RELATED ANXIETY, PROINFLAMMATORY CYTOKINES AND INSULIN RESISTANCE IN UKRAINIAN CHILDREN WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

N. Zavhorodnia[1], I. Klenina[2], O. Tatarchuk[2], R. Kislova[3], O. Petishko[2]

[1]SI "Institute Gastroenterology of NAMS of Ukraine", Pediatric Gastroenterology, Dnipro, Ukraine, [2]SI "Institute Gastroenterology of NAMS of Ukraine", Research, Dnipro, Ukraine, [3]SI "Institute Gastroenterology of NAMS of Ukraine", Diagnostic and Mini-Invasive Interventions, Dnipro, Ukraine

Contact E-Mail Address: nzavgorodni75@gmail.com

Introduction: Psychological stress as a result of the war in Ukraine negatively affects children's health, leading to the onset/exacerbation of metabolic dysfunction [1, 2].

Metabolic dysfunction-associated steatotic liver disease (MASLD) is a multifactorial condition that affects both adults and children and includes several mechanisms associated with excessive fat accumulation in hepatocytes, inflammation, and insulin resistance [3].

Aims & Methods: The aim of the study was to determine the impact of war-related anxiety on proinflammatory cytokines (IL-6, TNF-α) and insulin resistance in Ukrainian children with MASLD.

The study included 42 obese children with MASLD aged 6 to 17 years; the mean age was 12.00±0.56 years. Determination of the presence of liver steatosis was performed by transient elastography (FibroScan®502touch, Echosence, France). The presence of obesity was confirmed by bioimpedance analysis (TANITA MC-780MA, Japan). Screening for anxiety was performed using the Screen for Child Anxiety-Related Disorders (SCARED) questionnaire. Depending on the presence of anxiety, obese children with MASLD were divided into 2 groups: Group I - 12 children without anxiety disorders, Group II - 30 children with anxiety disorders. The control group consisted of 10 children of normal weight without anxiety disorders. Quantitative determination of insulin concentration in the serum was performed by ELISA using Monobind Inc. test systems, USA, and the HOMA-IR was calculated. Quantitative determination of the concentration of IL-6 and TNF-α in the blood serum was performed by ELISA using test systems from LDN LaborDiagnostika (Germany).

Results: An increased level of proinflammatory cytokines was observed in 50.0% of the children of group I and 56.7% of the children of group II. The median level of TNF-α was 3.2 times higher (p<0.05) in patients of group I and 2.5 times higher (p<0.05) in patients of group II compared to the control group. The content of anti-inflammatory IL-10 in the I and II groups did not differ from the control.

Moreover, the indicators of carbohydrate metabolism in obese children showed statistically significant differences: in patients of group I a significant increase in the median insulin level (2.1 times, p<0.05) and the HOMA-IR (2.7 times, p<0.05) was found compared to control group as well as in patients of group II - in 2.1 times (p<0.05) and the HOMA-IR - in 2.8 times (p<0.05), respectively.

Conclusion: Thus, the presence of anxiety in children with MASLD is accompanied by the elevation of proinflammatory cytokines and insulin resistance.

WAR-RELATED ANXIETY IN CHILDREN WITH METABOLIC-DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE

N. Zavhorodnia[1], Y. Stepanov[2], Y. Ocheretyanko[1], R. Kislova[3]
[1]SI "Institute Gastroenterology of NAMS of Ukraine", Pediatric Gastroenterology, Dnipro, Ukraine, [2]Institute of Gastroenterology of NAMN of Ukraine, Cathedra of Gastroenterology, Dnipro, Ukraine, [3]SI "Institute Gastroenterology of NAMS of Ukraine", Diagnostic and Mini-Invasive Interventions, Dnipro, Ukraine

Contact E-Mail Address: nzavgorodni75@gmail.com

Introduction: Pediatric metabolic-dysfunction-associated steatotic liver disease (MASLD) has become a global problem worldwide for the last decades [1].

The situation is only exacerbated in Ukraine during the war due to the lack of access to resources, in particular, healthy nutrition, sufficient physical activity, and psycho-social support [2, 3].

There is a need for investigation of war-associated emotional disorders that may contribute to MASLD progression.

Aims & Methods: To assess the structure of anxiety disorders in children with MASLD and to identify the psycho-emotional features of MASLD children of military parents.

The study involved 45 patients aged 6 to 17 years (mean age 11.8±1.5 years). The presence of obesity was evaluated using bioimpedance analysis (TANITA MC-780MA, Japan). Liver steatosis was established by transient elastography (FibroScan®502touch, Echosence, France) with controlled attenuation parameter measurement.

Based on obesity status and relation of parents to the military, the children were divided into 3 groups: 1 group – 29 MASLD children of civilian parents, 2 group – 8 MASLD children of military parents, and 3 group (control) – 8 normal weight children of civilian parents.

Screening for anxiety disorders was performed using the Screen for Child Anxiety-Related Disorders (SCARED) questionnaire. Statistical analysis was carried out using the Statistica 6.1 software package.

Results: An increased general level of anxiety was more frequently observed in children with MASLD compared to the control group, being detected in 34.5% of the 1 group ($p<0.05$) and 37.5% of the 2 group ($p<0.05$) patients. Among children from military families, moderate anxiety disorders were more prevalent (25.0%, $p<0.05$). Panic and/or somatic anxiety disorders were also more common among children with MASLD (1 group – 31.0%, 2 group – 37.5%) compared to the control group ($p<0.05$). Separation anxiety disorders were predominant across all groups (1 group – 44.8%, 2 group – 50.0%, 3 group – 50.0%, $p=0.94$). Children from military families showed significantly higher rates of generalized anxiety disorder (50.0%, $p<0.05$) and school phobia (50.0%, $p<0.05$).

Conclusion: During the war in Ukraine, separation anxiety disorders, increased general anxiety, panic and/or somatic anxiety disorders, and school phobias predominate in children with MASLD. Generalized anxiety disorders and school phobias are more prevalent among children of military parents, which should be considered for treatment program development for these patients.

Contact E-Mail Address: lukens.frank@mayo.edu

Introduction: MASLD/MASH is a spectrum of liver conditions characterized by excessive fat accumulation in the liver in the absence of significant alcohol consumption. Recent studies have highlighted the role of immune cells in the pathogenesis of MASLD.

Additionally, elevated serum IgA levels have been associated with advanced fibrosis in MASLD/MASH patients. Accordingly, IgA dysregulation could contribute to the pathogenesis and progression of MASLD/MASH. The aim of our study is to determine if IgA deficiency increases the risk of adverse events in the setting of MASLD/MASH.

Aims & Methods: A retrospective cohort study was performed using large population-based data from the TriNetX platform. Patients with diagnosed IgA deficiency and MASLD/MASH since January 1, 2014, were identified. This group was matched with patients with MASLD/MASH without IgA deficiency according to age, gender, demographics, comorbidities, and medication by using 1:1 propensity matching. The primary outcome was risk of hepatic decompensation, cirrhosis, and hepatocellular carcinoma (HCC), and secondary outcomes were all-cause mortality, major adverse cardiovascular events (MACE), and chronic kidney disease (CKD).

	MASLD/MASH with IgA Deficiency		MASLD/MASH control		HR (95% CI)
Outcomes	Included	Events	Included	Events	
HCC	673	10	674	10	1.01 (0.14, 7.19)
Hepatic decompensation	646	14	653	16	0.87 (0.42, 1.78)
Mortality	672	29	673	25	1.15 (0.67, 1.96)
MACE	556	43	550	24	1.79 (1.09, 2.96)
CKD	515	48	527	54	0.90 (0.61, 1.33)

Abbreviations: MASLD metabolic dysfunction-associated steatotic liver disease; MASH metabolic dysfunction-associated steatohepatitis; HCC hepatocellular carcinoma; MACE major adverse cardiovascular events; CKD chronic kidney disease; HR, hazard ratio; CI, confidence interval; AE, adverse events.

Table. Clinical Outcomes MASLD/MASH with IgA Deficiency vs MASLD/MASH control.

Results: A total of 841,865 adult patients with MASLD/MASH were identified, 674 of these individuals had IgA deficiency; 674 out of 674 (mean [SD] age, 51.4 [16.0] years; 383 [56.8%] female) were matched with 674 individuals (mean [SD] age, 51.7 [16.3] years; 378 [56.1%] female) without IgA deficiency. The IgA deficient group had significantly higher risk of

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

MACE (Hazard Ratio [HR], 1.79; 95% Confidence Interval [CI], 1.09-2.96). No significant differences were observed in developing HCC (HR, 1.01; 95% CI, 0.14-7.19), hepatic decompensation (HR, 0.87; 95% CI, 0.42-1.78), all-cause mortality (HR, 1.15; 95% CI, 0.67-1.96), and CKD (HR, 0.90; 95% CI, 0.61-1.33). No patients from our study developed cirrhosis.

Conclusion: Conversely to the expected increase in the liver-related outcomes, IgA deficient patients had no significant risk. Normally, IgA promotes fibrosis through the IgA-FcR signaling axis, and given that IgA is deficient, this condition can theoretically alter the immune landscape in MASLD.

Contrarily, the increased risk of MACE in IgA deficiency was previously studied, and it is most likely that IgA solely is an independent risk factor to develop MACE which is compatible with the result of our study. Further studies are required to analyze the impact of IgA in the prognosis of MASLD/MASH patients.

RETROSPECTIVE ANALYSIS OF LIVER METABOLISM ALTERATIONS FOLLOWING PCSK9 INHIBITOR THERAPY AFTER CORONARY INTERVENTION

H. Ohta[1], H. Ihara[1], T. Ozaki[2], PCI Group in SSJ
[1]Sapporo Orthopedics and Cardiovascular Hospital, Gastroenterology, Sapporo, Japan, [2]Sapporo Orthopedics and Cardiovascular Hospital, Cardiovascular, Sapporo, Japan

Contact E-Mail Address: hideohta@true.ocn.ne.jp

Introduction: Evolocumab, a PCSK9 inhibitor, is widely used to treat familial hypercholesterolemia (FH) and severe cardiovascular disease due to its potent LDL-C-lowering effects. However, given its mechanism involving hepatic LDL receptor pathways, concerns about liver dysfunction have emerged. Moreover, metabolic-associated fatty liver disease (MAFLD) commonly coexists with cardiovascular disease, potentially influencing treatment outcomes.

Aims & Methods: Aim is to evaluate the effects of Evolocumab on liver steatosis and hepatic function in patients undergoing percutaneous coronary intervention (PCI).

A retrospective study was conducted on 61 patients who received Evolocumab after PCI between April 2017 and October 2024 (11 with FH, 50 without). Liver steatosis was assessed via non-contrast computed tomography (CT), and hepatic function was evaluated using LDL-cholesterol levels and FIB-4 index at baseline and after 24 weeks of treatment.

Results:

1. LDL-C decreased significantly from 120 ± 48 mg/dL to 14 ± 3.1 mg/dL within two weeks of Evolocumab initiation.
2. Liver steatosis, as approximated by the liver-to-spleen attenuation ratio on CT, showed the improvement from 0.98 to 1.0 (no statistical significance), because of limitation by the CT sensitivity.
3. Six patients experienced drug induced liver dysfunction, necessitating discontinuation of therapy.
4. FIB-4 indices of 27% patients increased from 3.55 before to 4.33 after the treatment.
5. Subgroup analysis indicated mild improvement in hepatic steatosis markers: especially in younger patients with low FIB-4 indices, γ-GTP decreased from 89.4 to 48.6 IU/L, and cholinesterase (ChE) decreased from 410 to 317 IU/L by treatment.

Conclusion: Evolocumab demonstrates not only robust LDL-C reduction but may also exhibit potential benefits for liver steatosis, though we need accurate imaging such as Fibroscan. Nevertheless, attention is required regarding the risk of drug induced hepatic dysfunction, and observed improvements must be interpreted cautiously due to possible placebo effects following PCI.

Contact E-Mail Address: birguloflaz@gmail.com

Introduction: Currently, metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide and represents a major public health concern (1).

Its more severe form, metabolic dysfunction-associated steatohepatitis (MASH), is increasingly recognized as a leading cause of liver transplantation (2).

Although lifestyle changes, especially increased physical activity, are widely recommended in clinical practice, structured and supervised exercise programs are not yet well represented in the literature.

Aims & Methods: This study aimed to examine how an eight-week physiotherapist-supervised personalized exercise intervention can affect the quality of life in patients with MASH. A total of 20 patients aged 18-65 years with MASH were included and assigned to the intervention group (n=10; 8 males, 2 females; mean age 45.3±9.4 years; BMI 28.3±2.6) or a control group (n=10; 8 males, 2 females; mean age 47.6±7.1 years; BMI 30.1±1.9) by block randomization. Both groups were advised to follow a Mediterranean diet by a dietician.

The control group was advised to do 45 minutes of physical activity per day by a physiotherapist, while the intervention group completed an 8-week personalized exercise program. The exercise program consisted of one-hour sessions three times per week. Participants first completed four weeks of resistance training with exercise bands and free weights, then shifted to an aerobic exercise program on a bicycle ergometer set at 60% of their target heart rate for the final four weeks. Quality of life was assessed using the Chronic Liver Disease Questionnaire (CLDQ), which includes the subscales of fatigue, abdominal symptoms, systemic complaints, emotional state, anxiety, and activity.

Results: There were 8 males and 2 females in both groups, and the mean body mass index of the intervention group was 28.3±2.6 and the mean body mass index of the control group was 30.1±1.9. The groups were similar in terms of demographic characteristics. The intervention group

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

showed significant improvements in CLDQ subscales fatigue (p=0.009) and abdominal symptoms (p=0.041), activity (p=0.036) and total score (p=0.014) and this difference was statistically significant between the groups.

The control group showed improvement only in systemic symptoms (p<0.046) but this did not constitute a significant difference between the groups. No adverse effects related to exercise were reported.

Conclusion: This study shows that 8-week personalized exercise programs supervised by a physiotherapist can significantly improve the quality of life in individuals with MASH. Personalized exercise programs deserve greater focus in research, and exercise professionals should be integrated into the multidisciplinary care team for the clinical follow-up of patients diagnosed with MASH.

MAFLD: EPIDEMIOLOGICAL PROFILE AND FIBROSCAN® ASSESSMENT

A. Berradouane El Idrissi[1], M. Salihoun[1], H. Khlifa[1], I. Serraj[1], A. Mohamed[1], F. Bouhamou[1], S. Elaoula[1], N. Kabbaj[1]

[1]Ibn Sina Hospital, Mohammed V University, Hepato-Gastroenterology Digestive Functional Explorations Department, Rabat, Morocco

Contact E-Mail Address: asmaeberradouaneelidrissi@gmail.com

Introduction: Metabolic dysfunction-associated fatty liver disease (MAFLD) is the hepatic manifestation of a systemic metabolic disorder and is currently the leading cause of liver disease worldwide. Though often asymptomatic and slow to progress, MAFLD can lead to severe complications such as cirrhosis, hepatocellular carcinoma, and the need for liver transplantation in certain high-risk patients.

Aims & Methods: This study aims to describe the epidemiological, clinical, biological, and imaging characteristics of MAFLD, with a focus on FibroScan® results.

A retrospective cross-sectional study was conducted from August 2021 to December 2024, including 85 patients diagnosed with MAFLD and referred for FibroScan® to assess hepatic fibrosis and/or steatosis.

Results: Among 490 patients undergoing FibroScan®, 85 (17%) had MAFLD. The average age was 53 years (range: 20–72), with a female predominance (74%, sex ratio M/F: 0.3).

Metabolic syndrome were present in 90% of cases: hypertension (26.8%), type 2 diabetes (31.7%), dyslipidemia (13.4%), BMI overweight (43%), and obesity (41%).

Clinically, 78% were asymptomatic. Other reported symptoms included hepatic colic (15.8%), asthenia (1.2%), and nonspecific abdominal pain (4.8%).

Biological abnormalities (cholestasis and/or cytolysis) were found in 35.3% of patients, while 64.6% had normal liver function tests.

Abdominal ultrasound revealed steatosis in 81% of cases, hepatomegaly in 11%, heterogeneous liver in 2.4%, and a normal liver in 4.8%.

Reliable FibroScan® results were obtained using the M probe in 72% of patients; the XL probe was required in 28%.

The mean liver stiffness was 5.2 kPa: 90.2% had F0–F1 fibrosis, 9.7% had F2, with three cases of advanced fibrosis (F3–F4). The mean CAP value was 290 dB/m, with steatosis grades distributed as follows: S0 (19.5%), S1 (17%), S2 (17%), and S3 (46.3%).

Conclusion: MAFLD is a highly prevalent and often benign disease, but it carries the potential for serious complications, notably cirrhosis and hepatocellular carcinoma. Given its typically silent progression, non-invasive tools like FibroScan® play a key role in early detection and monitoring. Management is primarily preventive, focusing on addressing underlying metabolic risk factors.

ZONULIN LEVEL AS A RISK FACTOR FOR NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH DYSLIPIDEMIA

K. Kvit[1], N. Kharchenko[2], V. Prysyazhnyuk[3]

[1]Danylo Halytsky Lviv National Medical University, Therapy No1 and Medical Diagnostics, Lviv, Ukraine, [2]National Medical Academy of Postgraduate Education by P. Shupyk, Gastroenterology, Kyiv, Ukraine, [3]Bukovinian State Medical University, Chernivtsi, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: Increased intestinal permeability, mediated by zonulin, has been implicated in the pathogenesis of insulin resistance, dyslipidemia, and non-alcoholic fatty liver disease (NAFLD). Small intestinal bacterial overgrowth (SIBO) may further contribute to metabolic dysfunction through endotoxin-induced inflammation.

Aims & Methods: The aim was to determine zonulin concentrations in patients with dyslipidemia and NAFLD and analyze their relationships with metabolic parameters and the prevalence of small intestinal bacterial overgrowth (SIBO). A total of 342 patients with dyslipidemia were enrolled; NAFLD was confirmed in 152 of them based on ultrasound and steatometry. Fecal zonulin levels were measured using ELISA; SIBO was assessed by hydrogen breath test. Lipid profiles, high-sensitivity C-reactive protein (hsCRP), and HDL-C levels were also analyzed.

Results: Zonulin levels in patients with NAFLD (115±2.76 ng/g) exceeded the normal range (≤107 ng/g), compared to 87±0.28 ng/g in the dyslipidemia group without NAFLD (p<0.05). SIBO was present in 45% of dyslipidemic patients and 53.2% of those with NAFLD. A positive correlation was found between zonulin and hsCRP (r=0.65) and triglycerides (r=0.58), and a negative correlation between SIBO and HDL-C (r=–0.78) in the dyslipidemia group.

Conclusion: Elevated zonulin and increased intestinal permeability are associated with higher cardiometabolic risk in patients with NAFLD and dyslipidemia. Both zonulin and SIBO may serve as potential therapeutic targets for preventing progression of NAFLD and related metabolic disturbances.

Disclosure: Nothing to disclose.

Contact E-Mail Address: akskris88@gmail.com

Introduction: Nonalcoholic fatty liver disease (NAFLD) is a widespread metabolic disorder associated with intestinal dysbiosis, low-grade systemic inflammation, and small intestinal bacterial overgrowth (SIBO). Targeting the gut-liver axis through microbiome-modulating therapies may represent a promising approach to disease management.

Aims & Methods: The aim was to investigate gut microbiota alterations in NAFLD patients and assess the efficacy of microbiota-based therapy on metabolic, inflammatory, and structural liver parameters. The study included 152 NAFLD patients and 47 controls. Gut microbiota composition was evaluated using qRT-PCR, and SIBO was diagnosed via hydrogen breath testing. The therapeutic protocol included rifaximin (200 mg TID for 14 days), *Saccharomyces boulardii* CNCM I-745 (1 capsule BID for 30 days), and essential phospholipids (600 mg TID for 30 days). Liver function tests, inflammatory markers, and steatometry were assessed before and after treatment.

Results: Alterations in gut microbiota composition indicative of dysbiosis—including increased Firmicutes/Bacteroides ratio and Actinobacteria abundance—were identified in NAFLD. Strong correlations emerged between the F/B index and triglycerides ($r = 0.78$), TNF-α ($r = 0.77$), and between Actinobacteria and hsCRP ($r = 0.66$).

SIBO rates declined significantly post-treatment (51% → 17%). Liver enzymes, inflammatory markers, and steatometric parameters improved substantially ($p<0.05$).

Conclusion: Microbiota-targeted therapy combining rifaximin, *S. boulardii*, and phospholipids effectively corrected dysbiosis, reduced inflammation, improved metabolic parameters, and promoted liver structural recovery in NAFLD patients. These findings support incorporating microbiome-focused interventions into routine clinical practice for NAFLD.

MODULATING THE GUT-LIVER AXIS: PROBIOTIC THERAPY FOR MASLD MANAGEMENT

K. Kvit[1], N. Kharchenko[2], V. Kharchenko[3], M. Aksentiychuk[1]
[1]Danylo Halytsky Lviv National Medical University, Therapy No1 and Medical Diagnostics, Lviv, Ukraine, [2]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine, [3]National Medical Academy of Postgraduate Education by P. Shupyk, Gastroenterology, Kyiv, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD), formerly known as nonalcoholic fatty liver disease (NAFLD), has emerged as one of the leading causes of chronic liver disease worldwide. MASLD is closely associated with components of metabolic syndrome, including obesity, insulin resistance, dyslipidemia, and hypertension. The role of gut microbiota dysbiosis in MASLD pathogenesis is increasingly recognized, with microbial imbalance contributing to systemic inflammation and metabolic disturbances.

Aims & Methods: The aim was to determine gut microbiota composition in patients with MASLD and evaluate the impact of probiotic therapy on metabolic, inflammatory, and lipid parameters. The study included 152 patients diagnosed with MASLD.

Diagnosis was based on clinical, laboratory, and imaging findings, including ultrasound and steatometry, alongside cardiometabolic risk factors. Gut microbiota composition was evaluated using quantitative real-time PCR (qRT-PCR). Patients received a combined probiotic therapy containing *Saccharomyces boulardii* CNCM I-745, *Lactobacillus acidophilus* (LA-5), and *Bifidobacterium lactis* (BB-12). Changes in biochemical markers, lipid profiles, inflammatory parameters, and gut microbiota composition were assessed before and after therapy.

Results: At baseline, patients with MASLD demonstrated gut microbiota dysbiosis, characterized by an increased proportion of Firmicutes (50.3%) and Actinobacteria (15.34%), and an elevated Firmicutes/Bacteroides (F/B) index (5.02). Following probiotic therapy, significant improvements were observed: the proportions of Firmicutes and Actinobacteria decreased, the F/B index was reduced, and levels of ALT, AST, high-sensitivity C-reactive protein (hsCRP), total cholesterol, and triglycerides declined, while HDL-C levels increased. Positive correlations were identified between elevated Firmicutes and Actinobacteria and markers of cardiometabolic risk, such as hsCRP and triglycerides.

Conclusion: Gut microbiota dysbiosis is strongly associated with metabolic and inflammatory disturbances in MASLD. Combined probiotic therapy effectively corrected microbial imbalance, reduced systemic inflammation, and improved metabolic and lipid parameters. These findings support the role of microbiota-targeted interventions as an adjunctive approach in the comprehensive management of MASLD.

Disclosure: Nothing to disclose.

FROM DYSLIPIDEMIA TO MASLD: ZONULIN AS A MISSING LINK

K. Kvit[1], N. Kharchenko[2], E. Skyarov[3], V. Prystai[3], V. Kischak[4], M. Yakymiv[4]
[1]Danylo Halytsky Lviv National Medical University, Therapy No1 and Medical Diagnostics, Lviv, Ukraine, [2]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine, [3]Damylo Halytsky Lviv National Medical University, Lviv, Ukraine, [4]Gastrolife Clinic, Lviv, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD), formerly referred to as non-alcoholic fatty liver disease (NAFLD), and dyslipidemia are among the most common metabolic disorders worldwide. Disruption of intestinal barrier integrity, as reflected by elevated zonulin levels, has been implicated in insulin resistance and lipid metabolism disorders, contributing to the pathogenesis of MASLD.

Aims & Methods: The aim was to evaluate fecal zonulin levels in patients with dyslipidemia and MASLD, and to explore their potential role as risk factors for disease development and progression. The study included 342 patients with dyslipidemia, among whom MASLD was diagnosed in 152 cases based on ultrasound and steatometry findings. Fecal zonulin levels were measured by ELISA. Small intestinal bacterial overgrowth (SIBO) was diagnosed using hydrogen breath testing. Correlations between zonulin, inflammatory markers (high-sensitivity C-reactive protein, hsCRP), lipid profiles, and SIBO prevalence were analyzed.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: SIBO was detected in 45% of patients with dyslipidemia and 53.2% of patients with MASLD. Fecal zonulin levels in patients with MASLD (115±2.76 ng/g) significantly exceeded the normal upper limit (≤107 ng/g) and were higher compared to patients without steatosis. Zonulin levels positively correlated with hsCRP (r=0.65, p<0.05) and triglycerides (r=0.58, p<0.05). A strong negative correlation was observed between SIBO presence and HDL-C levels (r=–0.78, p<0.05) in patients with dyslipidemia.

Conclusion: Elevated zonulin levels and increased intestinal permeability are closely associated with systemic inflammation and lipid metabolism disturbances in MASLD. Zonulin and SIBO may represent novel therapeutic targets for the prevention and treatment of MASLD and metabolic disorders.

Disclosure: Nothing to disclose.

FIRMICUTES, ACTINOBACTERIA, AND THE DECLINE OF AKKERMANSIA: MICROBIAL MARKERS IN MASLD

K. Kvit[1], N. Kharchenko[2], V. Vdovychenko[1]
[1]Danylo Halytsky Lviv National Medical University, Therapy No1 and Medical Diagnostics, Lviv, Ukraine, [2]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD), formerly known as nonalcoholic fatty liver disease (NAFLD), is one of the most common chronic liver conditions worldwide. Alterations in gut microbiota composition and impaired gut barrier function are increasingly recognized as key contributors to MASLD development and progression.

Aims & Methods: The aim was to assess the gut microbiota composition in patients with MASLD and to evaluate its role in the development and progression of the disease. The study included 152 patients diagnosed with MASLD (mean age 46.5±0.89 years) and 150 control subjects without liver pathology (mean age 48.36±0.97 years). MASLD was diagnosed using liver ultrasound, hepatorenal index evaluation, and identification of cardiometabolic risk factors. Gut microbiota composition was analyzed by quantitative real-time PCR, focusing on the abundance of Firmicutes, Actinobacteria, Bacteroidetes, and Akkermansia muciniphila.

Results: Patients with MASLD demonstrated significantly increased levels of Firmicutes (50.3±2.46%) and Actinobacteria (15.34±2.87%) compared to controls (25.17±1.51% and 10.9±1.87%, respectively), alongside a higher Firmicutes/Bacteroides (F/B) index (5.02±2.61 vs. 2.1±1.74). The presence of Akkermansia muciniphila was substantially reduced in MASLD patients (33%) compared to the control group (63%).

Positive correlations were found between Actinobacteria levels and the F/B index (r=0.75, p≤0.05), as well as between the F/B index and triglyceride levels (r=0.68, p≤0.05). A negative correlation was observed between the presence of Akkermansia muciniphila and MASLD diagnosis (r=–0.69, p≤0.05).

Conclusion: MASLD patients show profound dysbiosis characterized by an increase in Firmicutes and Actinobacteria, an elevated F/B index, and a reduction in Akkermansia muciniphila abundance, indicating compromised gut barrier integrity. Akkermansia muciniphila may play a protective role against MASLD progression, highlighting the potential of microbiome-targeted therapies to prevent or mitigate disease development.

Disclosure: Nothing to disclose.

PP0863

FERRITIN PREDICTS LIVER FIBROSIS IN STEATOSIS: A READILY AVAILABLE, UNDERUSED MARKER BEYOND INFLAMMATION

Y. Dendane[1], M. Benderrou[1], O. Elmqaddem[1], H. Koulali[1], Z. Abdelkrim[1], Z. Ismaili[1], G. Kharrasse[1]
[1]Faculty of Medicine and Pharmacy/University Hospital Center Mohammed VI, Hepatology and Gastroenterology, Oujda, Morocco

Contact E-Mail Address: dendane.youness@gmail.com

Introduction: With the global rise in metabolic liver disease, there is an urgent need for scalable and affordable tools to detect liver fibrosis early—particularly in settings where elastography is unavailable. Ferritin is widely available and routinely tested, yet its potential role in liver fibrogenesis remains under-recognized. We hypothesized that in patients with hepatic steatosis, elevated ferritin reflects fibrotic remodeling independently of systemic inflammation or metabolic comorbidities.

Aims & Methods: To determine whether hyperferritinemia independently predicts significant fibrosis in steatotic patients, beyond inflammatory and metabolic factors, and to assess the consistency of this association across age and sex subgroups. This retrospective monocentric study included adults diagnosed with hepatic steatosis by ultrasound between January 2020 and December 2024.

- Exclusion criteria: secondary causes of liver disease (alcohol >20 g/day, viral hepatitis, drug-induced steatosis), and factors affecting ferritin (active infection, malignancy, recent transfusion).
- Significant fibrosis: FIB-4 ≥1.0, per AASLD and EASL guidelines for early detection.
- Hyperferritinemia: serum ferritin >90 ng/mL, based on internal cut-offs linked to early fibrotic progression.
- Demographic, metabolic, and inflammatory data—including CRP—were collected. Subgroup analyses were conducted by age (<50 vs. ≥50) and sex. ROC curves and multivariate logistic regression were used to assess predictive value.

Results: Ninety-nine patients were included (mean age 51.9 ± 13.2 years; 74% female; mean BMI 30.8 kg/m^2). Metabolic comorbidities included diabetes (38%), hypertension (23%), and dyslipidemia (18%). Hyperferritinemia was found in 48.5%, associated with older age (p=0.027), but similar BMI and metabolic profile. Significant fibrosis (FIB-4 ≥1.0) was more frequent in this group (77% vs. 42%, p<0.001). Mean ferritin levels were higher in fibrotic patients (127 vs. 82 ng/mL, p=0.003), while CRP levels did not differ (p=0.78). In multivariate analysis, age (OR=1.04 per year, p=0.005), CRP (p=0.011), and ferritin >90 ng/mL (OR=2.9, 95% CI [1.2–7.3], p=0.021) were independently associated with fibrosis. Ferritin alone had an AUC of 0.72; its predictive value remained significant in both men (AUC=0.75) and women (AUC=0.69), and was strongest in patients <50 years (AUC=0.78). Combining ferritin with FIB-4 increased discriminative performance (AUC=0.76), suggesting complementary utility.

Conclusion: In hepatic steatosis, serum ferritin >90 ng/mL independently predicts significant liver fibrosis, even after adjusting for CRP and metabolic comorbidities. Ferritin—an inexpensive and underused biomarker—may serve as a pragmatic fibrosis signal in primary care or resource-limited hepatology settings. Its discriminative power in younger patients highlights its potential for early risk stratification.

These findings support the integration of ferritin into composite non-invasive scoring systems and pave the way for multicentric prospective validation. Incorporating ferritin into fibrosis screening workflows, including telemedicine triage, may reduce underdiagnosis and optimize care pathways in steatotic liver disease.

FROM DYSBIOSIS TO DISEASE: THE GUT MICROBIOME'S ROLE IN MASLD

K. Kvit[1], N. Kharchenko[2]
[1]Danylo Halytsky Lviv National Medical University, Therapy No1 and Medical Diagnostics, Lviv, Ukraine, [2]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD), formerly known as nonalcoholic fatty liver disease (NAFLD), is a widespread chronic liver condition closely associated with obesity, insulin resistance, and dyslipidemia. Recent evidence points to gut microbiota dysbiosis as a key player in MASLD pathogenesis, affecting intestinal barrier function and systemic inflammation.

Aims & Methods: The aim was to investigate gut microbiota composition in patients with MASLD and assess its association with disease progression and gut barrier dysfunction. A total of 152 MASLD patients and 150 matched controls without liver pathology were examined.

Diagnosis was confirmed by ultrasound and steatometry, alongside assessment of cardiometabolic risk factors. Gut microbiota composition was analyzed using real-time PCR, focusing on Bacteroidetes, Firmicutes, and Actinobacteria. Hydrogen breath testing was used to diagnose small intestinal bacterial overgrowth (SIBO), and the presence of *Akkermansia muciniphila* was evaluated as a marker of gut barrier integrity.

Results: MASLD patients demonstrated a significant increase in Firmicutes (50.3%) and Actinobacteria (15.3%) proportions compared to controls, with a higher Firmicutes/Bacteroidetes (F/B) ratio. SIBO was detected in 52% of MASLD patients versus 40.5% in controls ($p<0.05$). The presence of *Akkermansia muciniphila* was notably lower in MASLD patients (33%) compared to controls (63%), suggesting impaired gut barrier function.

Strong positive correlations were observed between Actinobacteria abundance and the F/B index ($r=0.75$, $p<0.05$), while *Akkermansia muciniphila* presence negatively correlated with MASLD development ($r=–0.69$, $p<0.05$).

Conclusion: Gut microbiota dysbiosis, characterized by elevated Firmicutes and Actinobacteria and reduced *Akkermansia muciniphila*, is closely associated with MASLD pathogenesis. The findings highlight the potential of microbiota-targeted interventions for improving gut barrier function and modifying disease progression in MASLD patients.

Disclosure: Nothing to disclose.

PREVALENCE, GENETIC CHARACTERIZATION, AND LABORATORY PROFILING OF ACUTE INTERMITTENT PORPHYRIA IN SOUTHWESTERN SERBIA: A CROSS-SECTIONAL STUDY

S. Sagdati[1], I. Corovic[1,2], S. Vucelj[1,2], S. Muratovic[1], L. Kacar[1], A. Zukorlic[1], D. Alic[1], A. Nurovic[1,2], M. Mahmutovic[1]
[1]General Hospital of Novi Pazar, Novi Pazar, Serbia, [2]Faculty of Medical Sciences, University of Kragujevac, Center for Molecular Medicine and Stem Cell Research, Kragujevac, Serbia

Contact E-Mail Address: ira.corovic@gmail.com

Introduction: Acute intermittent porphyria (AIP) is a rare autosomal dominant disorder of heme biosynthesis, characterized by neurovisceral attacks and biochemical accumulation of porphyrin precursors. Despite its clinical severity, AIP often remains underdiagnosed, particularly in regions without established genetic testing programs. To date, no epidemiological or genetic studies have assessed the burden of AIP in southwestern Serbia. This study aimed to determine the prevalence of AIP, confirm genetic mutations, and analyze clinical and laboratory profiles of affected individuals.

Aims & Methods: We conducted a cross-sectional study involving 30 patients with clinically and biochemically confirmed AIP from two cities in southwestern Serbia, covering a total population of 141,333 inhabitants. The study was conducted over a one-year period. Among the 30 patients, 25 underwent genetic testing, and all were confirmed as heterozygous carriers of pathogenic *HMBS* mutations. Urinary levels of delta-aminolevulinic acid (ALA), porphobilinogen (PBG), uroporphyrin, and coproporphyrin were measured.

Routine analysis including complete blood count and biochemical parameters was performed during asymptomatic periods. Demographic data, family history of porphyria, the annual frequency of attacks, and givosiran therapy use were documented.

Results: Among the 30 patients, 4 were male (13.3%) and 26 were female (86.7%). The mean age was 47.69 years (range: 24–80 years). Ten patients (33.3%) reported a positive family history of porphyria. Genetic testing confirmed *HMBS* heterozygosity in all 25 tested individuals (100%).

Out of the total, 27 patients (90%) experienced fewer than three attacks per year, while three patients (10%) had more than three attacks annually and were receiving treatment with givosiran. Three patients (10%) were diagnosed with hepatocellular carcinoma (HCC).

Urinary ALA and PBG levels were elevated across all patients. Routine laboratory analyses performed during asymptomatic periods generally fell within reference ranges; however, in a subset of patients, mild elevations of urea, total cholesterol, AST, and ALT were observed, along with decreased hemoglobin levels, suggesting underlying metabolic and hepatic alterations even in the absence of acute attacks.

The estimated prevalence of clinically and biochemically confirmed AIP in the studied population was approximately 21.2 cases per 100,000 inhabitants, and the prevalence of genetically confirmed AIP was approximately 17.7 cases per 100,000 inhabitants.

Conclusion: This study provides the first epidemiological and genetic data on AIP in southwestern Serbia, revealing a notable prevalence in the local population. Despite clinical remission, subclinical laboratory abnormalities, including elevated urea, cholesterol, AST, and ALT, as well as reduced hemoglobin levels, were detectable in a subset of patients.

A significant proportion of patients presented without a positive family history, emphasizing the importance of systematic screening. The association with hepatocellular carcinoma highlights the need for long-term surveillance.

Importantly, this study represents preliminary results from the first year of investigation. Further research is ongoing, as not all potential cases have been detected, and there is a clear need to expand genetic testing and clinical evaluation in this population to fully assess the burden and progression of AIP.

Disclosure: Nothing to disclose.

Contact E-Mail Address: 17301050336@fudan.edu.cn

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is preceding to severe hepatic disorders, characterized by a high global incidence and poor prognosis. Early identification of high-risk individuals is crucial, yet accurate, long-term predictive tools remain scarce.

Aims & Methods: This study aims to identify accurate long-term biomarkers and develop predictive models for MASLD using plasma proteomics.

We analyzed proteomics data of 37,966 participants without baseline MASLD from southern United Kingdom, using multivariable Cox regression to conduct protein selection and model development. The top-ranking proteins were combined with clinical data and polygenic risk scores to develop models. The models were internally validated through 1,000 times bootstrap resampling within the Southern UK cohort, and externally validated in a preclinical Northern UK cohort (n = 14,986) and an inception Southern China cohort (n = 100). Cumulative MASLD incidences were compared across baseline protein concentration quintiles, and temporal trends in protein levels were assessed.

Results: Of the 2,737 proteins analyzed, five emerged as robust predictors for MASLD incidence within 5 years: CDHR2 (AUC = 0.812), GGT1 (AUC = 0.797), FUOM (AUC = 0.791), KRT18 (AUC = 0.789) and ACY1 (AUC = 0.777). Participants with higher baseline levels of these proteins faced markedly increased risks of MASLD (HRs = 7.05 - 9.81).

In the Northern UK cohort, the combination of 5 proteins showed prominent validated predictive accuracy across different time frames: 5-year (AUC = 0.838), 10-year (AUC = 0.772), over 10-year (AUC = 0.742), all-time (AUC = 0.756).

Combined with clinical predictors, the predictive performance is further enhanced: 5-year (AUC = 0.904), 10-year (AUC = 0.848), over 10-year (AUC = 0.799), all-time (AUC = 0.822). In the Southern China Inception cohort, the 5-Protein Panel also showed an outstanding performance (AUC = 0.912).

Conclusion: Our study identified five key proteins, established and validated prominent predictive models of MASLD up to more than 16 years before onset, offering novel potential strategies for ultra-early prediction and intervention.

Disclosure: Nothing to disclose.

WEIGHTING THE TRUTH: HOW OBESITY CHALLENGES FIBROSCAN® RELIABILITY IN FIBROSIS ASSESSMENT

Y. Dendane[1], O. El Mqaddem[1], H. Koulali[1], Z. Abdelkrim[1], G. Kharrasse[1], Z. Ismaili[1]
[1]Faculty of Medicine and Pharmacy/University Hospital Center Mohammed VI, Hepatology and Gastroenterology, Oujda, Morocco

Contact E-Mail Address: dendane.youness@gmail.com

Introduction: Non-invasive assessment of liver fibrosis is central to managing chronic liver disease. FibroScan® (transient elastography), FIB-4, and APRI are widely used, but obesity may impair FibroScan® performance by altering probe penetration and signal quality, particularly in metabolic liver disease. This may lead to fibrosis overestimation and inappropriate clinical decisions.

Aims & Methods:

This study aimed to evaluate the concordance between FibroScan®, FIB-4, and APRI in assessing advanced liver fibrosis, stratified by BMI, and to identify predictors of diagnostic discordance—particularly in obese patients where FibroScan® performance may be compromised.

We retrospectively included 120 consecutive patients with valid FibroScan® measurements (≥10 acquisitions, IQR/median <30%) and available FIB-4, APRI, and BMI data. Patients with confounders (ascites, cytolysis ≥3× ULN, cholestasis, or hepatic mass) were excluded.

Advanced fibrosis was defined using validated thresholds:

- FibroScan® ≥10.5 kPa (AASLD/EASL)
- FIB-4 >2.67
- APRI ≥1.5
- Concordance between FibroScan® and FIB-4 was assessed via weighted kappa, APRI serving as a third comparator. Patients were stratified by BMI (<30 vs ≥30 kg/m^2). Predictors of discordance were analyzed using logistic regression.

Results: Among 120 patients (mean age 47.2 ± 14.5 years; 55% female; mean BMI 26.3 ± 4.9 kg/m^2), 63% were non-obese. Advanced fibrosis was diagnosed in 34% (FibroScan®), 28% (FIB-4), and 20% (APRI).

In non-obese patients (n=76), concordance between FibroScan® and FIB-4 was strong (κ = 0.75), with only 11.2% discordance. APRI confirmed FibroScan® classification in 87% of cases.

In obese patients (n=44), concordance dropped sharply (κ = –0.27), with 63.6% discordance. APRI also poorly agreed with FibroScan® (κ = 0.09), reinforcing the discordance. Most discrepancies involved FibroScan® indicating advanced fibrosis not supported by serum markers.

Logistic regression confirmed BMI ≥30 as an independent predictor of discordance (OR 2.63; 95% CI 1.55–4.67; p < 0.001); age and sex were not associated.

Conclusion: FibroScan®, FIB-4, and APRI show good concordance in non-obese patients. However, obesity significantly impairs FibroScan® reliability, leading to frequent fibrosis overestimation. These findings support BMI-adapted strategies, including XL probe use or integration of serum markers, to improve diagnostic accuracy in metabolic liver disease.

Disclosure: Nothing to disclose.

PP0868

METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) IN TYPE 2 DIABETES MELLITUS: PREVALENCE, RISK FACTORS, AND IMPACT ON DIABETIC COMPLICATIONS

O. Ghallab[1], L. Elidrissi[1], F. Haddad[1], Z. Boukhal[1], F.Z. Elrhaoussi[1], M. Tahiri Joutei Hassani[1], W. Hliwa[1], A. Bellabah[1], W. Badre[1], H. Sabaoui[2], M. Iggar[2], N. Haraj[2], S. Elaziz[2], A. Chadli[2]
[1]Ibn Rochd Hospital Center, Gastroenterology, Casablanca, Morocco, [2]Ibn Rochd Hospital Center, Endocrinology, Casablanca, Morocco

Contact E-Mail Address: l.lailaelidrissi@gmail.com

Introduction: Metabolic Dysfunction–Associated Steatotic Liver Disease (MASLD) is currently the leading cause of chronic liver disease worldwide, affecting more than 65% of patients with Type 2 Diabetes Mellitus (T2DM).

The aim of our study was to determine the prevalence of MASLD among T2DM patients, with or without coexisting significant fibrosis, to assess its association with diabetic complications, and to identify the factors linked to MASLD in our population.

Aims & Methods: We conducted a retrospective, descriptive, and analytical study including T2DM patients admitted to the Endocrinology Department in 2019. MASLD diagnosis was based on the presence of hepatic steatosis detected by abdominal ultrasound or a Hepatic Steatosis Index (HSI) >36. Fibrosis was assessed using the Fibrosis-4 (FIB-4) index (with a threshold of ≥1.3 or <1.3). Chronic Kidney Disease (CKD) associated with T2DM was defined by an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 and/or dipstick-positive proteinuria (>1+). Diabetic Peripheral Neuropathic Pain (DPNP) was assessed using the Douleur Neuropathique 4 (DN4) questionnaire, and Diabetic Retinopathy was diagnosed via dilated eye examination.

Results: Among the 202 patients included, the median age was 57 years (±12 years) with a marked female predominance (sex ratio = 2.6). Regarding comorbidities, 58.4% of patients had hypertension and 34.2% had dyslipidemia. The median Body Mass Index (BMI) was 27 kg/m^2 (±5.62), with overweight or obesity present in 61.4% of the cohort. The median duration of diabetes was 10 years (±7.8 years). Impaired renal function (eGFR <60 ml/min/1.73 m^2) was found in 9.9% of patients, and proteinuria in 6.9%. Diabetic neuropathy (DN4 score ≥4) was present in 7.9% of patients, while diabetic retinopathy was diagnosed in 37.6% of cases.

The prevalence of MASLD in our cohort was 73.3%. The median FIB-4 score was 0.91 (±0.63), with 25.7% of patients presenting a FIB-4 >1.3. Statistical analysis identified several factors significantly associated with the presence of MASLD: female sex (p=0.004), dyslipidemia (p=0.004), BMI (p<0.001), alanine aminotransferase (ALT) levels (p<0.001), low-density lipoprotein cholesterol (LDL-C) levels (p=0.006), and triglyceride levels (p=0.013). In particular, higher BMI was strongly associated with MASLD (Odds Ratio [OR] = 1.970; 95% Confidence Interval [CI]: 1.580–2.460; p<0.001), as were elevated ALT levels (OR = 1.115; 95% CI: 1.053–1.18; p<0.001).

However, after adjustment, LDL-C levels (p=0.163), triglycerides (p=0.402), dyslipidemia (p=0.329), and sex (p=0.360) were no longer significantly associated with MASLD. Finally, a significantly higher proportion of CKD was observed in patients with MASLD (22.3%) compared to those without MASLD (9.2%, p=0.036), although this association was not maintained in the subgroup with advanced fibrosis (FIB-4 >1.3).

Conclusion: Our study confirmed the high prevalence of MASLD among patients with T2DM. Early screening is therefore essential, particularly in female patients and in those presenting with chronic kidney disease or other associated cardiometabolic risk factors such as obesity and dyslipidemia.

Introduction: Tuberculosis is the second leading cause of death from a single infectious agent, following COVID-19. It is a curable disease when treated properly with a combination of several antitubercular drugs over several months. Hepatotoxicity is a major side effect of antitubercular treatment, ranging from transient elevations in liver enzymes to acute liver failure.

Our study aimed to assess the prevalence of antitubercular drug-induced hepatotoxicity and its associated risk factors in digestive tuberculosis.

Aims & Methods: We conducted a retrospective study including 87 patients who were consecutively treated for peritoneal, intestinal, or hepatic tuberculosis in our department from January 2, 2018, to December 31, 2024. Patients with underlying chronic liver disease were excluded from the study. Hepatotoxicity was diagnosed when liver enzyme levels exceeded five times the normal without symptoms, or more than three times the normal with clinical symptoms, after excluding other potential causes of liver injury. A combined HRZE regimen was defined as a fixed-dose combination of isoniazid (INH), rifampicin, ethambutol, and pyrazinamide.

Results: The mean age at diagnosis was 47 years [range 15-83 years], with a female predominance (F/M sex ratio = 2.8). Metabolic syndrome was present in 14.9% of cases, and malnutrition in 33.3%. Peritoneal tuberculosis was found in 78.7% of cases, intestinal tuberculosis in 16.7%, and hepatic tuberculosis in 4.6%. Histology confirmed diagnosis in 96.5% of cases. A combined HRZE regimen was prescribed in 82.8% of cases, and a fractionated regimen in 17.2%. An INH acetylation test was conducted in 79.3% of cases, identifying a slow acetylation phenotype in 17.2%.

Fifteen patients developed hepatotoxicity (17.2% of cases). The average time to onset was 15 days [range 4-150 days]. Eight cases of acute liver injury were observed, with seven (87.5%) severe forms. No cases of acute liver failure were observed.

Hepatotoxicity was significantly associated with female gender (p=0.005), the presence of metabolic syndrome (p=0.004), malnutrition (p=0.001), and the slow acetylation phenotype of INH (p<0.0001).

Conclusion: Our study revealed a high prevalence of hepatotoxicity induced by first-line antitubercular treatment in digestive tuberculosis, with severe hepatic injury in the majority of cases. Therefore, it would be prudent to tailor treatment based on the INH acetylation test, particularly for women, as well as individuals with metabolic syndrome or malnutrition.

Introduction: Methotrexate (MTX) remains the cornerstone of treatment for rheumatoid arthritis (RA) and psoriatic arthritis (PsA), yet concerns about hepatotoxicity often lead to premature discontinuation.

Aims & Methods: This study aimed to reassess the risk of liver fibrosis in long-term methotrexate therapy and to identify clinical, metabolic, and treatment-related factors associated with hepatic changes. This was a prospective cohort study including 201 patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA) undergoing MTX therapy for ≥6 months. Liver stiffness was assessed using transient elastography (Fibroscan®) and acoustic radiation force impulse (ARFI). Hepatic steatosis was evaluated using the controlled attenuation parameter (CAP). Serum-based indices (FIB-4, APRI) were calculated.

Clinical and metabolic data—including BMI, waist/hip circumference, lipid profile, glucose, comorbidities, and alcohol use (B-peth)—were collected. Associations with liver parameters were analyzed using Spearman correlation and multivariable linear regression adjusted for age, sex, and diagnosis.

Results: Liver stiffness values were generally low, with minimal fibrosis detected by Fibroscan (median 4.7 kPa) and ARFI (median 2.85 kPa). ARFI and Fibroscan values showed weak but significant correlation ($\rho = 0.19$, $p = 0.03$). APRI, but not FIB-4, modestly correlated with both imaging modalities.

Multivariable regression identified no independent predictors of increased liver stiffness. In contrast, CAP-measured steatosis was significantly associated with higher BMI ($p = 0.002$) and waist circumference ($p = 0.001$), while MTX dose, duration, and alcohol intake (B-peth) showed no associations. Principal component analysis confirmed that steatosis clustered with metabolic rather than pharmacologic variables.

Conclusion: In this real-world cohort, significant liver fibrosis was rare despite prolonged MTX exposure. Hepatic steatosis, rather than fibrosis, emerged as the dominant hepatic alteration, driven primarily by modifiable metabolic risk factors.

These findings support the use of targeted metabolic assessment and intervention in MTX-treated patients rather than routine discontinuation based on fibrosis concern.

IMPACT OF HAVING A FIBROSCAN-BASED BIOFEEDBACK ON ALCOHOL CONSUMPTION: A QUALITATIVE ANALYSIS OF ALCOHOL RECOVERY NARRATIVES AND INTERVIEWS

M. Subhani[1], A. Sheikh[1], K. Jones[2], S. Rennick-Egglestone[2], A. Sheth[1], S. Ryder[1]
[1]University Hospitals Nottingham and University of Nottingham, Gastroenterology, Nottingham, United Kingdom, [2]University Hospitals Nottingham and University of Nottingham, Institute of Mental Health, Nottingham, United Kingdom

Contact E-Mail Address: aneeqa.shaikh@nhs.net

Introduction: Providing people who have alcohol use disorder (AUD) with feedback about their liver (biofeedback using Fibroscan) may influence their drinking behaviour. It is unclear if and how having a Fibroscan may support behaviour change. There are also questions about how receiving a 'normal' result influences an individual's feelings about their alcohol use.

Aims & Methods: This qualitative study aimed to explore people's experiences of receiving different Fibroscan results and the impact they felt it had on them. Seventeen qualitative transcripts (11 recovery narratives, 6 post-trial interviews) from the KLIFAD trial (ISRCTN16922410) were analysed. An initial realist programme theory of a complex intervention was produced using the literature and other psychological theories of behaviour change to predict how the Fibroscan may influence behaviour change.

A deductive qualitative analysis was conducted to find evidence for an initial programme theory of how the KLIFAD intervention may influence alcohol-related behaviour change. Initial ideas in the programme theory were amended based on qualitative insights.

Results: Of these participants, ten were ≥50 years of age, nine were male, 14 were white and three were of minority ethnicity, most were heavy drinkers. Fibroscan results ranged from normal (≤7 kPa=9), intermediate (8–14 kPa=4) to high (≥15 kPa=4).

At follow-up ten reported abstinence and seven reduction in alcohol consumption, none reported increased consumption. Fibroscan was seen by some participants as an opportunity (or a privilege not all get to have) to find out about their health, and a chance to "see inside what is going on". Those reflecting on receiving high scores described it as a *shock*, *rock bottom*, or an *instant turning point*. Most receiving normal results felt reassured and saw it as an opportunity to change their behaviour. Reducing the score by reducing alcohol use was described as a motivator for three participants.

Not all participants (n=2) felt Fibroscan would help reduce alcohol use, often due to acute drinking, co-existing mental health diseases, hopelessness, or memory issues. Other factors influencing its impact included health priorities, loneliness, supportive relationships, age, symptoms such as pain, language barrier, stage of change, recognition of alcohol issues, and service engagement. One participant expressed guilt about self-inflicted harm when preparing for the test.

Conclusion: This study highlights the varied impact of Fibroscan biofeedback on alcohol-related behaviour change, influenced by individual circumstances such as mental health, readiness to change, and social support. High Fibroscan scores often prompted reflection and action, while normal scores reassured and motivated. Addressing barriers and stigma could enhance its effectiveness.

CHECKPOINT INHIBITOR-INDUCED LIVER INJURY IN PATIENTS WITH ADVANCED SKIN CANCER: A SINGLE-CENTER EXPERIENCE

A. Liguori[1], S. Archilei[1], L. Quattrini[1], F. Brunetti[1], M. Salvi[1], G. Marrone[1], M. Biolato[1], L. Miele[1], M. Pompili[1], A. Di Stefani[1], K. Peris[1], A. Gasbarrini[1], A. Grieco[1]
[1]Catholic University Of Sacred Heart, Rome, Italy

Introduction: Immune checkpoint inhibitors (ICIs) are now considered the first-line treatment for advanced melanoma and non-melanoma skin cancers. One of the most commonly reported adverse events is checkpoint inhibitor-induced liver injury (ChILI), which occurs in approximately 10% of patients. For those who develop ChILI, it remains uncertain whether permanent discontinuation of the drug is necessary or if treatment can be safely resumed after a temporary pause, either with the same agent or with a different class of ICI. This report shares our center's experience with ChILI in patients receiving care for skin neoplasms at a tertiary-level facility.

Aims & Methods: This study aimed to analyse the prevalence of ChILI among patients treated with ICIs for skin cancers at our center. We included retrospectively all consecutive patients admitted to our facility who received ICI therapy for advanced melanoma or non-melanoma skin cancer between June 2016 and April 2024. The diagnosis and severity of ChILI were evaluated using the CTCAE v5.0 criteria, and the type of liver injury was classified based on international guidelines. Liver function tests (LFTs) were collected at baseline, after three treatment cycles, and at the time of suspected ChILI onset. Data on ChILI management and outcomes were also collected.

Results: We enrolled 111 patients (32.4% female, median age 75 years), including 70 patients (63.1%) with advanced melanoma and 41 (36.9%) with locally advanced or metastatic cutaneous squamous cell carcinoma. Among them, 3 patients (2.7%) received first-line therapy with anti-CTLA-4, 106 (95.5%) with anti-PD-1, and 2 (1.8%) were treated with a combination of both. The median duration of therapy was 10 months (IQR 5–21). ChILI developed in 8 patients (7.2%) after a median of 14 treatment cycles (IQR 7–20). According to the CTCAE severity scale, one case was grade 2, three were grade 3, and four were grade 4.

Among those who developed ChILI, 3 patients tested positive for anti-nuclear antibodies (ANA), 1 had a positive extractable nuclear antigen (ENA) test, and 2 had a known autoimmune disorder prior to initiating ICI therapy. All patients discontinued ICIs upon ChILI onset. Liver function tests normalized spontaneously in 4 patients, while 4 required corticosteroid treatment. Four patients underwent drug rechallenge, and only one of them received a new class of ICI.

Regarding extrahepatic adverse events, ChILI patients more frequently exhibited diarrhea and dermatological manifestations such as papular or bullous rashes (37.5% and 50%, respectively), with a significantly higher prevalence compared to patients without ChILI (7.8% and 15.4%, respectively; $p < 0.05$).

No significant differences in liver function test results were observed at baseline or after the third infusion between patients who developed ChILI and those who did not ($p > 0.05$).

Conclusion: Our study confirms the occurrence of liver toxicity associated with ICI therapy in cancer patients, with an incidence rate consistent with current international literature. The median time to ChILI onset—typically after multiple treatment cycles—supports the hypothesis of an indirect, immune-mediated mechanism rather than a direct toxic effect on the liver.

Notably, we found that ChILI is often preceded by dermatological and/or gastrointestinal adverse events.

Although based on a limited patient cohort, this observation may serve as an important clinical signal, helping physicians to anticipate ChILI, intervene earlier, prevent progression to more severe presentations, and initiate appropriate management promptly.

EARLY BILIRUBIN DYNAMICS PREDICT PROGNOSIS IN SEVERE ALCOHOLIC HEPATITIS

A. Bargas Bárbara[1], D. Abrantes[1], A.C. Bravo[1], B. Abreu[1], C. Gouveia[1], M. Canhoto[1], E. Barjas[1], M.L. Gloria[1]
[1]Hospital Beatriz Ângelo, Gastroenterology, Lisboa, Portugal

Contact E-Mail Address: bargasandre2@gmail.com

Introduction: Alcoholic hepatitis (AH) is a severe liver disease with high short-term mortality, making prognostic factors essential for patient management. Recently, it has been proposed that the trajectory of bilirubin evolution may serve as a prognostic predictor and help identify patients who do not benefit from corticosteroid therapy (CT).

This study aimed to evaluate the role of bilirubin trajectory as a predictor of prognosis and its potential utility in guiding treatment decisions in patients with AH.

Aims & Methods: Retrospective study including AH patients hospitalized between 2017 and 2025 in our hospital. Based on bilirubin trajectory between admission and day 4, patients were categorized into three groups: 'fast fallers' (FF) (bilirubin <0.8 x admission), 'static' (ST) (bilirubin of >0.9 – <1.2 x admission) and 'rapid risers' (RR) (bilirubin of ≥1.2 x admission) [1]. A p-value of < 0.05 was considered significant.

Results: The study included 99 patients (median age: 55 years [IQR 48-62], 83.7% male, median BMI: 25 kg/m^2), with a median follow-up time of 359 days (IQR 65-1155). Cirrhosis was present in 80%. From total patients 36% were FF 59% were ST and 5% were RR; Mortality rate between FF vs ST+RR showed no significant differences at any time point (p>0.05). Additionally, corticosteroid therapy did not influence 90-day mortality in FF patients (18% vs. 27%, p=0.55).

Analyzing only the patients with severe AH (MELD > 20) (55% of the cohort), 16% were FF, and 65.5% received corticosteroids. Mortality rates between FF and ST+RR, in severe AH patients were as follows: 12.5 vs 28.2% at 30 days, 12.5 vs 41.1% at 60 days and 18.8 vs 46.2% at 90 days. In survival analysis, FF patients at day 4 had significantly better 90-day survival compared to other groups (log-rank p=0.05). Among FF patients, corticosteroid therapy did not impact mortality (16% vs 20%, p=0.8).

Conclusion: This study highlights the prognostic value of bilirubin trajectory at day 4 in patients with alcoholic hepatitis. Severe AH patients categorized as 'fast fallers' demonstrated significantly lower mortality compared to other subgroups and CT did not significantly impact survival outcomes in this patients, suggesting that bilirubin trajectory may serve as an early indicator of good prognosis.

PP0874

A NOVEL PROGNOSTIC MODEL TO PREDICT MORTALITY IN PATIENTS WITH DRUG INDUCED LIVER INJURY IN INTENSIVE CARE UNIT, A STUDY FROM TERTIARY CARE HOSPITAL, PAKISTAN

F. Kayani[1], J. Khan[1]
[1]Bolan University of Medical and Health Sciences, Gastroenterology, Quetta, Pakistan

Contact E-Mail Address: farhana_kayani@hotmail.com

Introduction: DILI is one of the causes of acute liver injury leading to increased mortality rates and usually requires intensive care unit (ICU) admission , however it is uncommon and often challenging to diagnose DILI. Proper prognosis for these patients is crucial for early referral for liver transplantation.

Aims & Methods: In light of the paucity of data on DILI especially from South East Asia, this study aims to evaluate the clinical spectrum and predictors of mortality in ICU admitted patients with suspected DILI by building and validating a novel scoring system.

462/231 cases were identified and categorized on basis of COIMS/RUCAM score[1] and the exclusion of other liver diseases. Ratio (R value) between ALT(Alanine transferase) and AP (alkaline phosphatase) expressed as R>5; hepatocellular, R<2;cholestatic, and R >2 <5;mixed. Clinical and laboratory parameters were analyzed to identify the predictors of hospital mortality. The prognostic values for mortality were assessed by ROC analysis. A novel model was developed and internally validated using fivefold cross-validation.

Results: Out of 231 patients, there were 133 (57.6%) males with the mean age being 50.83 years (range, 20-94 years). DILI was classified as definite or highly probable in 31.1%, probable in 62.5%, and possible in 7.4% of cases. Pattern of liver injury was hepatocellular in 25.1%, cholestatic in 56.17% and mixed in 18.72% of patients. Mean total bilirubin levels, ALT and AP levels were 5.37mg/dl, 358.65 IU/L and 168.68 IU/L respectively.

Antituberculous (ATT) drugs were found to be the most common cause (63.9%) followed by homeopathic or herbal meds (9.5%), antiarrhythmic drugs (8.7%), statins (7.3%), antibiotics (6.1%), antifungals (5.6%), chemotherapeutic agents (4.4%) and antiepileptics (1.7%). Altered mental status was present in 98 (21.6%) of patients while rest presented with abdominal pain, vomiting, jaundice & pruritus; 57.1%, 57.1%, 54.1%, and 42.3% respectively.

In-hospital mortality was 26.5% and prolonged hospital stay was observed in 35.93% of patients. On multivariate analysis mortality was significantly greater in patients with altered mental status, male gender, increased age, hepatocellular pattern of DILI, increased INR (>1.5), increased bilirubin levels(>3 mg/dl) and arterial gradient (A-a gradient).

The newly developed prognostic model, incorporating age,gender,pattern of liver injury, alveolar–arterial gradient (A-a gradient),INR, total bilirubin level, INR, and HE grades, exhibited significantly improved performance in predicting 1-month and 3-month mortality with AUROC of 0.863 and 0.829, respectively.

Likewise, prolonged hospital stay was associated with female gender, increased ALT, AST aspartate aminotransferase levels, and mixed pattern of DILI.

Conclusion: DILI leads to increased mortality, and use of this prognostic model predicting mortality in patients with drug induced liver injury in intensive care unit can be useful. However, further rigorous validation is required in other liver-related ICUs.

Disclosure: Nothing to disclose.

Introduction: Methotrexate (MTX) is a cornerstone in the treatment of rheumatoid arthritis (RA). However, its potential hepatotoxicity, combined with the high prevalence of metabolic comorbidities in RA patients, warrants careful monitoring.

Aims & Methods: This study aimed to assess the prevalence of liver fibrosis in RA patients treated with MTX using validated non-invasive biological scores.We conducted a cross-sectional descriptive study involving 71 RA patients. Clinical, biological, and therapeutic data were collected. Liver fibrosis was assessed using the FIB-4, APRI, and NAFLD fibrosis scores. Statistical analysis was performed with SPSS.

Results: The mean age was 56.1 ± 11.3 years, with a female predominance (F/M ratio = 3.23). Metabolic syndrome was present in 43% of patients, and 7% reported alcohol consumption. The mean BMI was 28.4 kg/m^2. The average DAS28 was 4.2, indicating moderate to high disease activity. The mean duration of MTX exposure was 8.5 years, with a mean cumulative dose of 5.2 g.

FIB-4 score showed a low fibrosis risk (<1.3) in 66.7% of cases, intermediate risk (1.3–2.67) in 27.8%, and high risk (>2.67) in 5.5%. The APRI score was <0.5 in 90.3% of patients and ≥0.5 in 9.7%. NAFLD fibrosis score was low (<–1.455) in 58.7%, indeterminate in 34.9%, and high (>0.675) in 6.4%. High-risk patients more frequently exhibited metabolic syndrome (p=0.01) and elevated DAS28 scores (p=0.03).

Conclusion: While most RA patients treated with MTX show a low biological risk of liver fibrosis, approximately 6–10% present a high-risk profile. These findings highlight the importance of regular liver fibrosis screening, particularly in patients with metabolic risk factors or active inflammatory disease.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ericauholanda@gmail.com

Introduction: Alcoholic hepatitis (AH) is a form of acute liver injury with significant morbidity and mortality. Several scoring systems have been developed and used to predict mortality, including Maddrey's discriminant function (MDF), model for end-stage liver disease (MELD) and modified MELD including sodium (MELD-Na).

Aims & Methods: We conducted a systematic review of Pubmed, Embase, Cochrane Library and Web of Science to compare the accuracy of these scores in AH mortality prediction. The inclusion criteria include studies evaluating MDF, MELD and MELD-Na prognostic models for mortality, either as an assessment of a single score or in combination in patients with alcohol-related hepatitis.

Results: The pooled sensitivity and specificity of MDF for mortality prediction in 28 days were 0.862 (95%CI 0.714–0.940) and 0.538 (95%CI 0.322–0.741), respectively. In 90 days were 0.862 (95%CI 0.714–0.940) and 0.538 (95%CI 0.322–0.741), respectively.

The pooled sensitivity and specificity of MELD for mortality prediction in 28 days were 0.809 (95%CI 0.676–0.896) and 0.753 (95%CI 0.636–0.842), respectively. In 90 days were 0.809 (95%CI 0.676–0.896) and 0.753 (95%CI 0.636–0.842), respectively.

The pooled sensitivity and specificity of MELD-Na for mortality prediction in 28 days were 0.707 (95%CI 0.520–0.842) and 0.679 (95%CI 0.474–0.832), respectively. In 90 days were 0.707 (95%CI 0.520–0.842) and 0.679 (95%CI 0.474–0.832), respectively. No significant statistical difference was observed when comparing AUC of these scores.

Conclusion: Our study demonstrated no statistical difference between the prognostic models used at the admission of a patient with alcoholic hepatitis.

Disclosure: Nothing to disclose.

Contact E-Mail Address: moga.tudor@yahoo.com

Introduction: Alcoholic liver cirrhosis (ALC) is a complex condition marked by numerous complications, often leading to a poor prognosis and high mortality rates. This study evaluates the clinical characteristics, causes of hospitalization, and factors associated with prolonged hospital stay and in-hospital mortality among patients with alcoholic liver cirrhosis.

Aims & Methods: A retrospective study was conducted on 357 patients diagnosed with alcoholic liver cirrhosis in a tertiary gastroenterology department. The mean age was 57.8 ± 9.8 years, and 85% were male. Data on causes of hospital admission, length of stay, and clinical complications were analyzed. Associations with prolonged hospitalization (defined as >3 days) and in-hospital mortality were assessed using univariate and multivariate statistical analyses.

Results: The overall in-hospital mortality rate was 21.5%. The most common causes of admission included urinary tract infections (57.7%), hepato-renal syndrome (28.2%), digestive hemorrhage (22.6%), acute alcoholic hepatitis (19.3%), spontaneous bacterial peritonitis (8.4%), and pulmonary infections (5.6%). The median hospital stay was 6.6 days.

Variables significantly associated with prolonged hospitalization in univariate analysis included ascites (p<0.0001), spontaneous bacterial peritonitis (p=0.01), hepatic encephalopathy (p<0.0001), urinary tract infections (p<0.0001), and hepato-renal syndrome (p=0.09). In multivariate analysis, only urinary tract infection was independently associated with prolonged hospital stay.

Regarding in-hospital mortality, significant associations in univariate analysis were found with spontaneous bacterial peritonitis (p<0.0001), acute alcoholic hepatitis (p<0.0001), digestive hemorrhage (p<0.0001), and hepato-renal syndrome (p<0.0001). In multivariate analysis, only hepato-renal syndrome remained independently associated with mortality (p<0.0001).

Conclusion: Urinary tract infection is an independent predictor of prolonged hospitalization in patients with alcoholic liver cirrhosis, while hepato-renal syndrome is the only independent predictor of in-hospital mortality. These findings highlight the importance of early recognition and management of infections and renal complications in this high-risk population.

Disclosure: Nothing to disclose.

POST TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT HEPATIC ENCEPHALOPATHY: PREDICTORS, EARLY PREVENTION AND MORTALITY

A. Rozenfeld[1], N. Zmora[1], O. Shibolet[1], H. Katchman[1], L. Rabinowich[1]
[1]Tel Aviv Medical Center, Gastroenterology, Tel Aviv, Israel

Contact E-Mail Address: annaroz7@gmail.com

Introduction: Hepatic encephalopathy (HE) after Transjugular Intrahepatic Portosystemic Shunt (TIPS) affect 35-50% of patients. The use of prophylactic agents (Lactulose and Rifaximin) to prevent post-TIPS HE remains controversial and currently not recommended by professional guidelines. Our aim was to assess real world practice and identify potential predictors for post-TIPS HE and benefit from post-TIPS prophylaxis.

Aims & Methods: Retrospective cohort study of patients undergoing TIPS at the Tel-Aviv Medical Center (2016-2024). The primary outcome was overt HE, with secondary outcomes of liver transplantation (LT) and mortality.

Results: Seventy-nine patients underwent TIPS, median age was 60 years and 52% were male. Primary liver disease was metabolic dysfunction-associated steatohepatitis (MASH) in 34%, viral (20%), and alcohol-related liver disease (ALD) (16.5%). Indications for TIPS were variceal bleeding (52%) and refractory ascites (38%). Prior to the procedure 31% had ≥ 1 episodes of HE, 21.5% were treated with Lactulose and/or Rifaximin, and 58% were on betablocker treatment. At the time of the procedure, the patient's Child-Pugh score was A/B/C in 19%/66%/11% respectively, with a median

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. MELD-Na of 10.9. Median follow up was 22.75 months. Overall, 22 patients died during follow-up and 8 underwent liver transplantation. 45 patients (57%) developed post-TIPS HE, 60% of them during the first three months. Early post-TIPS HE treatment was given to 49%: 10% Lactulose, 5% Rifaximin, and 34% both. Among those patients, 44% were previously (pre-TIPS) on HE treatment. Development of HE was not predicted by pre-or post-TIPS MELD-Na or Child-Pugh score, TIPS diameter, postTIPS gradient, or post-procedure ammonia levels. Rates of HE also did not differ according to initial prophylaxis treatment (59% with treatment, 56% without, p=1). Pre-TIPS AST and albumin were associated with post-TIPS HE (36.6U/L vs. 60.44 U/L, p=0.03; 34.6g/dl vs. 31.8g/dl, p = 0.05). Prior beta-blocker treatment was associated with post-TIPS HE (14% vs 32%, p = 0.01) but not varices as the indication for TIPS. Mortality rate was not affected by the occurrence of post-TIPS HE (28% among those who developed HE vs. 26% among those who didn't, p = 1).

Conclusion: Early post-TIPS preventive treatment was mostly given to patients previously treated with Lactulose/Rifaximin, however it did not affect the rate of post-TIPS HE. Development of HE did not increase mortality.

ARGININE MODIFIED BY STENOTROPHOMONAS MALTOPHILIA PROMOTES SPONTANEOUS BACTERIAL PERITONITIS BY INHIBITING CD8⁺ T CELL EFFECTOR FUNCTION

Z. Chen[1], S. Liao[1], L. Zhou[1], Q. Tang[1], S. He[1], Z. Zhou[2]

Introduction: Spontaneous bacterial peritonitis(SBP) is the most common type of infection in patients with cirrhosis, with high mortality and recurrence rates[1].

The intestinal immune barrier is an important link in blocking intestinal bacterial translocation[2-3], but the mechanism of immune barrier changes in SBP in cirrhosis is unclear. The gut microbiota influences antitumor immunity by producing immunomodulatory metabolites[4].

However, microbial consumption of multiple metabolites may also influence host immune responses[5].

Here, we investigated the role of Stenotrophomonas maltophilia and its metabolites in the development of SBP.

Aims & Methods: We detected the bacterial composition of ascites and stool in patients with spontaneous bacterial peritonitis by 16S sequencing. The Stenotrophomonas maltophilia-SBP rat model was established by oral administration of carbon tetrachloride and Stenotrophomonas maltophilia. Metabolomics analysis was performed by liquid chromatography-mass spectrometry and single-cell sequencing was used to analyze changes in intestinal cell composition and gene expression. The biological functions of Stenotrophomonas maltophilia-conditioned medium and metabolites were determined in rat CD8⁺T cells.

Results: 16S sequencing found that the abundance of Stenotrophomonas maltophilia in SBP ascites samples was high and positively correlated with inflammatory indicators. Among 1876 patients with cirrhosis and ascites, patients infected with Stenotrophomonas maltophilia had significantly increased levels of procalcitonin, C-reactive protein, ascites lactate dehydrogenase, and polymorphonuclear leucocytes count. Animal experiments showed that Stenotrophomonas maltophilia derived from human ascites can promote the occurrence of SBP in rats. Single-cell sequencing results showed that it significantly increased CD8⁺T cell exhaustion in the ileum and reduced memory T cells.

Metabolomics analysis revealed that arginine was a significantly decreased metabolite in the supernatant of Stenotrophomonas maltophilia, and its downregulation was verified in rat serum and intestinal tissue.

Mechanistically, Stenotrophomonas maltophilia degrades arginine through arginine decarboxylase, inhibits mTORC1 activity, thereby reducing CD8⁺T cell effector function and ultimately promoting the progression of SBP. Arginine supplementation significantly inhibited the formation of SBP and improved intestinal barrier function.

Conclusion: Stenotrophomonas maltophilia has been shown to promote SBP in rats by degrading arginine. Arginine supplementation is a potential preventive measure for SBP.

Introduction: Factor Xa inhibitors, edoxaban, rivaroxaban, and apixaban, generally exhibit an acceptable safety and efficacy profile in patients with Child-Pugh A cirrhosis, while apixaban and edoxaban may also suitable in Child-Pugh B cirrhosis [1]. The suitability of rivaroxaban in this group remains uncertain and warrants further investigation. Only *in vitro* data

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

are available of the use of DOACs in the most severe forms of liver disease. Rivaroxaban decreased thrombin generation by 55% in controls, but only by 11%-38% in acutely ill cirrhotic patients [2].

Given the variability and limitations of existing evidence, current data are insufficient to support definitive clinical guidelines for DOAC use in severe hepatic impairment.

Aims & Methods: We studied ex vivo anticoagulant effects of the anti-Xa targeting DOAC rivaroxaban to decrease peak height (PH) and increase lag time (LT) in cirrhosis according to the severity of liver disease defined by the Child-Pugh (CP) classification. The baseline haemostatic capacity measured by thrombin generation (TG) will be compared with TG after spiking with rivaroxaban in both preventive and therapeutic doses. Sixty adult patients with an established diagnosis of cirrhosis were enrolled from the in- and outpatient hepatology clinics of the University Hospital of Ghent and the AZ Delta Hospital.

We selected 20 patients with CP A, 20 patients with CP B, and 20 patients with CP C cirrhosis. Ex vivo TG was analysed using ST Genesia with DrugScreen reagent at baseline and after spiking plasma samples with rivaroxaban (final concentrations 0, 67, and 300 ng/mL).

Results: In cirrhotic patients, higher rivaroxaban concentrations resulted in an increase in LT and a decrease in PH across all three patient groups (CP A, B, and C). However, no significant differences were observed between these groups, suggesting a comparable prolongation of LT and reduction in PH. When examining the percentage change in LT and PH according to the CP stage, a similar percentage change in LT was observed across all three CP stages.

In contrast, a markedly reduced percentual change in PH was noted in the CP C group with increasing rivaroxaban dosing (from baseline to 67 ng/mL to 300 ng/mL), indicating that the anticoagulant effect was less pronounced in patients with more severe liver dysfunction.

Conclusion: This study evaluates rivaroxaban potency in patients with cirrhosis in both preventive and therapeutic doses with the ST Genesia TG test, according to the severity of liver disease. We found that rivaroxaban reduces ex vivo haemostatic potential less efficiently in CP C patients compared to CP A and B. This may indicate a reduced anticoagulant effect of rivaroxaban in more severe liver disease.

These findings raise the question whether dose-adjustments and monitoring may be clinically useful in cirrhotic patients with a more advanced stage of liver disease.

Introduction: Cirrhosis is characterized by structural and functional hepatic alterations. The associated metabolic imbalances and psycho-neurological factors contribute to the high prevalence of sexual disorders and erectile dysfunction among affected patients.

The aim of our study was to identify factors associated with sexual dysfunction in cirrhotic patients.

Aims & Methods: We conducted a prospective cross-sectional study, collecting data from patients followed for cirrhosis at the gastroenterology department of Charles Nicolle Hospital in Tunis over a one-year period. Female sexual function was assessed using the FSFI questionnaire. Female sexual dysfunction was defined by an FSFI score below 26 (or below 20 in post menopausal women). Male sexual function was evaluated using the IIEF-15 questionnaire. Male sexual dysfunction was identified by an IIEF-15 score below 42.9. Erectile dysfunction was confirmed by an IIEF-5 score

below 26. An analytical statistical study was conducted, highlighting factors associated with sexual dysfunction in both female and male patient groups.

Results: We included 55 cirrhotic patients (24 women and 31 men), with a sex ratio (M/F) of 1.29 and a mean age at inclusion of 59.11 ± 12.16 years. Female sexual dysfunction was observed in 70.8% of female patients. Male sexual dysfunction was found in 61.3% of patients. Erectile dysfunction was reported in 74.1% of men.

Our study showed that the factors associated with female sexual dysfunction were: low economic status (p = 0.007), the presence of arterial hypertension (p = 0.026), and hepatic disease severity attested by Child-Pugh class B/C and MELD score >15 (p = 0.049 and p = 0.018, respectively).

In male patients, a higher prevalence of sexual dysfunction was found among smokers patients (p = 0.045; OR = 0.18; 95% CI [0.03; 1.05]) and them who consumed alcohol (p = 0.042; OR = 0.19; 95% CI [0.04; 0.94]). In multivariate analysis, only alcohol consumption was independently associated with male sexual dysfunction (p = 0.041; OR = 9.187). MELD score >15

Conclusion: In conclusion, our study highlights the high frequency of sexual disorders in cirrhotic patients and identifies several associated factors, notably the severity of liver disease, socioeconomic

status, and certain comorbidities. For these reasons, screening and appropriate management of sexual dysfunction is essential in cirrhotic patients especialy with advanced disease or comorbidities.

Introduction: In decompensated cirrhosis, portal hypertension (PH) and gut barrier dysfunction may contribute to a pro-oxidant, pro-inflammatory, and pro-thrombotic environment in the portal circulation, leading to severe complications. Previous studies have analyzed the alterations of human albumin (HA) structure in peripheral blood.

Aims & Methods: This study aimed to compare albumin microheterogeneity in blood samples from the portal vein, hepatic vein, and peripheral circulation in patients undergoing transjugular intrahepatic portosystemic shunt (TIPS), and to evaluate its potential role in predicting post-TIPS outcomes. Blood samples were collected from the portal vein, hepatic vein, and brachial vein in patients with decompensated cirrhosis during TIPS procedure placed for PH-related complications at Policlinico Umberto I, Rome. Albumin microheterogeneity was analyzed using liquid chromatography coupled with quadrupole time-of-flight (Q-TOF) mass spectrometry.

Results: Fifteen patients were enrolled in the study, mean age was 60±7 years, 11 (73%) were male and the majority had an alcohol related etiology [9(60%)], while the mean MELD-Na score was 14±3. Reversible oxidation of the HA cysteine 34 residue was the most abundant alteration found in the peripheral circulation [Nonmercaptalbumin-1 31% (IQR 27%-36%)], followed by the glycation of the HA molecule [16% (IQR 15%-18%)]. As a result of these alterations the amount of the native HA form was found to be significantly lower than that commonly found in healthy subjects [41% (IQR 38%-48%)].

An impaired structural profile of the HA molecule was also found in samples from the portal [Nonmercaptalbumin-1 31% (IQR 27%-34%); Glycated HA 16% (IQR 13%-18%)] and hepatic vein [Nonmercaptalbumin-1 30% (IQR 29%-37%); Glycated HA 17% (IQR 14%-18%)] although the extent of such alterations did not significantly differ between the three sites (p=0.629 and p=0.456 respectively).

As a result, no significant difference between the different compartments were found in the relative amount of the native HA form [portal: 44% (39%-49%); hepatic: 42% (38%-50%); peripheral 41% (38%-48%); p=0.593]. Despite this, a significant correlation between the native HA form and the MELD-Na score was found in the portal circulation (rho -0.579, p=0.025) but not in the hepatic (rho -0.365; p=0.179) or peripheral circulation (rho -0.241; p=0.401).

Moreover, the relative amount of the native form of HA was significantly associated with the development of ascites and hepatic encephalopathy within 6 months irrespective of the sampling site (Table 1).

Ascites			
	Yes	No	p-value
Portal vein (%)	37 (31-40)	48 (45-50)	0.005
Hepatic vein (%)	37 (28-40)	49 (46-52)	0.014
Brachial vein (%)	33 (27-40)	46 (41-52)	0.042
Hepatic encephalopathy			
	Yes	No	p-value
Portal vein (%)	39 (35-39)	48 (45-50)	0.004
Hepatic vein (%)	37 (37-38)	49 (46-52)	0.003
Brachial vein (%)	34 (32-38)	47 (42-52)	0.003

Table 1. Relative amount (%) of the native HA form found in the three vascular compartments in patients who developed or not ascites or hepatic encephalopathy within 6 months after TIPS. Data is reported as median (IQR).

Conclusion: Structural microheterogeneity of the HA molecule in the peripheral blood closely resembles that found in portal and hepatic circulation. The residual amount of the native HA form is associated with the development of ascites and hepatic encephalopathy within six months from TIPS placement

Disclosure: Nothing to disclose.

Introduction: Increased intestinal permeability is a central factor in the disruption of the gut-liver axis during cirrhosis. Innovative strategies focused on limiting intestinal inflammation are needed to restore the integrity of the mucosal, endothelial, and epithelial barriers in cirrhosis. Modulating the interaction between intestinal fibroblasts (Fib_{INT}) and cellular immunity in the lamina propria may help to restore intestinal homeostasis in cirrhosis.

Aims & Methods: A prospective experimental study was conducted using mice with advanced liver injury induced by oral administration of CCl_4 for 12 weeks (n=5). Control mice received olive oil as vehicle (n=5). Fib_{INT} activation, chemokine production, and immune recruitment were assesed in ileum samples through gene (RT-qPCR) and protein expression (immunofluorescence). Activation states of primary Fib_{INT} (CD45-CD326-CD90+) isolated from the small intestine and colon of control and cirrhotic mice were evaluated, as well as the expression of molecules involved in T-cell activation (MHC-II, CD40, CD80, CD86, OX-40L, PD-L1) by flow cytometry. Co-cultures of Fib_{INT} (cirrhosis) and T lymphocytes (control), and vice versa, were conducted to determine the modulatory effects of cell-to-cell interactions.

Results: An increase in gene (*COL1A1, FAP, PDPN*) and protein (α-SMA, Pdpn, Vim) expression of stromal cell activation markers was observed in the ileum during experimental cirrhosis. Augmented expression of chemokines (*CCL2, CXCL10*) in the ileum of cirrhotic mice correlated with increased leukocyte (CD45+) infiltration into the villi. Local increases in intestinal lymphocyte (CD3+) and macrophage (F4/80+) populations were

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

detected. In cirrhosis, the percentages of primary Fib_{INT} from the small intestine expressing stromal cell activation markers (Vim and Pdpn) and T-cell stimulation molecules (CD40, CD80, CD86) were elevated compared to control mice. Isolated Fib_{INT} from cirrhotic mice interacted with more CD4+ T lymphocytes *in vitro* and were more effective at inducing their activation (CD25+) and differentiation towards a Th17 profile (IL-17+). Similarly, CD4+ intestinal T lymphocytes from cirrhotic mice could activate Fib_{INT} isolated from control animals (Vim+, CD86+, OX40L).

Conclusion: Fib_{INT} are activated in experimental cirrhosis and acquire the ability to induce an inflammatory Th17 response. These findings suggest that modulating the interaction between intestinal fibroblasts and T lymphocytes may recover intestinal homeostasis in cirrhosis.

REAL-WORLD IMPACT OF EXTENDED BAVENO VI CRITERIA TO RATIONALISE ENDOSCOPIC VARICEAL SCREENING IN PATIENTS WITH CHRONIC LIVER DISEASE: A MULTISITE COHORT STUDY

T. Phan[1], C. Ho[1], A. Mitropoulos[1], J. Tse[1], B. McLeod[1], B. Xia[1], S. Hui[1,2], S. Le[1,2]

Introduction: Transient elastography (TE) enables early detection of compensated advanced chronic liver disease (cACLD), which can progress silently to clinically significant portal hypertension and oesophageal varices. Although gastroscopy remains the standard for variceal detection and eradication, it is invasive, costly, and associated with procedural risks. The Baveno VI consensus guidelines propose that cACLD patients with platelet counts >150,000/µL and liver stiffness <20 kPa can safely forgo routine gastroscopy, relying instead on annual TE and platelet monitoring. Recent European and UK studies have demonstrated an incremental net monetary benefit of approximately $3819 per patient with this approach; however, global adherence to the criteria remains suboptimal.

This retrospective cohort study aimed to assess the cost effectiveness and safety of the Baveno VI criteria relative to screening gastroscopies.

Aims & Methods: A retrospective cohort study was performed at a multisite tertiary center in Melbourne, Australia, analyzing 423 adults with compensated cirrhosis (Child-Pugh A) who underwent screening gastroscopy between February 2020 and May 2024.

The study aimed to assess the cost effectiveness and safety of Baveno VI criteria relative to screening gastroscopies. Clinical data were collected from electronic medical records, and costs were derived from the hospital finance department and the Australian Medicare Benefit Scheme (MBS).

The cost of TE was extrapolated as AUD 272.54 and gastroscopy as AUD 4512.00. The primary outcome was the incremental cost benefit of applying Baveno VI criteria; secondary outcomes included complications, mortality, and screening trends.

Results: Out of 423 patients, 43.5% had undergone TE within the preceding two years, and 66 (15.6%) met Baveno VI criteria to avoid endoscopy, none of whom demonstrated high-risk varices or experienced variceal bleeding.

Adverse events after endoscopy were uncommon in 7 patients (1.7%), with no related hospital admissions. Variceal bleeding occurred in 2 patients (0.5%) and overall mortality was 5.7% during the study period, but neither occurred among those meeting Baveno VI criteria. The incremental cost was AUD 4186.00 per patient, and the incremental benefit per TE performed was AUD 1134.40 (Table 1). Although TE use increased and endoscopy frequency decreased over time the trend did not reach statistical significance (p=0.37).

	N (%)
Total patients	423
Non-invasive	
Transient elastography in previous 2 years	184 (43.5%)
Morbidity / Mortality	
Variceal bleeds (N, %)	2 (0.5%)
Deaths (N, %)	24 (5.7%)
Cost data ($AUD)	
Incremental benefit of Baveno VI criteria	$4186.00
Incremental benefit per transient elastography performed	$1134.40

Table 1: Demographic, clinical and cost data in compensated patients with cirrhosis from 2020 to 2024.

Conclusion: Baveno VI criteria offer a safe and cost-effective alternative to routine endoscopic surveillance in cACLD. adopting Baveno VI criteria yielded an incremental cost benefit of AUD $4186 per patient, without affecting variceal bleeding or mortality. In our study cohort, 15.6% of patients from unnecessary procedures without compromising clinical outcomes.

Improving TE access and adherence to these guidelines could significantly reduce healthcare costs and patient burden, underscoring the importance of broader uptake of non-invasive screening strategies.

SIMPLIFIED RISK ASSESSMENT FOR SARCOPENIA AND MUSCLE ABNORMALITIES IN CHRONIC LIVER DISEASE PATIENTS USING EXISTING NUTRITIONAL ASSESSMENT TOOL

A. Hiraoka[1], S. Yoshio[2], F. Tada[1], H. Ohama[1], T. Ninomiyaa[1]
[1]Ehime Prefectural Central Hospital, Gastroenterology, Matsuyama, Japan, [2]National Center for Global Health Medicine, Human Immunology and Translational Research, Shinjuku, Japan

Introduction: Sarcopenia is characterized by loss of skeletal muscle mass and strength, and commonly observed in patients with chronic liver disease (CLD). However, simple and practical assessment tools for consideration of early intervention in patients with risk of progression of muscle abnormalities remain limited, as muscle volume assessment requires specialized expensive equipment not generally used by a family physician, e.g., computed tomography (CT) or bioelectrical impedance analysis.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: Using the Geriatric Nutritional Risk Index (GNRI), calculated based only on body weight, height, and serum albumin (AJCN 2005), the present study aimed to examine a novel scoring system used to assess risk of sarcopenia and muscle abnormality development in CLD patients.

This retrospective analysis was conducted using medical records of 1063 Japanese CLD patients (median age 70 years; male:female = 676:387; HCV:HBV:HBV and HCV:alcohol:others = 573:146:4:127:213; Child-Pugh A:B:C = 927:115:21; hepatocellular carcinoma history or complication = 300) who underwent related examinations from 2015 to 2024.

Muscle area at the middle of the L3 level shown by CT was evaluated using a 3D image analysis system, with the value for skeletal muscle index (SMI), determined based on muscle area (cm^2), calculated using the mean value for L3 level/height (m^2). Muscle volume loss (MVL) and handgrip strength decline (HGSD) were assessed according to the Japan Society of Hepatology criteria (SMI and HGSD cutoff values for male/female; 42/38 cm^2/m^2 and 28/18 kg, respectively).

Logistic regression analysis was then used to identify predictive factors for sarcopenia. Finally, a risk scoring system was developed based on the odds ratio (OR) values for significant factors.

Results: There were 145 patients (13.6%) with sarcopenia, 226 (21.3%) with HGSD, and 149 (14.0%) with MVL, with an abnormal GNRI status noted in 333 (31.3%). A scoring system was developed based on five predictive factors; abnormal GNRI (<98) (OR 4.88), elderly (65-74 years, OR 2.67), late-stage elderly (≥75 years, OR 6.09), female (OR 2.11), and advanced hepatocellular carcinoma (HCC) (TNM stage IV, OR 2.61), which remained following multivariate analysis.

Points were assigned based on OR value, with1 point for OR ≤3 and 2 points for OR ≥4. The rate of prevalence of sarcopenia, HGSD, and MVL showed a significant increase with a higher score, with those conditions seen in 2.4%, 13.8%, and 6.9%, respectively, of patients with low risk (0/1 points), 9.0%, 23.7%, and 19.8%, respectively, of those with moderate risk (2 points), 22.0%, 29.0%, and 18.8%, respectively, of those with high risk (3 points), and 38.8%, 27.5%, and 16.9%, respectively, of those with very high/super-high risk (4/5/6 points) (p<0.001).

Additionally, GNRI cutoff values for HGSD and MVL were 101.5 (AUC 0.670) and 97.5 (AUC 0.749), respectively, approximating the abnormal GNRI cutoff value of 98.

Conclusion: This GNRI-based scoring system is likely to be a simple, cost-effective tool that does not require any special equipment when assessing the risk of sarcopenia or muscle abnormalities. It may also be used in clinical practice as a method of identifying patients who require early intervention.

ASSESSING PROPHYLACTIC STRATEGIES AND PREDICTIVE FACTORS FOR POST-TIPS HEPATIC ENCEPHALOPATHY: A RETROSPECTIVE STUDY

C. Borges Chaves[1], M.I. Viegas[2], R. Regatia[2], H. Ribeiro[1], B. Rato[3], P. Donato[3], D. Perdigoto[1,4], P. Narra Figueiredo[1,4]

Contact E-Mail Address: carlosbchaves123@gmail.com

Introduction: Transjugular intrahepatic portosystemic shunt (TIPS) is a well-established procedure frequently employed to manage portal hypertension associated conditions such as variceal bleeding, ascites, and hydrothorax. However, despite its benefits, TIPS placement is frequently complicated by post-TIPS hepatic encephalopathy (HE), a condition that can significantly impact patient outcomes and quality of life.

Currently, there is a lack of consensus and robust evidence regarding the optimal prophylactic treatments for post-TIPS HE. There is a recommendation suggesting the use of rifaximin, which is based solely on a single randomized controlled trial[1,2]. Thus, more data are needed to assess the efficacy of prophylactic therapies in a real-world clinical setting.

Aims & Methods: This work aims to compare the efficacy of different prophylactic treatments (lactulose, rifaximin or both) and identify predictive factors for post-TIPS HE.

A retrospective study was conducted at a tertiary TIPS referral centre, including all adult patients who undergone TIPS placement between January/2021 and June/2024. Clinical records were reviewed to collect demographic data, prior decompensations, analytical results, medication and episodes of post-TIPS HE. A minimum of 6 months of follow-up was required. Statistical analysis was performed using SPSS Statistics version 26®.

Results: We included 83 patients, most of them male (n=69;83.1%) with a mean age of 60.1±1.3 years old. Most patients had alcoholic liver disease (n=58; 69.9%), followed by metabolic dysfunction and alcohol-related liver disease (n=6;7.2%). Prior to the procedure 22 (26.5%) patients had previous episodes of HE: 12 (14.5%) were medicated with lactulose, 2 (2.4%) with rifaximin and 8 (9.6%) with both. The remaining 61 (73.5%) had no previous medication. The primary indications for TIPS placement were variceal haemorrhage (n=50; 60.2% [pre-emptive n=21;42.0%]) and refractory ascites or hepatic hydrothorax (n=27;32.5%). The mean pre-TIPS and post-TIPS direct portal pressure were 31.0±0.9 mmHg and 22.2±0.7 mmHg, respectively.

After TIPS placement 19 (22.9%) were discharged with lactulose, 3 (3.6%) with rifaximin, 20 (24.1%) with both and 41 (49.4%) with no medication. The mean follow-up time after TIPS placement was 22.3±2.0 months. Twenty-five (30.1%) patients had post-TIPS HE and there were no differences between therapeutic strategies in preventing such episodes (lactulose: OR 2.6 (95%CI 0.7-9.2) p-value 0.14; rifaximin: OR 1.1 (95%CI 0.1-19.0) p-value 0.94; both OR 2.4 (95%CI 0.7-8.2) p-value 0.15).

Those discharged with no medication had less post-TIPS HE (OR 0.2 (95%CI 0.1-0.6) p-value 0.008), although these had also less pre-TIPS HE (p-value 0,046). Previous variceal haemorrhage (OR 3.2 (95%CI 1.0-9.9) p-value 0.046) and lower glomerular filtration rate (OR 0.98 (95%CI 0.96-0.99) p-value 0.03) were associated with higher risk for post-TIPS HE.

Conclusion: Our study found no significant differences between prophylactic treatments for post-TIPS HE. Notably, patients who did not receive prophylaxis had lower incidence of post-TIPS HE, although they also had

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. fewer pre-TIPS episodes of HE. This raises questions about the universal application of these treatments and suggests the need for a more individualized approach. The identification of risk factors such as a history of variceal haemorrhage and lower glomerular filtration rate may guide treatment decisions, emphasizing the need for tailored management strategies. Future studies with larger sample sizes and multicentre participation are needed to refine prophylactic recommendations.

Introduction: Esophageal varices are a leading cause of life-threatening upper gastrointestinal bleeding in cirrhotic patients. Carvedilol and endoscopic variceal ligation (EVL) are the main strategies for primary prophylaxis, but their comparative efficacy remains a topic of debate. Additionally, recent studies have explored combining carvedilol with EVL, but the potential added benefit of this approach remains unclear.

Aims & Methods: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs), performing a comprehensive search of PubMed, Embase, Cochrane, and ClinicalTrials.gov to identify and evaluate studies comparing carvedilol vs. EVL or carvedilol plus EVL vs. carvedilol alone in patients at risk of esophageal variceal bleeding. Statistical analyses were conducted using R and RStudio, applying a random-effects model with 95% confidence intervals.

Results: Nine RCTs comprising 1,443 patients were included. Carvedilol significantly reduced six-month variceal bleeding compared to EVL (RR 0.57; 95% CI 0.36–0.90; p=0.01; I^2=0%). No significant differences were found in overall variceal bleeding (RR 0.97; 95% CI 0.61–1.53; p=0.90; I^2=61%), one-year bleeding (RR 0.86; 95% CI 0.46–1.62; p=0.63; I^2=51%), one-year all-cause mortality (RR 1.31; 95% CI 0.91–1.90; p=0.15; I^2=0%), or bleeding-related mortality (RR 1.32; 95% CI 0.71–2.48; p=0.38; I^2=0%). Hypotension occurred in 3% (95% CI 0.00–0.05) of patients receiving carvedilol. Dysphagia (52%; 95% CI 0.25–0.80) and variceal recurrence (14%; 95% CI 0.00–0.31) were reported in the EVL group. Combination therapy showed no clear benefit over monotherapy for six-month bleeding (RR 1.69; 95% CI 0.90–3.17; p=0.10; I^2=0%) or mortality (RR 1.47; 95% CI 0.36–5.92; p=0.59; I^2=61%).

Conclusion: Carvedilol and EVL appear similarly effective for primary prophylaxis of variceal bleeding, though carvedilol may offer short-term benefits with fewer adverse effects. Combination therapy did not demonstrate added efficacy over monotherapy.

EXPANDING THE SCOPE OF TIPS: IS THERE A RENAL BENEFIT IN ADVANCED CHRONIC LIVER DISEASE? A TERTIARY REFERRAL CENTRE EXPERIENCE

M.I. Viegas[1], C. Borges Chaves[2], R. Regatia[1], H. Ribeiro[2], D. Perdigoto[2], P. Narra Figueiredo[2]

Introduction: Patients with advanced chronic liver disease (ACLD) are prone to different renal injury phenotypes, associated with poor prognosis and limited treatment options. Transjugular intrahepatic portosystemic shunt (TIPS) diverts portal blood flow, potentially increasing systemic blood volume, which can be reflected in renal hemodynamics.

Aims & Methods: We intend to evaluate the impact of TIPS on renal function in decompensated ACLD. Retrospective cohort study conducted at a large referral center, involving consecutive patients who underwent TIPS placement between January/2021 and June/2024, with a 180-day follow-up. Excluded patients in regular hemodialysis and aged ≤18.

We divided the study population into two groups based on baseline glomerular filtration rate (GFR ≥90 ml/min/1.73 m^2, calculated using the CKD-EPI formula): those with normal GFR (nGFR group) and those with reduced GFR (aGFR group).

We then analysed the demographic and clinical characteristics of each group, as well as the impact on renal function at two time points following TIPS placement: days 1–7 and days 90–180.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 78 patients were included, 85% of whom were male (n=66), with a mean age of 61 ± 11 years. Of these, 31% (n=24) had an abnormal GFR prior to TIPS placement (aGFR group), while 69% (n=54) had a normal GFR (nGFR group).

Regarding the primary etiology of ACLD, alcohol-related liver disease (ALD) was the most common cause in both groups (72%, n=56), followed by viral hepatitis (10%, n=8) and metabolic dysfunction with ALD (MetALD) (8%, n=6). In both groups, most patients were classified as Child-Pugh score B (nGFR: n=26; aGFR: n=16) and the mean MELD-Na score was 15 ± 5 in the nGFR group and 18 ± 7 in the aGFR group (p <0.05).

The main indications for TIPS placement were similar across groups, with variceal hemorrhage—either as pre-emptive TIPS (30%, n=23) or rescue TIPS (31%, n=24)—and refractory ascites (31%, n=24) being the most frequent. In both groups, TIPS placement was most commonly dilated to 8 mm (77%, n=60), while 10 mm dilation was performed in 12% (n=9).

The table below presents a comparison of pre- and post-TIPS pressure values, along with the evolution of GFR in both nGFR and aGFR groups at pre-TIPS, 1–7 days post-TIPS, and 90–180 days post-TIPS.

	Direct portal pressure pre-TIPS (mean ± SD)	Direct portal pressure post-TIPS (mean ± SD)	p-value	Pre-TIPS GFR	1-7 Day Post-TIPS GFR	90-180 Day Post-TIPS GFR
nGFR	30±7mmHg	23±6mmHg	p=0.511	103 (IQR: 99-112)	107 (IQR: 100-115)	100 (IQR: 81-108)
aGFR	32±6mmHg	21±5mmHg	p=0.151	45 (IQR: 35-68)	76 (IQR: 38-92)	79 (IQR: 42-95)

Comparing the pre- and post-TIPS values in the nGFR group: there was a significant increase in GFR pre- and 1–7-day post-TIPS (Z:−3.772, p<0.001), but there were no changes comparing pre- and 90-180-day post-TIPS (Z:-1.779, p=0.075). However, comparing the pre- and post-TIPS values in the aGFR group: there was a significant increase in both GFR pre- and 1–7-day and 90-180-day post-TIPS (Z:−3.315, p<0.001; Z:-2.201, p=0.028; respectively).

Conclusion: We observed an early renal improvement shortly after TIPS placement, however, this improvement was only sustained over time in the group with previously altered renal function. The transient nature of the renal benefits observed may be attributed to the complex hemodynamic changes following TIPS, highlighting the need for further studies to optimize long-term renal outcomes.

Despite the limitations of this study, such as the small patient subset, its retrospective nature, the use of the eGFR equation based on creatinine in ACLD patients and incomplete follow-up, studies like this are necessary, as renal impairment in ACLD is linked to higher morbidity and mortality, making it a key prognostic factor for post-TIPS survival.

Contact E-Mail Address: ritaregatia@gmail.com

Introduction: Chronic liver disease remains one of the most common causes for hospital admission and is associated with high morbidity and mortality rates. Timely and adequate management within the first 24 hours is crucial for improving clinical outcomes in cases of decompensated cirrhosis.

This study aimed to evaluate the impact of implementing a care bundle checklist during the first 24 hours of hospital admission on management and outcomes of decompensated cirrhosis.

Aims & Methods: We developed an adapted care bundle (based on the BSG/BASL care bundle, AASLD quality measures proposal, Baveno VII consensus, and EASL guidelines) and compared two patient groups from two Portuguese hospital centers: Group-A (retrospective, pre-care bundle implementation) and Group-B (prospective, post-care bundle implementation).

Results: A total of 224 patients (Group-A: 148; Group-B: 76) were included. More than one decompensation was observed in 118 patients (52.7%), and 69 patients (30.8%) were experiencing their index hospitalization for liver decompensation. Regarding etiology, alcoholic liver disease was the most common (*n*=200; 89.3%).

The groups were similar in terms of gender, age, length of hospital stay, and Child-Pugh and MELD-Na scores at admission. The most common decompensations were gastrointestinal bleeding (*n*=91; 40.6%), ascites (*n*=75; 33.5%), and hepatic encephalopathy (*n*=72; 32.1%).

Group B was more likely to present with multiple decompensations at admission and exhibited significantly higher rates of acute kidney injury, hepatocellular carcinoma, acute-on-chronic liver failure, and portal vein thrombosis (p<0.05).

Following care bundle implementation, we found significant improvements in patient care. At admission, patients were significantly more likely to undergo urine and blood cultures, chest X-ray, and abdominal ultrasound (p<0.05), receive diagnostic paracentesis (p<0.05), and have an accurate alcohol history documented (p=0.04).

During admission, Group-B was significantly more likely to be prescribed lactulose for encephalopathy prophylaxis, vasopressor therapy for gastrointestinal bleeding, and venous thromboembolism prophylaxis, as well as undergo nutritional assessment (p<0.05).

While in-hospital mortality rates were similar (4.7% vs. 5.3%; p=1), 6-week mortality rates (8.8% vs. 3.9%; p=0.01) and 3-month readmission rates (31.1% vs. 15.8%; p=0.02) were significantly lower in the post-intervention cohort.

Conclusion: The implementation of a standardized care bundle was associated with higher rates of appropriate investigation and treatment within the first 24 hours of hospital admission and improved patient outcomes, reducing 6-week mortality and 3-month readmission rates.

Disclosure: Nothing to disclose.

ACCURACY OF MEFIB INDEX FOR RULING IN/OUT AT-RISK MASH AND SIGNIFICANT FIBROSIS. SYSTEMATIC REVIEW AND DIAGNOSTIC ACCURACY META-ANALYSIS

K. Malandris[1], A. Katsoula[1], A. Liakos[1], T. Karagiannis[1], P. Paschos[1], E. Theocharidou[1], E. Gigi[1], G. Kalopitas[1], E. Bekiari[1], E. Sinakos[1], A. Tsapas[1]
[1]Aristotle University of Thessalonik, Thessaloniki, Greece

Contact E-Mail Address: kostas_malandris@yahoo.gr

Introduction: Patients with metabolic-dysfunction associated steatohepatitis (NAFLD activity score ≥4) and significant fibrosis (≥F2) (at-risk MASH) are at increased risk for disease progression. Following the approval of the first agent for the management of noncirrhotic MASH, timely identification of these patients is of major importance. Magnetic resonance elastography (MRE) combined with Fibrosis-4 index (MEFIB index) enables the noninvasive diagnosis of at-risk MASH and significant fibrosis, and has been assessed in several studies.

Aims & Methods: To assess the overall performance of MEFIB index for diagnosing at-risk MASH and significant fibrosis. We searched Medline, Cochrane library and Web of science up to February 2025. We included diagnostic accuracy studies assessing the performance of MEFIB index for ruling in (MRE ≥3.3 kPa plus FIB-4 ≥1.6) and ruling out (MRE <3.3 kPa plus FIB-4 <1.6) at-risk MASH and significant fibrosis using liver biopsy as the reference standard. We calculated pooled diagnostic accuracy estimates using bivariate random-effects models, and assessed risk of bias using the Quality Assessment of Diagnostic Accuracy Studies 2 tool.

Results: We included seven studies with 3,356 participants. Most studies were at unclear or high risk for bias primarily due to concerns related to patient selection. Across all participants, 54% were females and 55.8% had type 2 diabetes. The average mean age and body mass index (BMI) of participants were 56.2 years and 30.3 kg/m2 respectively. Mean aspartate aminotransferase and alanine aminotransferase were 47.0 IU and 61.3 IU, respectively. The average mean FIB-4 and MRE values were 1.75 and 3.6 kPa respectively.

Across studies with available data, the prevalence of at-risk MASH and significant fibrosis were 31.3% and 60.1% respectively. For ruling in at-risk MASH, MEFIB index yielded a pooled specificity of 0.94 (95 % CI 0.74, 0.99), and a positive likelihood ratio (LRp) of 5.3 (1.8, 15.7). For ruling out at-risk MASH, MEFIB index had a pooled sensitivity of 0.77 (0.62, 0.88) and a negative likelihood ratio (LRn) of 0.34 (0.23, 0.52). For ruling in significant fibrosis, MEFIB index resulted in a summary specificity of 0.93 (0.85, 0.97) with LRp 8.2 (4.5, 14.9). For excluding significant fibrosis, the pooled sensitivity and LRn of MEFIB index were 0.88 (0.79, 0.94) and 0.16 (0.08, 0.31) respectively.

Conclusion: MEFIB index has acceptable accuracy for diagnosing at-risk MASH and significant fibrosis. Proposed rule in (MRE ≥3.3 kPa plus FIB-4 ≥1.6) and rule out (MRE <3.3 kPa plus FIB-4 <1.6) thresholds can be used to identify both target conditions in high prevalence settings and facilitate patient recruitment in clinical trials.

Disclosure: Nothing to disclose.

Introduction: Erectile dysfunction (ED) is a common complication in men with cirrhosis, significantly impairing quality of life. However, evidence on effective pharmacological treatment in this population remains limited.

Aims & Methods: To evaluate the efficacy and safety of phosphodiesterase-5 (PDE-5) inhibitors for the treatment of ED in men with advanced chronic liver disease. A systematic search of MEDLINE, Embase, and the Cochrane CENTRAL Register of Controlled Trials was conducted to identify randomized controlled trials and prospective observational studies assessing PDE-5 inhibitors in cirrhotic patients with ED.

A pooled analysis was performed to evaluate changes in the erectile function domain of the International Index of Erectile Function (IIEF) and the incidence of adverse events. Heterogeneity was assessed using the Cochrane Q test and I^2 statistic, with $p < 0.10$ and $I^2 > 25\%$ indicating significant heterogeneity.

Results: Three studies including 129 patients, all treated with tadalafil, were analyzed. The characteristics of the included studies are summarized in Table 1. The pooled mean difference in the IIEF erectile function domain was 6.49 (95% CI: 5.01–7.98; $p < 0.01$), demonstrating a clinically meaningful improvement. Adverse events occurred in 31.6% (95% CI: 10.5–64.4%) of patients, with no serious events reported.

Study	Study design	No. of patients	Age (years), mean (SD)	Tadalafil dosage (mg)	CTP score, mean (SD)	Ascites present, n (%)	MELD score, mean (SD)	β-blocker usage, n (%)	Diuretics usage, n (%)	Follow-up (weeks)	IIEF score baseline, mean (SD)

*IIEF-5 score, ‡daily dosage; †age range of included patients; §every two days.
Abbreviations: RCT: randomized controlled trial; P: prospective observational study; CTP: Child-Turcotte-Pugh Score; MELD: Model for end-stage for liver disease; IIEF: International index for erectile function (Erectile function domain); IIEF-5:5-item version of the International Index of Erectile Function; n.a.: data not available.

Table 1: Baseline characteristics of included studies.

Conclusion: PDE-5 inhibitors, particularly tadalafil, appear to be effective and well tolerated for the treatment of ED in men with cirrhosis. Further large-scale studies are warranted to validate these findings and assess long-term safety.

Disclosure: Nothing to disclose.

Introduction: Although patients with acute-on-chronic liver failure (ACLF) often demonstrate preserved thrombin generation (TG), they concurrently display hypocoagulable profiles on rotational thromboelastometry (ROTEM) [1]. The extent to which these findings explain the increased bleeding risk in acutely ill cirrhotic patients remains unclear [1–5].
Moreover, most studies do not distinguish between portal hypertensive (PH) and non-PH bleeding, complicating accurate estimation of NPH bleeding prevalence.

Aims & Methods: This is a case-control study, comparing haemostatic profiles of acute decompensation (AD) and ACLF (=cases) to stable cirrhosis (SC) (=controls). Coagulation profiles were evaluated including INR, aPTT, PT, fibrinogen, coagulation factors and inhibitors and advanced global haemostatic tests (ROTEM, TG assay (TGA) ± thrombomodulin (TM)). Secondary objectives focused on identifying associations between coagulation parameters and NPH bleeding and thrombotic events.

Results: A total of 215 patients were included (SC: 122; AD: 53; ACLF: 40). The median Child-Pugh (CP) and MELD-Na scores increased progressively from SC to AD to ACLF (P< 0.001). NPH bleeding occurred in 8,4% (n=18), with higher rates in ACLF (30,8%, P<0,001) and AD (18.9%, P=0.011) than in SC (5.7%). Thrombotic events were observed in 7.0% (n=15).
TGA without TM revealed that ACLF patients had significantly shorter lag time compared to SC, shorter time to peak, reduced peak height and endogenous thrombin potential (ETP) compared to SC/AD; though TM normalized these effects. ETP inhibition by TM was reduced significantly across the three groups. ROTEM parameters showed marked hypocoagulable features in ACLF vs SC/AD, while AD and SC were comparable. Hypocoagulability (≥5 abnormal ROTEM parameters out of 6 parameters) was present in 1.8% of SC, 8.3% of AD, and 22.2% of ACLF patients (P<0.001 for SC vs ACLF); hypercoagulability was rare (2.8% in ACLF). INR and aPTT were significantly prolonged and FVIII elevated, while fibrinogen, PT, and pro- and anticoagulants were reduced in AD/ACLF compared to SC. ROTEM and TGA parameters correlated significantly with MELD-Na and CP scores (P<0,001).
Patients with NPH bleeding had higher CP and MELD-Na scores (P<0,001 and P=0,006), and a greater prevalence of AD (33,3%) and ACLF (38,9%) compared to non-bleeders (22,8% AD; 16,1% ACLF). Hypocoagulability on ROTEM was more frequent among bleeders (31.3% vs 4.5% in non-bleeders, P=0.002). Bleeders also showed greater impairment in INR, aPTT, PT, and most coagulation factors (except FVIII and PS). Multivariate analysis identified ROTEM-defined hypocoagulability as an independent risk factor for NPH bleeding (OR 12.93, 95% CI: 1.13–150.28, P=0.041). No significant differences in coagulation parameters were observed between patients with and without thrombotic complications.

Conclusion: TG demonstrated accelerated initiation and reduced thrombin potential in ACLF vs SC/AD, though TM normalized these effects. ROTEM demonstrated pronounced hypocoagulability in AD/ACLF vs SC. These coagulation abnormalities are paralleling their advanced liver dysfunction.
NPH bleeding events clustered in AD/ACLF cohorts and were associated with ROTEM-defined hypocoagulability. The convergence of ROTEM hypocoagulability as an independent risk factor for NPH bleeding and its prominence in acutely ill cirrhotic patients underscores the heightened NPH bleeding prevalence and ROTEM detected coagulation dysfunction in this patient population.

Introduction: Cirrhotic patients undergo intricate changes in their haemostatic system, resulting in a 'rebalanced haemostasis'. In patients with acute decompensation (AD) and acute-on-chronic liver failure (ACLF), this delicate balance is particularly susceptible to disruption by external

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

stressors such as infections or acute kidney injury (AKI) rendering them more vulnerable to haemostatic complications than individuals with stable cirrhosis [1,2].

Aims & Methods: This case-control study evaluated coagulation profiles (INR, aPTT, PT, fibrinogen, coagulation factors and inhibitors, rotational thromboelastometry (ROTEM), and thrombin generation assay (TGA) [BleedScreen/ (BS) ThromboScreen (TS) ± thrombomodulin (TM)]) in 215 cirrhotic patients, comparing subgroups with/without AKI or bacterial infection to assess haemostatic impact.

Results: The cohort included 215 patients, with 37 (17.2%) having AKI and 31 (14.4%) bacterial infections. AKI patients had higher median Child-Pugh (11 vs 7, P<0.001) and MELD-Na scores (25 vs 11, P<0.001) than non-AKI patients, with more AD (32.4% vs 23%) and ACLF (59.5% vs 10.1%, P<0.001). Infected patients also showed higher CP (9 vs 7) and MELD-Na scores (33 vs 12, P<0.001), with more ACLF (51.6% vs 13%, P<0.001).

In the overall cohort, AD and ACLF patients have more hypocoagulability on ROTEM than SC. TG was preserved in AD compared to SC but showed more hypocoagulable features in ACLF, which were offset after TM addition. Both TG and ROTEM abnormalities correlated with liver disease severity.

Bacterial infection was linked to increased TG capacity (endogenous thrombin potential (ETP)-TM: 928.15 vs. 770.10 nm·min, P=0.030) and significantly less ETP suppression by TM (11.07% vs. 30.33%, P<0.001). Despite a greater prevalence of ACLF, ROTEM profiles did not differ between infected and non-infected patients. Standard coagulation assays revealed a hypocoagulable state, with lower levels of FII, VII, X, IX, and XI, while fibrinogen and platelet counts remained similar. Hypercoagulable features included increased FVIII and decreased protein S, (PS) and C (PC), and antithrombin (AT).

In the AKI group, TGA showed significantly accelerated TG in BS and TS with reduced TG capacity in TS. After TM addition, no differences in TG speed or total TG capacity were noted. Patients with AKI showed a significantly lower ETP inhibition by TM. ROTEM showed prolonged clotting times in INTEM and EXTEM and reduced maximum clot firmness in FIBTEM, with overall more hypocoagulability (21.2% vs. 4.2%, P=0.003). Standard coagulation assays showed mixed features in AKI, with increased INR, prolonged aPTT and reduced fibrinogen, FII, V, VII, X, IX, and XI levels, along with elevated FVIII and reduced AT and PC. Platelet counts were similar.

Conclusion: Global coagulation assays (TGA and ROTEM) showed similar profiles in infected vs non-infected cirrhotic patients, with some hypercoagulable features on TGA in infection, despite high ACLF prevalence (>50%). In contrast, AKI showed accelerated TG but reduced TG capacity, more hypocoagulable ROTEM features, and lower coagulation factors and inhibitors.

Although ACLF rates were comparable in AKI and infection groups, hypocoagulability was more pronounced in AKI, where in the infection group coagulation status was preserved or showed even some hypercoagulable features. This indicated that these coagulation abnormalities reflect the effects of these destabilizing factors rather than disease severity alone.

Contact E-Mail Address: elenitripaki@outlook.com

Introduction: Patients with liver cirrhosis, particularly those with decompensated cirrhosis, are at significant risk of morbidity from viral and bacterial infections, which can also affect the progression of liver disease. Therefore, international guidelines recommend full vaccination coverage of these patients against a range of pathogens, irrespective of age.

Aims & Methods: The aim of our study was to evaluate vaccination coverage in a group of inpatients with cirrhosis. We retrospectively analysed patients with liver cirrhosis who were admitted after presenting to the emergency department and were hospitalised between 2019 and 2022 in the First Propaedeutic Department of Internal Medicine of Aristotle University of Thessaloniki.

The patients were evaluated with regard to their vaccination status and the presence of antibodies against hepatitis A and hepatitis B. Active vaccination against influenza was defined as vaccination during the latest vaccination period. Only the vaccinations administered prior to hospitalisation were included, and not those that were recommended afterwards. Patients who were diagnosed with cirrhosis during hospitalisation were excluded from the study.

Results: 182 patients were recorded, with a mean age of 65.4 ± 13.1. The patients were predominantly male (67%). Alcohol-related liver disease (47.8%), metabolic-associated steatohepatitis (18.1%) and chronic hepatitis B (11%) were the most common causes of cirrhosis. The majority of patients were classified as Child-Pugh stage B (51.6%), followed by stage C (31.9%) and A (16.5%). Most patients (79.7%) had decompensated cirrhosis. Regarding exposure to hepatitis B, 86 out of 157 patients (54.8%) required vaccination, of whom 25.6% (22/86) were already vaccinated.

Concerning hepatitis A, 89 of the 108 (83.5%) patients who were checked tested positive for antibodies without being vaccinated, while only two of the remaining 19 (10.5%) had been vaccinated.

As for influenza vaccination, 41.2% received the vaccine during the last vaccination season. Additionally, 21.4% of the patients had undergone vaccination against pneumococcus. The only correlation observed about vaccination coverage was the increased rates of pneumococcal vaccination in patients of Child-Pugh B cirrhosis compared to patients with Child-Pugh A or C (p=0.042).

Conclusion: Our study underlines the low vaccination coverage of patients with cirrhosis. Thus, the need to intensify vaccination efforts is highlighted, as infectious complications could be critical for patients with cirrhosis, not only due to their immediate morbidity but also because of their potential impact on the progression of liver disease.

PP0895

TRACKING THE SHIFT: NLR VARIATION AS AN EARLY MARKER OF INFECTION IN CIRRHOTIC DECOMPENSATION

A. Gnaba[1], N. Elleuch[1], I. Lassoued[1], H. Jaziri[1], A. Ben Slama[1], W. Dahmani[1], M. Ksiaa[1]
[1]Sahloul University Hospital, Department of Hepato-Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: Infection is one of the most feared precipitants of acute decompensation (AD) in cirrhotic patients, making early detection crucial for timely intervention. In this context, the neutrophil-to-lymphocyte ratio (NLR) has emerged as a promising biomarker reflecting the inflammatory and infectious burden.

Aims & Methods: This study aimed to investigate the relationship between NLR and the prediction of infection in patients admitted to manage cirrhosis-related acute decompensation.

We conducted a retrospective study over 12 months (August 2022 to September 2023), including patients with a confirmed diagnosis of cirrhosis who were hospitalized for acute decompensation.

Clinical and laboratory data from the same decompensation episode were collected. The NLR during decompensation (NLR-AD) and the change in NLR (ΔNLR) were calculated as follows:

• NLR = Neutrophil count / Lymphocyte count

• ΔNLR = NLR during decompensation – baseline NLR

Receiver operating characteristic (ROC) curves were used to assess the predictive performance of these variables. Associations with infection types were also analyzed.

Results: Eighty-three patients were included, with a mean age of 62.4 ± 10.8 years and a male-to-female ratio of 1.13. The main reasons for admission were hepatic encephalopathy (HE) in 32 patients (38.6%), oedemato-ascitic decompensation in 26 patients (31.3%), and variceal upper gastrointestinal bleeding in 25 patients (30.1%).

Among these patients, 24 (28.9%) developed infections, including: 6 cases of spontaneous bacterial peritonitis (SBP) (25%), 11 urinary tract infections (UTIs) (45.8%), 4 skin/soft tissue infections (16.7%), 3 lower respiratory tract infections (12.5%).

Median values were: Baseline NLR: 2.6 (IQR [1.7–4.1]), NLR during AD: 4.33 (IQR [3–6.25]) and ΔNLR: 1.29 (IQR [0.3–3.3]).

An NLR-AD ≥ 4.4 was significantly associated with infection (AUC = 0.692; p = 0.006; 95% CI [0.565–0.819]). Similarly, a ΔNLR > 2.15 was also predictive (AUC = 0.696; p = 0.005; 95% CI [0.571–0.821]).

Wilcoxon testing confirmed a statistically significant increase between baseline NLR and NLR-AD (p < 0.001).

A ΔNLR > 2.9 was strongly associated with SBP (AUC = 0.820; p = 0.009; 95% CI [0.719–0.921]), while no significant association was observed between ΔNLR and other types of infections, or between NLR-AD and any specific infection type, including SBP.

Multivariate analysis showed that only ΔNLR was independently predictive of infection (p = 0.01), with ΔNLR > 2.9 being specifically associated with SBP (p = 0.045).

Conclusion: This study highlights the clinical value of the neutrophil-to-lymphocyte ratio (NLR) as a predictive biomarker for infection in patients with acute decompensation of cirrhosis. A significant increase in NLR (ΔNLR) was strongly associated with the presence of infection, particularly spontaneous bacterial peritonitis. These findings suggest that NLR and its dynamic variation from baseline (ΔNLR) may serve as useful tools for early infection detection and risk stratification in this vulnerable patient population.

Disclosure: Nothing to disclose.

SILENT INFECTIONS, LOUD MARKERS: BIOLOGICAL PREDICTORS OF BACTERIAL INFECTION IN ACUTELY DECOMPENSATED CIRRHOSIS IN A TUNISIAN POPULATION

A. Gnaba[1], N. Elleuch[1], I. Lassoued[1], H. Jaziri[1], A. Ben Slama[1], W. Dahmani[1], M. Ksiaa[1]
[1]Sahloul University Hospital, Department of Hepato-Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: Diagnosing bacterial infections in patients with acutely decompensated cirrhosis (AD) is often challenging, as typical signs may be absent, and the clinical presentation may be limited to nonspecific deterioration of general condition. However, delayed management is associated with high mortality once infection is established. Early diagnosis of bacterial infection (BI) is therefore critical to improve outcomes.

Aims & Methods: This study aimed to identify predictive biological markers of bacterial infection in patients with AD cirrhosis, which would support earlier and more targeted therapeutic interventions.

We conducted a retrospective study over 12 months (August 2022 to September 2023), including patients with established cirrhosis hospitalized for an episode of acute decompensation.

Bacterial infection was diagnosed based on clinical, biological, and cytological criteria.

White blood cell (WBC) count, neutrophil count, lymphocyte count, and C-reactive protein (CRP) levels were recorded both at the time of admission for AD and from baseline values obtained during a compensated period within the previous three months.

The biological markers assessed included: ΔWBC (difference between admission and baseline WBC count),%Neutrophils (proportion of neutrophils among total WBC), ΔNeutrophils (admission minus baseline neutrophil count), ΔWBC/Lymphocyte ratio, ΔLymphocytes (admission minus baseline), Neutrophil-to-Lymphocyte Ratio (NLR), ΔNLR (NLR at admission minus baseline NLR).

Receiver Operating Characteristic (ROC) curves were generated to identify predictive thresholds of each biomarker for infection, and Area Under the Curve (AUC) values with corresponding p-values were calculated to assess performance. Multivariate logistic regression was then used to identify independent predictors of bacterial infection, expressed as odds ratios (OR) with 95% confidence intervals (CI).

Results:

A total of 83 patients were included, with a mean age of 62.4 ± 10.8 years and a male-to-female ratio of 1.13.

The main reasons for admission were hepatic encephalopathy (32 patients, 38.6%), ascitic decompensation (26 patients, 31.3%), and variceal gastrointestinal bleeding (25 patients, 30.1%).

Bacterial infection was identified in 24 patients (28.9%), including spontaneous bacterial peritonitis (SBP) in 6 cases (25%), urinary tract infections in 11 (45.8%), skin infections (erysipelas, cellulitis) in 4 (16.7%), and respiratory infections in 3 (12.5%).

Significant associations were found between infection and the following biomarkers:

• ΔNeutrophils > 1,550/mm^3 (AUC = 0.658; p = 0.025),

• %Neutrophils > 72.3% (AUC = 0.687; p = 0.008),

• ΔWBC/Lymphocytes > 3.1 (AUC = 0.691; p = 0.007),

• NLR > 4.4 (AUC = 0.692; p = 0.006),

• ΔNLR > 2.9 (AUC = 0.696; p = 0.005),

• CRP > 21 mg/L (p < 0.001).

On multivariate analysis, two independent predictors of bacterial infection were identified: ΔNLR > 2.9 (p = 0.038; OR = 3.8; 95% CI: 1.1–13.5), CRP > 21 mg/L (p < 0.001; OR = 21.8; 95% CI: 5.1–82).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our findings highlight the value of ΔNLR and CRP as useful biomarkers for detecting bacterial infection in cirrhotic patients with acute decompensation, even in the absence of overt clinical signs. These parameters may help prompt early and focused investigations for potential infectious sources, ultimately improving patient management and prognosis.

Disclosure: Nothing to disclose.

Introduction: Cirrhotic cardiomyopathy (CCM), cardiac dysfunction in liver cirrhosis of any aetiology in the absence of a primary cardiac cause predisposes to morbidity and mortality before and after Liver Transplantation (LT). Global longitudinal strain (GLS) measurement is included in the updated CCM criteria to detect subclinical myocardial dysfunction. Myocardial work (MW) is a novel echocardiographic measure, combining GLS with simultaneous blood pressure measurements has been found to correlate well with invasively measured global myocardial function. MW is not reported in cirrhosis and CCM.

Aims & Methods: The primary aim was to evaluate global cardiac function in decompensated cirrhosis using advanced echocardiographic parameters at rest and with dobutamine stress echo (DSE), and to study their association with development of a composite clinical outcome including acute kidney injury/hepatorenal syndrome, refractory ascites, cardiac failure and death over the subsequent 12 months. The secondary aims were to report the prevalence of CCM and to assess its association with the study outcome; to assess the diagnostic utility of cardiac biomarkers (NT-pro-BNP and cardiac troponin T) in CCM, and re-assess cardiac function at 12 months of successful LT.

Prospective study of cirrhotic patients with ascites or undergoing LT assessment from January 2021 to August 2022, with 12-month follow-up. After a written consent, clinical profile, Model for End-stage Liver Disease sodium (MELD Na) score, and cardiac biomarkers were evaluated. Transthoracic echo and DSE measured GLS and calculated MW (GWI (global work index), GCW (global constructive work), GWE (global work efficiency) and GWW (global wasted work). Statistical analysis was conducted using SPSS IBM Statistics version 29. Difference in estimated marginal mean difference in MW between baseline and DSE were obtained using repeated measures of ANOVA. Univariate analysis of clinical, echocardiographic and demographic features on the study outcome was assessed using either independent t-test or chi-squared test as appropriate. Significant predictors from the univariate analysis (p<0.05) were included in multivariate Cox regression analysis.

Results: 96 patients with mean±SD age 56±11 years; (58% male; 59% alcohol misuse) were studied. The mean±SD MELD Na was 17±11. 16 patients underwent LT; 53 developed the composite clinical outcome. MELD Na, troponin, LVEF, rest and peak GLS, rest and peak GWI, peak GWE and E/e' were significantly higher in patients meeting study outcome in univariate analysis. MELD Na and E/e' were positively associated in multivariate analysis with HR (95%CI)=1.075:1.018–1.135; p=0.009 and HR=1.179; 1.037–1.340; p=0.012 respectively.

There was a significant decrease in GLS and MW on DSE. There was a significant correlation between MELD Na and rest GLS (r=0.30, p<0.001). Based on new CCM criteria, systolic dysfunction was detected in 17% and diastolic dysfunction in 13% and CCM in 27%.

There was no association between CCM and the composite study outcome. Median (IQR) troponin was 13.5 ng/ml (7.0–24.0) and BNP was 189 (pg/ml) (53.0–374.0). There was no association between these biomarkers and CCM. Ten patients evaluated post LT, demonstrated significant improvements in GLS, MW and LVEF.

Conclusion: In our patients with advanced cirrhosis, the study revealed increased myocardial work without any augmentation on DSE. CCM observed in a quarter of patients, had no impact on clinical course before/after LT. Further studies are warranted to validate the updated CCM criteria and improve its clinical utility.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ralucaioanaavram@gmail.com

Introduction: Currently, there are several prognostic scores developed to predict mortality in liver cirrhosis. Child-Pugh-Turcotte (CPT) and MELD-Na scores are the most used and validated in current practice. Recently, BAVENO consensus issued new recommendations for a better assessment of the rate of decompensation of liver cirrhosis as well as long- and short-term mortality rates.

In this study, we aimed to evaluate the accuracy of both CPT and MELD-Na scores to predict BAVENO stages.

Aims & Methods: We conducted a retrospective study in which consecutive patients with liver cirrhosis admitted to the St. Spiridon Emergency Hospital Iasi between January 2023 and April 2024, were included. All cases were assigned to different prognostic stages according to BAVENO and MELD-Na and CPT scores were compared between the groups.

Results: Of the 155 patients included, 54.8% were males, with an average age of 57.81±12.36 years. According to BAVENO staging, 68% of patients were classified as a BAVENO stage 6, 10% as stage 5, 5% as stage 4, 10% as stage 3, 6% as stage 2, and 1% as stage 1. We found a positive correlation between MELD-Na Score and Child Pugh Score (r=0,774) with significant p-value (P<0.0001).

Furthermore, our results demonstrate superior sensitivity and specificity for the MELD-Na score (98.7% and 97.9%, AUC-0.997) compared to the Child-Pugh score, which showed a sensitivity of 71.2% (AUC-0.792) to predict a stage 6 diagnosis and worst prognosis overall.

At a cut-off of 34, MELD-Na score was the most accurate to discriminate between BAVENO stage 5 and 6, a cut off of 22 between BAVENO 4 and 5 and a cut off of 13 was the most accurate to discriminate between BAVENO stage 3 and stage 4.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Mortality rates and poor prognosis increase exponentially with liver cirrhosis decompensation, thus their assessment through predictive scores remains a highly desirable target for clinicians, MELD-Na score retaining its superiority in predicting the evolution through the BAVENO stages.

Disclosure: Nothing to disclose.

COMBINATION OF MELD SCORE WITH NEUTROPHIL-TO-LYMPHOCYTE RATIO PREDICTS IN-HOSPITAL MORTALITY IN ACUTE-ON-CHRONIC LIVER FAILURE

V. Papastergiou[1], D. Kozompoli[1], G. Kalogiros[1], I. Mylonas[1], D. Provi[1], S. Themeli[1], A. Agorogianni[1], E. Georgilis[1], K. Fiagkousakis[1], E. Vergenaki[1], K. Mousourakis[1], C. Chatzievangelinou[1], M. Mela[1], K. Varytimiadis[1], E. Archavlis[1], N. Viazis[1]

Introduction: Prediction of early mortality is crucial in patients with Acute on Chronic Liver Failure (ACLF), a highly fatal syndrome characterized by intense systemic inflammation and organ failure. Performance of the Model of End-stage Liver Disease (MELD) appears to be suboptimal in ACLF, although the prognostic potential of combining MELD with inflammatory indexes remains uncertain.

Aims & Methods: The aim of the study was to evaluate a combination of MELD with neutrophil-to-lymphocyte ratio (NLR) for in-hospital mortality prediction in patients with ACLF.

A retrospective cohort study was conducted evaluating consecutive ACLF patients followed till hospital discharge. The predictive ability and optimal cut-points of MELD and NLR calculated on admission were determined by ROC analyses. Four prognostic groups, determined by score combinations below or above the optimal cut-points, were analyzed with respect to in-hospital mortality.

Results: A total of 122 patients (50.8% males, mean age 61.8±12.1) were hospitalized with ACLF between April 2021 and February 2023. The etiology of pre-existing liver disease was alcoholic in 44.3% and in-hospital mortality was 31.1%. The areas under ROC were 0.79 for MELD and 0.68 for NLR, with optimal cut-off points 20 (sensitivity/specificity: 0.89/0.57) and 5.1 (sensitivity/specificity: 0.84/0.60), respectively.

Compared to patients with low MELD and NLR scores, patients with high scores displayed significantly higher in-hospital mortality (73.7% vs 6.7%; adjusted OR=13.96, p=0.007), whereas those with a single elevated score did not (high-MELD/low-NLR: 15.4%; adjusted OR=1.98, p=0.49; low-MELD/high NLR: 14.2%; adjusted OR=1.30, p=0.79).

Conclusion: In patients hospitalized with ACLF, a combination of high baseline MELD and NLR appears to delineate poor prognosis, correlating with a high risk of in-hospital death.

Disclosure: Nothing to disclose.

PP0900

A PRACTICAL MODEL FOR STRATIFYING ESOPHAGEAL VARICES SEVERITY IN PATIENTS WITH CIRRHOSIS

P. Wehbe[1], A. Kahwagi[1], C. Doueihy[1], B. Younes[1], C. Yaghi[1], E. Mahfouz[1], J. Amara[1], K. Honein[1], R. Slim Karam[1]
[1]Hotel Dieu de France, Beirut, Lebanon

Contact E-Mail Address: antony.kahwagi@net.usj.edu.lb

Introduction: Esophageal varices (EV) are a critical complication of portal hypertension in patients with cirrhosis, and early detection is essential to prevent potentially life-threatening hemorrhage. The Baveno VII consensus recommends performing endoscopy in patients with transient elastography (TE) values exceeding 20 kPa and platelet counts below 150,000/mm^3. While endoscopy remains the gold standard for diagnosis, non-invasive tests are gaining importance as a promising alternative for predicting EV(1).

The objective of our study is to predict the grade of varices in cirrhotic patients using a score derived from both their biological blood test results and clinical parameters.

Aims & Methods: The objective of our study was to predict the grade of varices in cirrhotic patients using a score derived from their biological blood test results and clinical parameters. This retrospective study involved patients recruited from Hôtel-Dieu de France, with data collected a few months prior to their gastroscopy for esophageal varices detection.

We calculated the ALBI-PLT score based on the method described by Inoue-Yuri et al.(2). The modified ALBI-PLT (mALBI-PLT) score was derived from the mALBI grade, assigning 1 point for grades 1 or 2a, and 2 points for grades 2b or 3. It also incorporated platelet counts, awarding 1 point for counts greater than 150,000/µL and 2 points for counts of 150,000/µL or lower.

In addition to the mALBI-PLT score, we considered various variables, including blood test results and established predictive scores such as Child-Pugh, MELD-Na, FIB-4, and APRI.

Results: This study analyzed 108 cirrhotic patients (mean age: 63.94 years, 64.8% men, 33.03% had hepatocellular carcinoma (HCC)) out of 115 recruited, excluding cases with missing data. Key predictors of varice grades included lymphocyte count (L, $\beta = -0.43$, $p = 0.011$) and sodium (Na^10, $\beta = -3.22 \times 10^{-22}$, $p = 0.005$) as significant negative associations. Positive associations were observed for the modified ALBI-platelet score ($\beta = 0.43$, $p < 0.001$), HCC ($\beta = 0.51$, $p = 0.005$), and gastrointestinal (GI) bleeding ($\beta = 0.48$, $p = 0.013$).

A derived formula for predicting varice grades is: VariceGrade = 3.49 − 0.43×ln(L) + 0.43×mALBI-PLT score − 3.22×10^−22×Na^10 + 0.51×HCC + 0.48×GI Bleeding.

The model showed strong specificity (94.5%) for identifying varices when the score was ≥ 1 and high sensitivity (97.8%) for excluding grade 3 varices when the score was ≤ 2.

Conclusion: This study introduces a non-invasive scoring system to accurately stratify esophageal varices severity, optimizing clinical decision-making and endoscopic screening in cirrhotic patients.

PP0901

COMPARISON OF EFFICACY OF ENDOSCOPIC BAND LIGATION (EBL) WITH ARGON PLASMA COAGULATION (APC) IN THE MANAGEMENT OF BLEEDING GASTRIC VASCULAR ECTASIAS (GVE)

A. Salim[1], M. Akram[2], T. Ahmed[1], F. Mengal[1], K. Malik[1]
[1]Shaikh Zayed Hospital, Gastroenterology, Lahore, Pakistan, [2]Jinnah Hospital Lahore, Gastroenterology, Lahore, Pakistan

Contact E-Mail Address: kmalik2009@gmail.com

Introduction: Gastric vascular ectasias are a common complication of liver cirrhosis and resultant portal hypertension. Traditional therapy with argon plasma coagulation is expensive. Endoscopic band ligation offers a simpler and more cost effective therapy with similar results.

Aims & Methods: Comparison of efficacy of endoscopic band ligation (EBL) with argon plasma coagulation (APC) in the management of bleeding gastric vascular ectasias (GVE).

The study period was from August 2021 to April 2025. It was carried out in the Department of Gastroenterology and Hepatology, Shaikh Zayed Hospital, Lahore, Pakistan. It was a randomized controlled trial.

30 patients of chronic liver disease who had presented with upper gastrointestinal bleeding due to Gastric Vascular Ectasias , as seen on upper GI endoscopy were recruited. All patients were explained procedural details and informed consent was taken. They were then randomly divided into two groups, A & B, of 15 patients each. Patient in group A underwent EBL while those in group B were treated with APC. After initial endoscopic therapy, these patients were followed up at 2 and 4 weeks.

Efficacy of therapy was assessed by using clinical parameters (recurrence of bleeding manifest as hematemesis/malaena/both), laboratory parameters (drop in hemoglobin) and endoscopic parameters (GVE bleed seen after initial therapy).

Results: One patient from both groups was lost to follow up. Four patients, two out of each group passed away before their last endoscopy session.

In group A (EBL), 4 out of the remaining 12 patients (33 %) needed repeat therapy at 4 weeks while 8 patients (66%) showed post banding healing not requiring repeat banding during the study period.

In group B (APC), 5 out of remaining 12 patients (42%) needed repeat therapy at 4 weeks. 7 out of 12 patients (58 %) did not need repeat therapy. There was one episode of GI bleeding in a patient undergoing band ligation which was managed conservatively with PPI and surcralfate. No other significant procedure related side effects were encountered in either groups.

Conclusion: Endoscopic Band Ligation is comparable in efficacy to Argon Plasma Coagulation for management of Gastric Vascular ectasias, offering significant cost benefits and ease of therapy.

FRAILTY IN CIRRHOTIC PATIENTS: PREVALENCE AND PREDICTIVE FACTORS

N. Bouazizi[1], W. Dahmani[1], N. Elleuch[1], E. Hamemi[1], A. Ben Slama[2], J. Hanen[2], A. Braham Ep Krifa[2], M. Ksiaa[2]
[1]Hospital Sahloul Sousse, Sousse, Tunisia, [2]CHU Sahloul, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: nihelbouazizi99@gmail.com

Introduction: Frailty is a complex clinical syndrome characterized by a reduction in physiological reserves and an increased vulnerability to stressors. Although it is often associated with aging, frailty also affects younger populations, particularly patients with severe chronic illnesses such as cirrhosis.

The objective of our study was to assess the prevalence of frailty among cirrhotic patients in a Tunisian population and to identify associated risk factors.

Aims & Methods: An analytical cross-sectional study was conducted over a three-month period in the gastroenterology department of Sahloul University Hospital in Sousse. Patients aged 18 to 70 years, diagnosed with cirrhosis (based on clinical, biological, morphological, endoscopic, and/or histological criteria) were included. Patients with severe chronic diseases that could overestimate frailty or with osteoarticular diseases limiting mobility were excluded.

Frailty was assessed using the Clinical Frailty Scale (CFS) for global frailty (GF) and the Short Physical Performance Battery (SPPB) for physical frailty (PF).

Results: A total of 50 patients were included. The median age was 59 ± 9.2 years, with a male-to-female ratio of 1.5. The main etiologies of cirrhosis were metabolic liver disease (38%) and hepatitis B-related cirrhosis (28%). According to the Child-Pugh score, 39% of patients were classified as Child A, 36% as Child B, and 26% as Child C, with an average MELD score of 14.2 ± 5.9.

Regarding frailty, 42% of patients exhibited GF and 46% had PF.

Univariate analysis revealed several factors significantly associated with GF, namely: female gender (p=0.035), age >60 years (p=0.02), presence of grade I hepatic encephalopathy (p=0.038), presence of ascites (p<0.001), BMI < 18.5 kg/m^2 (p=0.037), sedentary lifestyle (p<0.001), MELD score >15 (p=0.001), and Child-Pugh score B-C (p=0.003).

For PF, similar results were observed: age >60 years (p=0.03), presence of ascites (p<0.001), sedentary lifestyle (p=0.009), and MELD score >15 (p=0.001).

Multivariate analysis identified independent risk factors associated with both GF and PF as: age >60 years, presence of ascites, and a MELD score >15.

Conclusion: This study highlights the high prevalence of frailty among cirrhotic patients, emphasizing the importance of systematic assessment of this condition in clinical practice. Age, ascites, and the severity of cirrhosis were found to be significant indicators of frailty. These findings suggest the need to implement targeted rehabilitation programs to improve physical function and quality of life in this patient population.

PP0903

HYPONATREMIA IN CIRRHOTIC PATIENTS WITH ASCITES: WHAT TREATMENT AND WHAT IS THE OUTCOME?

D. Azzouzi[1], M. Borahma[2], F.Z. Chabib[1], N. Lagdali[1], F.-Z. Ajana[1], M. Kadiri[3]
[1]University Mohamed V, Ibn Sina Hospital, Hepato-Gastro-Enterology Departement C, Rabat, Morocco, [2]Mohammed the Vth University, Ibn Sina Hospital, Gastroenterology C, Rabat, Morocco, [3]Ibn Sina Hospital, Rabat, Rabat, Morocco

Contact E-Mail Address: azzouzidriss.ad@gmail.com

Introduction: Hyponatremia is a frequent complication of cirrhosis and is a prognostic factor correlated with the severity of cirrhosis and influencing survival and the occurrence of complications, but this relationship is not yet well defined.

Aims & Methods: This was a single-centre retrospective descriptive and analytical study, including all cirrhotic patients admitted to our department in ascitic decompensation with hyponatremia between January 2019 and march 2025. The natremia threshold of 130 mmol/l was chosen because it is widely accepted to define hyponatraemia in cirrhotic patients.

In our study, we compared 2 groups of patients: group A: fluid restriction + albumin infusion and group B: fluid restriction alone. Predictive factors of hyponatremia development and its impact on the outcome were evaluated.

The aim of this study was to identify predictive factors of hyponatremia in cirrhotic patients with ascites, assess its prognostic impact on complications and survival, and compare the effectiveness of two treatment strategies—fluid restriction alone versus fluid restriction combined with albumin infusion—in correcting hyponatremia and improving clinical outcomes.

Results: Out of a total of 127 cirrhotic patients, forty patients with ascites and hyponatraemia (Na < 130 mmol/L) were included in the comparative analysis. These patients were divided into two groups: twenty patients received fluid restriction combined with albumin infusion (group A), and twenty patients received fluid restriction alone (group B). The mean age across both groups was 54.7 years, ranging from 19 to 80 years, with a sex ratio M/F of 0.7.

The causes of liver cirrhosis in our patients were: autoimmune (n=15), viral (n=11), undetermined (n=9), metabolic (n=2), genetic (n=2) and alcoholic (n=1).

Child-Pugh stage was B in 55% and C in 45%. The mean MELD score was 18 [7-48]. The prevalence of dilutional hyponatremia as defined by a serum sodium concentration ≤130 mmol/L or ≤135 mmol/L was 10.5% and 31.4% respectively.

The mean MELD score was 18, ranging from 7 to 48. The prevalence of dilutional hyponatremia, defined as serum sodium ≤130 mmol/L or ≤135 mmol/L, was 10.5% and 31.4%, respectively. A serum sodium level ≤130 mmol/L was significantly associated with more advanced liver disease, including Child-Pugh C (OR=7.84; p<0.001) and MELD >16 (OR=6.76; p=0.001).

Group A demonstrated a significantly greater improvement in natremia (mean increase of 4.5 mmol/L versus 1.2 mmol/L in group B; p=0.02), as well as a lower incidence of complications such as hepatic encephalopathy and hepatorenal syndrome. Although the difference in global survival at one year between the two groups (33.3% in group A vs. 12.5% in group B) The main precipitating factors of hyponatremia identified were excessive diuretic use (n=18), spontaneous bacterial peritonitis (n=12), gastrointestinal bleeding (n=6) and constipation (n=4). In several cases (n=8), multiple triggers were observed concurrently. The presence of hyponatremia was associated with a higher incidence of complications during hospitalization. Survival without complications was significantly reduced in patients with hyponatremia when a serum sodium concentration ≤135 mmol/L was used as the threshold (p=0.012). Moreover, survival free from hepatic encephalopathy and hepatorenal syndrome was significantly lower in hyponatremic patients (p<0.0001).

Analysis of prognostic factors revealed that serum sodium ≤130 mmol/L (HR=2.92; p=0.004), Child-Pugh C stage (HR=3.45; p=0.002), MELD score >18 (HR=2.67; p=0.007), and development of hepatic encephalopathy or hepatorenal syndrome during hospitalization (HR=4.21; p<0.001) were significantly associated with poor outcomes. Treatment of hepatic encephalopathy included systematic use of rifaximin and lactulose alongside management of the underlying precipitating factor. Overall survival at one year was significantly lower in patients with hyponatremia (22.5% vs. 68.7%), as was mean global survival (8.3 months vs. 32.8 months; p<0.0001).

Conclusion: Low serum sodium levels were significantly associated with more advanced liver disease and increased short-term morbidity and mortality in cirrhotic patients with ascites. Our findings suggest that albumin infusion, in addition to fluid restriction, is more effective in correcting hyponatremia and may help reduce the incidence of severe complications such as hepatic encephalopathy and hepatorenal syndrome.

Therefore, serum sodium appears to be a valuable prognostic marker. The clinical benefit of correcting hyponatremia should be further confirmed in larger prospective studies.

Disclosure: Nothing to disclose.

Introduction: Spontaneous bacterial peritonitis (SBP) is a severe complication of cirrhosis, associated with high mortality. Its diagnosis relies on diagnostic paracentesis and the polymorphonuclear neutrophil (PMN) count in ascitic fluid. The neutrophil-to-lymphocyte ratio (NLR), a simple and accessible inflammatory marker, may reflect the systemic response to SBP and serve as an additional diagnostic tool.

The aim of this study was to evaluate the diagnostic performance of NLR and C-reactive protein (CRP) in SBP among cirrhotic patients hospitalized for ascitic decompensation.

Aims & Methods: We conducted a retrospective study including all cirrhotic patients hospitalized for ascitic decompensation between January 2021 and January 2025. Patients with hepatocellular carcinoma were excluded. NLR was calculated from the complete blood count performed on the first day of hospitalization. Demographic, clinical, biological, imaging, and outcome data were analyzed.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Fifty-eight patients were included, with a mean age of 65.3 years [42–73 years] and a male-to-female ratio of 0.52. Cirrhosis was of viral origin in 28 cases (48.3%), including 18 cases of hepatitis B-related cirrhosis (31.0%) and 10 cases of hepatitis C-related cirrhosis (17.2%). Other etiologies included non-alcoholic steatohepatitis (NASH) in 12 patients (20.7%), alcoholic cirrhosis in 5 (8.6%), primary biliary cirrhosis in 7 (12.1%), and cryptogenic cirrhosis in 6 (10.3%). According to the Child-Pugh classification, 21 patients (36.2%) were classified as A, 27 (46.6%) as B, and 10 (17.2%) as C.

SBP was diagnosed in 22 patients (37.9%). The mean CRP level was 12.8 mg/dL [4–68 mg/dL], and the mean NLR was 6.28 [0.53–45.31]. NLR was significantly higher in patients with SBP (3.43 vs. 1.82, p = 0.03), as was CRP (11.83 mg/dL vs. 9.35 mg/dL, p = 0.04).

ROC curve analysis identified optimal thresholds of 2.78 for NLR and 10.83 mg/dL for CRP, with good discriminatory power. For the diagnosis of SBP, an NLR ≥ 2.78 showed a sensitivity of 88.3% and a specificity of 88.9%, while a CRP ≥ 10.83 mg/dL had a sensitivity of 92.6% and a specificity of 87.6%. Logistic regression analysis revealed that combining NLR and CRP further improved diagnostic performance, achieving a sensitivity of 94.4% and a specificity of 96.7%.

Conclusion: Both NLR and CRP are significantly elevated in patients with SBP and demonstrate good diagnostic value. Their combination enhances diagnostic accuracy, supporting their potential use as non-invasive, complementary tools for the early detection of SBP in cirrhotic patients.

ALBI OUTPERFORMS MELD AND CHILD-PUGH IN PREDICTING SHORT-TERM MORTALITY IN CIRRHOTIC PATIENTS WITH GASTROINTESTINAL HEMORRHAGE

J.L. López Chacón[1], A. Sanchez[1], D. Campos[1], K. Molina[1], J.R. Aguirre Ayala[1], V.K. Linares Leal[1]
[1]Hospital Roosevelt, Guatemala, Guatemala

Contact E-Mail Address: j.l.lopez.0005@gmail.com

Introduction: Gastrointestinal (GI) hemorrhage accounts for 30% of acute decompensations in cirrhotic patients, with 60% originating from variceal bleeding. Each decompensation episode carries an in-hospital mortality rate of 13%, and a 6-week mortality rate of 20%, commonly assed using Child Pugh (CP) and MELD scores. The ALBI (Albumin-Bilirubin) score, which includes only two variables, offers a simplified evaluation of liver function. However, there is limited data on its utility in predicting short-term mortality in cirrhotic patients with GI hemorrhage.

Aims & Methods: This study aimed to evaluate the association between ALBI Score with short-term mortality in cirrhotic patients with GI hemorrhage. We conducted a prospective, cross-sectional study between January and December of 2023 at Hospital Roosevelt, Guatemala, including cirrhotic patients admitted for GI hemorrhage. Informed consent was obtained from all participants. Categorical variables were analyzed using the chi-square test, normally distributed continuous variables with Student's *t*-test, and non-normally distributed variables with the Mann-Whitney U test. Logistic binary regression and AUROC analysis were used to assess associations with short-term mortality. Statistical analyses were performed using SPSS.

Results: A total of 187 patients were included: 50.8% female and 49.2% male, with a mean age of 56 among survivors and 58 among non-survivors. Of these, 52.9% had a prior diagnosis of cirrhosis, while 47.1% were newly diagnosed. Cirrhosis etiology was metabolic in 50.2%, alcoholic in 42.7%, autoimmune in 4.3%, HCV in 1.6%, and HBV in 1.1%.

At admission, 80.8% had no ascites and 97.3% had no hepatic encephalopathy. he causes of GI hemorrhage were 86.1% esophageal varices, 3.2% gastric varices, 9.1% gastric ulcers, and 1.6% esophagitis.

Non-survivors had significantly lower systolic blood pressure (93.90 ± 16.3 mmHg vs. 107.92 ± 17.4 mmHg; $p = 0.002$) and mean arterial pressure (69.50 ± 14.5 mmHg vs. 79.67 ± 11.7 mmHg; $p = 0.005$) compared to survivors. Non-survivors exhibited significantly higher INR (1.79 ± 0.56 vs. 1.52 ± 0.41; $p = 0.026$) and total bilirubin (5.85 ± 8.73 mg/dL vs. 2.02 ± 2.82 mg/dL; $p = 0.031$), and lower serum albumin levels (2.40 ± 0.43 g/dL vs. 3.10 ± 0.54 g/dL; $p < 0.001$).

Prognostic scores were significantly higher among non-survivors: MELD (19.25 ± 10.09 vs. 13.57 ± 5.47; $p = 0.002$), MELD-Na (20.35 ± 9.76 vs. 14.44 ± 6.42; $p = 0.002$), Child-Pugh (9.15 ± 2.21 vs. 7.18 ± 1.90; $p < 0.001$), and ALBI score (-0.96 ± 0.51 vs. -1.76 ± 0.58; $p < 0.001$). Additionally, the length of hospital stay was significantly shorter among non-survivors (3.90 ± 3.82 days) compared to survivors (6.59 ± 5.58 days; $p = 0.001$).

Scores	Mortality In-Hospital	Mortality at 4 weeks	Mortality at 6 weeks
ALBI	AUC: 0.850 95% CI (0.780 - 0.921) p: 0.000	AUC: 0.881 95% CI (0.823 - 0.938) p: 0.000	AUC: 0.867 95% CI (0.806 - 0.927) p: 0.000
Child Pugh (CP)	AUC: 0.762 95% CI (0.668 - 0.857) p: 0.000	AUC: 0.819 95% CI (0.739 - 0.900) p: 0.000	AUC: 0.805 95% CI (0.728 - 0.881) p: 0.000
MELD	AUC: 0.714 95% CI (0.606 - 0.822) p: 0.002	AUC: 0.785 95% CI (0.693 - 0.878) p: 0.000	AUC: 0.786 95% CI (0.700 - 0.871) p: 0.000
MELD-Na	AUC: 0.711 95% CI (0.599 - 0.823) p: 0.002	AUC: 0.778 95% CI (0.683 - 0.873) p: 0.000	AUC: 0.783 95% CI (0.696 - 0.870) p: 0.000

Multivariable analysis showed that:

- Higher ALBI score was significantly associated with mortality (Risk Ratio 25.80; 95% CI: 6.75–98.67; $p < 0.001$),
- Hospital stay <5 days (RR 9.91; 95% CI: 2.07–47.47; $p = 0.004$),
- Endoscopy performed within 12 hours (RR 7.53; 95% CI: 2.01–28.15; $p = 0.003$).

Conclusion: The ALBI score outperforms CP and MELD scores in predicting short-term mortality (in-hospital, 4 weeks, and 6 weeks) in cirrhotic patients with GI hemorrhage. Observed mortality was 10% in-hospital, 13% at 4 weeks, and 16% at 6 weeks.

Disclosure: Nothing to disclose.

EFFECTS OF LOLA ON THE GUT MICROBIOME AND PATIENT REPORTED QUALITY OF LIFE

D. Habich[1], A. Horvath[1,2], N. Feldbacher[1,2], L. Celcer[1,2], V. Stadlbauer-Köllner[1,2]
[1]Center for Biomarker Research in Medicine (CBmed), Graz, Austria, [2]Medical University of Graz, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Graz, Austria

Contact E-Mail Address: vanessa.stadlbauer@medunigraz.at

Introduction: Liver cirrhosis is characterized by microbial dysbiosis, intestinal inflammation and a weakened gut barrier and associated with an increased risk of complications. We previously observed a positive influence of L-ornithine-L-aspartate (LOLA) on gut microbiome composition in cirrhosis (1).

The current study aimed to investigate the effect of LOLA on microbiome dysbiosis, quality of life, sarcopenia, intestinal permeability, inflammation and metabolite composition.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: In this monocentric, open-label, phase 4 study, LOLA (18g/day) was administered orally for three months to liver cirrhosis patients with hepatic encephalopathy grades (0-2). We investigated changes in their gut microbiome composition (16s rRNA sequencing, alpha and beta diversity, differential abundance), quality of life (SF36), blood ammonia concentrations, measurements of sarcopenia and frailty (appendicular lean muscle mass, anthropometric measures, liver frailty index, SARC-F), biomarkers of gut permeability, inflammation and sarcopenia as well as metabolic alterations in stool, serum, and urine.

Results: 65 patients were enrolled, and 52 patients completed the 3-month study (40.4% female, age 62 (58; 65)). While LOLA reduced the abundance of the genus Romboutsia, it did not significantly change overall microbiome diversity. LOLA led to a significant improvement in the vitality dimension of the SF36 questionnaire (45 (35; 60) to 50 (45; 60), p=0.019) and decreased plasma ammonia levels in patients with elevated baseline ammonia (69.5 (54; 225) to 46.0 (22; 66) µmol/L, p=0.004)

Although muscle mass generally declined across the study, this was not observed in patients whose elevated ammonia levels improved. Sarcopenia and frailty scores and the muscle biomarkers myostatin, irisin, fibroblast growth factor 21, insulin-like growth factor 1 were unaffected by LOLA treatment. Diamine oxidase, a marker of gut barrier dysfunction, significantly decreased (from 12.75 U/mL (11.25; 17.45) to 11.15 U/mL (9.9; 15.65), p=0.016), while LPS binding protein, a marker of innate immune response to bacterial translocation, significantly increased (from 17.05 µg/mg (14.7; 19.8) to 17.39 µg/mg (16.2; 21.9), p=0.006). Calprotectin, zonulin and sCD14 did not show significant changes.

Metabolomic analysis revealed an increase in serum alanine levels (pFDR=0.014) with additional subtle shifts in lipoprotein and amino acid profiles.

Conclusion: In summary, LOLA was associated with an improvement in vitality, an important patient-reported outcome accompanied by alterations in gut microbial composition and prevented muscle loss in patients with hyperammonaemia.

Furthermore, LOLA was associated with improvements in gut permeability and endotoxin handling. The slight increase in alanine observed in the metabolomics analysis may be a consequence of LOLA metabolism. LOLA may be a valuable supportive treatment for enhancing quality of life in cirrhosis by targeting the gut liver axis and may be particularly beneficial in preventing muscle loss in patients with hyperammonaemia.

STUDY ON NEW PREDICTIVE MODEL FOR ESOPHAGOGASTRIC VARICES REBLEEDING IN LIVER CIRRHOSIS BASED ON CLINICAL CHARACTERISTICS

W. Guo[1], Y. Chen[1], Y. Yangxu[1], K. Yin[1], M. Zhang[1]
[1]The First Affiliated Hospital of Xi'an Medical University, Department of Gastroenterology, Xi'an, China

Contact E-Mail Address: 15829309416@163.com

Introduction: To explore a new non-invasive, simple and feasible clinical prediction model for rebleeding after esophagogastric varices in patients with liver cirrhosis, so as to provide reference for early prediction of rebleeding, reduce the incidence of rebleeding and mortality, and improve the clinical outcome of patients.

Aims & Methods: This retrospective study included 177 patients with liver cirrhosis and esophagogastric variceal bleeding treated endoscopically at the First Affiliated Hospital of Xi ,an Medical University (September 2018–October 2023). Participants were stratified into rebleeding (n=93) and non-rebleeding (n=84) groups. Clinical data encompassed demographics, comorbidities (hepatic encephalopathy, ascites, portal hypertension), etiology (hepatitis B/C, alcohol-related, others), laboratory parameters (hematologic, hepatic, coagulation profiles), imaging features (main portal vein diameter), endoscopic findings (LDRf classification, red sign, mosaic-like changes, mottled changes of gastric mucosa), and treatment details (dosage of tissue adhesive, dosage of lauromacrogol, treatment methods), Prognostic scores (MELD, CTP, ALBI, APRI, FIB-4, NLR, RPR, GPR, DAR, DPR) were calculated.

The measurement data in accordance with normal distribution were expressed as mean ± standard deviation, and the independent sample t test was used. Non-normally distributed measurement data were expressed as median and interquartile range , and the rank sum test was used, and the chi-square test was used for count data.

Logistic regression model was used to analyze the risk factors of rebleeding in EGVB patients (non-rebleeding group =0, rebleeding group =1 were classified). $P < 0.05$ indicated that the difference was statistically significant. The Receiver Operating Characteristic Curve (ROC) was used to evaluate the model.

Results: 1.Univariate analysis showed that there were statistically significant differences in WBC, NEU, RBC, HGB, TBIL, CHE, ALP, ALB, PT, INR, APTT, TT, NH3, the diameter of main portal vein, the maximum diameter of varicose vein, risk factors, red sign, and the amount of tissue adhesive used ($P < 0.05$). There were significant differences in MELD score, CTP grade, FIB-4 index, DPR, DAR, NLR and ALBI scores among the scores ($P < 0.05$).

2.Multivariate analysis showed that RBC, CHE, ALP, ALB, APTT, TT, portal vein diameter, and tissue adhesive dosage were independent predictors in clinical examination. NLR and ALBI score were independent predictors in score.

3. According to the results of multivariate analysis, a joint examination model (composed of 8 independent predictors in the multivariate analysis of clinical examination) and a joint scoring model (composed of 2 independent predictive scores in the multivariate analysis of scoring) were constructed. ROC analysis was used to compare the predictive value of the joint examination model and the joint scoring model.

Examination of the combined model (AUC=0.906, $P < 0.001$, Youden index =0.71, sensitivity =81.7%, specificity =89.3%, 95%CI: 0.864-0.948) was better than the combined scoring model in predicting rebleeding in patients with EGVB (AUC=0.775, $P < 0.001$, Youden index =0.425, sensitivity =69.9%, specificity =72.6%, 95%CI: 0.706-0.843).

Conclusion: The combined model can predict the rebleeding of EGVB patients after endoscopic treatment, which is worthy of further clinical application.

Disclosure: Nothing to disclose.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. PP0908

INCIDENCE OF BACTERIAL INFECTIONS IN CIRRHOTIC PATIENTS WITH ACUTE VARICEAL BLEEDING RECEIVING ANTIBIOTIC PROPHYLAXIS

K. Supasaringkarn[1], C. Bunchorntavakul[1]
[1]Rajavithi Hospital, Gastroenterology, Bangkok, Thailand

Contact E-Mail Address: Dr_chalermrat@yahoo.com

Introduction: Antibiotic prophylaxis has been recommended to reduce the risk of infection and mortality in patients with cirrhosis and acute variceal bleeding (AVB). Recent data from Europe indicated that, despite antibiotic prophylaxis, bacterial infections, particularly of the respiratory tract, still occur in a subset of AVB patients, even with the administration of prophylactic antibiotics. Nonetheless, evidence concerning infections in AVB patients in Asia is limited and may differ from that in Western countries.

Aims & Methods: This retrospective study aimed to determine the incidence of bacterial infections among patients with AVB and to identify characteristics correlated with the occurrence of infection. Data from consecutive cirrhotic patients with AVB admitted to a tertiary care center, Rajavithi Hospital, Bangkok, between January 1, 2018, and October 31, 2024 were reviewed and analyzed. Patients with clinical signs of infections on admission were excluded.

Results: A total of 77 patients were included, with 67 (87%) being male. The average age was 52.88 ± 12.16 years. The predominant causes of cirrhosis were alcohol (66.2%), hepatitis C virus (27.3%), and hepatitis B virus (16.9%). The severity of cirrhosis was categorized as Child-Pugh A, B, and C in 31.2%, 24.2%, and 24.6% of patients, respectively.

All patients were administered intravenous ceftriaxone as prophylactic antibiotic upon admission and underwent esophagogastroduodenoscopy within 48 hours, with 82% receiving endoscopic variceal ligation. Bacterial infections were identified in 12 patients (15.6%).

The observed infection types included pneumonia (41.6%), primary bacteremia (25%), spontaneous bacterial peritonitis (16.7%), and urinary tract infection (16.7%). The median time to infection commencement was 2 (1-15) days, and the median duration of hospitalization was 5 (2-6) days, with a mortality rate of 6%. In univariate analysis, significant predictors of infections included Child-Pugh class B/C (p=0.004), BMI (p=0.037), histoacryl glue injection (p=0.044), and serum albumin (p=0.003).

A multivariate analysis revealed a statistically significant link between low serum albumin levels and the occurrence of bacterial infection, with an adjusted odds ratio of 0.13 (95% CI: 0.02 - 0.94); p=0.043.

Conclusion: Bacterial infections, especially pneumonia, remain a significant concern in cirrhotic patients with AVB despite the use of prophylactic antibiotic, particularly in individuals with hypoalbuminemia.

PP0909

RED BLOOD CELL DISTRIBUTION WIDTH AS A BIOMARKER OF SEVERITY IN LIVER CIRRHOSIS: A CROSS-SECTIONAL STUDY

M. Rahaoui[1,2], D. El Ouahabi[2], O. Elmqaddem[1,2], H. Koulali[1,2], Z. Abdelkrim[1,2], Z. Ismaili[1,2], G. Kharrasse[1,2]
[1]Faculty of Medicine and Pharmacy, Mohammed First University, Digestive Disease Research Laboratory, Oujda, Morocco, [2]Mohammed VI University Hospital Center, Hepato-Gastroenterology, Oujda, Morocco

Contact E-Mail Address: rahaouimaissae@gmail.com

Introduction: Red blood cell distribution width (RDW), is a routinely available parameter from complete blood counts, reflecting variability in erythrocyte size. Beyond its traditional hematological use, RDW has emerged as a potential prognostic marker in various systemic diseases, including chronic liver disease.

Aims & Methods: In this cross-sectional study, 200 cirrhotic patients with varying degrees of severity and etiologies were enrolled from a tertiary care hepatogastroenterology department. RDW was assessed in all patients, with a normal range set between 11% and 15%.

Our aim is to assess the relationship between RDW values and cirrhosis severity, as evaluated by Child-Pugh scores and the Model for End-Stage Liver Disease (MELD). Statistical analyses included ANOVA, post-hoc Tukey tests, and Spearman correlation to determine the association between RDW and cirrhosis severity.

Results: Our study comprised 200 cirrhotic patients, 111 females and 89 males, with an average age of 58,06 ± 15.21 years (range: 19–95).The patients were distributed across different disease stages: 99 had Child-Pugh score A, 80 had Child-Pugh score B, and 21 had Child-Pugh score C.

ANOVA test was conducted to compare the mean RDW across the different Child-Pugh stages (A, B, and C). The analysis revealed a statistically significant difference between the 3 groups: A (15,83), B (17,02), C (18,04) ($p < 0.001$). Tukey's post-hoc test showed that: Stage C had a significantly higher RDW compared to stages A ($p = 0.020$) and B ($p = 0.020$). These results suggest a progressive increase in RDW with worsening severity of liver disease.

Among patients classified as Child A, only 36.4% exhibited a high RDW, while in groups Child B and Child C, higher rates of RDW were observed, reaching 68.7% and 87.5% respectively. A significant positive correlation was found between the Child-Pugh stage and the RDW ($p < 0.001$), as assessed by Spearman's correlation test.

Similarly, a significant positive correlation was found between the MELD score and the RDW ($p < 0.001$). This finding suggests that patients with more advanced liver disease, tend to exhibit greater anisocytosis, possibly reflecting underlying inflammation, nutritional deficiencies, or bone marrow stress.

Conclusion: In conclusion, our findings suggest that RDW tends to rise with the progression of hepatic dysfunction, underscoring its potential as a simple and accessible biomarker for assessing disease severity in patients with cirrhosis. Nonetheless, further studies are needed to comprehensively evaluate the utility of RDW as a reliable predictor of cirrhosis severity.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ayari.myriam@hotmail.fr

Introduction: Sarcopenia is increasingly recognized as a major prognostic factor in patients with hepatocellular carcinoma (HCC). Its evaluation may improve patient risk stratification and therapeutic decision-making

Aims & Methods: To assess the prevalence of sarcopenia among patients with hepatocellular carcinoma (HCC), identify associated factors, and evaluate the MELD-sarcopenia score as a potential predictor of mortality.

We conducted a retrospective monocentric study over a 10-year period, including patients aged over 18 years with a confirmed diagnosis of HCC based on radiological, biological, and/or histological criteria.

Only patients with an available abdominal CT scan including the L3 vertebral level were included. Exclusion criteria were liver transplantation, other primary liver tumors, non-HCC malignancies, incomplete records, or poor-quality imaging. Sarcopenia was diagnosed by calculating the Total Psoas Area Index (TPAI) on CT, using thresholds of 5.45 cm^2/m^2 for men and 3.85 cm^2/m^2 for women. MELD and MELD-sarcopenia scores were calculated. Survival time from HCC diagnosis was recorded.

Results: Among 30 screened patients, 5 were excluded due to missing imaging. In the final cohort of 25 patients, the prevalence of sarcopenia was 52%. Compared to non-sarcopenic patients, sarcopenic patients were older (67.6 vs 56 years) and more often male. The most frequent etiology in sarcopenic patients was hepatitis C (46.2%), while hepatitis B was predominant in non-sarcopenic patients (58.3%).

Cirrhosis was mostly compensated in both groups. HCC was typically unifocal, infiltrative, and multilobar in both groups. The mean time from HCC diagnosis to death was shorter in sarcopenic patients (13.4 vs 33.9 months).

Male sex and older age were significantly associated with sarcopenia ($p < 0.05$), whereas tumor characteristics, Child-Pugh class, and biological tests were not. Kaplan-Meier analysis showed a tendency toward worse survival in patients with higher MELD-sarcopenia scores, although the difference was not statistically significant ($p > 0.05$).

Parameters	Sarcopenic Group	Non-Sarcopenic Group
Mean age	67.6 years	55.0 years
OMS status	OMS 0-1: 8 (61.5%) OMS 2: 3 (38.5%)	OMS 0-1: 11 (91.7%) OMS 2: 1 (8.3%)
Child-Pugh class	Compensated: 66.7% Decompensated: 33.3%	Compensated: 54.5% Decompensated: 45.5%
MELD score	Median: 11 IQR: 3.25	Median: 14 IQR: 5.5
ALBI grade	Grade 1: 23.1% Grade 2: 53.8% Grade 3: 15.4%	Grade 1: 16.7% Grade 2: 33.3% Grade 3: 41.7%
MELD-sarcopenia score	Median: 21.35 IQR: 3.25	
Mortality	Deceased: 76.9% Alive: 23.1%	Deceased: 83.3% Alive: 16.7%
Median survival time after HCC diagnosis	13.4 months	33.9 months

Table : Comparison of clinical and survival characteristics between sarcopenic and non-sarcopenic patients with hepatocellular carcinoma.

Conclusion: Sarcopenia is highly prevalent among patients with HCC and is independently associated with male sex and older age. The MELD-sarcopenia score appears to be a promising tool for mortality risk stratification and may aid clinical decision-making.

PROGNOSTIC SIGNIFICANCE OF ELF TEST COMPARED TO LIVER BIOPSY IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

A. Liguori[1], F. D'Ambrosio[2], N. Viceconti[1], F. Termite[1], L. Petrucci[1], S. Cardinali[3], S. Galletti[3], L. Riccardi[3], F. Pizzolante[3], N. De Matthaeis[3], M.E. Ainora[3], M.A. Zocco[1], M.C. Giustiniani[1], G. Marrone[3], M. Biolato[3], F.M. Vecchio[4], A. Grieco[3], M. Pompili[1], A. Urbani[2], M. Sanguinetti[2], A. Gasbarrini[1], L. Miele[1]
[1]Catholic University of Sacred Heart, Internal Medicine, Rome, Italy, [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Laboratory and Infectious Sciences, Rome, Italy, [3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Internal Medicine and Gastroenterology, Rome, Italy, [4]Fondazione Policlinico Universitario A. Gemelli IRCCS, Woman, Children and Public Health Sciences, Rome, Italy

Contact E-Mail Address: lig.antonio91@gmail.com

Introduction: Liver fibrosis stands out as the main prognostic risk factor in MASLD. The enhanced liver fibrosis (ELF) score is a composite of direct fibrosis biomarkers that reflect extracellular matrix turnover. While the ELF test exhibits high diagnostic accuracy for advanced liver fibrosis in MASLD patients, its role as a prognostic biomarker remains uncertain.

Aims & Methods: Our aim is to compare the prognostic effectiveness of ELF, liver stiffness measurement (LSM), FIB4, and liver histology in patients with MASLD.

We retrospectively enrolled patients with MASLD who underwent liver biopsy between 2013 and 2023. The ELF score was automatically using a serum sample collected at baseline. FIB4 computation, LSM with Fibroscan and liver biopsy were performed at baseline. Liver fibrosis stage was assessed according to the NASH CRN Scoring System.

The primary outcome was a composite endpoint including all-cause mortality, hepatocellular carcinoma, liver transplantation or complications related to cirrhosis (ascites, variceal bleeding, hepatic encephalopathy, MELD≥15). Subjects were stratified based on existing literature cut-offs for ELF (<9.8, 9.8-11.2, >11.2), LSM (<10, 10-15, >15 kPa), FIB-4 (<1.3, 1.3-2.67, >2.67), and histology (F≤2, F3, F4) to assess the risk of occurrence of the primary outcome.

Results: We included data of 289 patients (30.4% female, median age 50y [IQR 39-58]). Over a median follow-up time of 41 months (IQR 21-68), the composite endpoint occurred in 34 (11.8%) patients. The frequency of the primary outcome exhibited a stepwise increase with ELF scores <9.8 (0.5%), 9.8 to 11.2 (14.5%) and >11.2 (69.7%). Survival curves for comparisons between groups revealed significant differences for all index tests based on pre-defined histological and non-invasive test stratification (Log Rank test $p < 0.05$).

At multivariate Cox regression analysis, ELF and liver histology were significant predictors of the primary outcome after adjusting for gender, diabetes, age and BMI. (ELF > 11.2 vs < 9.8 HR 132.7 [95%CI 15.6-1127.4 $p<0.01$], 9.8-11.2 vs <9.8 HR 22.5 [95%CI 2.8-184.3 $p=0.04$]) (F4 vs F≤2 HR 92.0 [95%CI 20.1-421.9 $p<0.01$], F3 vs F≤2 HR 10.2 [95%CI 2.3-45.5 $p=0.05$]). Furthermore, the intermediate and high risk group defined by LSM had a

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significantly higher risk of developing the composite outcome compared to the low-risk group (LSM 10-15kPa vs <10kPa HR 5.51 [95%CI 1.25 – 24.18 p=0.02], LSM >15kPa vs <15 kPa HR 22.89 [95%CI 6.17 – 84.94 p<0.01]). Intermediate risk group according to FIB4 displayed no significant higher risk of composite outcome compared to low-risk group (HR 2.87 [95%CI 0.53 – 15.55 p=0.22]).

Conclusion: The ELF test demonstrated comparable performance to histologically evaluated fibrosis in forecasting clinical outcomes. It should be regarded as a viable alternative to liver biopsy for conducting prognostic assessments in patients with MASLD.

Disclosure: Nothing to disclose.

PP0912

OPTIMISING VARICEAL SCREENING IN PORTAL HYPERTENSION: THE ROLE OF LIVER AND SPLENIC STIFFNESS MEASUREMENT

F. Barker[1], M. Long[1]
[1]St Thomas' Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: florence.barker@nhs.net

Introduction: Portal hypertension is a major complication of advanced chronic liver disease (ACLD) and is associated with gastro-oesophageal varices, a leading cause of morbidity and mortality. The British Society of Gastroenterology (BSG) recommends oesophagogastroduodenoscopy (OGD) for variceal screening in all patients with cirrhosis, which could result in a high volume of unnecessary procedures. Given increasing demands on NHS services and the need for cost-effective resource allocation, strategies to reduce unnecessary endoscopy are critical.

The Baveno VI and VII consensus workshops propose non-invasive criteria to optimise variceal screening. Baveno VI suggests that patients with a liver stiffness measurement (LSM) less than 20 kPa and a platelet count greater than 150×10^9/L can safely avoid OGD. Baveno VII further refines this by recommending non-selective beta-blocker (NSBB) therapy in patients with clinically significant portal hypertension (CSPH), defined as LSM greater than 25 kPa, thereby eliminating the need for screening endoscopy in this group. For patients not clearly stratified by Baveno VI or VII criteria, splenic stiffness measurement (SSM) offers an additional non-invasive tool to refine risk assessment. Incorporating SSM in this intermediate-risk group may further reduce the need for OGD, with recent data showing a high negative predictive value for ruling out high-risk varices.

Aims & Methods: We aim to quantify the reduction in endoscopy burden achieved by applying Baveno VI and VII criteria in ACLD patients.

A retrospective analysis was conducted on 1,703 patients who underwent 1,802 FibroScans between January 1, 2024, and December 31, 2024. Patients were stratified based on LSM and platelet counts into the following categories:

1. BSG Criteria: All patients with LSM ≥10 kPa requiring OGD.
2. Baveno VI Criteria: Patients with LSM <20 kPa and platelet count $\geq150\times10^9$/L, for whom OGD could be safely avoided.
3. Baveno VII Criteria: Patients with CSPH (LSM ≥25 kPa) recommended for NSBB therapy without the need for screening OGD.
4. Patients requiring OGD: Those not meeting Baveno VI criteria and without CSPH.

Results: Liver stiffness distribution:

- <10 kPa: 1,534 patients
- 10–14.9 kPa: 136 patients
- 15–19.9 kPa: 44 patients
- 20–24.9 kPa: 31 patients
- ≥25 kPa: 57 patients

Impact of Adopting Baveno VI and VII:

- BSG Guidelines: 274 patients (LSM ≥10 kPa) would require OGD.
- Baveno VI: 149 patients (LSM <20 kPa, platelets ≥150) could avoid OGD.
- Baveno VII: 57 patients (LSM ≥25 kPa) would be managed with NSBB, avoiding OGD.
- Total Reduction: 206 out of 274 patients (~75%) could avoid OGD.

Conclusion: Adopting Baveno VI and VII criteria would significantly reduce the need for variceal screening endoscopy in ACLD patients. By applying these thresholds, up to 75% of OGDs could be avoided, optimising NHS resources and reducing patient burden. These findings support the routine use of non-invasive risk stratification in ACLD management.

Introduction: Noninvasive assessment of liver fibrosis is essential in the management of chronic liver diseases. APRI and FIB-4 are simple, low-cost tools widely used for this purpose. This study aimed to evaluate the diagnostic performance of APRI and FIB-4 in identifying significant fibrosis (≥F2) and cirrhosis (F4), using transient elastography (FibroScan) as the reference standard, and to explore their clinical and biochemical correlations.

Aims & Methods: We conducted a cross-sectional study at the Institute of Gastroenterology and Hepatology, Iași, Romania, between January 1st, 2024 and April 1st, 2025. A total of 106 patients with chronic liver disease were included. Laboratory tests were used to calculate APRI and FIB-4 scores, and liver stiffness was measured by FibroScan. For diagnostic accuracy we performed ROC curve analysis and Pearson correlation coefficients were used to assess relationships between noninvasive scores and clinical-biological variables. Statistical analysis was performed using MedCalc® Statistical Software version 23.2.1 (MedCalc Software Ltd, Ostend, Belgium).

Results: For the detection of significant fibrosis (≥F2), the area under the ROC curve (AUC) was 0.748 for APRI ($p < 0.001$) and 0.752 for FIB-4 ($p < 0.001$). In diagnosing cirrhosis (F4 ≥12.5 kPa), FIB-4 demonstrated superior diagnostic accuracy (AUC 0.836, $p < 0.001$) compared to APRI (AUC 0.797, $p < 0.001$). A FIB-4 threshold of 1.45 provided a sensitivity of 68.6% and a specificity of 83.3% for detecting significant fibrosis. High cut-offs (≥2.0 for

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

APRI and ≥4.0 for FIB-4) were associated with a specificity exceeding 96%. A significant positive correlation was observed between APRI and FIB-4 (r = 0.96, p < 0.001). Moreover, FIB-4 correlated moderately with FibroScan values (r = 0.514), while APRI showed a weaker correlation (r = 0.423).

Conclusion: The results of this study confirm that both APRI and FIB-4 are effective noninvasive tools for the staging of liver fibrosis, with FIB-4 demonstrating superior diagnostic accuracy, particularly for cirrhosis.

The moderate correlation between FIB-4 and FibroScan (r = 0.514) supports its potential role as a reliable surrogate marker, especially in settings where access to elastography is limited, outperforming the weaker correlation of APRI (r = 0.423) that suggests a lower predictive power, aligning with findings from previous studies that emphasized FIB-4's stronger association with liver stiffness and histological fibrosis progression.

The high specificity associated with elevated cut-off values enhances the clinical applicability of these scores for ruling in advanced fibrosis and cirrhosis, minimizing the need for unnecessary imaging or biopsies.

Overall, integrating FIB-4 and APRI into routine clinical practice could improve early identification of at-risk patients, optimize resource allocation, and facilitate timely therapeutic interventions.

RECURRENT HEMORRHAGE IN GASTRIC VARICEAL RUPTURE: IDENTIFYING KEY RISK FACTORS FOLLOWING BIOLOGICAL GLUE INJECTION

A. Gnaba[1], A. Sabbek[1], M. Ben Abdelwahed[1], I. Jemni[1], A. Guediche[1], M.H. Loghmari[1], L. Safer[1]
[1]Fattouma Bourguiba University Hospital of Monastir, Department of Hepato-Gastroenterology, Monastir, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: Hemorrhage due to gastric variceal rupture (GVR) represents a major clinical challenge in patients with portal hypertension (PH), carrying a high mortality rate in the absence of adequate medical and endoscopic management.

Aims & Methods: The aim of our study was to identify risk factors associated with rebleeding from gastric varices within 6 weeks following biological glue injection, and assess its impact on mortality.

This retrospective analytical study included all patients admitted to the hepatogastroenterology department of Monastir between January 2014 and October 2023 for gastrointestinal bleeding solely due to gastric varices (GV), treated with endoscopic hemostasis using biological glue injection. Gastric varices were classified according to the Sarin classification.

Results: A total of 75 episodes of gastric variceal rupture (GVR) were recorded in 33 patients, with a mean age of 58 years and a sex ratio of 0.94. Cirrhosis was the primary etiology of portal hypertension (PH) in 72.7% of cases, with most cases presenting in advanced stages (37% Child B and 22% Child C).

Across bleeding episodes, gastric varices were distributed as follows: GOV1 in 24%, GOV2 in 42.7%, and IGV1 in 32% of cases. Concurrent esophageal varices were present in over 90% of cases, and hypertensive gastropathy (HTG) was observed in 50%. Rebleeding occurred in 50% of patients, with a median recurrence interval of 345 days and a 6-week rebleeding rate of 18.7%.

At 6 weeks, risk factors significantly associated with GVR recurrence included advanced cirrhosis (Child B7 or higher), concurrent hepatic decompensation, active bleeding at endoscopy, GOV2-type varices, and HTG presence.

In multivariate analysis, only hypertensive gastropathy (HTG) emerged as an independent predictor of GVR recurrence during follow-up. Hepatic mortality reached 42.4% (14 patients), with a median survival of 35 weeks [95% CI: 3-143 weeks].

Mortality was significantly higher in patients with rebleeding (75% vs. 31.8%; p<0.001).

Conclusion: Six-week rebleeding from gastric variceal rupture (GVR) is strongly associated with advanced liver disease, the presence of hypertensive gastropathy (HTG), and active bleeding during endoscopy. This recurrence, particularly pronounced in diabetic patients, significantly elevates hepatic mortality risk in both the short and medium term.

Disclosure: Nothing to disclose.

Introduction: Cirrhosis is a serious liver disease that irreversibly damages the liver, leading to serious complications and represent a major cause of mortality.

Aims & Methods: The aim of the study was to define predictive factors of early mortality in cirrhotic patients.

We carried out a retrospective, monocentric, cross-sectional study, over a 4-year period from January 2021 to January 2025, in our hepato-gastroenterology department, including all cirrhotic patients hospitalized during this period. We conducted a descriptive and analytical statistical study subdividing patients into two groups: first group (G1), includes cirrhotic patients who died within 5 years of cirrhosis diagnosis; and a second group (G2) including those with a survival time of more than 5 years.

Data collected included demographics (age, sex), comorbidities, cirrhosis etiology, cirrhosis severity scores (Child-Pugh; MELD), history of previous cirrhosis complications (ascitic decompensation ; Spontaneous Bacterial Peritonitis; hepatorenal syndrome ; variceal haemorrhage; portal thrombosis; hepatocellular carcinoma ; hepatic encephalopathy; Acute on Chronic Liver Failure (ACLF)), as well as indication for liver transplantation was sought.

All these data were entered and analyzed in a database using SPSS version 21.0.

Results: Two hundred thirty patients were included in this study. Seventy-six patients who died within 5 years of cirrhosis diagnosis (33%). Eight variables reached statistical significance in both In univariate and multivariate analysis (p < 0.05):

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Early mortality was significantly higher in patients with Child C cirrhosis and a higher Meld score (>15) than in those with Child B cirrhosis (89% vs. 17%; p= 0.02; OR= 5.8), indicating advanced liver disease as a predictive factor of early mortality.
Six types of cirrhosis complications reached statistical significance (p < 0.05), which are spontaneous bacterial peritonitis especially if complicated by septic shock or organ failure, hepatorenal syndrome and its complications, variceal haemorrhage especially if recurrent and abundant, hepatocellular carcinoma, in cases of advanced hepatic encephalopathy, and ACLF can increase the risk of early death by 78% if in an advanced stage.
The indication for liver transplantation is also predictive of early mortality, especially if waiting times are too long (p= 0.04; OR= 4.2).
For other complications of cirrhosis: ascitic decompensation and portal thrombosis, they do not appear to increase the risk of early death in cirrhotic patients
Furthermore, no statistically significant differences were found between the two groups with regard to demographic characteristics, the existence or absence of comorbidities, and the etiology of cirrhosis.
Conclusion: Cirrhosis is a major cause of mortality, linked to the advanced stage of liver disease and its serious complications, including variceal hemorrhage, spontaneous bacterial peritonitis, hepatorenal syndrome and ACLF.

Introduction: The coexistence of HBV and hepatic steatosis is frequent, but its impact on the progression of liver disease remains poorly characterized and much debated.
Aims & Methods: We aim by this study to determine the prevalence, associated factors, consequences of this association and response to treatment.
A retrospective analysis was conducted over 20 years from 2005 to 2025 on a single-center cohort of 124 patients with chronic HBV, of whom 16.1% (n=20) had steatosis (confirmed by imaging). Demographic, virological, metabolic and histological (fibrosis stage) characteristics were compared between the groups with and without steatosis. And statistical tests (Chi², Mann-Whitney, logistic regression) were used.
For the comparison, we defined:
- Group A: combining steatosis and HBV
- Group B: HBV without steatosis.
Results: The prevalence of steatosis in patients with HBV in our series was 16.1%, with a mean age of 52.1 years higher than that of patients with HBV without steatosis, (45.8 years), with a p-value of 0.02. Furthermore, in our work there was a clear female predominance, with a sex ratio of 3 F/H in group A vs 0.9F/H in group B with a p-value of 0.04.
In the history of our patients, we found that 30% of patients had high blood pressure in group A compared with 18% in group B, 10% had diabetes in group A compared with 8% in the other group, and there was no significant difference in smoking habits (15% compared with 12%). Statistical regression did not find any significant correlation in those signs. On the other hand, in the case of dyslipidemia, there was a slight predominance of group A (15% vs. 10%) with a p-value of 0.045.
The analysis of hepatic test didn't show any big difference between results of GGT, PAL and ASAT but for ALAT there was a higher in patients with steatosis with a median of 62 vs 52,1 and a p-value of 0,02.
Our study also found no difference in serological results: 95% of patients with steatosis were Hbs Ag positive, with the presence of Hbc Ab in all patients at the time of diagnosis. These results were not very different from those of patients without steatosis (Hbs Ag positive in 96.8% and Hbc Ab positive in all patients). Only 10% of patients had a positive Hbe Ag in group A vs 7.2% in group B. The median viral load before treatment was 1870 UI/ml vs 2450 UI/ml with no real difference noted between the 2 groups, confirmed by statistical regression which found a p=0.82 value.
Our study found no real impact on liver disease, showing no worsening of fibrosis (30% F≥2 with steatosis vs 25% without, p=0.62*).
After analysis using the association Chi² test, our study found similar virological responses under treatment (83% in group A vs 78% in group B, p=0.75*).
Conclusion: In this cohort, steatosis in HBV patients (16.1%) was associated with age and female sex. Hepatic test showed a higher ALAT fold among patient with steatosis. However, higher viral load or more severe fibrosis was not demonstrated. Steatosis in HBV does not appear to have a negative influence on the course of the disease. These results suggest that the management of HBV with steatosis should primarily target virological control, without requiring any specific therapeutic adaptation.
Disclosure: no conflict of interest.

Contact E-Mail Address: l.kupcinskas@gmail.com
Introduction: The Lithuanian HCV screening programme started in May 2022. General practitioners (GPs) received special promoting fee for serological HCV antibody testing: 1. For people born between 1945 and 1994 (once in a lifetime) and 2. For people who inject drugs (PWID) or HIV-positive people (annual testing). This initiative is the first in Central and Eastern Europe.
Aims & Methods: The aim of this study was to assess the results of the first 34 months of the programme and the different scenarios for achieving the WHO 2030 targets. GPs invited people to perform a serum blood test for HCV antibodies. Anti-HCV positive patients were referred to a gastroenterologist or infectologist for HCV RNA testing, and if result was positive, direct-acting antiviral (DAA) therapy was prescribed. Information about patients was obtained from the database of the National Health In-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

surance Fund. The Markov disease progression model elaborated by the CDA Foundation was used to assess HCV elimination progress. The data from the 2022-2023 screening were used as inputs. Three scenarios were developed: the 'Base' scenario - return to pre-screening program level in 2023 and 2 scenarios with different extents of treatment.

Results: At the beginning of 2022, about 1.8 million people born in 1945-1994 lived in Lithuania. Between May 5, 2022 and February 28, 2025, from this population 1362472 people (75.7%) were tested for HCV antibodies. Positive test results were found in 1.28% of cases. In the risk group, 8396 PWID and/or HIV+ people were screened, of whom 28.9 % were seropositive. Among anti-HCV+ persons 83.8% was from population and 16.2 % from risk groups. Specialists consulted 58% anti-HCV+ persons and viremia was detected in 53,1 %. Among anti-HCV+ persons from population specialist consulted 63%, but only 29% from risk group (p<0.001). Referral to specialist delay were related with specialist waiting lines, and compliance and motivation problems in risk (PWID and/or HIV+) group. During 34-month (May 2022- February 2025) period 3 times more HCV patients were treated with DAA than during the same period before starting of the program (7577 vs 2470). The Markov disease progression model to assess HCV elimination progress showed the following scenarios: Scenario 1: if the same number of patients are treated as before the screening, the WHO targets will not be reached. Scenario 2: treating 70% of infected patients will meet most but not all WHO targets. Scenario 3: by treating all infected patients by 2030, the WHO target will be met by saving 150 lives and preventing 90 new cases of decompensated cirrhosis and 120 cases of hepatocellular carcinoma.

Conclusion: Our data show that in a European country with a moderate HCV seroprevalence, a population-based screening program is feasible: more than 75% (almost 1.4 million) of the population born between 1945 and 1994 was screened, and the number of patients treated has increased by more than 3 times in the first 34 months of the program (as compared to the same time period prior to the program). However, despite abolishment of restrictions to DAA treatment in the country, special measures to increase motivation and compliance of risk group patients to program logistic are necessary to achieve WHO 2030 targets in Lithuania.

SMALL INTESTINAL BACTERIAL OVERGROWTH POSITIVITY AS A PREDICTIVE MARKER FOR ELEVATED FIB-4 SCORES IN CHRONIC HEPATITIS: A RETROSPECTIVE COHORT ANALYSIS

R. Hasanov[1,2], E. Abdullayeva[3], G. Babayeva[2]
[1]German Hospital, Gastroenterology, Baku, Azerbaijan, [2]Azerbaijan State Advanced Training Institute for Doctors named after A.Aliyev, Terapiya, Baku, Azerbaijan, [3]Istanbul NS Clinic, Gastroenterology and Hepatology, Baku, Azerbaijan

Contact E-Mail Address: doctor_rh@mail.ru

Introduction: Chronic hepatitis, primarily caused by HBV, HCV, or HDV infections, remains a silent yet progressive condition leading to advanced hepatic fibrosis and cirrhosis. Non-invasive assessment tools, such as the FIB-4 score, play a crucial role in early-stage risk stratification. Emerging evidence suggests a potential interaction between gut microbiota alterations-particularly Small Intestinal Bacterial Overgrowth (SIBO)-and liver function, mediated through the gut-liver axis.

Aims & Methods: Aim: To evaluate the association between SIBO status and FIB-4 scores among patients with chronic hepatitis, and to assess whether SIBO positivity serves as an independent marker of hepatic fibrosis severity.

Methods: We retrospectively analyzed clinical and biochemical data from 122 patients with confirmed viral hepatitis. Parameters included age, gender, liver enzyme levels (ALT, AST, ALP, GGT), SIBO breath test results, and viral titers. FIB-4 scores were calculated using standard formulas. Patients were grouped based on SIBO status (positive vs. negative). Boxplot analysis and correlation metrics were used to visualize and quantify associations.

Results: Patients with SIBO positivity exhibited significantly higher median FIB-4 scores (1.87) compared to those who were SIBO-negative (1.23), ($p < 0.05$). The boxplot analysis underscored a wider interquartile range and rightward skew in SIBO-positive individuals. A moderate positive correlation (Spearman's rho = 0.41) was observed between viral titers and FIB-4 levels, indicating a synergistic impact of microbial overgrowth and viral load on liver fibrosis progression.

Conclusion: SIBO positivity appears to correlate with elevated FIB-4 scores in chronic hepatitis patients, suggesting microbial dysbiosis as a potential contributor to fibrotic burden. Incorporating gut health assessment into routine liver disease screening may enhance early detection of high-risk individuals.

Further prospective studies are recommended to explore causality and therapeutic modulation of the gut-liver axis.

Disclosure: Nothing to disclose.

Introduction: Esophageal varices (EVs) are a common and life-threatening complication of portal hypertension in patients with liver cirrhosis, affecting nearly 50–60% of cirrhotic individuals. Timely detection of EVs, particularly those at high risk of bleeding, is critical in guiding appropriate surveillance and prophylactic strategies. Endoscopy remains the gold standard for diagnosis; however, its invasive nature highlights the need for reliable non-invasive alternatives. Recent advances in elastography have introduced spleen stiffness measurement (SSM) as a promising surrogate marker for portal hypertension and variceal presence.

Aims & Methods: This study aimed to evaluate the clinical utility of spleen stiffness measurement using the novel 100-Hz module of Fibroscan in predicting the presence and severity of esophageal varices in patients with compensated liver cirrhosis, and to compare its performance with liver stiffness measurement (LSM).

This cross-sectional research was performed on fifty cases with compensated cirrhosis at Bab Alshaaria University Hospital's Department of Hepatology, Gastroenterology, and Infectious Diseases from September 2023 to February 2024. All patients underwent detailed clinical and laboratory

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. evaluation, abdominal ultrasound, Fibroscan (for both SSM and LSM), and upper gastrointestinal endoscopy to assess for EVs. The diagnostic accuracy of SSM and LSM in predicting EVs was analyzed, and cutoff values were determined.

Results: Of the 50 patients enrolled, 33 (66%) were diagnosed with esophageal varices, of which 18 (54.5%) had high-risk varices. SSM values were significantly higher in patients with EVs compared to those without. At a cutoff value of 43.3 KPa, SSM achieved a sensitivity of 82% and specificity of 95% in detecting EVs. In comparison, LSM at a cutoff of 13.5 KPa yielded a sensitivity of 73% and specificity of 72%. Importantly, SSM also demonstrated a strong correlation with the severity of varices, allowing differentiation between high-risk and low-risk cases.

Conclusion: Spleen stiffness measurement using the 100-Hz Fibroscan module is a highly sensitive and specific non-invasive tool for identifying esophageal varices in patients with compensated cirrhosis. Its superior predictive accuracy compared to liver stiffness measurement supports its integration into clinical practice as a screening method to reduce unnecessary endoscopic procedures. Future prospective studies are warranted to validate these findings and establish standardized cutoff values for broader clinical application.

VIRAL HEPATITIS OPPORTUNISTIC SCREENING IN PATIENTS ADMITTED TO THE UNIVERSITY HOSPITAL IN SIENA

C. Stasi[1,2], T. Marzotti[1], F. Nassi[1], G. Giugliano[1], S. Rentini[3], R. Accioli[1], R. Macchiarelli[3], L. Gennari[1], P.E. Lazzerini[1], S. Brillanti[1], Le Scotte HCV screening group
[1]University of Siena, Department of Medical, Surgical and Neuroscience Sciences, University of Siena, Siena, Italy, [2]Link Campus University, Department of Life Science, Health, and Health Professions, Rome, Italy, [3]Azienda Ospedaliero Universitaria Senese "Santa Maria alle Scotte", Siena, Italy

Contact E-Mail Address: cristina.stasi@gmail.com

Introduction: Chronic viral hepatitis is among the principal public health problems and a leading cause of morbidity and mortality. The advent of direct-acting antiviral agents (DAAs) impressively changed the management of chronic Hepatitis C virus (HCV) infection. In parallel, WHO's global hepatitis strategy aims to reduce new hepatitis infections by 90% and deaths by 65% from 2016 to 2030 and to identify undiagnosed individuals with chronic hepatitis infection before clinical progression. Currently, a free screening for HCV infection is offered in Italy to subjects born between 1969 and 1989 and also to subjects under the care of addiction services (SerD) and those in detention. In line with national screening plans, the Tuscany Region activated free screening among these subjects.

Aims & Methods: This study aimed to define the prevalence of chronic HCV infection in patients over 55, specifically those not included in free HCV screening programs, aligning with global, regional, and national plans for HCV elimination.

Additionally, the study provides a linkage to the care of those infected, evaluates the hepatitis B virus (HBV) prevalence in a subgroup of patients, and describes the clinical features of this study population. Patients born before 1969 hospitalized to the Internal Medicine and Gastroenterology Divisions at Santa Maria alle Scotte Hospital in Siena prospectively underwent screening for HCV antibodies. The gastroenterology cohort was evaluated for HBV infection. All enrolled patients were assessed for comorbidities, treatment and transaminase levels (aspartate aminotransferase [AST] and alanine aminotransferase [ALT]).

Results: A total of 207 subjects, of whom 169 resided in Siena, were divided into three cohorts based on the department where they were admitted and underwent HCV screening. Patients present a high prevalence of comorbidities (88.4%), among them common were cardiovascular diseases (68.1%), cancer (35.3%), liver and hepatobiliary diseases (28%), and diabetes (22.2%). In the entire study population, 15.5% of patients received immunomodulating drugs.

Overall, 63 patients (30.4%) showed the presence of elevated transaminase levels, 8 patients (3.9%) were anti-HCV positive, and 2 were HCV RNA positive (0.9%). Of 96 patients in the gastroenterology cohort, 9 (9.4%) had HBV infection, of whom 8.4% had HBsAg-negative infection.

Conclusion: An active HCV infection prevalence of 0.9% was found in hospitalized patients (> 55 years old). A substantial proportion of people in the gastroenterology cohort residing in South-Eastern Tuscany carried occult HBV infection (8.4%). The increase in transaminase levels can be linked to the combined presence of liver and hepatobiliary diseases and the administration of immunomodulatory drugs.

This study confirms that an opportunistic screening can contribute to identifying the submerged people affected by viral hepatitis.

Introduction: The most common aetiology of hepatocellular carcinoma (HCC) is chronic hepatitis B infection. CAMP-B score is designed as an easy to use predictive model to assess HCC risk in patients after hepatitis B surface antigen seroclearance (HBsAg), using cirrhosis, age, male sex, platelet count as parameters.

Aims & Methods: This study aims to evaluate the use of CAMP-B score for predicting HCC risk in patients in different stages of chronic hepatitis B infection. We also aimed to compare CAMP-B score with PAGE-B and mPAGE-B scores in predicting HCC risk.

This retrospective study enrolled 322 chronic hepatitis B patients which visited the Gastroenterology Clinic of the University of Health Sciences Şişli Hamidiye Etfal Training and Research Hospital between December 2017 and December 2019. Patients were classified into low-, intermediate- and high-risk groups according to their CAMP-B, PAGE-B, and mPAGE-B

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. scores. The predictive power of these scores for HCC risk was evaluated using incidence rates, Kaplan-Meier analysis, and Receiver Operating Characteristic (ROC) analysis.

Results: The incidence of HCC was 3.4% (n=11), with an incidence rate of 3 per 1000 person-years. The CAMP-B score effectively distinguished between low-, intermediate- and high-risk groups (p<0.001). Compared to PAGE-B (AUC=0.913) and mPAGE-B (AUC=0.929) scores, CAMP-B score demonstrated the highest discriminatory power (AUC=0.949). CAMP-B score classified %68.6 (n=221) of patients as low risk while, PAGE-B classified %44.1 (n=142) and mPAGE-B classified %46.3 (n=149) as low risk (Table 1). Among high-risk patients, the incidence rate was calculated as 32 per 1000 person-years for CAMP-B, 15 for PAGE-B, and 13 for mPAGE-B (Table 1). There was a significant association between age, platelet count, ALP and GGT levels and HCC development in multivariate analysis.

		Total Cohort – n (%)	HCC not Present – n (%)	HCC Present – n (%)	Incidence Rate (time-person)
CAMP-B	Low	221 (68.6)	221 (100.0)	0 (0.0)	0
	Intermediate	80 (24.8)	76 (95.0)	4 (5.0)	4
	High	21 (6.5)	14 (66.7)	7 (33.3)	32
PAGE-B	Low	142 (44.1)	142 (100.0)	0 (0.0)	0
	Intermediate	140 (43.5)	136 (97.1)	4 (2.9)	2
	High	40 (12.4)	33 (82.5)	7 (17.5)	15
mPAGE-B	Low	149 (46.3)	149 (100.0)	0 (0.0)	0
	Intermediate	120 (37.3)	118 (98.3)	2 (1.7)	1
	High	53 (16.5)	44 (83.0)	9 (17.0)	13

Table 1. Classification of Patients into Low-, Intermediate- and High-Risk Groups Accoring to CAMP-B, PAGE-B, and mPAGE-B scores.

Conclusion: The CAMP-B score emerged as an effective tool for predicting HCC risk in chronic hepatitis B patients. This is the first study to show CAMP-B score can be used as a tool to predict the risk of HCC in Caucasian patients having chronic hepatitis B.

Introduction: The LiverRisk score was recently developed as a tool for predicting liver fibrosis and liver-related outcomes in the general population. We aimed to evaluate the predictive performance of the LiverRisk score for liver fibrosis and overall mortality in HCV patients treated with direct acting antivirals.

Aims & Methods: This was retrospective, descriptive and analytical study conducted in a gastroenterology department over 8 years including patients diagnosed with chronic hepatitis C. Data were collected from patient records and during their follow-up. The data normality test for this study was conducted using the Shapiro-Wilk test. The discrimination ability of the Liver Risk Score was evaluated using the Area Under the Receiver Operating Characteristic (AUROC) curve. Overall mortality was assessed at the conclusion of the follow-up period.

Results: Among 165 patients monitored for hepatitis C and treated with direct-acting antivirals, only 68 (41.2%) patients were eligible for this study. Mean age at diagnosis was 61±13.2 year; sex ratio M/W was 0.78 .10 (14.7%) of the patients were tobacco users. 22 (32.4%) had hypertension, and 14 (20.5%) had diabetes.

Regarding hepatic risk factors; 5 (7.5%) had alcohol use disorder, and use of cannabinoid substances was reported in 5 (3%) of the cases.1 (1.4%) had history of drug injection. 7 (10.6%) had a history of bloodletting and tattoos, and 4 (6%) had high-risk sexual practices.

Regarding the circumstances of diagnosis, 23 (39.7%) patients were diagnosed incidentally, 18 (26.4%) following an evaluation for asthenia, 4 (6.9%) presented with abdominal pain, and 3 (4.4%) exhibited signs of portal hypertension.

In terms of laboratory findings, 25 (36.7%) had cytolysis, 7 (10.2%) showed biochemical cholestasis, 16 (23.52%) had thrombocytopenia, and 5 (7.3%) presented with sign of hepatocellular insufficiency. Hepatitis B coinfection was identified in 3 (4.4%) cases.

The most frequent genotype was 1b, identified in 18 (45%) patients, followed by genotype 2 in 17 (25%). Genotypes 1a, 3, and 4 were observed in 5 (7.3%) patients.

On ultrasound, 15 (22%) patients showed signs of chronic liver disease, and 8 (11.7%) exhibited signs of portal hypertension. A total of 26 (38.2%) patients underwent upper endoscopy, among whom 13 (19.11%) had esophageal varices, 2 (2.9%) had gastric or gastroesophageal varices (GOV), and 9 (13.2%) presented with hypertensive gastropathy.

46 (75.4%) were treated with Sofosbuvir and Daclatasvir, followed by Sofosvubir and Velpatasvir for 9 (14.8%). Sustained virological response was achieved for 51 (91.1%) patients.

For fibrosis, 19 (30.2%%) were at stage F4, 9 (14.3%) at stage F3, 13 (20.6%) at stage F2, and 22 (34.9%) at stage F0-F1. Median Liver risk score was 7.58[6.28;8.5].

The LiverRisk Score exhibited high accuracy in predicting liver stiffness and outperformed traditional serum biomarkers of fibrosis. Its discriminatory capacity for detecting liver stiffness ≥10 kPa was reflected by an AUROC of 0.848, compared to 0.779 for the FIB-4 test. After 5 years follow up 8 (11.76%) patients died. LiverRisk score was associated with the risk of all cause of mortality (HR= 1.34, 95% IC[0.98;1.83], p = 0.047).

Conclusion: The LiverRisk score is an accurate tool to predict liver fibrosis and mortality in HCV patients treated with direct acting antivirals.

EPIDEMIOLOGY, CLINICAL MANIFESTATIONS, AND FACTORS ASSOCIATED WITH HOSPITALIZATION OF HEPATITIS E VIRUS INFECTION IN THE HELSINKI UNIVERSITY HOSPITAL AREA, 2020–2024

E. Kilkki[1], P. Arkkila[2], E. Ruotsalainen[3]
[1]University of Helsinki, Helsinki, Finland, [2]Helsinki University Hospital, Gastroenterology, Helsinki, Finland, [3]Helsinki University Hospital, Division of Infectious Diseases, Inflammation Center, Helsinki, Finland

Contact E-Mail Address: eliel.kilkki@gmail.com

Introduction: Hepatitis E virus (HEV) infection in Europe is predominantly due to zoonotic genotype 3, transmitted via undercooked pork, game or shellfish (1,2). In the Helsinki and Uusimaa Hospital District (HUS), 70 laboratory-confirmed cases occurred from 2020–2024, with a pronounced peak in early 2024 (3). Seroprevalence in high-income countries ranges from ~6 % to > 50 %, increasing with age and swine exposure (1,2).
While most infections are asymptomatic or mild, patients with underlying liver diseases may have more severe outcomes. Diagnosis relies on anti-HEV IgM/IgG serology and PCR detection of viral RNA (4).

Aims & Methods: Objective of this study is to investigate the epidemiology of hepatitis E virus (HEV), its clinical manifestations, and factors associated with hospitalization in the Helsinki University Hospital (HUS) area between 2020 and 2024. We conducted a retrospective registry study including all patients diagnosed with hepatitis E in the HUS area from January 2020 to December 2024. Data were collected from the electronic health record system, the laboratory database, and the shared contact-tracing software of the HUS Epidemiology Unit and Uusimaa welfare regions.
Variables analyzed comprised demographic data, symptoms at presentation, key laboratory parameters (ALT, bilirubin, C-reactive protein), probable sources of infection, and details of hospitalization episodes.

Results: Study population: 70 patients (median age 58 years [IQR 45–67]; 58.6 % male).
Clinical manifestations: 92.2 % were symptomatic. The most frequent symptoms were fatigue (55.9 %), abdominal pain (47.5 %), nausea (45.8 %), and jaundice (42.6 %).
Laboratory findings: Median peak ALT was 1 153 U/L (IQR 544–1 538); median peak bilirubin 39 µmol/L (IQR 17–79); median peak CRP 22 mg/L (IQR 11–32).
Genotypes: Of 19 genotyped cases, 3c (21.1 %), 3e (21.1 %), and 3f (57.9 %), with genotype 3f predominant.
Infection sources: Cold-smoked sausages (e.g., mettwurst) were implicated in most domestic cases (69.6 % of identified sources), especially during the early 2024 outbreak. Other identified sources were unspecified meat products (6.5 %), berries (6.5 %), contact with wild animals (e.g., hunting, 4.3 %), blood transfusion (4.3 %), pork meat (4.3%), and game meat (4.3%).
Hospitalization: 50.7 % required ≥1 night of inpatient care. Hospitalized patients were older, had higher ALT, bilirubin, and CRP values, and more comorbidities than outpatients.
Predictors of hospital stay: In a multivariable zero-inflated negative binomial model, higher peak CRP was independently associated with longer hospital stay ($\beta = 0.02$; $p = 0.005$).

Conclusion: The early-2024 surge of HEV cases in the HUS area represents an internationally rare, large genotype 3 outbreak. Cold-smoked meat products were identified as the principal transmission route, although infections linked to blood transfusions, consumption of raw berries, and wildlife contact also occurred. Cases were disproportionately concentrated in men over 50 years of age. Among hospitalized patients, peak CRP emerged as the strongest predictor of inpatient care, and both mortality and incidence of hepatic insufficiency were relatively high given high sanitation standards in Finland. Further multicenter, inter-regional studies are needed to establish statistically robust risk factors for severe outcomes and to guide clinical and public health interventions.

DIFFERENCES IN BASELINE CHARACTERISTICS OF DIRECT ACTING ANTIVIRAL (DAA)-TREATED GREEK HCV PATIENTS ACCORDING TO SOURCE OF INFECTION

S. Siakavellas[1], O. Anagnostou[1], P. Antonakaki[1], M. Manolakopoulou[1], N. Tsiamperas[1], C. Charalampous[1], E.M.M. Trifylli[1], H. Kranidioti[1], G. Kontos[1], N. Papadopoulos[1], M. Deutsch[1], S. Manolakopoulos[1]

Contact E-Mail Address: s.siakavellas@gmail.com

Introduction: With the introduction of direct-antiviral medication (DAAs), eradication of HCV infection is considered now an achievable goal. While people with history of drug use (PWHD) form the most common population at risk for the infection, in Greece historically there has been a significant proportion of patients arising from the general population with no prior drug use. These two different subgroups exhibit different characteristics, that may be pertinent in the management of HCV infection and long-term follow up.

Aims & Methods: The aim of this study was to identify potential differences in the makeup of these two HCV patient subgroups.
The HERACLIS cohort, is the largest national HCV registry of patients treated with DAAs in tertiary liver centers from 2015 until 2024. Clinical data and characteristics were obtained from medical records, while transient elastography (TE) measurements and APRI score calculations were conducted at baseline. Patients were followed up initially for the duration of their treatment.

Results: 930 patients were included in the study, 69.8% (n=649) of them were men with median age 52 years old and 9.2% of these had decompensated liver disease at DAA initiation. 56.8% (n=528) of this cohort were PWHD, while the rest had been infected in another manner (non-PWHD). When comparing these two populations, PWHD were younger in age (47.1±9,8 vs 56.9±13.1 years, p<0.001) and with lower BMI (24.4±4.4 vs 26.4±4.7 kg/m2, p<0.001).
Non-PWHD cases had more often diabetes (13.6% vs 2.7%, p<0.001), hypertension (10.7% vs 8.8%, p<0.001) as well as decompensated liver disease (13.5% vs 6.1%, p<0.001). This was also reflected by TE measurements

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(13.9±10.9 vs 10.9±7.7 kPa, p=0.001) but not by the APRI score. Moreover, PWHD patients tended to have been more often infected with genotype 3 (64% vs 30%, p<0.001) while for other genotypes no such stark differences were observed. There was no significant variance observed regarding DAA regimen use but non-PWHD patients tended to suffer more often from adverse events secondary to DAA treatment (3.1% vs 0.7%, p=0.001).

Conclusion: The Greek PWHD and non-PWHD populations of HCV patients seem to exhibit different baseline characteristics which may be relevant to treatment selection and long-term follow up regimens. The main differences observed imply the concomitant presence of an element of metabolic syndrome in the non-PWHD cohort with a subsequent potential effect on the degree of underlying liver fibrosis.

Introduction: Chronic hepatitis B (CHB) remains a major global health concern due to its potential progression to cirrhosis and hepatocellular carcinoma. Accurate staging of liver fibrosis is essential for guiding clinical decisions. Non-invasive assessment methods such as the AST to Platelet Ratio Index (APRI) and transient elastography (Fibroscan) are increasingly used alternatives to liver biopsy.

Aims & Methods: To assess the diagnostic accuracy of the APRI score for detecting liver fibrosis in CHB patients, using Fibroscan as the reference standard.

This retrospective study included 68 CHB patients who underwent liver stiffness measurement via Fibroscan. APRI scores were calculated based on AST levels and Platelet counts. Fibrosis stages were classified from F0 to F4. Correlations between APRI and fibrosis stages were analyzed, and receiver operating characteristic (ROC) curves were generated to evaluate diagnostic performance.

Results: A total of 68 patients with chronic hepatitis B were included in the study, with a mean age of 47years and an ecart type of 11,1 years (age range: 20-82 years). Liver stiffness values measured by Fibroscan ranged from 5 to 16 kPa, allowing fibrosis staging from F0 to F4. The distribution of fibrosis stages was as follows: F0 (n =5) , F1 (n = 42), F2 (n = 13), F3 (n = 2), and F4 (n =6).

The mean APRI score among all patients was 0.55 (range: 0.09-2.36). A moderate but statistically significant correlation was found between APRI scores and fibrosis stages assessed by Fibroscan (r=0.45, p<0.05).

Patients with significant fibrosis (≥F2) had significantly higher APRI scores compared to those with minimal fibrosis (F0-F1) (1.05±0.65 vs. 0.32±0.41; p=0.01). (ROC) curve analysis revealed that an APRI cut-off of 0.72 provided the best balance for identifying significant fibrosis yielded an AUC of 0.68 (95% CI: 0.56-0.80), with a sensitivity of 66.7% and specificity of 71.1%.

For the detection of cirrhosis (F4), the optimal APRI cut-off was 0.86. At this threshold, the AUC was 0.71 (95% CI: 0.59-0.83), with sensitivity of 73.3% and specificity of 68.2%

Conclusion: While transient elastography remains he more precise tool, the APRI score demonstrates acceptable diagnostic performance for identifying significant fibrosis and cirrhosis in CHB patients. Its affordability and accessibility make it a valuable screening tool, especially in resource-limited settings.

ASSESSMENT OF FIBROSIS REGRESSION UNDER ENTECAVIR IN CHRONIC HEPATITIS B USING TRANSIENT ELASTOGRAPHY

S. Massanou[1], R. Harbi[2], I. Akkari[3], S. Mrabet[4], E. Ben Jazia[3]

[1]Hôpital Farhat Hached Sousse, Service de Gastro-Entérologie, Sousse, Tunisia, [2]Faculté de Medecine Ibn Al Jazzar de Sousse, Sousse, Tunisia, [3]Farhat Hached Hospital Sousse, Gastroenterology, Sousse, Tunisia, [4]Farhat Hached University Hospital Sousse, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: massanou.selma@gmail.com

Introduction: Chronic hepatitis B (CHB) can progress to cirrhosis or hepatocellular carcinoma. Entecavir (ETV) is a first-line antiviral therapy that can lead to fibrosis regression. This study aimed to assess changes in liver stiffness using transient elastography (TE) and determine the rate of fibrosis regression during ETV therapy.

Aims & Methods: A 10-year retrospective cross-sectional study was conducted in a Tunisian tertiary hospital. CHB patients treated with ETV for ≥48 weeks and with both pre- and post-treatment TE were included. Fibrosis regression was defined as a ≥2 kPa decrease in liver stiffness or a ≥1-stage improvement. Liver stiffness was measured using FibroScan® before treatment and after a minimum of 6 months of therapy.

Results: Among 129 patients, 113 had pre-treatment TE (87.6%). Median baseline liver stiffness was 8.8 kPa [3.2–33]. Fibrosis distribution: F2 (28.3%), F3 (27.4%), and F4 (19.5%). After a median of 10 months on ETV, liver stiffness significantly decreased to 5.8 kPa (p<0.001). Fibrosis regression was observed in 61.9% of cases. Fibrosis stage improved in 65 patients (57.5%), was stable in 35 (31%), and worsened in 13 (11.5%) cases. Higher rates of regression were associated with younger age, lower BMI, better adherence, and biochemical/virological response.

Conclusion: ETV therapy significantly reduced liver stiffness in CHB patients, with fibrosis regression in over 60% of cases. Transient elastography is an effective tool for non-invasive fibrosis monitoring during antiviral treatment.

VARIABILITY IN SEHCAT CUTOFF VALUES FOR DIAGNOSIS AND SEVERITY CLASSIFICATION OF BILE ACID MALABSORPTION: CLINICAL IMPLICATIONS

G. Kaur[1], D. Saraee[1], F. Umenze[1], S. Khadka[1]
[1]Scunthorpe General Hospital, Surgery, Scunthorpe, United Kingdom

Contact E-Mail Address: subodh.khadka@nhs.net

Introduction: The SeHCAT test is a critical diagnostic tool for bile acid malabsorption (BAM), a recognized cause of chronic diarrhoea that significantly impacts patients' quality of life. By measuring the retention of a radio-labelled bile acid analogue over seven days, SeHCAT classifies BAM severity. However, variability in cutoff values and nomenclature across clinical settings has led to inconsistencies in diagnostic sensitivity and specificity. Lower cutoffs (e.g., less than (<) 5%) prioritize specificity but risk missing mild cases, while higher thresholds (e.g., <15%) improve sensitivity but may lead to overdiagnosis. Individualized interpretations based on clinical context could enhance diagnostic precision.

Aims & Methods: We aimed to study the impact of this cutoff value variability in our patients in comparison with literature. We undertook a 5year retrospective analysis of all patients who underwent SeHCAT testing for suspected BAM from January 2019-2023. Relevant PubMed studies in last 10 years and NICE Diagnostic Guidance (DG7)/related studies were also reviewed.

Results: Nineteen studies were included; 3 comprehensively addressed cutoff variability. NICE tasked the Kings Technology Evaluation Centre (KiTEC) with exploring this in 1,036 patients across 38 UK centres. Results highlighted inconsistent cutoff classifications, some using "normal (>15%), borderline (5–19%), abnormal (0–4 & 0-14%)"; others employing "normal (>15%), mild (10–14.9%), moderate (5–9.9%), severe (0–4.9%)." NICE recommends a 15% cutoff for diagnosis. In our study, 353 patients underwent SeHCAT testing during the period 2019-2023. Of these, 175 (49.57%) were diagnosed with BAM; of these, 47 patients (26.86%) were classed as mild, 63 (36%) as moderate and 65 (37.14%) as having severe BAM, based on the latter nomenclature, in line with most UK centres and were managed accordingly.

Conclusion: Variability in SeHCAT cutoff values significantly affects BAM diagnosis/severity classification and therefore appropriate management. Standardizing cutoff thresholds and integrating SeHCAT results into a holistic clinical framework is essential to balance sensitivity and specificity. Further research is needed to validate cutoff ranges and establish evidence-based guidelines for optimal patient outcomes.

GENETICS-BASED ANALYSIS IDENTIFIES PLASMA GLYCOCHENODEOXYCHOLATE GLUCURONIDE AS A POTENTIAL PROTECTIVE FACTOR FOR PRIMARY SCLEROSING CHOLANGITIS

W. Yu[1,2,3], J. He[1,2], L. Qin[1,2]
[1]The First Affiliated Hospital of Soochow University, Department of General Surgery, Suzhou, China, [2]The First Affiliated Hospital of Soochow University, Pancreatic diseases center, Suzhou, China, [3]Soochow University, Suzhou Medical college, Suzhou, China

Contact E-Mail Address: yuwangjianfei@163.com

Introduction: Primary sclerosing cholangitis (PSC) is a major type of autoimmune cholestatic liver disease with unknown etiology, characterized by cholestasis, abnormal biliary epithelial homeostasis, biliary tract fibrosis and consequently liver dysfunction[1,2].

Notably, PSC further elevates the risk of developing cholangiocarcinoma[3]. Investigating the underlying causal factors could contribute to the development of novel therapeutic strategies, thereby mitigating the burden on public health systems imposed by these conditions.

Altered bile acid (BA) homeostasis is an intrinsic facet of cholestatic liver diseases. The toxicity of bile acids is associated with the severity of cholestatic diseases[4,5].

Among all BA components, hydrophobic BAs such as chenodeoxycholic acid (CDCA) and deoxycholic acid (DCA)[6] are considered the main toxic components to the bile duct epithelium and hepatocytes. Besides, glycochenodeoxycholic acid (GCDCA) has been used to model BA toxicity both in vivo and in vitro[7].

The clinical usefulness of plasma BA in cholestatic diseases was studied via BA profiling in cholangitis cohorts, and the clinical utility was analysed[4,8].

Nevertheless, no large-scale epidemiology studies have identified the causal relationship between individual components of BA and the pathogenesis of cholangitis, especially the sequence between changes in BA composition and disease onset.

In this study, we extracted summary statistics of 32 plasma BA components from the largest metabolome GWAS dataset to date[9] as exposures and performed two-sample MR using 2 datasets of PSC as outcomes, followed by reverse MR, to assess the causal relationship between BAs and the pathogenesis of this disease.

Aims & Methods: We aimed to identify causal bile acid components on PSC using mendelian randomization. Summary statistics for primary sclerosing cholangitis were retrieved from European Bioinformatics Institute and FinnGen Consortium, and plasma bile acid components data were obtained from European Bioinformatics Institute. BA profiles of PSC patients by GC-MS were retrieved from published researches.

Statistical analyses used the inverse variance weighted(IVW), weighted median(WM), maximum likelihood(ML) and MR-Egger algorithm, followed by various sensitivity analyses and reliability evaluation.

Results: Plasma level of glycochenodeoxycholate glucuronide(GCDCG) is negatively correlated with primary sclerosing cholangitis (IVW: OR=-0.12, p=0.0269 in EBI dataset, OR=-0.38, p=0.0299 in FinnGen dataset). No reverse causal effect was identified(IVW: p=0.7067 in EBI dataset, p=0.5158 in FinnGen dataset). GCDCG was decreased in bile of patients with PSC compared with healthy controls (logFC=-2.09, p=0.010).

Conclusion: Our findings provide evidence regarding the risk of primary sclerosing cholangitis for individuals with low level of plasma glycochenodeoxycholate glucuronide, and targeting the transformation of glycochenodeoxycholate into its glucuronide may be a novel therapeutic strategy to primary sclerosing cholangitis.

THE ALTERATIONS OF BILE ACIDS SPECTRUM AND SMALL INTESTINAL BACTERIAL OVERGROWTH IN PATIENTS AFTER CHOLECYSTECTOMY: A PROSPECTIVE STUDY

I. Biriuchenko[1,2], O. Barabanchyk[3], V. Bulda[3], V. Korendovych[4], M. Pugach[5], N. Korendovych[4], N. Dolgaia[6]

Contact E-Mail Address: doctor.gastro@yahoo.com

Introduction: Diarrhea after cholecystectomy is a well-known complication that worsens the quality of life of the patient and may become a real challenge for the doctor.

Both changes in the bile acids spectrum (BAsS) and possible changes in microbiota and Small Intestinal Bacterial Overgrowth (SIBO) may have a major impact. What is primary in this circle is not fully understood.

Aims & Methods: The aim was to assess BAsS and SIBO in patients prior to cholecystectomy, three and twelve months after cholecystectomy.

Methods: Initially, the bile of the patients was obtained directly from the gallbladder after it was removed during the surgery. For the second and third time, the bile of the same patients after cholecystectomy was obtained in 3 and 12 months postoperatively, after the intubation of the duodenum under ultrasound control. The spectrum of BA was assessed using photocalorimetry.

To assess the possible influence of SIBO, all the patients underwent a hydrogen breath test before cholecystectomy, and if SIBO was confirmed, they were not included in the study. Successive hydrogen breath tests were performed 3 and 12 months after cholecystectomy to all the patients who were included. The data were analyzed using parametric and non-parametric methods of evaluating the results through the Statistica program (StatSoft Inc, USA).

Results: 14 patients, predominantly women (71.4%) were enrolled in the study. The spectrum of BA three months after cholecystectomy showed a tendency for secondary BA (deoxycholic acid) to predominate over primary BA (cholic acid) (P>0.05). After 12 months, the BAs pool returned to the baseline in most of the patients (P>0.05). SIBO was not registered in patients 3 months after cholecystectomy, but it was detected in 50% of cases (P>0.05) after 12 months.

Conclusion: The predominance of secondary BA in the early postoperative period probably indicates an increase in the number of bacteria, for the transformation of primary BA in the ileum, but the breath test is not sensitive enough to determine this.

Over time, if the equilibrium in a complex mechanism of BA homeostasis is not achieved (the amount of bile in the ileum, bacteria, FXR, etc.), this may lead to the SIBO development.

Disclosure: Nothing to disclose.

METABOLIC CONSEQUENCES OF CHOLECYSTECTOMY: DATA FROM AN ORIGINAL STUDY

Y. Fominykh[1], K. Nadzhafova[2]
[1]NMRC named after V. A. Almazov, Propedevtic of Internal Diseases, St. Petersburg, Russian Federation, [2]NMRC named after V. A. Almazov, St. Petersburg, Russian Federation

Introduction: Gallstone disease (GSD) is considered one of the most common diseases of the digestive system. According to publications, in the modern world there is a steady trend towards an increase in the prevalence of GSD among young people. According to WHO forecasts, if current growth rates continue, by 2050 every fifth inhabitant of the planet will suffer from GSD. Heredity is the most important risk factor for the development of the disease. It is no longer nonsense to detect cholelithiasis in childhood with a frequency of about 5%.

Aims & Methods: To study the effect of cholecystectomy on the metabolism of lipids and bile acids in the blood plasma of patients with cholelithiasis. The study involved 96 patients aged 22-45 years with cholelithiasis (gallstones) who underwent elective laparoscopic cholecystectomy. They were divided into 2 representative groups according to the lipid profile of their blood plasma: “Normal lipid spectrum” and “Changes in the lipid spectrum”.

Clinical data, questionnaires, lipidogram, chromatography-mass spectrometry of bile acids in blood plasma and bile were used. After surgery, half of the patients with changes in the lipid spectrum received ursodeoxycholic acid (UDCA) for 3 months. Repeated examination was performed 3 months and 1 year after cholecystectomy.

Results: Lipidogram indices in the groups differed statistically significantly. Plasma bile acid levels differed significantly for cholic and ursodeoxycholic acids. In the “Normal lipid spectrum” group, an improvement was observed after 3 months, and a significant deterioration in lipidogram indices was observed after a year. In the “Changes in lipid spectrum” group, an improvement in lipidogram indices was observed after 3 months only in patients taking UDCA.

No statistically significant changes were found after a year. Patients with GI have an imbalance of bile acids: an increase in the levels of choleic, deoxycholic, glycocholic, and taurocholic acids, and a decrease in the level of henodeosquicholic.

After cholecystectomy, plasma concentrations of elevated acids, as well as initially reduced henodeoxycholic, decrease. In patients with a normal blood lipid spectrum, cholecystectomy has a negative effect on lipidogram parameters. Cholecystectomy increases the risk of deterioration of the lipid spectrum by 1.6 times. Taking UDCA improves blood lipid spectrum parameters.

Conclusion: Based on the results of the study, a patent was registered for the invention “Method for predicting lipid spectrum disorders and recurrent stone formation in young people after cholecystectomy for cholelithiasis” No. RU 2799862 C1

Introduction: Observational studies have associated cholecystectomy with cardiometabolic disorders and colorectal cancer. This is of clinical importance as the case volume of cholecystectomy has increased exponentially and cardiometabolic disorders pose a significant health burden. Understanding post-cholecystectomy gut microbiome changes may help clarify some of these observations. Published data on cholecystectomy-related gut microbiome changes are limited and mainly cross-sectional in study design, lack adequate taxonomic resolution or prediction of functional pathways as 16S rRNA sequencing rather than shotgun metagenomics sequencing was used, and observed microbiome changes have not been correlated with concomitant changes in the metabolome[1].

Aims & Methods: This exploratory prospective cohort study aimed to examine the changes in gut microbiome and systemic metabolome post-cholecystectomy. Subjects aged 21 to 65 years undergoing cholecystectomy for treatment of symptomatic gallstone disease were enrolled. Exclusion criteria included the use of antibiotics or probiotics within one month, appendicectomy, bowel surgery and inflammatory bowel disease. Biospecimens (stool, plasma and urine) were collected at baseline and one-month post-cholecystectomy. Stool microbiome was analysed by shotgun metagenomics sequencing, with assessment of ω^2 effect size (derived from weighted Jaccard distance), α (Mann-Whitney U test for unpaired and Wilcoxon signed-rank test for paired tests) and β diversity indices (PCoA and PERMANOVA), as well as differentially abundant bacterial taxa and functional pathways (Maaslin2 R package, using false discovery rate [FDR] < 0.1). Systemic metabolome (plasma, stool and urine) was examined by targeted liquid chromatography-mass spectrometry, and Orthogonal Partial Least Squares Discriminant Analysis was performed to identify metabolites that were different post-cholecystectomy, using paired t-tests and FDR < 0.1. Correlation analysis of changes in stool microbiome and metabolome was performed.

Results: A total of 26 subjects were enrolled. The mean age was 47 years (12), with 62% (16/26) male and mean body mass index (BMI) 25.57 kg/m^2 (3.75). Other clinical meta-data were smoking in 15.4% (4/26), alcohol consumption in 11.5% (3/26), use of proton pump inhibitors (PPI) in 7.7% (2/26), statins usage in 23.1% (6/26), and presence of fatty liver in 15.4% (4/26). The microbiome profile of the enrolled cohort was similar to matched asymptomatic controls with intact gallbladder (with or without gallstones). One-month post-cholecystectomy, the ω^2 effect size was 0.006 (80% power, $\alpha < 0.05$). Significant differences were observed for β diversity

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. indices after controlling for drinking status, presence of fatty liver and use of PPI. There were 32 differentially abundant bacterial taxa and 124 differentially abundant functional pathways.
Analysis of observed microbiome and systemic metabolome changes revealed correlation of 9 species with plasma bile acid (chenodeoxycholic acid [CDAC]), 20 species with plasma lipids, 3 species with stool bile acids (CDCA), 9 species with stool carboxylic acids and 2 species with urinary trimethylamine N-oxide.
Conclusion: Cholecystectomy resulted in significant changes in the stool microbiome and systemic metabolome. Such changes may help explain the epidemiological association with cardiometabolic disorders. Further larger scale prospective cohort studies with longer duration of follow-up are needed to confirm these observations.

SURGEON VERSUS RADIOLOGIST INTERPRETATION OF INTRAOPERATIVE CHOLANGIOGRAPHY IN LAPAROSCOPIC CHOLECYSTECTOMY: A POPULATION-BASED STUDY

O. Krakau[1], J. Osterberg[2,3,4], L. Enochsson[5,6], G. Sandblom[2], M. Blohm[2,4,3]
[1]Södersjukhuset, Department of Surgery, Stockholm, Sweden, [2]Karolinska Institutet, Department of Clinical Science and Education, Stockholm, Sweden, [3]Mora Hospital, Department of Surgery, Mora, Sweden, [4]Uppsala University, Centre for Clinical Research Dalarna, Falun, Sweden, [5]Umeå University, Department of Surgical Gastroenterology, Stockholm, Sweden, [6]Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden

Contact E-Mail Address: kakan.krakau@hotmail.se
Introduction: In laparoscopic cholecystectomy (LC), intraoperative cholangiography (IOC) is recommended to clarify biliary anatomy, detect choledocholithiasis and identify complications. IOC interpretation may be performed by either surgeons or radiologists, but it remains unclear which approach is preferable. This study investigates how the type of medical specialist interpreting the IOC affects surgical outcomes and operating time.
Aims & Methods: All LCs registered in the Swedish Registry of Gallstone surgery and Endoscopic retrograde Cholangiopancreatography (GallRik) between January 1, 2009, and December 31, 2020, were included. A complementary survey was distributed to all participating surgical clinics to determine local IOC interpretation practices. Registry and survey data were linked and outcomes were analysed using mixed model analysis and logistic regression.
Results: A total of 118.556 procedures from 61 surgical units were included. Operating time was longer when radiologists assessed the IOC (mean differences 11.3 minutes; 95% CI 1.60-20.89). Intraoperative complications were more common with radiologist interpretation (2.6% vs 1.5%; OR 0.58, 95% CI 0.52-0.63), while postoperative complications were slightly higher with surgeon-led interpretation (8.2% vs 7.3%; OR 1.14, 95% CI 1.08-1.20). Bile duct injury rates (0.3%; OR 1.0, 95% CI 0.79-1.27) and detection of choledocholithiasis (12.4% vs 12.6%; OR 1.02, 95% CI 0.90-0.99) were similar between groups.
Conclusion: Surgeon-led IOC interpretation is associated with shorter operating times and fewer intraoperative complications, without increasing the risk of bile duct injury or missed choledocholithiasis. Routine radiologist involvement may be unnecessary and an inefficient use of resources.

Policlinico San Matteo, Gastroenterology and Digestive Endoscopy Unit, Pavia, Italy

Contact E-Mail Address: stefano.fabbri20@gmail.com
Introduction: Endoscopic Papillectomy (EP) represents the gold standard treatment for ampullary adenoma. Despite high rates of clinical success, EP is still burdened by a non-negligible rate of adverse events, with bleeding being one of the most frequent, with a reported pooled rate of 10.6%. Despite differences in presentation and in severity, the majority of the EP-related bleeding can be managed endoscopically. Various techniques, including epinephrine injection, argon plasma coagulation (APC), hemoclips, biliary stents have been employed to manage bleeding, but robust evidence supporting their efficacy are still lacking. Recently, the introduction of a novel haemostatic peptide gel has expanded the toolbox of endoscopic haemostatic agents.
Aims & Methods: This study aims to evaluate the safety and efficacy of this new haemostatic agent in controlling bleeding in patients undergoing EP. This is a multicenter, retrospective study from 4 high-volume centers in Italy, including all consecutive patients treated with the novel heamostatic peptide gel for the management of active EP-related bleeding, between 2019 and 2024. Clinical success was defined as the achievement of hemostasis using the hemostatic gel, either alone or in combination with other techniques, for the treatment of active intraprocedural or delayed EP-related bleeding, without subsequent rebleeding
Results: A total of 16 patients were included in the study. In 15 patients, haemostatic gel was used to manage intraprocedural bleeding, while one patient was treated for delayed bleeding. An oozing bleeding was shown in 13 cases, a spurting bleeding in one case, while in 3 cases no active bleeding was present, although a visible vessels was found in two patients and one ulcer with an adherent clot in one case. Six patients were treated exclusively with haemostatic gel, while the remaining patients received combination treatments, including epinephrine injection (5 cases), clipping (6 cases), biliary stenting (2 cases), and fibrin glue application (1 case). The application of hemostatic gel was successful in 100% of cases, despite the use of side-viewing duodenoscopes with elevator. Clinical success of haemostatic gel application after the first bleeding episode was achieved in 75% (12/16) of patients.
However, 4 out of 16 patients (25%) experienced rebleeding within one day after the first treatment. The severity of bleeding ranged from mild to moderate, effectively controlled endoscopically in all cases except one, in which a radiologic embolization was needed in order to achieve bleed control and was therefore classified as severe. No gel-related adverse events were reported.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Conclusion: This novel peptide gel could represent a promising and safe tool to manage active bleeding related to EP. Further prospective studies are needed to confirm its efficacy.

Introduction: Management of poscholecystectomy complications has been variably discussed. Various options exist but the recent trend has been towards the endoscopic retrograde approach favoring a simultaneous diagnostic and therapeutic potential.

Aims & Methods: Objetive: A single institution retrospective analysis of 203 with bile duct injuries (BDI) after laparoscopic cholecystectomy (LC). We studied the various endoscopic modalities to evaluate the efficacy of the approach.

Patients and Methods: From January 2005 to January 2025, a retrospective analysis was conducted of 5528 patients referred to the endoscopy department.

During this period, 434 were referred after related BDI. These 434 (7,8%) are BDI. 231(53,2%) after open cholecystectomy and 203 (46,8%) after LC, formed the basis for this study. 154 (75,8%) were female and 49 (24,2%) were male, with an average age of 49,1years (range,13-88 years).

The clinical presentation of the BDI: jaundice 134 (66,0%); pain 47 (23,1%); fever 79 (38,9%); persistent drainage 75 (36,9%); pruritus 74 (36,4%) and acute biliary pancreatitis 18 (8,8%). ERCP was used in all cases.

Results: There were 103 patients with stricture (26 total transaction and 77 partial) and 64 (31,6%) patients with leaks and 36 (17,7%) had a combination of leaks and stricture. Endoscopic diagnosis was feasible in all cases. Subsequently, 170 (83, 7%) patients were considered for endotherapy and endoscopic treatment was interrupted in 17 patients, required surgical intervention, success healing was shown in 90%.

There 64 biliary fistulae: 40 of the cystic stump, 20 of the common hepatic and 2 of the right hepatic and 2 of the left hepatic; 36 (17,7%) biliary fistulae with stenosis (9 complete transaction and 27 partial transaction) and 103 stenosis (26 total transaction and 77 partial). The 35 total transaction required surgical treatment; however two were treated by endoscopies.

There was success in the endoscopic treatment of biliary fistulae, which 64 esphincterotomy transpapilar (ETP) and four stents. 27 patients with biliary fistulae with stenosis were 6 ETP; 11 ETP with stents; 8 ETP, dilatation, stents and two ETP with dilatation and two patients need the surgical treatment. 71/77 (92,2%) patients with stenosis could be treated: 34 ETP, stents; 36 ETP, dilatation, stents; and 3 ETP, dilatation.

Complications occurred in 6 (3, 5%), perforation (n = 1), mild pancreatites (n=3), and cholangitis (n=2) and 17 patients failed endoscopic treatment.

Conclusion: The ERCP in biliary complications of LC is feasible and with good results. It firms as coadjuvant treatment of the definitive surgery and in some situations being the method close for the definitive treatment.

Disclosure: No Conflict of Interest.

USING ENDOSCOPIC RADIAL INCISION AND CUTTING COMBINED WITH ERCP TO TREAT BILIARY-ENTERIC ANASTOMOTIC STRICTURE

L. Wang[1,2], S.-B. Luo[1], Z.-Q. Liu[1]

[1]Zhongshan Hospital, Fudan University, Shanghai, China, [2]Shanghai Geriatric Medical Center, Endoscopy Center, Shanghai, China

Contact E-Mail Address: wangli503@163.com

Introduction: Enteroscopy-assisted ERCP (E-ERCP) is used to treat biliary-enteric anastomotic stricture and common bile duct stones after alimentary tract reconstruction. However, anastomotic stricture usually responds poorly to balloon dilation caused by severe fibrosis.

Here, we report a novel technique, endoscopic radial incision (ERI) combined with E-ERCP, to treat biliary-enteric anastomotic stricture and common bile duct stones.

Aims & Methods: From October 2023 to November 2024, six patients with biliary-enteric anastomotic stricture and common bile duct stones who responded poorly to balloon dilation received ERI combined with E-ERCP in Zhongshan Hospital, Fudan University. The primary outcomes were relief of biliary-enteric anastomotic stricture and the removal of common bile duct stones. The secondary outcome was the complication rate of the procedure.

Results: The mean age was 48 and 3 patients were male. All 6 patients successfully received ERI combined with E-ERCP. Four patients with anastomotic stricture were incised by Hook knife, while two patients with the

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Hook knife not reaching the anastomotic area was incised by the top of the snare. After the ERI, the diameters of the biliary-enteric anastomotic stoma enlarged from 3 mm to 10 mm. The mean diameter of common bile duct stones was 8 mm.

All the common bile duct stones were removed by basket catheter successfully, confirmed by intraoperative common bile duct radiography and postoperative MRCP.

The mean procedure time was 32 minutes and the mean postoperative hospitalization time was 2 days. No intraoperative and postoperative complications occurred.

Conclusion: ERI combined with E-ERCP, as a novel technique, could be an effective and safe method to treat biliary-enteric anastomotic stricture and common bile duct stones after alimentary tract reconstruction.

ENDOSCOPIC PAPILLECTOMY: INSIGHTS FROM 15 YEARS OF EXPERIENCE TREATING EARLY AMPULLARY TUMORS

P. Rocha[1], F. Vidal Lima[1], R. Pimentel[1], M. Gravito-Soares[1,2], E. Gravito-Soares[1,2], P. Narra Figueiredo[1,2]

Introduction: Ampullary tumors account for 0.6-0.8% of the digestive cancers[1]. Most are sporadic, but associations with familial adenomatous polyposis (FAP), neurofibromatosis type I (NF1), and Muir-Torre syndrome have been reported[2,3,4].

Endoscopic papillectomy (EP) is increasingly performed for the management of non-invasive lesions[1].

This study assessed the efficacy, predictive factors for success, complications, and recurrence rates associated with EP.

Aims & Methods: Retrospective, single-center study of patients undergoing EP between January 2010 and January 2025. Data on patient demographics, medical history, procedural events, adverse events and follow-up were analyzed.

Results: Among 49 patients (mean age 61.4 ± 14.0 years, 53.1% male), 69.4% had sporadic lesions, 28.6% had FAP, and 2% had NF1. Most lesions were confined to the papillary mound (89.8%), while 10.2% were laterally spreading tumors involving the papilla (LST-p). Mean lesion size was 15.2 ± 6.5 mm. Complete resection was achieved in 83.7% of cases. En bloc resection (79.6%) was significantly associated with higher complete resection rates (97% vs. 40%, $p < 0.001$). Laterally spreading features were highly associated with piecemeal resection (80% vs. 13.6%, $p < 0.001$) and incomplete resection (100% vs. 5.3%, $p < 0.001$).

Adverse events occurred in 46.9% of cases, including pancreatitis (30.6%, mild in 80%), intra-procedural bleeding (20.4%), and delayed bleeding (10.2%), all successfully managed endoscopically. Perforation occurred in 8.2% and was managed endoscopically, while one case of cholecystitis required surgery. Median hospital stay was 4 days. Recurrence occurred in 7 cases, 100% at first follow-up visit, and were successfully endoscopically treated.

Conclusion: EP is an effective and relatively safe intervention for the treatment of ampullary lesions. Complete resection is more frequently attained for lesions confined to the papillary mound and when en bloc resection is feasible. While adverse events are frequent, most are mild and managed conservatively/endoscopically. All recurrences were detected at the first follow up, emphasizing the value of early re-evaluation.

PREDICTORS OF CLINICAL SUCCESS AND COMPLICATIONS FOLLOWING ENDOSCOPIC GALLBLADDER DRAINAGE FOR ACUTE CHOLECYSTITIS IN HIGH-RISK SURGICAL PATIENTS: A RETROSPECTIVE STUDY

N. Shumka[1], P. Karagyozov[1]

[1]Acibadem City Clinic University Hospital Tokuda, Clinic of Gastroenterology, Sofia, Bulgaria

Contact E-Mail Address: shumkanadica97@gmail.com

Introduction: Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) has emerged as a minimally invasive alternative to percutaneous drainage for high-risk surgical patients with acute cholecystitis. Although EUS-GBD is gaining traction in clinical practice, real-world data in complex and high-risk patients remain scarce, particularly regarding outcomes in perforated or malignant cases. While its efficacy is increasingly recognized, data on predictors of success and complications remain limited.

Aims & Methods: This retrospective study explored potential clinical and procedural factors associated with outcomes following EUS-GBD. Patients undergoing EUS-GBD for acute cholecystitis between October 2021 and January 2024 at a tertiary center were included. All procedures were performed by endoscopists with advanced training in interventional EUS. Data on demographics, comorbidities, procedural details, and outcomes were collected. Clinical success was defined as resolution of sepsis or cholecystitis symptoms within 48 hours. Complications included bile leak, infection, and the need for reintervention. Due to the limited sample size, statistical analysis was descriptive and exploratory.

Results: Thirteen patients (6 females, median age 69.1 years [IQR 45–90]) underwent EUS-GBD during the study period. Indications included gallstones (53.8%), malignant cystic duct obstruction (38.4%), and ischemia (7.7%). Reasons for non-surgical management included terminal malignancy (n=6, 46.2%), coronary artery disease (n=5, 38.5%), cirrhosis with hepatocellular carcinoma (n=1, 7.7%), and the patient's choice (n=1, 7.7%). Lumen-apposing metal stents (LAMS) were placed transgastrically in 10 patients (n=10, 77%) and transduodenally in 3 (n=3, 23%).

Two patients (15.4%) presented with gallbladder perforation and pericholecystic abscess at the time of EUS-GBD. Both cases achieved full resolution following the drainage procedure, indicating that EUS-GBD may serve as a valuable rescue therapy in complicated acute cholecystitis.

Clinical success was achieved in 12 out of 13 patients (92.3%). One patient (7.7%) developed a bile leak, associated with the presence of ascites and hepatocellular carcinoma. Median post-procedural hospital stay was 6.8 days (IQR 3–20). Exploratory analysis suggested a trend toward

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

higher complication rates in patients with ascites and those undergoing transgastric drainage, though no definitive conclusions could be drawn. At 30-day follow-up, no late adverse events or stent-related complications were reported.

Conclusion: EUS-GBD is a highly effective and safe treatment option for acute cholecystitis in patients unfit for surgery, with rapid symptom resolution and acceptable hospital stay duration. Notably, the resolution of pericholecystic abscesses in two cases of gallbladder perforation suggests that EUS-GBD may be beneficial even in more complex clinical scenarios. Preliminary data from this small cohort suggest that the presence of ascites and transgastric access may increase the risk of adverse events. These findings support the role of EUS-GBD not only as a safe alternative in high-risk patients but also as a potentially definitive solution in anatomically and clinically challenging cases.

Further prospective studies with more significant patient populations are warranted to validate these early observations and optimize outcomes in this vulnerable population.

Disclosure: Nothing to disclose.

TRANSPAPILLARY GALBLADDER DRAINAGE IN THE CLINICAL PRACTICE – PILOT STUDY

Z. Bosze[1], R. Bor[1], A. Fabian[1], D. Magyar[1], B. Vasas[2], B. Kui[1], F. Szanto[1], B. Farkas[1], A. Balint[1], E. Iványi[1], P. Bacsur[1,3], M. Rutka[1], A. Paszt[4], K. Farkas[1,3], T. Molnár[1], Z. Szepes[1]

Introduction: The Tokyo Guideline 2018 recommends laparoscopic cholecystectomy as the gold standard therapy for acute cholecystitis regardless of the severity and the onset of symptoms, as long as the patient is fit for surgery. Approximately 20% of the patients undergo acute cholecystectomy in our region, and in the remainder of the patients, we have to take into consideration the likelihood of recurrent inflammation after the regression with conservative therapy.

According to the TG 2018, the drainage of the gallbladder is recommended in grade II and grade III cholecystitis. This can be carried out by interventional radiologist as percutaneous transhepatic gallbladder drainage (PTGBD), by endoscopist as transpapillary gallbladder drainage (TPGBD) or endosonography-guided gallbladder drainage (EUS-GBD).

Aims & Methods: The primary endpoint of our prospective, non-randomized, observational study was to determine the technical (successful stent implantation into the gallbladder) and clinical success (repeated need for drainage and absence of recurrent cholecystitis) of TPGBD in those patients that underwent it from 01.01.2023 at the University of Szeged. Our secondary endpoint was the comparison of the time of hospitalization between the patients who underwent clinically successful TPGBD and those who underwent PTGBD for grade II/III cholecystitis.

Results: Altogether 19 patients had undergone TPGBD, 74% of them were female, the average age was 64,53. Previously 21% had cholecystitis, 47% had cholecystolithiasis, while 16% had choledocholithiasis and 11% of the patients gone under PTGBD. TPGBD was carried out because of grade II cholecystitis in 89% of the patients, and grade III in the rest of them. 63% was considered at least a 3 in the ASA physical status classification. Altogether the technical success rate was 58%, a cholangioscop was used in 37% of the cases. The successful canulation rate of the bile duct was 89%, while the canulation rate of the cystic duct was 68%. There were two cases, where after the canulation of the cystic duct the implantation of the plastic stent was not possible. 3 patients were referred for PTGBD after an unsuccessful TPGBD, the remainder patients with an unsuccessful TPGBD received conservative therapy.

After a technically successful TPGBD, only one patient went under PTGBD due to his severe comorbidities, rather than a repeated TPGBD. 6 patients underwent cholecystectomy averagely in 8,5 weeks after the TPGBD, the remainder of patients did not have neither the need for repeated drainage nor any symptoms requiring urgent care due to cholelithiasis.

Comparing this group with 11, randomly chosen patients who underwent PTGBD for at least grade II cholecystitis during the period of the study, we detected that the time of hospitalization after the drainage was less (8,2 days vs 13,3 days), and less patients required repeated drainage or had recurrent cholecystitis (1 vs 4).

Conclusion: Although TPGBD imposed a great challenge before the use of cholangioscop in everyday practice, nowadays it is becoming an accepted part of the therapeutic algorithm in the treatment of cholecystitis, where an acute cholecystectomy is not performed.

Our results suggest that TPGBD can lead to shortened hospitalization and have less complications than TPGBD. Our findings will serve as a basis for a future extension of the study and for the design of a randomised prospective study with a control group.

Introduction: In patients with complete biliary obstruction, conventional treatments such as metallic stents or balloon dilation are often not feasible. Therefore, the endoscopic technique of magnetic compression becomes an alternative for these patients. However, there are few reports in the literature regarding the efficacy and safety of this less invasive approach for the recanalization of biliary structures, particularly in the context of liver transplantation.

Aims & Methods: We aimed to conduct a systematic review with meta-analysis on the safety and efficacy data of magnetic compression for the treatment of complete biliary anastomosis obstructions following liver transplantation. We searched PubMed, Embase, and Cochrane Library for studies evaluating magnetic compression anastomosis for the treatment of complete biliary anastomosis obstructions after liver transplantation. The odds ratio (OR) was used for binary outcomes and the mean difference (MD) for continuous outcomes, with their respective 95% confidence interval (CI).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: This single arm meta-analysis included three studies and 27 patients. Technical success was achieved in 23/27 patients (85.19%; 95%CI 66,54-94.33; I2=0%). Magnet aproximation failed in two patients; in the remaining, recanalization was achieved in 23/25 (94,25%; 95%CI 48.74-99.65; I2=0%).

Conclusion: This systematic review and meta-analysis demonstrated that for the recanalization of completely obstructed biliary ducts after liver transplantation, the magnetic compression technique achieved satisfactory technical success and a high degree of therapeutic success. This indicates that this less invasive approach is a viable alternative for treating patients in this condition.

Introduction: ERCP is the cornerstone for managing biliary and pancreatic duct diseases. However, performing in patients with surgically altered anatomy poses significant challenges. Traditional ERCP techniques often fail in these cases due to difficulties in accessing the papilla. This has led to the development of alternative techniques like enteroscopy-assisted ERCP (e-ERCP) and endoscopic ultrasound-directed transenteric ERCP (EDEE).

e-ERCP while it can be successful, is technically demanding, time-consuming, and associated with a higher risk of complications while EDEE involves using EUS guidance to create a temporary anastomosis between the stomach and the intestinal segment containing the papilla. EDEE offers a more direct and stable route to the biliary tree, However, it requires specialized equipment (lumen-apposing stents) and expertise.

Aims & Methods: Retrospective observational, patients undergoing EDEE or e-ERCP at the CMN 20 de Noviembre between 2018-2024

Results: This study compared two endoscopic procedures, e-ERCP and EDEE, for accessing the biliary tract in patients with altered anatomy. The average age of the patients was 48 years, with a standard deviation of 14 years, and 61% were women. Most patients (81%) underwent e-ERCP, while only 9% underwent EDEE. Regarding the success of the procedure, e-ERCP had a technical success rate of 87%, endoscopic success rate of 93%, and clinical success rate of 75%. On the other hand, EDEE, although performed in a small number of patients, showed a 100% success rate in all three categories.

Adverse events occurred in 5% of patients. 72% of patients had altered anatomy due to a pancreaticoduodenectomy, and 90% had a Roux-en-Y hepaticojejunostomy. In addition, dilations were performed in 72% of patients, stents were placed in 17%, and sphincterotomy or precut was performed in 17%.

Conclusion: The average cost of EDEE was 120,000 pesos (6,000 USD), while that of e-ERCP was 40,000 pesos (2,000 USD). Despite the difference in cost, EDEE showed a 100% success rate in this study, suggesting that it could be a cost-effective option for patients with altered anatomy in whom e-ERCP is not feasible or has failed. However, a cost-effectiveness analysis, considering the cost of the procedure divided by the proportion of clinical success, showed that e-ERCP was more cost-effective than EDEE.

Studies with a larger number of patients are needed to confirm these findings and to evaluate the safety and cost-effectiveness of EDEE compared to e-ERCP.

This study is limited by the small number of patients with EDEE and the lack of information on the type of complications, the duration of the procedures, and long-term survival. It is recommended to expand the research with more patients and to perform a statistical analysis to formally compare the two procedures.

Introduction: Uncomplicated choledocholithiasis may progress to obstructive jaundice, cholangitis, or acute pancreatitis[1]. The current therapeutic standard for choledocholithiasis is Endoscopic Retrograde Cholangiopancreatography (ERCP), however, this procedure is associated with a complication rate of approximately 10%. Identifying factors that contribute to spontaneous resolution of uncomplicated choledocholithiasis may allow clinicians to avoid unnecessary ERCP, thereby minimizing procedural risks and costs.

Aims & Methods: This retrospective cohort study was conducted to identify predictive factors for spontaneous passage of biliary stones in patients diagnosed with uncomplicated choledocholithiasis. We included patients who underwent ERCP for confirmed choledocholithiasis, excluding those with a history of prior ERCP or complications related to untreated biliary calculi, such as obstructive jaundice, acute cholangitis, or acute pancreatitis. The primary endpoint was the rate of spontaneous resolution of choledocholithiasis prior to ERCP.

Results: A total of 104 patients were included, 61.5% female with a mean age of 68 ± 14 years. Most patients (62.5%) presented with abdominal pain and/or abnormal liver enzymes, while the remaining 37.5% were diagnosed incidentally.

Among the 104 patients, 21.6% showed no evidence of lithiasis on ERCP, despite the identification of stones >3 mm on imaging studies. The median time to the endoscopic procedure was similar between patients with and without stones on ERCP (12 IQR 25 vs. 15 IQR 24 weeks; p=0.821). Imaging findings, such as common bile duct ectasia (p=0.517), intrahepatic

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

bile duct dilation (p=0.528), and the number of calculi (p=0.236), did not associate with spontaneous resolution. The average size of the largest stone was also comparable between patients with and without choledocholithiasis identified on ERCP (9 ± 4 mm vs. 8 ± 4 mm; p=0.452). The presence of peri-diverticular papillae did not impact the likelihood of spontaneous resolution (p=0.777).

Remarkably, patients with an intact gallbladder exhibited a significantly higher rate of spontaneous resolution (31.5%) compared to those with prior cholecystectomy (6.1%, p=0.005). This association was confirmed as an independent predictor of spontaneous resolution (OR 7.1, 95% CI: 1.5–33.3, p=0.013).

Conclusion: Spontaneous resolution of uncomplicated choledocholithiasis is common, especially in patients with an intact gallbladder. Our data support a conservative approach in these patients, such as performing endoscopic ultrasonography immediately prior to ERCP to identify those who may not require intervention.

RECURRENT CBD STONES IN CHOLECYSTECTOMIZED PATIENTS: A MISSED RISK IN POST-ERCP MANAGEMENT

A. Azarkan[1], Y. Dendane[1], O. Elmqaddem[1], H. Koulali[1], G. Kharrasse[1], Z. Abdelkrim[1], Z. Ismaili[1]
[1]Faculty of Medicine and Pharmacy/University Hospital Center Mohammed VI, Hepatology and Gastroenterology, Oujda, Morocco

Contact E-Mail Address: azarkananas@gmail.com

Introduction: Recurrent choledocholithiasis is an often-overlooked complication in cholecystectomized patients, even after successful endoscopic clearance. Despite the absence of the gallbladder, bile duct stones may recur, exposing patients to repeated ERCPs, complications, and rising healthcare costs. To our knowledge, few studies have focused exclusively on stone recurrence in cholecystectomized patients following ductal clearance.

Aims & Methods: This study aimed to characterize the clinical and endoscopic profile of recurrence in this population and to explore potential risk factors and preventive strategies to optimize long-term outcomes.

We performed a retrospective single-center study including all cholecystectomized patients who underwent ERCP for CBD stones between May 2016 and October 2024. Patients with confirmed ductal clearance and no stent placement at index ERCP were screened.

Recurrence was defined as symptomatic choledocholithiasis confirmed by cross-sectional imaging and treated with repeat ERCP. Demographic, clinical, biochemical, and endoscopic parameters were collected.

We specifically analyzed stone burden, CBD diameter, type of sphincterotomy, and follow-up strategy to identify patterns of recurrence and potential targets for prevention.

Results: Among 287 cholecystectomized patients, 16 (5.6%) experienced stone recurrence after initial clearance. Most were women (87.5%), with a mean age of 66.6 ± 13.3 years. Cardiometabolic comorbidities were frequent: hypertension (25%), diabetes (18.8%), and obesity (12.5%), with a mean BMI of 27.6 kg/m^2. At index ERCP, all had multiple stones (mean: 2.8) and a dilated CBD (mean diameter: 14.5 mm). Only 25% underwent wide sphincterotomy, while the remaining had incomplete or limited sphincterotomy. The median time to recurrence was 12 months (range: 3 months–5 years). None had structured follow-up or preventive therapy post-clearance.

Conclusion: This real-life series suggests a distinct recurrence profile in cholecystectomized patients: advanced age, female sex, metabolic comorbidities, multiple CBD stones, persistent duct dilation, and absence of wide sphincterotomy. Although limited by sample size, these observations highlight the need for individualized post-ERCP strategies in at-risk patients.

Notably, this recurrence rate may be underestimated due to possible missed cases in patients not readmitted. Future prospective studies should assess whether early wide sphincterotomy, structured long-term follow-up, and adjuvant therapies such as ursodeoxycholic acid can reduce recurrence and improve long-term outcomes.

Disclosure: Nothing to disclose.

ROLE OF ENDOSCOPIC BILIARY STENTING IN ACCESS TO CHEMOTHERAPY IN PATIENTS WITH UNRESECTABLE MALIGNANT OBSTRUCTION

G. Boryczka[1], M. Hartleb[1], M. Janik[2]
[1]Medical University of Silesia, Department of Gastroenterology and Hepatology, Katowice, Poland, [2]Univeristy of Silesia, Institute of Biomedical Engineering, Katowice, Poland

Contact E-Mail Address: gboryczka@sum.edu.pl

Introduction: Endoscopic drainage is standard of care in malignant biliary obstruction (MBO).

Aims & Methods: The aim of this study was to investigate efficacy of biliary stenting in providing access to systemic chemotherapy. Patients with biliary obstruction (bilirubin >2.5 mg/dl) caused by unresectable biliary or pancreatic cancer were retrospectively analyzed with respect to use of chemotherapy and survival. Laboratory data were analyzed at baseline, 7-10 and 28-35 days following biliary stenting.

Results: Patients with MBO (n=78) were allocated into one of three groups according to bilirubin level [mg/dl] 2.5 – 5.99 (group 1), 6.0 - 15.0 (group 2) and >15 (group 3). On first blood testing mean bilirubin declines from baseline in respective groups were: 1.19 (29.5%), 3.77 (38.5%) and 7.1 (27.3%), and on second measurement 1.61 (40%), 5.69 (58.2%) and 13.0 (50%). Chemotherapy was applied in 28 (35.8%) patients, less frequently in group 3 than in group 1 (31.2% vs 44.0%; p =0.07) and group 2 (vs 38.1%; p =0.06). Mean survival time was 4.8 ±2.8 months and was significantly shorter in group 3 as compared to group 2 (3.8 ±2.0 vs 6.2 ±3.9 months; p =0.02) and to group 1 (vs 5.4 ±2.7 months; p =0.03).

Conclusion: In two-thirds of patients with MBO endoscopic biliary drainage does not grant access to chemotherapy. Use of chemotherapy and survival time are significantly higher in patients with bilirubin level below 15 mg/dl as compared to those with greater bilirubinemia, but in patients with bilirubin level below 6 mg/dl the biliary drainage is minimally effective.

Disclosure: None.

PP0944

INDETERMINATE BILIARY STRICTURES: A RETROSPECTIVE STUDY

P. Nehring[1], M. Ciszewska[2], A. Przybyłkowski[1]
[1]Medical University of Warsaw, Department of Gastroenterology and Internal Medicine, Warsaw, Poland, [2]Medical University of Warsaw, Warsaw, Poland

Contact E-Mail Address: piotr.nehring@gmail.com

Introduction: Diagnosis of biliary obstructions is a challenge especially when histopathology is inconclusive. Indeterminate biliary strictures often require additional verification and a personalized approach.

Aims & Methods: This study investigates the prevalence, characteristics, and natural history of indeterminate biliary strictures. This retrospective study covers patients treated with ERCP because of jaundice due to biliary stricture(s) of unknown etiology.

Exclusion criteria were prior liver transplantation, visible tumor, lithiasis, acute pancreatitis, PSC, or any known cause of dilated biliary ducts with subsequent biliary stricture diagnosed with imaging studies (US, CT, MRI, or EUS) and serology and clinical data.

A diagnosis of potentially benign biliary stricture was based on cytology/histopathology evaluation of samples taken on primary ERCP. The study participants were monitored every 2–3 months with further endoscopic, imaging, and serological evaluations as needed.

Results: A total of 510 patients were treated with primary ERCP for biliary obstruction of indeterminate etiology. The 186 (36.5%) had biliary strictures with negative cytology/histopathology (category II per Papanicolaou guidelines), of these 55 (29.6%) had strictures in the liver hilum, 22 (11.8%) in the common bile duct (CBD), and 108 (58.1%) in the intrapancreatic region. Malignancy was confirmed in subsequent tests in 40 patients (21.5%). A benign cause was diagnosed in 77 cases (41.4%), including pancreatitis, PSC, ischemia, IgG4-SC, and Mirizzi syndrome, while 69 strictures (37.1%) remained indeterminate. Strictures in the liver hilum had a higher rate of eventual malignancy (30%) compared to CBD (23%) and intrapancreatic (16%) localization.

Lithiasis was more common in intrapancreatic strictures (12%), while PSC was more frequent in hilar strictures (14%). During 6-month follow-up of the 69 indeterminate cases: 17 patients received a diagnosis (8 lithiasis, 5 malignancies, 2 chronic pancreatitis, 1 benign neoplasm, 1 IgG4-SC), 4 patients died from unrelated causes, 48 cases (25.8% of the potentially benign stricture group) remained indeterminate.

Conclusion: A quarter of benign biliary strictures remain indeterminate in 6 months follow-up, while 20% of patients with indeterminate receive diagnosis of malignancy.

Disclosure: Nothing to disclose.

PRECANCEROUS GALLBLADDER LESIONS IDENTIFIED ON PRIOR IMAGING: A RETROSPECTIVE ANALYSIS AND CLINICAL IMPLICATIONS

J. Kaneko[1], T. Otsu[1], M. Takinami[1], Y. Takahashi[2], S. Tamura[1]
[1]Iwata City Hospital, Gastroenterology, Shizuoka, Japan, [2]Iwata City Hospital, Hepatology, Shizuoka, Japan

Contact E-Mail Address: meganerock10@gmail.com

Introduction: Gallbladder cancer (GBC) has a poor prognosis due to its aggressive nature and limited treatment options. Although early diagnosis through imaging is critical, it remains difficult—particularly in cases of focal gallbladder wall thickening (FGWT), which can mimic benign conditions such as adenomyomatosis or chronic cholecystitis.

Aims & Methods: This study aimed to identify lesions that progressed to GBC (precancerous lesions of GBC; PLGBC) by evaluating prior imaging and to describe their clinical characteristics and outcomes. Patients diagnosed with GBC at Iwata City Hospital between 2014 and 2024 were retrospectively reviewed. Those who had prior imaging—defined as abdominal ultrasound (US), computed tomography (CT), or magnetic resonance imaging (MRI) performed more than three months before GBC diagnosis—were included for analysis. PLGBC was defined as a lesion identifiable on prior imaging but not diagnosed as GBC, and corresponding to the site of subsequently diagnosed GBC. Imaging features and clinical outcomes were compared between patients with and without PLGBCs.

Results: Among 140 patients diagnosed with GBC, 66 (47%) had prior imaging available for review and were included in the analysis. The median age at GBC diagnosis was 80 years (interquartile range [IQR]: 71–86), with 33 male patients (50%). The median interval between prior imaging and GBC diagnosis was 753 days (IQR: 404–1796). The modalities of prior imaging included CT only in 42 patients, US only in 7, MRI only in 1, US and CT in 6, CT and MRI in 6, US and MRI in 3, and all three modalities in 1 patient. PLGBCs were identified in 32 patients (48%). Regarding lesion morphology, 28 patients presented with FGWT, 2 patients with diffuse gallbladder wall thickening (DGWT), and 2 patients with gallbladder polyps. Lesion locations were the neck in 5 patients, the body/fundus in 25 patients, and the entire gallbladder in 2 patients. Features such as intramural stones or Rokitansky–Aschoff sinuses (RAS) were observed in 15 patients, and gallstones in 7 patients.

No significant differences were found between patients with and without PLGBCs regarding resectability (36% vs. 35%, P = 1.00), radical resection rates (13% vs. 13%, P = 1.00), or survival from diagnosis (median: 640 vs. 791 days, P = 0.96). Six patients with PLGBC were diagnosed with GBC during observation of gallbladder lesions (median follow-up: 406 days, range: 350–552 days), and all underwent successful radical resection of GBC.

Conclusion: PLGBCs were identified in approximately half of the patients who had undergone imaging before their GBC diagnosis, with FGWT being the predominant imaging feature. Recognizing PLGBCs and ensuring appropriate follow-up may enable timely surgical intervention, offering a potential opportunity to improve outcomes in patients with GBC.

Disclosure: Nothing to disclose.

Introduction: Endoscopic papillectomy (EP) for duodenal ampullary tumors is primarily performed for lesions confined to the papilla, particularly adenomatous changes. However, early complications such as bleeding (0-21.6%), pancreatitis (0-23.1%), and perforation (0-8.3%) occur at relatively high rates. Post-EP bleeding, due to anatomical characteristics of the ampulla of Vater, can be challenging to manage and may worsen, making it critical to identify factors associated with this complication to reduce its frequency.

Aims & Methods: The study aimed to investigate the factors associated with post-endoscopic papillectomy bleeding in patients with ampullary tumors. This study included 39 patients (39 lesions), excluding residual

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and accessory ampullary lesions, who underwent EP at our institution between March 2011 and October 2024. We evaluated univariate analysis and SHAP values based on tree-based models for several factors related to post-EP bleeding. Hyperparameters of each model were optimized by optuna, and those models were trained with the Python package scikit-learn (version 1.3.0).

Results: The cohort included 1 adenocarcinoma, 32 adenomas, 1 neuroendocrine neoplasm, and 5 cases of ampullary inflammation, with a mean age of 66.7 years (23 males, 16 females).

Patient factors included: The American Society of Anesthesiologists (ASA) Physical Status Classification I/II/III in 5/21/13 participants, median Charlson Comorbidity Index (CCI) of 1 (range 0-7), 15 cases with a history of alcohol consumption, median Brinkman Index of 100 (range 0-1680), median total bilirubin of 0.7 mg/dL (range 0.2-2.1), median serum amylase of 80 IU/L (range 36-296), median platelet count of 198,000/µL (range 113,000-494,000), median PT-INR of 0.98 (range 0.86-1.14), median APTT of 28.7 seconds (range 23.0-39.4), median CEA of 1.9 ng/mL (range 0.3-12.8), and median CA19-9 of 7.7 U/mL (range 0.8-76.4).

Antithrombotic agents were used in 4 participants (1 on low-dose aspirin, 1 on clopidogrel, and 2 on direct oral anticoagulants), and periampullary diverticula were observed in 3 cases. Median tumor size was 10.3 mm (range 2.0-45.0). Procedural factors included a median total procedure time of 56 minutes (range 23-230), with 36 cases receiving endoscopic biliary stenting and 38 cases receiving endoscopic pancreatic duct stenting. The electrosurgical units ICC200/VIO300D/VIO3 were used in 9/19/11 cases, respectively. Protease inhibitors were used in 9 participants, NSAID suppositories (25mg/50mg) in 5/24 cases, and local hemostatic measures included epinephrine spray in 8 cases, thrombin spray in 8 cases, and hemostatic peptide solutions in 5 cases.

Clipping for ulcer after resection was performed in 33 cases. Post-EP bleeding within 30 days occurred in 12 cases (30.8%), including 9 moderate and 3 severe cases. Univariate analysis revealed that a history of alcohol consumption was significantly associated with post-EP bleeding (Odds ratio [OR] 2.33, 1.14-4.79, P = 0.02).

Feature importance was evaluated using the mean absolute SHAP values across all participants. In the Random Forest model, the top contributing features were CA19-9 (mean |SHAP| = 0.026), CCI (mean |SHAP| = 0.024), and a history of alcohol consumption (mean |SHAP| = 0.023). In contrast, the XGBoost model identified tumor size (mean |SHAP| = 0.315), a history of alcohol consumption (mean |SHAP| = 0.244), and platelet count (mean |SHAP| = 0.198) as the most important features.

Conclusion: In our cohort, a history of alcohol consumption is a robust factor associated with post-endoscopic papillectomy bleeding.

Disclosure: Nothing to disclose.

MALIGNANT BILIARY STRICTURES: WHAT IS THE NUTRITIONAL STATUS?

Y. Aroudam[1], M. Acharki[2], M. Salihoun[1], F. Bouhamou[1], I. Serraj[1], N. Kabbaj[1]

[1]Ibn Sina Hospital, EFD-HGE, Rabat, Morocco, [2]CHU Ibn Sina Unité de, EFD-HGE, Rabat, Morocco

Contact E-Mail Address: Aroudamyousra2@gmail.com

Introduction: Malignant biliary strictures are mainly secondary to biliopancreatic cancer, and inevitably affect the nutritional status of these icteric patients. Deterioration of this nutritional status conditions therapeutic management, particularly surgery.

The aim of this study is to assess the nutritional status of patients with biliary stenosis.

Aims & Methods: All patients with non-operable malignant biliary stenosis who underwent endoscopic biliary drainage were included from 2015 to 2022 in a single-center descriptive and analytical study. Patients with advanced WHO 3/4 impairment of general condition were excluded.

Nutritional status was assessed before and after the procedure (3-6 months) on the basis of weight, BMI, weight change, nutritional risk index (NRI), albumin and CRP levels. The various data collected were analyzed using SPSS software.

Results: 200 patients were included: mean age 59 years (18-96 years) with no clear gender predominance (sex ratio=1.04). The etiology of malignant biliary stenosis was dominated by cholangiocarcinoma in 112 cases (56%), followed by pancreatic cancer in 64 cases (34%), extrinsic compression in 16 cases (8%) and ampulloma in 8 cases (4%).

Endoscopic biliary drainage was performed in 192 cases (96%), bilio-digestive anastomosis in 6 cases (3%) and trans-hepatic drainage in 2 cases (1%).

Pre-therapeutic nutritional assessment showed that: 100% of patients had significant weight loss with a mean of 21.91%, 71.5% had anorexia and 47% were underweight (BMI < 18.5 kg/m2), 83.5% had hypoalbuminemia and 84% had elevated CRP.

An improvement in nutritional status was noted 3 to 6 months after biliary drainage, with an improvement in: underweight from 47% to 17%, severe undernutrition from 61.5% to 22.06%, anorexia from 71.5% to 18.61% and an increase in mean albumin level from 29g/l to 34.52g/l and a decrease in mean CRP level from 61.73 mg/l to 26 mg/l. The 6-month survival rate was 72.5% (n=145).

Conclusion: Malignant biliary strictures are essentially linked to cholangiocarcinomas, with a clear impact on nutritional status, represented by weight loss in all cases, anorexia in around ¾ of cases and underweight in around 50%. The impact of biliary drainage on nutritional status is clear, since there is an improvement in the various clinical and biological factors assessing the latter.

Disclosure: Nothing to disclose.

Introduction: Perihilar cholangiocarcinoma (pCCA) is a rare malignancy originating from the bile duct bifurcation which is often diagnosed in an advanced stage. Most patients require endoscopic or percutaneous biliary drainage, as they present themselves with jaundice and/or cholangitis. In most Western countries, only palliative chemotherapy (pCTx) is offered to these patients, positively impacting overall survival and quality of life. Unfortunately, median survival is still poor, with only 10.6 months in patients receiving pCTx, compared to a dismal 4.0 months in patients receiving best supportive care (1).

For non-resected pCCA, there is much debate on the optimal technique of biliary drainage, which is often deemed necessary to initiate pCTx. This study aimed to investigate the impact of biliary drainage on pCTx initiation and survival in patients with non-resected pCCA.

Aims & Methods: Individual patient data from all Dutch patients diagnosed with non-resected pCCA between 2015 and 2020 were retrieved from the Netherlands Cancer Registry. Survival data was last updated on 1st of February 2024. Data was retrieved and de-identified by trained data clerks. The primary outcome was pCTx initiation. Secondary outcome was overall survival. For both the primary and secondary outcome, associations were investigated for several (biliary drainage) factors by multivariable competing risk regression analysis. Initial drainage procedure and initiation of pCTx were treated as time-varying covariates. Sensitivity analysis for pathologically proven pCCA was performed.

Results: A total of 1265 patients (median age of 74 years [IQR: 66-82 years]) were included, of whom 242 patients (19.1%) received pCTx after a median interval of 72 days [IQR 43-110 days] after initial presentation. Patients who underwent biliary drainage did not receive pCTx more often. If performed, drainage at a referral hospital (HR:0.65, 95%CI: 0.42-0.99), ≥3 drainage procedures performed (HR:0.53, 95%CI: 0.32-0.88), and drainage performed ≥14 days after presentation (HR:0.70, 95%CI: 0.49-0.99) were associated with no pCTx. Median overall survival for those who received pCTx and those who did not was 12.8 months [95%CI: 11.7-14.2] and 2.7 months [95%CI: 2.4-3.1].

Receiving of pCTx was associated with improved overall survival (HR:0.61, 95%CI: 0.51-0.73), but biliary drainage was not. If performed, biliary drainage by percutaneous trans-hepatic catheter placement compared to endoscopic plastic stenting (HR:1.27, 95%CI: 1.02-1.57) was associated with diminished survival, and drainage performed ≥14 days after presentation (HR: 0.76, 95% CI: 0.65-0.88) was associated with improved overall survival. Sensitivity analysis for pathologically confirmed pCCA showed similar results.

Conclusion: The need for biliary drainage did not affect the initiation of pCTx. When indicated, biliary drainage should be performed as quick as possible in an academic center to improve the rate of patients receiving pCTx.

Contact E-Mail Address: loris.marmo@gmail.com

Introduction: Endoscopic papillectomy (EP) is the preferable therapeutic strategy for non-invasive ampullary adenomas (AA), meaning limited to ampulla of Vater or sphincter of Oddi and with no invasion of the submucosa or further duodenal layers and no regional lymph node involvement, and with limited intraductal growth. To date, international guidelines recommend staging any AA with both MRI and EUS prior to EP, regardless of the size, the endoscopic appearance, and the grade of dysplasia. This implies a risk of superfluous examinations, especially for small non-deconstructed lesions.

Aims & Methods: The primary aim of this study is to evaluate the accordance rate between ERCP and EUS images in terms of AA intraductal growth definition. A monocentric, prospective, interventional study has been conducted including all consecutive patients referred to the Digestive and Interventional Endoscopy Unit of ASST Grande Ospedale Metropolitano Niguarda for endoscopic papillectomy from January 2024. Inclusion criteria was the availability of pre-EP staging MRI with no evidence of lymph node and metastatic involvement. All consecutive patients, prior to voluntary informed consent, underwent CE-EUS, which results have been blinded to ERCP endoscopist. Demographic, clinical, endoscopic and pathological data were collected.

Results: To date, a total of 20 patients have been enrolled (M 49%, median age 58 years [38-71]); they were referred to EP mainly after an incidental diagnosis (50% of the cases) during EGDS (45% of the cases) or EUS (25% of the cases). No cases of FAP among them was included. Median AA diameter was 20 mm [15-28.8], mostly Paris 0-Is (50%) and 0-IIa (45%) lesions, mainly with a non-LST behaviour (60%) and a non-deconstructed mucosal pit pattern (Kudo IIIL, 62.5%). At EUS, 5 (25%) presented a >5mm main pancreatic duct (MPD) dilation, and 10 (50%) a common bile duct (CBD) dilation, with a median CBD diameter of 12 mm [8-15]; CBD intraductal involvement was reported in 5 cases (for a median extension of 3 mm [2.5-9.3]), while DPP in 1 (with a 3 mm extension). Previous cholecystectomy was performed in 6 (30%) cases, and previous sphincterotomy in 3 (15%). Concordance with cholangiografic ERCP images was of 19/20 (95%) cases: in 1 case EUS revealed a small CBD involvement, not confirmed at ERCP and at subsequent histology on the R0 specimen. All AA were resected thorough endocut hot snare polypectomy, mainly (60%) en-bloc. After EP, 18 (90%) cases underwent concomitant biliary and pancreatic plastic stenting, and 13 (65%) mechanical and injectional hemostasis. Reported AEs were 2 cases of bleeding, 2 pancreatitis and 1 cholangitis, all managed endoscopically. At specimen histology, 14 (70%) cases were low-grade dysplasia adenomas, 3 (15%) high-grade, and 1 (5%) adenocarcinoma (which underwent surgery), with 5/19 (26.3%) cases of R1/R2. 6/19 (31.6%) cases (all the R1/R2 and 1 R0) presented a residual adenoma at 2-months-follow-up: all of them were treated with Habib ablation with negative histological controls after a median of 2 procedures. After a 5.4 months median follow-up time, only 1 recurrence was reported, successfully treated endoscopically.

Conclusion: According to our limited experience, pre-EP EUS did not provide any additional nor incisive information for the therapeutic management of any-size AA without lymph node and metastatic involvement. Further data from this ongoing prospective study and hopefully from RCT will help identify a specific subgroup of AA which would effectively benefit from CE-EUS/MRI staging prior to EP, thus sparing unnecessary examinations.

Disclosure: Nothing to disclose.

Introduction: Pancreatic exocrine insufficiency (PEI) is a condition characterized by inadequate secretion or activity of pancreatic enzymes, resulting in the maldigestion and malabsorption of nutrients. While PEI is most commonly associated with chronic pancreatitis and cystic fibrosis, it also occurs frequently in the context of pancreatic and peri-pancreatic malignancies. In patients with pancreatic cancer PEI arises due to direct tumor infiltration, ductal obstruction, parenchymal destruction, or as a consequence of surgical resection.

Other gastrointestinal malignancies, such as ampullary or biliary tree cancers, may also contribute to PEI through similar mechanisms. Importantly, PEI in cancer patients is often under-recognized, despite its significant impact on nutritional status, quality of life, and overall prognosis. Timely identification and management of PEI in malignancy-associated cases is crucial to optimize clinical outcomes and support ongoing cancer therapies.

Aims & Methods: The objective of this study is to assess the incidence of PEI in patients with biliopancreatic and ampullary tumors, to explore potential differences in PEI occurrence based on tumor location and to investigate possible associations between PEI and relevant biomarkers.

We conducted a retrospective observational analysis of a consecutively recruited patient cohort including patients diagnosed with biliopancreatic and ampullary tumors at a tertiary care hospital between 2016 and 2024.

PEI was defined as fecal elastase-1 (FE-1) levels below 100 µg/g.

At the time of diagnosis, we collected data on demographic characteristics, tumor-related variables, the incidence of PEI, and serum nutritional markers.

Results: We included 408 patients with malignancies potentially associated with PEI. Of these, 54.2% were male, with a mean age of 72 years (range: 38–101) and a mean body mass index (BMI) of 25.45 (SD ± 4.28).

The types of malignancies included were pancreatic ductal adenocarcinoma (PDAC) in 63.5% of patients, cholangiocarcinoma (CCA) in 23.8%, ampullary tumors in 9.8%, and gallbladder tumors in 2.9%. The overall

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

incidence of PEI at the time of diagnosis was 38.2%. Among subgroups, the incidence was 51.4% in PDAC patients, 13.4% in those with CCA, and 25% in those with ampullary tumors. PEI incidence was significantly associated with elevated HbA1c (>5.8%, $p<0.01$) and Ca 19-9 levels (>37 U/mL, $p<0.01$).

In PDAC, tumors located in the pancreatic head were associated with a significantly higher incidence of PEI (58.8%) compared to tumors in the body (27.8%) and tail (21.7%) ($p<0.01$). In this subgroup, PEI was significantly associated with elevated HbA1c (>5.8%, $p=0.03$), elevated Ca 19-9 (>37 U/mL, $p=0.04$), and elevated bilirubin (>1.2 mg/dL, $p<0.01$).

In contrast, among CCA patients, no significant differences in PEI incidence were observed based on tumor location, and no significant associations were found between PEI and the clinical or laboratory variables analyzed .

Conclusion:

- PEI is observed not only in patients with PDAC but also in those with CCA and ampullary tumors at the time of diagnosis.
- Given the high incidence of PEI in tumors located in the pancreatic head, empirical pancreatic enzyme replacement therapy should be considered in this subgroup.
- In PDAC patients, the presence of PEI is significantly associated with endocrine dysfunction, hyperbilirubinemia secondary to biliary obstruction and elevated Ca 19-9 levels.

Introduction: Endoscopic papillectomy(EP)is a viable treatment option for ampullary lesions(AL). While many studies have reported low morbidity and acceptable outcomes, early attempts to pool data from these initial experiences have produced conflicting conclusions regarding key technical aspects.

To address these uncertainties, we conducted a systematic review and pooled analysis to evaluate the safety and efficacy of EP for AL,identifying factors that may influence outcomes.

Aims & Methods: Electronic databases (Medline, Scopus and EMBASE) were searched up to September 2024. Studies that included patients with endoscopically resected AL were eligible. Efficacy and safety outcomes were pooled by means of a random-effects model to obtain a proportion with a 95% confidence interval(CI). Univariable meta-regression analyses were conducted to explore potential factors affecting outcomes.

Results: A total of 60 studies (4,859 lesions) published between 2002 and 2024 were analyzed. Complete resection was achieved in 86.2% of cases, though intraductal involvement limited success. The recurrence rate was 18.6%, however, the majority (89.3%) of patients were managed endoscopically without surgery.

The pooled adverse event (AE) rate was 30.0%, with bleeding (12.2%) and post-procedural pancreatitis (11.1%) being the most common complications. Prophylactic stenting reduced pancreatitis risk, while intraductal involvement increased perforation risk. Adjunctive treatments for intraductal involvement were associated with an increased risk of papillary stricture.

Conclusion: Endoscopic papillectomy is a safe and effective treatment for ampullary lesions. However, lesions with intraductal extension pose a higher risk of incomplete resection and perforation, warranting careful evaluation of the benefit-risk balance in these cases.

While prophylactic pancreatic stenting may reduce the incidence of post-procedural pancreatitis, optimizing strategies to minimize overall adverse events remains a key focus for future research.

A REVIEW OF THE SPECTRUM OF REFERRAL PATTERNS IN PATIENTS DIAGNOSED WITH BILE ACID MALABSORPTION

S. Khadka[1], D. Saraee[1], F. Umenze[1], G. Kaur[1]
[1]Scunthorpe General Hospital, Surgery, Scunthorpe, United Kingdom

Contact E-Mail Address: subodh.khadka@nhs.net

Introduction: Bile acid malabsorption (BAM) arises from dysregulation of enterohepatic bile acid recycling and production. Patients usually present with chronic diarrhoea, usually to gastroenterology but also to many other different clinical specialties. However, the index of suspicion and appropriate referral for a SeHCAT study for confirmation of the diagnosis is very variable. This obviously results in inconsistent success in the management of these patients.

Aims & Methods: This study aims to evaluate the spectrum of referral patterns in our patients sent for a SeHCAT test over a five-year period. We retrospectively reviewed 353 patients who underwent a SeHCAT study for suspected BAM from January 2019 for a five-year period. Clinical data, including referrer details, the probable cause of BAM, management and follow up was extracted from medical records and analysed.

Results: Of the 353 patients reviewed, 175 (49.57%) were diagnosed with BAM after a SeHCAT study. The main referrals for SeHCAT were from Gastroenterologists -272 patients (77.05%). The remaining 81 patients were largely referred by Colorectal surgeons with interest in lower GI physiology (41 patients); other referring specialties included other colorectal surgeons (7 patients) and specialties as varied as upper GI, general medicine, care of the elderly, respiratory medicine and even urology (33 patients). Of the 175 patients found to have BAM, 78.86% had been referred from gastroenterology, 11.43% from Colorectal surgeons with interest in lower GI physiology, 1.14% from other colorectal surgeons and 8.5% from the mix of other specialties.

Of the referred patients, gastroenterologists were likely to be accurate in their suspicion of BAM in 50.73% cases, Colorectal surgeons with an interest in lower GI physiology in 48.78% and other colorectal surgeons in 40% cases.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our findings highlight significant variations in the diagnosis and hence management of BAM. A high index of suspicion is essential in managing patients with chronic diarrhoea with risk factors for BAM as they can present with their symptoms to different specialties.

On the other hand, unnecessary SeHCAT testing can result from inappropriate referrals. When presenting to gastroenterologists, these patients are managed appropriately; however, they may present to the general surgeons after laparoscopic cholecystectomy, or the colorectal surgeons after ileal resection for Crohn's disease, right hemicolectomy for cancer etc and to physicians where BAM due to causes such as metformin must be considered.

They may present to any specialty such as Upper GI Surgery or Urology or Care of the elderly with symptoms other than diarrhoea and only be incidentally found on careful clinical assessment. These findings call for cross-specialty improved education regarding BAM diagnosis and management to improve outcomes in patients with BAM.

COST-EFFECTIVENESS OF BILIARY DRAINAGE MODALITIES IN OPERABLE MALIGNANT HILAR BILIARY OBSTRUCTION

R. Singh[1], I. Ali[1], S. Menon[1]

[1]University Hospitals Birmingham NHS Foundation Trust, Department of Gastroenterology, Birmingham, United Kingdom

Contact E-Mail Address: Raminderjit.Singh@uhb.nhs.uk

Introduction: With the increase in the incidence of hilar cholangiocarcinoma, resection centres have seen an increase in the incidence of operable hilar malignancies. Biliary drainage of the future liver remnant (FLR) prior to resection has been demonstrated to improve surgical outcomes. Traditionally, preoperative biliary drainage has been achieved using either percutaneous (PTBD) or endoscopic (ERCP) techniques, with PTBD being favoured in many centres. Single operator cholangioscopy (SOC) via ERCP or PTBD, can enhance diagnostic yield and may optimise drainage. We sought to compare current drainage modalities incorporating SOC techniques in a cost effectiveness model.

Aims & Methods: A cost effectiveness model was developed using Markov healthcare states. PTBD cholangioscopy assisted drainage was compared to ERCP-cholangioscopy assisted drainage, 'standard' fluoroscopy assisted ERCP drainage with brush cytology and PTBD drainage with fluoroscopy guided endobiliary biopsy and drainage. Patients could cycle through each clinical drainage modality with crossover modalities in case of failure of a technique (e.g PTBD drainage for ERCP failure and PTBD external drainage for failure of PTBD cholangioscopy and internal-external drainage). Healthcare associated quality of life data were extracted from the literature to develop utilities used in the model. Procedure related complications were incorporated. Deterministic and Probabilistic sensitivity analysis (PSA) were performed over 1000 patient runs. Incremental cost effectiveness ratios (ICER) were calculated for a willingness to pay (WTP) threshold of £30,000 and net monetary benefits (NMB) for each strategy were derived.

Results: Base-case cost benefit analysis demonstrated that a strategy of ERCP-cholangioscopy assisted drainage (strategy 2, Table 1) was the most cost-effective strategy (Cost £1,895, effectiveness 0.51) and absolutely dominated the PTBD drainage strategies with an ICER of 8,630. The NMB for the ERCP and cholangioscopy strategy was the highest amongst the comparative strategies.

Strategy	Dominance	Cost (£)	Effectiveness (QALY)	ICER	NMB at £30K
1. ERCP, brushings, stent	Undominated	1,072	0.41	reference	11,303
2. ERCP, SOC and biopsies, stenting	Undominated	1,895	0.51	8,630	13,341
3. PTBD drainage + endobiliary biopsy	Absolutely dominated	2,887	0.27	-4180	5,231
4. PTBD drainage + percutaneous SOC	Absolutely dominated	3,616	0.25	-6678	3,889

Table 1: Base case analysis.

On PSA, ERCP, SOC and stenting was the most cost-effective intervention with a mean cost of £ 1,895 (97.5% CIs (1,894-1,896)) / 0.51 QALYs, in comparison to ERCP, brushings, stent (£ 1,072 (1,048-1,098) / 0.41, PTBD drainage + endobiliary biopsy (£ 2,887 (2,855-2,927) / 0.27 and PTBD drainage + percutaneous SOC £ 3,618 (3,604-3,625) / 0.25. The ERCP-SOC strategy also delivered the greatest NMB at £ 13,340 in comparison to the other strategies. 1-way sensitivity analysis and threshold analysis did not identify any variable that impacted on the overall model.

Conclusion: A strategy of ERCP and SOC assisted sampling and biliary drainage seems to be the most cost-effective pre-operative biliary drainage option for resectable hilar biliary obstruction.

Disclosure: The authors have no disclosures to make.

Introduction: Endoscopic ampullectomy is a minimally invasive technique for treating non-invasive ampullary lesions and in patients who are poor surgical candidates. Compared to surgical approaches, endoscopic ampullectomy have lower morbidity and mortality rates.

Aims & Methods: The aim of this study was to describe the safety and outcome of this procedure from a single tertiary center experience.A retrospective study conducted on patients with non-invasive ampullary lesions. Data were collected from our database and parameters related to ampullectomy outcome and complications were retrospectively analyzed. EUS evaluation of the stage and intraductal extension was performed in all patients. Snare sizes between 20 to 30 mm were used in these patients. Electrosurgical unit setting ENDOCUT Q effect 2 was used for resection. All patients were given indomethacin suppositories. Submucosal injection was performed only where the ampullary lesions extend to the duodenal mucosa.

Results: From 2015 to 2024, a total of 15 patients were included in the study. There was 9 males and 6 females. Their median age was 56 years (55-75). Lesions range from 20 to 50 mm in size, with average size of 25 mm. Prophylactic pancreatic duct stenting was performed in all cases of which none developed pancreatitis. Biliary stenting was performed in 3

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cases (20%) with cholangitis. Submucosal injection was performed in 2 lesions with extension to the duodenal mucosa. Post resection histology showed adenoma with low grade dysplasia in 9 patients (60%), adenoma with high grade dysplasia in 2 patients (13.3%), adenoma with focal adenocarcinoma in 2 patients (13.3%), hyperplastic lesion indefinite for dysplasia in 1 patient (6.7%) and hamartoma in 1 patient (6.7%).

Enbloc resection was achieved in 14 (93.3%), while piecemeal in 1 case (6.7%). Recurrence observed in 1 patient (6.7%) with focal adenocarcinoma. Biopsy from the recurrent growth revealed focal adenocarcinoma and patient underwent surgical resection.

No recurrence was observed in the patient with piecemeal resection for 24 months of follow up. Intra-procedural bleeding occurred in 2 patients (13.2%) and managed successfully with snare tip coagulation and hemoclips, delayed melena (after 24 hours) in 1 patient (6.7%) controlled with conservative management.

Only 1 of the 12 patients (8.3%) without biliary stents developed ampullary stenosis post-procedure and managed with plastic biliary stent. There was no report of perforation, need for emergency surgery or 30-days mortality in this series.

Conclusion: Endoscopic ampullectomy seems effective and safe treatment option in cases with non-invasive ampullary lesions. Careful patient selection & adherence to follow up is the best way to achieve best therapeutic outcome.

INNOVATIVE ERCP TRAINING: BRIDGING EDUCATIONAL GAPS WITH NEXT-GENERATION 3D-PRINTED SIMULATORS

O. Ozturk[1], M. Ergul[1], Y. Çağır[2], A. Atay[1], M.b. Durak[3], I. Yuksel[1,4]

Contact E-Mail Address: dr.mucahitergul@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is recognized as a foundational procedure within the realm of interventional gastroenterology. Nevertheless, a significant amount of hands-on experience is required to achieve proficiency in this procedure, particularly with regard to the performance of sophisticated therapeutic maneuvers. Access to authentic training cases remains limited, while the use of cadaveric or live animal models presents distinct ethical, logistical and financial challenges (1). The advent of 3D printing technology paved the way for the development of advanced medical simulators. This study utilized computer-aided design and fused deposition modeling techniques to engineer an ERCP simulator that is both anatomically accurate and enables the training of trainee physicians in the intricate procedures of their chosen discipline (2). The simulator's modular design allows it to replicate a spectrum of papillary conditions, enabling targeted training in anatomies that are resistant to cannulation, as well as high-risk procedures like precut sphincterotomy and fistulotomy.

Aims & Methods: The design process for the ERCP simulator employed accessible parametric modeling software. Fabrication of the primary structural components, including the pancreas, the duodenum, and the bile ducts, were undertaken using polylactic acid (PLA) filament, a material that is both widely accessible and economical, thereby ensuring adequate rigidity and durability. The interchangeable papillary components were produced using flexible thermoplastic polyurethane (TPU) 95A filament, selected for its elasticity and capacity to be readily incised during procedures such as endoscopic sphincterotomy (EST). This allowed for easy exchangeability and facilitated the acquisition of skills by novice endoscopists.

This process were selected on the basis of accessibility, user-friendly interface and cost-effectiveness, enabling replication in diverse settings. The biliary and pancreatic ductal lumens were meticulously calibrated to represent a range of procedural difficulty, with internal diameters that closely mirrored real anatomical variations.

Results: The simulator exhibited a high degree of anatomical and biomechanical fidelity, featuring a structurally stable duodenal framework and a flexible papillary interface. The simulator accurately reproduced tactile feedback experienced by gastroenterologists during ERCP, thereby validating its efficacy as a training tool.

Furthermore, the simulator was enabled meticulous rehearsal of EST through sphincterotomy incisions and facilitated fistulotomy simulation using an elastomeric papilla structure. The simulator's design is both cost-effective and easily replicable, making it a valuable asset for continuing education and training in this field (3,4).

Conclusion: The ERCP simulator, fabricated using 3D printing technology, can be regarded as both technologically advanced and economically efficient for a number of complex procedures. These encompass endoscopic sphincterotomy, precut techniques, fistulotomy and stent placement. The simulator's design, featuring a modular papillary system, was crafted to provide a structured and progressive learning environment for novice users as well as experienced endoscopists.

The simulator's cost-effectiveness, ease of scaling up and potential for wide dissemination signify a paradigm shift in ERCP education, facilitating proficiency acquisition in complex interventional endoscopy with greater efficiency and safety. Further investigations are needed for the simulator in ERCP training.

EVALUATION OF THE EFFICACY OF ANTIBIOTIC PROPHYLAXIS IN PREVENTING POST-ERCP CHOLANGITIS: IDENTIFYING HIGH-RISK PATIENTS

V. Storer[1], L.M. Vivian[1], M. Bucci[1], A. Busatto[1], L. Zornetta[1], A. Borsato[1], B. Perini[1], M. Ghisa[1], F. Ferrara[1]
[1]Padua University Hospital, Gastrointestinal Endoscopy Unit, Gastroenterology Department, Padova, Italy

Contact E-Mail Address: vittoriostorer95@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is still considered the endoscopic standard of treatment for biliary obstruction and lithiasis. Among the most common ERCP complications, the biliary tree bacterial contamination and cholangitis could be managed with pharmacological treatment or prevented with antibiotic prophylaxis. Although ESGE Guidelines recommend performing prophylaxis only in few cases with strong indications, such as post liver-transplantation patients, hilum strictures and primary sclerosing cholangitis, clear data about indicators predictive of post-ERCP cholangitis development are lacking.

Aims & Methods: Our aims were to investigate whether antibiotic prophylaxis could reduce post-ERCP cholangitis and to evaluate any potential risk factor that could aid in identify patients who most benefit from it. A monocentric, retrospective, case-control study was conducted enrolling all patients who underwent ERCP between January 2023 and May 2024 in our third- degree referral centre. Patients with stronger indication for antibiotic prophylaxis (such as liver-transplanted patients or primary sclerosing cholangitis) and patients who were already on ant ibiot ic s were exc luded.

We defined as ant ibiot ic prophylaxis a single dose of 1 g intravenous ceftriaxone 1 hour prior to the procedure. We defined cholangitis as the onset of temperature >38°C for more than 24 hours combined with cholestasis (according to Tokyo criteria).

Results: We enrolled 216 patients who underwent elective ERCP for biliary obstruction whose aetiology comprised of 120 choledocholithiasis, 72 malignancies, 24 others. Of those, 126 patients received antibiotic prophylaxis before the procedure and 90 did not. ERCP degree of difficulty performing Schutz score showed greater statistically significant difficulty in the first group (1.57 ± 0.69; 1.28 ± 0.54 p<0.001).

However, post-ERCP cholangitis occurred less frequently in this group (3/126) versus patients without antibiotic prophylaxis (9/90) with statistically significant difference [2.38%vs10.0%; OR=0.18, p=0.031].

Analysing the subgroup of patients with Charlson Comorbidity Index (CCI) scores ≥ 5 the incidence rate of cholangitis was significantly lower in antibiotic-treated patients (1/59) versus control patients (7/48; 1.69% vs 14.5%; p=0.021).

Moreover, the incidence rate of cholangitis in patients with pre-ERCP bilirubin levels more than 2.5 mg/dL was significantly lower in the antibiotic prophylaxis group (0/40) versus not antibiotic-treated patients (6/42; 0% vs 14.3%; p= 0.026).

Conclusion: Antibiotic prophylaxis prior to elective ERCP in patient with biliary obstruction reduce the incidence of post-procedure cholangitis especially in patients with CCI scores ≥ 5 or with pre-procedural bilirubin levels > 2.5 mg/dL. More studies are needed to recommend pre-ERCP routine or selected high-risk groups use of antibiotic prophylaxis.

Disclosure: Nothing to disclose.

OPTIMISING ERCP SAFETY IN PREGNANCY: REAL-WORLD EVIDENCE OF MATERNO-FETAL PROTECTION AND RADIATION-FREE TECHNIQUES

H. Marulanda[1,2], J.A. Rodríguez Criollo[1], G. Jaramillo[2,3], J. Frias-Ordoñez[1,4], L. Otero[2,1], E. Otero[2], D. Giron Pelaez[5], W. Otero[2,1]

Contact E-Mail Address: Jsfriaso@unal.edu.co

Introduction: Pancreatobiliary disease during pregnancy, though uncommon, poses significant risks. Gallstone-related disorders affect 3–12% of pregnancies and may progress to life-threatening complications such as cholangitis or biliary pancreatitis. Endoscopic retrograde cholangiopancreatography (ERCP) is a highly effective therapeutic approach; however, concerns about foetal radiation exposure and procedure-related maternal complications limit its broader acceptance. There remains a need for rigorous real-world data on the safety and neonatal outcomes of ERCP during pregnancy.

Aims & Methods: This retrospective observational study aimed to evaluate the safety of ERCP in pregnant patients, focusing on two key outcomes:
1. Maternal and foetal safety during and after the procedure, and
2. Effectiveness of radiation-minimisation strategies, including fluoroscopy reduction and abdominal shielding.

We reviewed 25 pregnant patients undergoing ERCP at a tertiary referral centre. Indications included choledocholithiasis (84%), cholangitis (4%), biliary pancreatitis (4%), and stent management (8%). Mean maternal age was 19.2 years; mean gestational age at ERCP was 28.3 weeks. Fluoroscopy usage, post-ERCP complications, Apgar scores, and neonatal follow-up at day 30 were recorded. Fluoroscopy-minimising techniques included suction-verification of bile and stent release without imaging.

Results: No maternal or foetal adverse events occurred peri- or post-procedure. ERCP was performed successfully in all 25 patients, with 23 (92%) undergoing sphincterotomy. Fluoroscopy was utilised in 20 cases (80%), with lead shielding employed in all. In five cases (20%), ERCP was conducted without fluoroscopy by using alternative bile verification techniques. Apgar scores ranged from 7 to 10, and all neonates exhibited normal development at 30-day follow-up.

Parameter	Value
Total procedures	25
Mean gestational age (weeks)	28.3
ERCP with fluoroscopy	20 (80%)
ERCP without fluoroscopy	5 (20%)
Maternal complications	0
Foetal complications	0
Mean Apgar score	9
Sphincterotomy performed	23 (92%)
Normal neonatal development (day 30)	100%

Conclusion: This study confirms that ERCP can be safely performed during pregnancy when executed by skilled endoscopists adhering to radiation-limiting protocols. Fluoroscopy-free ERCP appears feasible in selected cases, significantly reducing foetal radiation exposure without compromising efficacy.

Our findings support ERCP as a viable and safe therapeutic option in pregnant patients with biliary obstruction, providing novel evidence for the growing implementation of protective strategies and alternative imaging techniques in high-risk obstetric settings.

FROM FRAGMENTATION TO INFLAMMATION: MECHANICAL LITHOTRIPSY AS A TRIGGER FOR POST-ERCP PANCREATITIS

M. Serio[1], F. Ridolfi[1], A. Ortolani[1], A. Graziosi[1], G. Falcioni[1], S. Maltoni[1], A. Scarcelli[1]
[1]UOC Gastroenterologia ed Endoscopia Digestiva - AST Pesaro Urbino, Pesaro - Fano, Italy

Contact E-Mail Address: mariaelenaserio@yahoo.it
Introduction: Post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP) is the most frequent adverse event following ERCP, with an incidence of 3–10% in the general population and up to 40% in high-risk patients. Risk factors are commonly classified as patient-related (young age, female sex, suspected sphincter of Oddi dysfunction) or procedure-related (precut sphincterotomy, difficult cannulation, pancreatic duct manipulation). However, the impact of specific therapeutic maneuvers—such as stone extraction techniques and biliary drainage—on PEP risk remains uncertain.
In particular, the role of mechanical lithotripsy as an independent risk factor is still poorly defined. Moreover whether the systematic use of prophylaxis has actually reduced PEP incidence over time—particularly in high-risk cases—also remains uncertain.
Aims & Methods: This study aimed to retrospectively assess both patient- and procedure-related risk factors for post-ERCP pancreatitis, with a focus on therapeutic interventions whose impact remains uncertain. Findings were also compared with existing literature to refine individual risk profiles and inform preventive strategies.
We retrospectively analyzed 678 consecutive inpatients (49% male, 51% female; mean age 72.7 ± 13.4 years) admitted to our Gastroenterology Unit treated with ERCP for various indications (e.g., choledocholithiasis, pancreatic cancer, biliary strictures) between January 2020 and December 2024. All procedures were performed by experienced interventional endoscopists. PEP incidence was compared across categorical variables using chi-squared or Fisher's exact tests (significance threshold $p < 0.001$). Age was compared using the Mann–Whitney U test. Variables significant in univariate analysis were included in a multivariate logistic regression model.
Results: Thirty-six cases of PEP were identified (5.3%), including 58% mild, 34% moderate, and 8% severe. No procedure-related deaths were reported. Patients with PEP were significantly younger (median age 69 vs 76 years, $p = 0.01$). Independent risk factors included suspected sphincter of Oddi dysfunction (OR = 7.8, $p < 0.001$) and mechanical lithotripsy (OR = 4.20; 95% CI: 1.38–12.78; $p = 0.007$), while biliary stenting was protective (OR = 0.17; 95% CI: 0.04–0.67; $p = 0.01$). Nasobiliary drainage showed a non-significant trend toward protection (OR = 0.67; $p = 0.34$), and pancreatic stenting was not significantly associated with reduced risk ($p = 0.54$). No significant associations were found for stone extraction method, periampullary diverticulum, sphincterotomy, or precut. PEP incidence declined from 6.3% in 2020 to 3.8% in 2024 ($p = 0.22$), possibly reflecting improved prophylaxis.
Conclusion: Suspected sphincter of Oddi dysfunction and younger age were confirmed as significant PEP risk factors. Mechanical lithotripsy emerged as a high-risk maneuver, while biliary stenting appeared protective. These findings suggest procedure-specific risks should be integrated into individual preventive strategies.
Disclosure: Nothing to disclose.

THE SAFETY AND EFFICACY OF SAME-SESSION ENDOSCOPIC ULTRASOUND FINE NEEDLE BIOPSY AND ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOR DISTAL MALIGNANT BILIARY OBSTRUCTION - A SINGLE HIGH-VOLUME CENTER EXPERIENCE

S. Chiriac[1], C. Sfarti[1], H.-O. Minea[1], S. Zenovia[1], A. Rotaru[1], R. Stafie[1], R. Nastasa[1], I. Girleanu[1], R. Avram[1], L. Huiban[1], E. Stratina[1], C.M. Muzica[1], A.M. Singeap[1], P. Oana Cristina[1], T. Cuciureanu[1], C. Stanciu[2], A.-V. Trifan[1]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Gastroenterology, Iasi, Romania, [2]St Spiridon Emergency Hospital, Institute of Gastroenterology and Hepatology, Iasi, Romania

Contact E-Mail Address: stefannchiriac@yahoo.com
Introduction: Distal malignant biliary obstruction represents an important indication for endoscopic ultrasound (EUS) and endoscopic retrograde cholangiopancreatography (ERCP). Often, patients who present with obstructive jaundice and/or cholangitis undergo emergency cross-sectional imaging that identifies locally advanced pancreatic lesions, biliary strictures, or ampullary tumors that require both pathological confirmation as well as biliary drainage.
Current recommendations indicate that both EUS and ERCP should be performed in a complementary fashion, both for tissue acquisition and biliary drainage. Combining these techniques in one session is not yet standard practice in all services.
Aims & Methods: Aims: We aimed to assess the rate of adverse effects and procedural success in patients undergoing both EUS and ERCP in a single session compared to separate sessions in our unit, a high-volume tertiary care center in North-Eastern Romania.
Methods: We performed a retrospective study including consecutive patients hospitalized for obstructive jaundice and/or cholangitis determined by distal malignant biliary obstruction suspected on cross-sectional imaging, hospitalized in the "St. Spiridon" Universitary Emergency Hospital from January 2022 to January 2023, who underwent both EUS and ERCP. We compared patients who had both procedures carried out in the same session with patients who had separate sessions of EUS and ERCP.
The primary outcome was the rate of adverse effects. The secondary outcomes were the success of the procedures and the hospitalization duration.
Results: Forty-nine patients were included. 30 patients underwent a separate session of EUS and ERCP, while 19 patients received EUS and ERCP during the same session. The adverse effects rate was similar between the 2 groups, and only related to ERCP (post-ERCP pancreatitis, 1 patient from the same session group vs 2 patients from the separate session group, bleeding, in 1 patient from the same session group and 1 patient from the separate session group). No deaths were noted. The procedure success was also similar in both groups, 28 patients from the separate session group, respectively 18 patients from the same session group had both procedures performed successfully. Concerning hospital duration, there was a slightly longer mean duration in the separate session group compared to the same session group (12 days vs 8 days).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: There was no significant difference regarding the rate of adverse effects or procedure success in patients who underwent both EUS and ERCP in the same session compared to separate sessions when these procedures were performed to manage distal malignant biliary obstruction. However, the mean hospitalization time was higher when the two procedures were performed in separate sessions.

Introduction: Acute cholangitis (AC) is a life-threatening condition requiring urgent biliary drainage. Endoscopic biliary drainage (EBD) with endoscopic sphincterotomy (EST) is often performed to facilitate bile flow and prevent post-ERCP pancreatitis (PEP). However, patients with sepsis-induced coagulopathy (SIC) are at increased risk of bleeding, raising concerns about the safety of EST in this population[1, 2]. This study aimed to evaluate the risk of adverse events (AEs) and clinical outcomes of EBD with versus without EST in AC patients with SIC.
Aims & Methods: A multicenter retrospective cohort study was conducted using propensity score matching. AC patients with SIC who underwent EBD with EST (EST group) or without EST (non-EST group) were analyzed. The primary endpoint was to compare the AE rate of EBD with EST versus EBD without EST in AC patients with SIC using propensity score matching. Secondary endpoints included the comparison of clinical outcomes (Ethics Committee Approval No. 2876-D38).
Results: Among 238 patients, 72 underwent EST and 166 did not. The incidence of AEs was significantly higher in the EST group than in the non-EST group (16.7% vs. 1.8%, P < .001), particularly for bleeding AEs (11.1% vs. 0.6%, P < .001). PEP incidence was similar (4.2% vs. 1.2%, P = .143). Propensity score-matched analysis confirmed these findings. No significant differences were observed in clinical success or 28-day survival rates.
Conclusion: EST significantly increases bleeding risk in AC patients with SIC without reducing PEP or improving clinical outcomes. Given these findings, EBD without EST should be recommended to minimize bleeding risk while ensuring effective biliary drainage.

Introduction: Cholangioscopy-assisted electrohydraulic lithotripsy (CA-EHL) is a novel and effective method for the treatment of difficult bile duct stones that are refractory to conventional endoscopic therapy (CET).
Aims & Methods: Our objective was to compare the clinical and financial outcomes of CA-EHL and CET in the management of difficult bile duct stones.
Patients with difficult bile duct stones diagnosed via endoscopic retrograde cholangiopancreatography (ERCP) were retrospectively allocated into two groups: Group I: CET (January 1, 2022 – December 31, 2022), and Group II: CA-EHL (January 1, 2023 – January 31, 2025).
Patient characteristics, success rate of stone removal, complication rates, mortality, unplanned readmissions within 30 days, intensive care unit (ICU) admissions, length of hospital stay, and cumulative treatment costs were analyzed.
Results: Group I included 37 patients, as did Group II. There were no significant differences between the groups in terms of median age (73 vs. 74 years), gender distribution (male:female = 16:21 vs. 13:24), or Charlson comorbidity index (median: 4 vs. 3; P>0.05). The success rate of stone

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

clearance was significantly higher in Group II (32.4% vs. 91.9%; P<0.001). Surgical intervention was significantly more common in Group I (32.4% vs. 5.4%; P=0.006). Patients in Group II spent significantly less time in the surgical ward (average: 2.9 vs. 0.4; P=0.0466). There were no significant differences between the groups in the number of complications (9 vs. 11 cases, P=0.452), time spent in the internal medicine ward (median: 6 vs. 8 days; P=0.704), mortality, 30-day unplanned readmission, or ICU admission rates (P>0.05). The cumulative treatment cost was significantly higher in Group II (3,917 vs. 10,241 €/patient; P<0.001).

Conclusion: CA-EHL represents a safe and effective approach for managing difficult bile duct stones refractory to standard endoscopic techniques. Although the treatment is associated with higher costs due to the expensive instrument, it significantly enhances bile duct clearance and decreases the necessity for surgical intervention. These results support the broader adoption of cholangioscopy-guided lithotripsy in clinical practice, particularly for complex stone cases.

Disclosure: Nothing to disclose.

PP0962

THE IMPACT OF PAPILLA MORPHOLOGY ON THE CHOICE OF ADVANCED CANNULATION TECHNIQUES IN ERCP - INSIGHTS FROM AN INTERNATIONAL SURVEY

E. Tari[1,2], B. Eross[1,3]
[1]Semmelweis University, Centre for Translational Medicine, Budapest, Hungary, [2]Szent György Teaching Hospital of County Fejér, First Department of Internal Medicine, Székesfehérvár, Hungary, [3]Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary

Contact E-Mail Address: edina.tari@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography is the primary therapeutic procedure for pancreaticobiliary disorders, yet bile duct cannulation failure rates

remain 5–20% even among experienced endoscopists. The Haraldsson classification (2017) defines four papilla types, some linked to higher failure and complication rates. Limited research exists on how papilla morphology impacts rescue techniques.

Aims & Methods: This study aims to survey ERCP practitioners to assess the influence of major papilla morphology on their bile duct cannulation strategies. We hypothesize that tailoring cannulation techniques to papilla type may improve success rates and reduce complications.

We are conducting an ongoing international survey targeting physicians who routinely perform ERCP, focusing on how major papilla morphology affects cannulation strategies.

The survey was developed using REDCap, a secure web-based platform for data collection, and distributed via professional societies, mailing lists, and social media platforms. It includes questions on respondent demographics, ERCP experience, use of papilla classification systems, and preferred cannulation techniques.

Responses are collected anonymously. Initial analysis involves descriptive statistics, with further statistical evaluation planned as data collection progresses. Participation is voluntary, and the survey remains open to ensure broad inclusivity and representation.

Results: Among the 141 respondents, 27% reported using a classification system for papilla morphology. Of these, 57.9% were from certified training centers and 60.5% were affiliated with university-based hospitals. Additionally, 55.3% of classification system users had more than five years of experience, compared to 67% among non-users. Rescue cannulation strategies varied significantly based on papilla type and guidewire placement. For type I papilla, when the guidewire did not enter the pancreatic duct, 35.5% opted for needle-knife precut (NKP), 30.5% for needle-knife fistulotomy (NKF), and 28.4% continued with the standard technique. In contrast, if the guidewire was inadvertently inserted into the pancreatic duct, the double guidewire technique (DGT) was the most common first-line approach (54.6%), followed by prophylactic pancreatic stent (PPS) placement combined with NKF (21.4%) and transpancreatic precut papillotomy (TPPP) (9.2%). For type II papilla, NKP was the most frequently chosen technique (41.1%) when there was no guidewire entry into the pancreatic duct, whereas DGT was preferred (58.9%) when the guidewire was in place.

A similar pattern was observed with type III papilla, where DGT was favored (48.9%) in cases of pancreatic duct guidewire placement, and NKP was the leading choice (40.4%) when no guidewire was used. For type IV papilla, DGT was selected by 51.8% of respondents when the guidewire entered the pancreatic duct, while 41.8% preferred to continue with the standard cannulation technique in the absence of guidewire entry.

Conclusion: Differences were observed between classification system users and non-users. DGT was preferred when the guidewire entered the pancreatic duct, while NKP was commonly used when it did not. These findings suggest that adapting techniques based on papilla morphology may improve cannulation success.

FULLY COVERED METAL STENTS FOR LARGE COMMON BILE DUCT STONES: A PROMISING SECONDARY CARE STRATEGY

M. Said Noor[1], I. Fantoni[1], D. Mohandas[1], A. King[1], A. Leahy[1], M. Shariff[1]
[1]Watford General Hospital , West Hertfordshire Teaching Hospitals NHS Trust, Gastroenterology, Watford, United Kingdom

Contact E-Mail Address: drmsaidnoor@gmail.com

Introduction: It is recognised that large common bile duct (CBD) stones present a significant challenge in endoscopic practice. A key performance indicator of >80% clearance at the initial ERCP has been recommended to standardise quality of care. Standard techniques such as sphincterotomy +/- balloon sphincteroplasty are usually sufficient; however, in difficult cases, plastic stents are frequently placed to maintain biliary drainage, with elective repeat ERCP planned. When clearance remains unsuccessful, options such as mechanical lithotripsy or cholangioscopy may be employed, though these are often limited to tertiary care centres. Fully covered self-expanding metal stents (FCSEMS) have been proposed as a novel strategy to remodel the distal CBD and facilitate stone retrieval at subsequent procedures.

While this approach is not currently included in formal UK guidelines, its use is expanding in complex cases. We report our early experience comparing plastic stents alone with a combination of fully covered metal stents and coaxial plastic stents in a secondary care setting.

Aims & Methods: This was a retrospective observational study conducted at a large secondary care NHS trust. We included patients undergoing ERCP between 2019 and 2024 in whom complete stone clearance could not be achieved at the initial procedure and a stent was placed. Only patients with confirmed choledocholithiasis and naïve papillae at first ERCP were included.

All patients had large CBD stones, defined as stones greater than 10 mm in diameter. Patients were categorised according to whether a plastic stent alone or a fully covered metal stent with coaxial plastic stent was used at

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

the index procedure. A 7Fr pigtail plastic stent was used in all cases; for the FCSEMS group, a fully covered metal stent was inserted with a plastic stent placed through it. Data were collected from endoscopy records and electronic patient notes. Outcomes assessed included complete stone clearance at second ERCP, need for mechanical lithotripsy, number of ERCP procedures, and referral to tertiary care for cholangioscopy. Fisher's exact test and unpaired t-tests were used for statistical analysis.

Results: A total of 63 patients were included, with 46 in the plastic stent group and 17 in the FCSEMS group. Complete stone clearance for large stones (>10 mm) at second ERCP was achieved in 63.0% of patients in the plastic group compared with 76.5% in the FCSEMS group (p=0.380). Mechanical lithotripsy was required in 8.7% of plastic stent cases and 5.9% of FCSEMS cases (p=1.000). Referral to tertiary care for cholangioscopy occurred in 30.4% of the plastic group and 11.8% of the FCSEMS group (p=0.195). The mean number of ERCPs per patient was similar between groups, with an average of 2.50 procedures in the plastic group and 2.41 in the FCSEMS group (p=0.601).

Conclusion: The use of fully covered metal stents with coaxial plastic stents was associated with promising trends, including higher rates of complete stone clearance for large CBD stones and fewer referrals to tertiary centres. Although these findings did not reach statistical significance, they suggest a clinically relevant benefit that merits further investigation. The higher observed clearance rate and reduced need for cholangioscopy may support FCSEMS as a valuable adjunct in managing difficult bile duct stones.

These results should be interpreted cautiously given the small size of our dataset, but they provide an encouraging basis for future prospective studies aimed at optimising CBD stone management and potentially reducing the need for tertiary care referral.

CHOLANGIOSCOPY-GUIDED ELECTROHYDRAULIC LITHOTRIPSY VERSUS LASER LITHOTRIPSY FOR THE TREATMENT OF CHOLEDOCHOLITHIASIS: SINGLE CENTER EXPERIENCE

F. Bronzini[1], G. Scaramuzza[2], M. Blois[1], C. Sterpi[1], A. Sostilio[1], R. Manta[1]

[1]Spedali Riuniti di Livorno, Azienda Toscana Nord Ovest, Unità operativa complessa endoscopia digestiva, Livorno, Italy, [2]Pisa University, Gastroenterology, Pisa, Italy

Contact E-Mail Address: bronzinifrancesco90@gmail.com

Introduction: Choledocholithiasis (CCL) is one of the most common serious presentations of cholelithiasis. ERCP is the first-line treatment for the clearance of common bile duct stones (CBDSs). "Difficult" biliary stones are defined according to their diameter, shape, location, or because of anatomical factors. In these cases, gallstones cannot be removed using standard ERCP and additional interventional techniques are required. ESGE has recommended the use of cholangioscopy-assisted lithotripsy as one of the main treatment methods for difficult CBDSs.

This study aims to compare the safety and efficacy of cholangioscopy-assisted holmium-laser lithotripsy (LL) with electrohydraulic-lithotripsy (EHL) in the treatment of difficult CBDSs.

Aims & Methods: This is a retrospective study conducted at a tertiary endoscopic referral center. We enrolled thirty-one consecutive patients who had undergone cholangioscopy-assisted laser and/or electrohydraulic lithotripsy for difficult bile duct stones from November 2021 to March 2025. All patients underwent biochemical/clinical and imaging assessment prior to therapeutic ERCP. Intraductal lithotripsy efficacy was assessed based on bile duct clearance achievement (technical success) while clinical success was defined as bilirubin level decrease of one third 48 hours after the procedure. Safety outcomes were assessed based on the occurrence of any intra-/post-procedural complications. Procedural time was also recorded.

Results: A total of thirty-one patients with difficult gallstones were enrolled and retrospectively analyzed (M/F: 14/17; median age = 82 years). In 8 out of 31 cases (25%) a double therapeutic endoscopic session was needed to achieve CBD clearance. The bile duct was intubated via the ampulla of Vater using single-operator cholangioscopy.

Gallstones were fragmented using laser lithotripsy in 12/31 cases (39%) while electrohydraulic lithotripsy was used in 16/31 cases (51%); 3 out of 31 patients (10%) required both techniques to obtain CBD clearance. Technical success was achieved in 27/31 cases (87%).

Clinical success was observed in 26/27 cases (96%).Patients treated with LL had an overall median stone clearance success rate of 92%, whereas EHL achieved a median stone clearance success rate of 87%. Combined techniques only achieved 67% success. No complications were observed in all 31 procedures.

Conclusion: LL and EHL are both highly effective and safe forms of POC-guided lithotripsy for the treatment of large bile duct stones. LL seems to be more effective, although it requires longer procedural times, compared to EHL.

The success rate of the combined techniques is low when compared to the data for the individual techniques, but this could be because the three cases under consideration were particularly complex. This might suggest that if one intraductal lithotripsy technique fails, it is not indicated to attempt a second method, but more data on this would be needed to draw conclusions.

FORGOTTEN BILIARY PLASTIC STENTS IN A HIGH-VOLUME ERCP UNIT - DON'T YOU FORGET ABOUT ME

H. Coelho[1], D. Ceia[1], S. Bragança[1], A.C. Garcia[1], M. Francisco[1], F. Correia[1], G. Alexandrino[1], M. Cardoso[1], J.T. Canena[1], L.C.C. Lourenço[1], D. Horta[1]

[1]ULS Amadora/Sintra, Gastroenterology, Lisboa, Portugal

Contact E-Mail Address: henriquecoelho.1996@gmail.com

Introduction: Plastic biliary stents that have not been removed for more than 12 months are considered forgotten stents. In this study, we sought to evaluate which factors are associated with forgetting biliary stents and their consequences.

Aims & Methods: Retrospective analysis, in a high-volume ERCP unit, of patients who underwent ERCP between 2016 and 2023 with placement of plastic biliary stents. Procedures in which the patient died or the prosthesis was surgically removed less than 1 year after its placement were excluded.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 555 procedures in 425 patients (49% female, age 68.9±16.8 years) were included. The reasons for placement were: malignant stenosis 29.2% (n=162); choledocholithiasis 23.8% (n=132); benign stenosis 22.7% (n=126); bile leak 7.2% (n=40); acute cholangitis 6.7% (n=37); Mirizzi syndrome 4.7% (n=26); gallstones 4.3% (n=24); post-sphincterectomy bleeding 0.9% (n=5); intrahepatic lithiasis 0.5% (n=3).

Thirty-four procedures (6.1%) with forgotten stents were identified in 34 patients (35.3% female, age 64.4±17.3 years). The most frequent reasons for non-removal were: non-referral after cholecystectomy (n=15) or after hospital discharge (n=11). Among the indications for placement, gallstones (OR 9.71, p < 0.001) and Mirizzi syndrome (OR 3.02, p = 0.049) were associated with an increased risk of forgetting the device.

In 10 patients, extraction was endoscopic, 2 had spontaneous migration, 1 had surgical extraction, and 7 patients died for unrelated reasons. The rest (n=14) were recruited for removal during this study. A total of 9 patients of this group responded to the call and it was confirmed the spontaneous migration of the plastic stent in na abdominal radiography.

8 patients (23.5%) presented complications: acute cholangitis (n=4), jaundice (n=2), abdominal pain (n=1) and liver abscess with septic shock (n=1).

Conclusion: Forgotten stents constitute a rare event but with a significant risk of complications. Following this analysis, we created a database in order to improve the timing until the extraction of stents and reduce related adverse events.

Disclosure: Nothing to disclose.

PP0966

EFFICACY OF ACOUSTIC MONITORING OF RESPIRATORY RATE DURING SEDATION FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY-RELATED PROCEDURES

J. Kohisa[1], M. Sato[1], K. Kamimura[1], Y. Suda[1], K. Hanano[1], S. Hori[1], K. Morishita[1], T. Doi[1], T. Owaki[1], A. Osaki[1], K. Takaku[1], N. Waguri[1]
[1]Niigata City General Hospital, Gastroenterology and Hepatology, Niigata, Japan

Contact E-Mail Address: jun-g2588@angel.ocn.ne.jp

Introduction: Most serious adverse events during procedural sedation and analgesia (PSA) are caused by ventilation disorders, and close monitoring of respiratory status is considered important. However, in endoscopic procedures, especially endoscopic retrograde cholangiopancreatography (ERCP), the use of C-arm X-ray TV systems and patient-positioning devices can easily make it difficult for us to observe the movement of the patient's thorax. Although using capnography is recommended for ventilation monitoring during sedation for endoscopy, acoustic respiratory monitoring is used in PSA situations and other settings as a more convenient method for monitoring respiratory status.

Aims & Methods: In this study, we examined the outcomes of acoustic respiratory rate monitoring during sedation for ERCP-related procedures. We retrospectively reviewed 261 consecutive patients (493 procedures) who underwent ERCP-related procedures at our hospital between April 2024 and January 2025. We analyzed patients' backgrounds, sedation methods, and complications. All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. This retrospective observational study received ethical approval by the Institutional Review Board (IRB) of our hospital.

Results: The median patient age was 75 years, and 172 men and 89 women were included in the study. The target diseases for treatment included bile duct stones in 122 patients, malignant biliary strictures in 108 patients, benign biliary strictures in 20 patients, and other diseases in seven patients. The median procedure time was 30 min (9-140 min), the median doses of midazolam and pentazocine used were 4 mg (0-11 mg) and 7.5 mg (0-30 mg), respectively. Dexmedetomidine was administered to 46 (9.3%) patients. The number of minor cardiopulmonary events during PSA was 45 (9.1%), included hypotension in 20 patients, bradycardia in 15, depression of the respiratory rate in 13, and decreased SpO_2 in one. The number of patients with decreased SpO_2 was significantly lower than the number of patients with depression of respiratory rate (p=0.001). Rapid recovery was observed in all patients, and permanent interruption of the procedure or mortality was not observed.

Conclusion: The use of acoustic monitoring of the respiratory rate allowed the procedure to be performed without serious complications. In particular, it seems important to detect a decrease in respiratory rate so that early action can be taken before it leads to a decrease in SpO_2.

Although this monitoring method has some drawbacks, such as the fact that it only evaluates the respiratory rate and not ventilation, its simplicity makes it a useful option for safe endoscopic procedures, especially in settings staff resources.

Disclosure: Nothing to disclose.

RETROSPECTIVE REVIEW OF THE ROLE OF BOTOX INJECTION AND SPHINCETROTOMY IN THE MANAGEMENT OF FUNCTIONAL HEPATOBILLARY PAIN

J. O'Connell[1], A. Al-Joudeh[1]
[1]Sheffield Teaching Hospitals, Gastroenterology, Sheffield, United Kingdom

Contact E-Mail Address: oconnej@tcd.ie

Introduction: Managment of functional hepatobillary pain remains a significant challenge for physicians. Botulinum toxin injection of the ampulla of vatter and endoscopic sphincterotomy has been shown to be an effective treatment with diagnostic and prognostic benefit, however, it has a relatively high complication rate.

Aims & Methods: To assess the effectiveness and complication rate of botox injection and sphincterotomy for treatment of sphincter of oddi dysfunction (SOD). And assess if response to botox injection is predictive of durable response to completion sphincterotomy. Patients were identified from a single centre endoscopy database from January 2014 until October 2024 using the keyword searches "Botox" and "Botulinum". Studies were included if 100IU botox injection to the ampulla was done at endoscopy for the purpose of treating SOD. SOD was defined as per the ROME IV criteria and classified as per Milwaukee classification.

Baseline clinical, demographic, endoscopic, and radiological data were collected. Symptomatic response was assessed through interrogation of clinical notes post procedure. Patients who progressed on to sphincterotomy were identified, and symptomatic response to this was obtained from clinical review of notes at 3 months and 1 year post procedure. For categorical variables Fisher's exact test was used.

Results: 364 duodenoscopies were identified from the database, 74 duodenoscopies from 52 patients were included. 13 patients had more than one botox injection. 77% (40 patients) were female, and the median [range] age at first procedure was 41.2 [21.7 - 66.6] years. 1 (1.9.%), 44 (84.6%), and 7 patients (12.5%) had type I, Type II, and Type III SOD respectively. Diclophenac was given at time endoscopy in 26 (36%) procedures. Four patients were admitted for 24 hours with non-pancreatitis related abdominal pain post procedure. Three patients had no data on response post botox injection. 42 (85%) patients reported improvement in

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

their symptoms following botox injection. 35 of the 44 patients with type II SOD responded. 6 of the 8 patients with type III, and the only type I patient responded. 25 (48%) patients in total progressed on to sphincterotomy (one type I, 22 type II, and 2 Type III). 10 patients with no response to botox progressed on to sphincterotomy. 10 patients had >1 sphincterotomies for treatment of SOD. 36 post botox sphincterotomies were included, 8 (22%) had complications. There were 5 (14%) micro-perforations, there was one (2.8%) pancreatitis and two (5.5%) admissions for abdominal pain without evidence of pancreatitis. No patient had requirement for ICU or surgery. Initial response to sphincterotomy was at 3 months was 72% (18). Twelve (48%) patients (11 type II SOD, and one Type III) had durable response at one year.

There was a trend that patients who responded to botox injection were more likely to have response from sphincterotomy at one year, 10 patients (55%) compared to two (28%) Patients who did not respond to botox injection responded to sphincterotomy at one year. However, this was not statistically significant (p=0.37).

Conclusion: Our data indicated a low incidence of complication to botox injection with no recorded cases of pancreatitis. There was a trend that patients who responded to botox injection may be more likely to respond to sphincterotomy. Further data is required, however there was a trend towards patients who responded to botox injection being more likely to benefit from sphincterotomy.

Disclosure: Nothing to disclose.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) plays a central role in the treatment of multiple biliary and pancreatic disorders. Despite the technical improvements reached in the past few decades, ERCP remains one of the endoscopic procedures with the highest complication rates. Post-ERCP cholangitis is the most common infectious complication and has a multifactorial origin.

Aims & Methods: The aim of our retrospective analysis was to identify patient-, procedural-, and operator-related factors associated with post-ERCP cholangitis. We analyzed the biliary drainage procedures performed at the Endoscopy Unit of Reggio Emilia in 2022, for a total of 517 procedures. We excluded procedures performed for acute cholangitis according to Tokyo 2018 criteria, patients who had recently undergone cholecystectomy (during the same hospitalization or within two weeks prior to the ERCP) and patients with ongoing abscess collections. We so included 164 procedures performed on patients who did not have a diagnosis of acute cholangitis or confounding factors at the time of the procedure. Then we compared patients who developed cholangitis according to Tokyo 2018 criteria within 30 days from ERCP with patients who did not, and perfomed univariate and multivariate analyses to define potential risk factors associated with post-ERCP cholangitis.

Results: 31/164 (19%) patients of our cohort developed post-ERCP cholangitis. The univariate analysis revealed that presence of stenosis (83.9% vs 41.4%; p<0.001), placement of biliary stents (90.3% vs 42.1%; p<0.001), particularly multi-stent vs plastic or metallic (42.9% vs 16.1%; p 0.028), median duration of the procedure (92 vs 69 min; p 0.003), and the performance of pneumatic dilatations (22.6% vs 6.8%; p 0.008) were significantly associated with the occurrence of post-ERCP cholangitis; we also found that antibiotic therapy (58.1% vs 82%; p 0.004), balloon passages with Fogarty (25.8% vs 51.9%; p 0.009), and a history of previous ERCPs (2.6% vs 44.4%; p 0.026) were potential protective factors. Demographic characteristics of the cohort (sex, ASA score, age), operator expertise, and other technical factors such as sphincterotomy, sphincteroplasty, pre-cut, papillectomy, lithotripsy, as well as the placement of pancreatic stents, bioptic sampling, nasobiliary tubes (NBT), or the use of Spyglass and Dormia baskets, did not show a significant association with the development of post-ERCP cholangitis.

At the multivariate analysis, duration of the procedure (OR 1.01 [95%CI 1-1.02]) and placement of biliary stents (OR 9.57 [95%CI 2.64-34.67]) remained significant risk factors, while antibiotic therapy (OR 0.22 [95%CI 0.08–0.61]) was confirmed as a potential protective factor.

Conclusion: Post-ERCP cholangitis have a multifactorial etiology. In our cohort, duration of the procedure and placement of biliary stents showed significant association with the development of this complication, while antibiotic therapy was a protective factor. Further studies are needed to confirm our findings and to define which measures can be implemented to reduce post-ERCP cholangitis.

IMPROVING DOCUMENTED ADVICE REGARDING ANTICOAGULANTS AND ANTIPLATELETS IN PATIENTS UNDERGOING ERCP

E. Creed[1], S. Gurung[1], V. Theis[1], K. Clark[1], A. Motam[1], G. FarrellBinns[1]

Contact E-Mail Address: sweekriti.gurung@merseywestlancs.nhs.uk

Introduction: Endoscopic Retrograde Cholangio-Pancreatography (ERCP) is performed to treat pathology within the biliary system. Patients undergoing this may be on systemic anticoagulation. ERCP is classed as a high-risk bleeding procedure within BSG guidelines. This would necessitate anticoagulation interruption to prevent bleeding. It is recognised however, that resumption of antiplatelets and anticoagulants is associated with improved survival and reduced incidence of thrombotic complications. Thus, all patients should have a clear anticoagulation plan.

Aims & Methods: Attendances for ERCP over a 6-month period were analysed. Of the 132 patients, 33 (25%) were taking either an antiplatelet, warfarin or a Direct Oral Anticoagulant (DOAC). Medical records were reviewed in relation to pre-procedure management of these medications, advice from the endoscopist regarding resumption and whether these medicines were managed appropriately thereafter.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Several interventions were then made; a change to the reporting software led to a prompt relating to antiplatelet/anticoagulant medications, an education campaign for post graduate doctors in training and medication guidance summaries visible in the endoscopy department.

A second 6-month review was then undertaken to evaluate if there had been any improvement in outcomes. In this time frame, 143 patients underwent ERCP of whom 27 (16.7%) were taking antithrombotic therapy.

Results: Results are in Table 1:

	Pre-Intervention	Post Intervention
Pre-procedure appropriate management	48.5%	70.9%
Documented advice on endoscopy report	10%	30%
Post procedure appropriate prescribing	36.3%	70%

One common error was holding of anticoagulation/antiplatelet medication from admission in anticipation of ERCP. This led to long periods off anticoagulation whilst awaiting ERCP.

Documented advice was given more frequently on Endoscopy reports in cases where the patient required further procedure.

It was challenging to analyse post procedural management for inpatients, as the quality of ward round documentation and discharge letters was variable.

Conclusion: Further education to junior staff around utility of BSG anticoagulation guidelines greatly improved pre and post procedure management and thus forms a cornerstone to improve care. Further education to more senior staff may also improve decision rationale and medication advice in ward round documentation and discharge paperwork.

Human factors also need to be considered; limited advice is likely related to high endoscopy workload pressures, with sub analysis showing that advice is improved when further intervention is required or in higher risk settings, illustrating that antithrombotic decisions are considered by the endoscopist. Improved documentation at procedure with the support of upgrades to reporting software will enhance post procedure care and consequently reduce demands on the service.

USEFULNESS OF PERORAL CHOLANGIOSCOPY IN THE DIAGNOSIS AND CLINICAL STAGING OF PRIMARY SCLEROSING CHOLANGITIS

T. Fukuma[1], T. Fujisawa[2], H. Isayama[2], K. Tomishima[2], S. Ishii[2], A. Suzuki[2], M. Ushio[1], Y. Yamaguchi[2], H. Hagiwara[2], Y. Jimbo[2], I. Ikoma[2], D. Kabemura[2], M. Ikemura[2], H. Ota[2], D. Namima[2], Y. Takasaki[2], T. Osada[1]

Introduction: Primary sclerosing cholangitis (PSC) is known to present characteristic cholangiographic findings; however, detailed observations using peroral cholangioscopy (POCS) have rarely been reported. We previously reported that POCS findings in PSC can be classified into three types: active (inflammatory), chronic (scarring), and tumorous (tumor-like). These findings may aid in the differential diagnosis of PSC and may be useful in predicting prognosis.

Aims & Methods: We aimed to analyze POCS findings in PSC in detail based on this classification and to clarify their characteristics by evaluating the frequency of each finding, their temporal changes, and comparisons with other biliary diseases.

We retrospectively reviewed 22 patients with PSC who underwent POCS between February 2018 and February 2023. For comparison, we included 19 cases of hepatolithiasis, 25 cases of cholangiocarcinoma, and 3 cases of IgG4-related sclerosing cholangitis (IgG4-SC). Twelve POCS findings were categorized into three types: active (mucosal erythema, ulcers, fibrous white exudates, irregular surface), chronic (longitudinal scarring, annular scarring, pseudodiverticula, stenosis), and tumorous (dilated vessels, tortuous vessels, friability, mass formation). In addition, we included "punched-out lesion (POL)" as an original finding. Each finding was graded on a 5-point scale (0–4) based on the extent or number of lesions, and scores were calculated for each type.

We conducted three analyses: (1) correlation between cholangiographic and POCS findings in PSC, (2) temporal changes in POCS findings in PSC, and (3) comparison of POCS findings between PSC and other biliary diseases.

Results: In the first analysis, annular scarring (100%), stenosis (89%), POL (89%), and longitudinal scarring (86%) were frequently observed in PSC. Annular scarring was identified in all cases with a shaggy appearance on cholangiography, and stenosis were present in all ducts with band-like stricture. In ducts showing diverticulum-like outpouchings, longitudinal and annular scarring, pseudodiverticula, and POL were consistently seen, whereas other findings were absent. In the second analysis, active and tumorous scores varied over time even within the same case, whereas chronic scores remained stable or showed a progressive increase. A negative correlation was observed between active and chronic scores (p-value <0.001, r =-0.702). In the third analysis, chronic findings and POL were significantly more common in PSC compared to other diseases (p-value <0.001). Pseudodiverticula were seen exclusively in PSC, while dilated and tortuous vessels and friability were significantly more frequent in cholangiocarcinoma and IgG4-SC (p-value <0.001).

Conclusion: These findings suggest that the characteristic cholangiographic findings of PSC are mainly formed by chronic scarring. Diverticulum-like outpouchings reflect only fibrotic changes. Furthermore, the coexistence of inflammation and fibrosis, along with the time-dependent progression of fibrosis, is a unique feature of PSC, although active inflammation may obscure chronic findings.

Finally, longitudinal scarring and POL were particularly prominent in PSC, and pseudodiverticula were highly specific to this disease, suggesting their usefulness in differential diagnosis.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In conclusion, chronic findings on POCS are characteristic of PSC and may serve as a helpful tool in its diagnosis and differentiation from other biliary diseases.

Contact E-Mail Address: firdaouss.ai5@gmail.com

Introduction: ERCP is the first-line procedure for the treatment of choledocholithiasis. Spontaneous migration of common bile duct (CBD) stones through the duodenal papilla is a phenomenon observed in some cases. This migration can render ERCP unnecessary and potentially avoid complications.

The objective of our study is to evaluate the factors associated with the spontaneous migration of CBD stones.

Aims & Methods: This is a retrospective descriptive and analytical study including 547 patients who underwent ERCP for CBD lithiasis between January 2020 and January 2025.

All patients underwent MRCP for the diagnosis of CBD lithiasis.

A positive MRCP was defined as the presence of stones in the CBD.

A positive ERCP was defined as the presence of stones in the CBD at cholangiography.

We divided the patients into 2 groups:

- Group A (n=309): MRCP + and ERCP +
- Group B (n=265): MRCP + and ERCP –

Statistical analysis was performed using JAMOVI software.

Results: The mean age in Group A was 59.1 +/- 13.8 years and in Group B was 56.9 +/- 13.2 years, with no statistically significant difference (p=0.056).

The sex ratio (M/F) in Group A was 0.7 and in Group B was 0.54, with a significant female predominance in both groups (p=0.03).

There was no statistically significant difference regarding the CBD diameter and the presence of a periampullary diverticulum between the two groups.

When comparing Groups A and B, patients with a small stone diameter (P=0.001), a single stone (p=<0.001), and distal stones (P=0.04) tended to spontaneously evacuate their stones.

Conclusion: In our study, the factors associated with the spontaneous migration of CBD stones are a small stone diameter, a single stone, and distal stone location.

Disclosure: Nothing to disclose.

THE ADDED VALUE OF PERORAL CHOLANGIOSCOPY IN THE DIAGNOSIS OF INDETERMINATE BILIARY STRICTURES

I. Dobreva[1], P. Karagyozov[1], I. Zhecheva[1], K. Elatrebi[2], M. Kichuk[1]

[1]Acibadem City Clinic University Hospital Tokuda, Clinic of Gastroenterology, Sofia, Bulgaria, [2]National Hepatology and Tropical Medicine Research Institute, Cairo, Egypt

Contact E-Mail Address: i.jecheva1994@abv.bg

Introduction: Indeterminate biliary strictures pose a significant diagnostic challenge, as they can result from a wide spectrum of both benign and malignant conditions. Differentiating between these is crucial due to different management strategies. Conventional methods like endoscopic retrograde cholangiopancreatography (ERCP) with brush cytology have limited sensitivity, often leading to repeated procedures and delays in treatment. Peroral cholangioscopy (POC) offers direct bile duct visualization and targeted biopsies, improving diagnostic accuracy. Modern systems, like the SpyGlass™ DS, enhance procedure feasibility and image quality.

Aims & Methods: Aims: The aim of our study is to assess the effectiveness of single-operator peroral cholangioscopy system (POCS) with its digital version *SpyGlass™ Direct Visualization System* with SpyBite biopsies as a promising modality for accurate diagnosis of biliary strictures.

Method: We performed a two-center retrospective analysis of prospective database from March 2019 to March 2025. Each patient underwent peroral cholangioscopy using *SpyGlass™ Direct Visualization System with* SpyBite biopsies for the diagnosis of indeterminate biliary strictures.

Results: We identified 162 patients who underwent peroral cholangioscopy during the study period (96 males and 66 females). The medium age of the patients was 63.04 years. There was 100 % technical success of the procedure. All patients underwent POCS due to indeterminate biliary strictures. Before the procedure CT scan was performed and positive for biliary stenosis in 115 (70.9%) of the cases. The biliary stenoses were located as follows: 20 (12.3%) in the distal common bile duct, 29 (17.9%) in the proximal common bile duct, 102 (62.9%) at the hepatic hilum and 11 (6.7%) in the intrahepatic bile ducts.

Benign disease was diagnosed in 39 (24.07 %) of the patients. Visual impression for malignant desease (at least one of the following- tortuous dilated vessels, friability and easily bleeding, infiltrative stricture, polipoid mass, nodular eleveted lesion, vegetative mass, fish-egg lesion, finger - like villiform lesion and irregular papillary or granular lesion) was found in 123 (75.9%) of the patients. The most reliable correlation with malignancy was found to be the presence of infiltrative strictures - 113 (69.7%) patients. A final diagnosis of cholagiocarinoma was established in 84 (51.8%) of them. In 39 (24.07%) patients, no tumor cells were found in the specimen. Visual impression accuracy with SpyGlass was 100% (with 100% sensitivity and 100% specificity). SpyBite biopsies accuracy was 69.05 % (with 68. 3% sensitivity and 100% specificity).

Conclusion: POC has proven valuable in evaluating indeterminate biliary strictures, offering advantages over ERCP by allowing real-time visualization and targeted biopsies. Our study supports POC's superior accuracy,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

especially in identifying malignant lesions, with visual impression achieving up to 100% sensitivity and specificity. However, POC adoption is limited by operator expertise, the need for standardized interpretation, and availability.

While adverse events are rare (<10%), careful patient selection is essential. In conclusion, POC holds substantial promise as a key diagnostic tool for indeterminate biliary strictures, with ongoing improvements enhancing its clinical role.

Disclosure: No conflict of interest.

ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE ELDERLY

H. Chehboune[1], F.-Z. Chabib[1], M. Kadiri[2], N. Lagdali[3], F.Z. Ajana[4], M. Borahma[3]
[1]Faculty of Medicine and Pharmacy, Mohammed V University, Medicine C, Ibn Sina University Hospital Center, Rabat, Morocco, [2]Ibn Sina Hospital, Rabat, Morocco, [3]Mohammed the Vth University, Ibn Sina Hospital, Gastroenterology C, Rabat, Morocco, [4]CHU Ibn Sina, SMMAD, Moroccan Society of Digestif Diseases, Rabat, Morocco

Contact E-Mail Address: houda.chehboune@gmail.com

Introduction: Managing biliopancreatic disease in elderly patients is a growing challenge, where the balance between benefit and risk becomes increasingly delicate. ERCP remains a fundamental tool, but its application in older adults requires individualized technical and clinical considerations.

The aim of our study was to evaluate the characteristics of elderly patients who underwent ERCP.

Aims & Methods: We conducted a retrospective descriptive study from January 2019 to January 2025, including all patients aged ≥65 years who underwent ERCP. Collected data encompassed demographic characteristics, clinical presentation, procedural indications, technical success, therapeutic approaches, and procedure-related complications.

Results: We recorded 186 patients : 62.36% women (n=116) and 37.6% men (n=70), with a median age of 75 years [IQR: 71–80]. The most frequent presenting symptoms were biliary colic (43.4%, n=79), acute cholangitis (23.6%, n=43), cholestatic jaundice (11.8%, n=22), and acute pancreatitis (10.8%, n=20).

ERCP was indicated for benign pathology in the majority of cases, primarily for choledocholithiasis (56.5%, n=104). Other benign etiologies (11%, n=12) included post-cholecystectomy syndrome, biliary pancreatitis, bile duct injury, and Sump syndrome.

Malignant indications included pancreatic head tumors (20.7%, n=38), hilar cholangiocarcinoma (7.1%, n=13), ampullary carcinoma (6.5%, n=12), and gallbladder carcinoma (3.8%, n=7).

The technical success rate for benign pathology was 97.4% (n=113), with a failure rate of 2.6% (n=3). In malignant indications, the success rate was 90% (n=63), with failures (10%, n=7) primarily due to duodenal obstruction or an intradiverticular papilla.

Stenting strategies included uncovered self-expandable metal stents (33.2%, n=43), covered metal stents (3.8%, n=7), and plastic stents (7.6%, n=14).

Intra-procedural bleeding following sphincterotomy occurred in 2.7% of cases (n=3); two were managed with epinephrine injection and one with hemostatic clipping. No delayed post-procedural complications were reported.

Conclusion: ERCP appears to be a safe, effective, and well-tolerated procedure in elderly patients. When guided by appropriate indications and expert technique, age does not represent a limitation but rather a parameter requiring adapted procedural planning.

Disclosure: Nothing to disclose.

Introduction: Endoscopic sphincterotomy (ES) remains the reference treatment for type I and type II sphincter of Oddi dysfunction (SOD) following the failure of well-conducted medical therapy. However, it is an invasive procedure that presents technical challenges for biliary cannulation and carries an increased risk of post-endoscopic retrograde cholangiopancreatography (ERCP) acute pancreatitis in this indication.

The aim of our study was to describe the technical difficulties encountered during ERCP in patients with suspected SOD.

Aims & Methods: This was a retrospective, single-center study including all patients who underwent ES for the treatment of SOD between 2018 and 2024. Demographic, clinical, and endoscopic data were collected and analyzed.

Results: A total of 37 patients were included, with a mean age of 64.16 years and a marked female predominance (73%). SOD was diagnosed following an episode of cholangitis or acute pancreatitis in 51.4% of cases. Several technical difficulties were encountered, such as challenging papillary orientation (16.2%) and peri-diverticular location (10.8%).

Unintentional access to the main pancreatic duct occurred in 73% of cases, leading to the placement of a prophylactic pancreatic stent in 37.8%. Biliary cannulation was achieved in all patients.

Advanced cannulation techniques were required in 88.1% of cases, including the use of needle-knife sphincterotomes (35.1%), fistulotomies (45%), and transpancreatic sphincterotomy (8%).

Conclusion: ERCP in patients with suspected SOD is a true technical challenge. In our study, advanced biliary cannulation techniques were necessary in 88.1% of cases. These procedures thus require a high level of expertise in interventional endoscopy.

Disclosure: Nothing to disclose.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is commonly performed in post-liver transplant (LT) patients for biliary complications, but it carries risks such as acute pancreatitis (AP) and acute kidney injury (AKI). Rectal indomethacin, an NSAID, reduces post-ERCP pancreatitis in the general population; however, its safety in post-LT patients with potentially compromised liver function is unclear. This study evaluated the association between rectal indomethacin use and clinical outcomes in post-LT patients undergoing ERCP, using a large multinational population-based dataset.

Aims & Methods: A retrospective cohort study was performed using large population-based data from the TriNetX platform. We identified post-LT patients undergoing ERCP medicated with rectal indomethacin between January 1, 2014, and November 24, 2024. This cohort was matched 1:1 with post-LT patients undergoing ERCP not medicated with rectal indomethacin, using propensity matching based on age, gender, demographics, and comorbidities. Outcomes included risk of all-cause mortality, acute pancreatitis (AP), acute kidney injury (AKI), acute interstitial nephritis (AIN), renal replacement therapy, and ICU admission. Cox-proportional hazards models were used to estimate hazard ratios (HRs) with 95% confidence interval (CI).

	Post-LT Patients Undergoing ERCP with Indomethacin		Post-LT Patients Undergoing ERCP without Indomethacin		HR (95% CI)
Outcomes	Included	Events	Included	Events	
Mortality	714	10	712	10	0.67 (0.11, 3.99)
Acute pancreatitis	717	25	717	28	0.89 (0.52, 1.53)
AKI	717	103	717	85	1.23 (0.93, 1.64)
Acute interstitial nephritis	717	0	717	0	-
Renal replacement therapy	717	28	717	27	1.04 (0.61, 1.77)
ICU	717	49	717	55	0.89 (0.61, 1.31)

Abbreviations: LT, liver transplant; ERCP, endoscopic retrograde cholangiopancreatography; AKI, acute kidney injury; ICU, intensive care unit; HR, hazard ratio; CI, confidence interval.

Table 2. Outcomes Associated with Use of Indomethacin in Post-LT Patients Undergoing ERCP.

Results: A total of 4,642 post-LT patients undergoing ERCP were identified, of whom 717 individuals were medicated with rectal indomethacin. Among these, 717 patients medicated with rectal indomethacin (mean [SD] age, 53.7 [13.5] years; 267 [37.2%] female) were matched with 717 individuals (mean [SD] age, 54.5 [13.1] years; 266 [37.1%] female) not medicated with rectal indomethacin. The indomethacin group had no significant differences when compared to those not receiving rectal indomethacin; AKI (HR, 1.23; 95% CI, 0.93-1.64), renal replacement therapy (HR, 1.04; 95% CI, 0.61-1.77), all-cause mortality (HR, 0.67; 95% CI, 0.11-3.99), AP (HR, 0.89; 95% CI, 0.52-1.53), and ICU admission (HR, 0.89; 95% CI, 0.61-1.31).

Conclusion: Rectal indomethacin use in post-LT patients undergoing ERCP was not associated with significant differences in renal, hepatic, or clinical outcomes compared to those not receiving indomethacin. These findings support the cautious use of rectal indomethacin in post-LT patients undergoing ERCP, particularly when the risk of post-ERCP pancreatitis is high. The absence of a significant signal for harm may continue to encourage its use as a preventive measure, though clinicians should remain vigilant for potential renal and hepatic decompensation in high-risk patients.

Future research should focus on elucidating the mechanisms underlying indomethacin's effects in this unique population and exploring alternative prophylactic strategies where appropriate.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a pioneering procedure in the management of pancreatobiliary diseases. However, access to the common bile duct is not always easy, even in expert hands, with a failure rate ranging between 5% and 10%. A second attempt or alternative cannulation techniques are often required before considering surgery.

Aims & Methods: The aim of this study was to assess the ERCP failure rate in a tertiary care center.

This was a retrospective, descriptive, and analytical study conducted in a hepatogastroenterology department. It included patients who underwent ERCP with failed bile
duct cannulation over a 6-year period.

Results: Out of 801 ERCP procedures performed, 14 failures (1.7%) were recorded. Among these patients, 28.6% (4 patients) underwent a second ERCP attempt, with one of them being
successful. The indications for ERCP were: pancreatic head tumor in 43% of cases (6), common bile ductstones in 36% (5), cholangiocarcinoma in 14% (2), and bile duct trauma in 7% (1). The techniques used for cannulation were primarily guidewire-assisted cannulation in 79% of cases (11) and precut sphincterotomy in 21% (3). 8 patients (62%) had surgical drainage and 5 patients (38%) underwent endoscopic ultrasound-guided drainage after ERCP failure.

Conclusion: Our study demonstrates a low ERCP failure rate, comparable to that of international centers. Surgical intervention was more common early in the experience, prior to the introduction of endoscopic ultrasound-guided drainage in our practice.

Disclosure: Nothing to disclose.

CLINICAL OUTCOMES OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY-GUIDED REMOVAL OF COMMON BILE DUCT STONES IN ELDERLY PATIENTS

S. Matsubara[1], T. Arai[1], R. Sunada[1], K. Nakagawa[1], M. Ikeda[1]
[1]Saitama Medical Center, Saitama Mecical University, Gastroenterology and Hepatology, Kawagoe, Japan

Contact E-Mail Address: saburo.matsubara@gmail.com

Introduction: Endoscopic removal of common bile duct stones (CBDS) via endoscopic retrograde cholangiopancreatography (ERCP) is the first-line treatment. In developed countries, the number of ERCP procedures for CBDS in elderly patients is increasing with the aging population.

Elderly patients often present with poor performance status (PS), are frequently on antithrombotic therapy, and have multiple comorbidities. These factors raise concerns about an increased risk of ERCP-related complications; however, the safety and efficacy of ERCP in this population have not been fully evaluated.

Aims & Methods: The aim of this study was to assess the outcomes of ERCP for CBDS in elderly patients. Among 548 patients with symptomatic CBDS treated at our institution between April 2017 and February 2024, we excluded 81 cases involving altered anatomy, use of endosonography-assisted rendezvous technique, spontaneous stone passage, and biliary pancreatitis. The remaining 467 patients undergoing ERCP at our institution were retrospectively analyzed.

The patients were divided into an elderly group (E group: ≥75 years, n=241) and a younger group (Y group: <75 years, n=226), and short- and long-term outcomes were compared between the two groups.

Results: Patient Characteristics: The median age was 81 years (range: 75–99) in the E group and 68 years (range: 21–74) in the Y group. Male sex was less frequent in the E group (55% vs. 68%, p=0.006). The E group had significantly higher rates of antithrombotic use (39% vs. 24%, p=0.001), American Society of Anesthesiologists physical status ≥ III (57% vs. 35%, p=0.001), and concomitant cholangitis (52% vs. 41%, p=0.012).

Median stone size was slightly larger in the E group (8 mm vs. 6 mm, p=0.14), and the median bile duct diameter was significantly wider (10 mm vs. 9 mm, p=0.001).

Comorbidities were more prevalent in the E group: cardiovascular disease (34% vs. 22%, p=0.004), hypertension (52% vs. 39%, p=0.004), malignancy (33% vs. 18%, p=0.001), and dementia (11% vs. 2%, p=0.001).

Although endoscopic sphincterotomy (EST) was the most common papillary intervention in both groups, endoscopic papillary large balloon dilation (EPLBD) was more frequently performed in the E group (31% vs. 10%). Lithotripsy rates were similar between groups (22% vs. 16%, p=0.2).

Outcomes: Complete stone removal was achieved in 96% of the E group and 98% of the Y group (p=0.2). The median number of treatment sessions was 1 in both groups (range: 1–3, p=0.13).

Overall complication rates were comparable (8% vs. 7%, p=0.63). In the E group, complications included pancreatitis (n=15), bleeding (n=5), perforation (n=1), and aspiration pneumonia (n=1); in the Y group, pancreatitis (n=10) and bleeding (n=5) were observed.

No procedure-related mortality occurred in either group. There was no significant difference in the cumulative recurrence rate of stones after complete removal (p=0.29).

Multivariate analysis using variables such as age, sex, presence of cholangitis, bile duct diameter, lithotripsy, and gallbladder stones revealed no definite predictors of recurrence.

Conclusion: Although recent studies have reported the potential utility of long-term biliary stenting in elderly patients, stent occlusion leading to cholangitis remains a concern. Repeated hospitalizations in elderly patients can decrease activities of daily living. Therefore, we prioritize complete stone removal in patients with a favorable long-term prognosis. This study demonstrates that even in patients aged 75 years and older, active treatment of CBDS via ERCP might be effective and safe.

Disclosure: Nothing to disclose.

REAL WORLD CRITERIA FOR ERCP TIMING IN ACUTE CHOLANGITIS

I. Simao[1], P. Figueiredo[1], T. Santos Nunes Bana Costa[1], C. Chagas[1]
[1]Unidade Local de Saúde Lisboa Ocidental, Lisbon, Portugal

Contact E-Mail Address: inesrsimao@gmail.com

Introduction: The cornerstone of acute cholangitis treatment is antibiotic therapy combined with biliary drainage. The Tokyo Guidelines 2018 provide severity grading criteria that help predict prognosis and identify patients requiring early biliary drainage. While mild cholangitis can often be managed initially with antibiotics alone, moderate and severe cases typically require early and emergent drainage, respectively.

Our aim is to explore factors influencing the timing of ERCP in acute cholangitis and its impact on clinical outcomes.

Aims & Methods: This retrospective single-center cohort study included patients diagnosed with acute cholangitis who underwent ERCP between March 2022 and March 2023 in a tertiary hospital with ERCP. Diagnosis and severity grading were based on the Tokyo Guidelines 2018.

Descriptive and statistical analyses were performed to evaluate patient characteristics, severity classification, timing to ERCP and related clinical outcomes.

Results: A total of 104 patients underwent ERCP for acute cholangitis; 55 were female (52.9%) and the median age was 77 years. Based on the Tokyo 2018 criteria, 28 patients (26.9%) had grade III cholangitis, 52 (50%) grade II and 24 (23%) grade I. Only 5 patients (4.8%) underwent ERCP within 24 hours of admission—2 with grade III, 1 with grade II and 2 with grade I. Within 72 hours, 31 patients (29.8%) had undergone ERCP—9 with grade III, 16 with grade II and 6 with grade I.

Notably, 70.8% of grade III cases were submitted to ERCP more than 72 hours after admission, with a median of 3 days of antibiotics before the procedure.

There was no statistically significant association between ERCP timing and patient age, cholangitis severity, intensive/intermediate care admission or anticoagulant/antiplatelet use. However, admission on a Friday or Saturday was significantly associated with delayed ERCP (p=0.007), with 91% of these patients undergoing ERCP after 72 hours, compared to 56% for admissions on other days.

Cholangitis severity correlated significantly with total hospital stay (grade I: 7 ± 3 days, grade II: 8 ± 3.8 days, grade III: 10.5 ± 9 days; p=0.001). ERCP timing was also associated with total antibiotic duration (<24h: 9 ± 2.6 days, 24–72h: 8 ± 3 days, >72h: 10 ± 4.8 days; p=0.043). The 30-day mortality rate was 4.8%, with no significant association with ERCP timing or severity grade.

Conclusion: In this real-world cohort, ERCP was frequently delayed beyond the recommended window, even in severe acute cholangitis. Weekend admission was a significant contributor to this delay. However, no association was found between ERCP timing and 30-day mortality, likely due to small sample size. These findings highlight the need for optimized access to biliary drainage, particularly during weekends, to better meet guideline recommendations.

NAVIGATING BILIARY ACCESS: TECHNIQUES AND PREDICTORS FOR DIFFICULT CANNULATION IN ENDOSCOPIC CHOLANGIOPANCREATOGRAPHY

A. Abdul Majeed[1], A.S. Butt[1]
[1]Aga Khan University Hospital, Medicine, Karachi, Pakistan

Contact E-Mail Address: ammara.jahanzeb@aku.edu

Introduction: Despite being standard modality to manage a wide range of pancreaticobiliary pathologies the technical complexities and potential complication rates make provision of standardized ERCP services challenging especially in low middle income countries (LMICs). Hence, expertise and availability of ERCP services confined to limited centers in many LMICs. Successful biliary cannulation is the cornerstone for ERCP. Failure to cannulate common bile duct (CBD) not only lead to an unsuccessful procedure but also increases the risk of ERCP related complications.

Aims & Methods: Aims: Successful biliary cannulation is essential for a successful ERCP. Data regarding success rate of various cannulation techniques is limited from LMIc. The study aims to estimate the successful cannulation rate of various techniques used during ERCP for cannulation and to determine factors predicting difficult biliary cannulation.

Methods: This observational, cross-sectional study was conducted at Aga Khan University Hospital, Pakistan from July 2024 till March 2025. Patients of either gender ≥ 18 years of age who underwent ERCP were included. Difficult biliary cannulation was defined with reference to the ESGE guidelines. Clinical and procedural data was recorded for each patient.

Results: Out of 196 ERCPs performed during study period 133 (67.9%) were with difficult cannulations. Out of 113 cases successful biliary cannulation was done in 112(84.2%). The median no of times cannulation was attempted was 4 (range 1-30) with cannulation time ≤ 5 minutes in 52.6%, 5-10 minutes in 15% and ≥ 11 minutes in 27.8% cases. In majority of cases (94.7%) cases wire guided cannulation technique was used followed by double wire guided technique. No statistically significant difference was found among various cannulation technique. The number of cannulation attempts, and cannulation time were identified as predictors of successful biliary cannulations.

	OR	95% CI	P value
Number of cannulation attempts	1.1	1.1-1.2	< 0.001
Cannulation time	2.5	1.5-4.3	< 0.001
Periampullary Diverticulum	1.3	0.2-6.4	0.70
Types of ampulla	1.16	0.714-1.88	< 0.54
Biliary cannulation technique	0.76	0.13-4.3	< 0.76

Table 1: Factors affecting successful cannulation.

Conclusion: Despite a high rate of difficult biliary cannulation, an overall success rate of 84.2% was achieved. Wire-guided cannulation was most commonly used, with no significant difference among techniques. Cannulation attempts and time were key predictors of success, highlighting the importance of early recognition and strategy adjustment.

WHEN ENDOSCOPIC SPHINCTEROTOMY IS NOT ENOUGH: EFFICACY AND SAFETY OF DILATION-ASSISTED STONE EXTRACTION FOR CHALLENGING BILIARY STONES: A TERTIARY CENTER EXPERIENCE

O. Nacir[1,2], F.E. Lairani[1,2], A. Ait Errami[1,2], S. Oubaha[1,3], Z. Samlani[1], K. Krati[1,2]

Contact E-Mail Address: o.nacir@uca.ac.ma

Introduction: Difficult biliary stones and complex bile duct anatomy often limit the efficacy of endoscopic sphincterotomy (EST) alone. Dilation-Assisted Stone Extraction (DASE), involving large balloon dilation following EST, has emerged as a complementary technique to improve stone clearance.

This study aimed to evaluate the safety and effectiveness of DASE performed either after primary EST in patients with naïve papilla or as a rescue strategy following prior EST.

Aims & Methods: A retrospective review was conducted on all patients who underwent DASE between January 2018 and December 2024 at the Department of Gastroenterology and Digestive Endoscopy, Mohammed VI University Hospital, Marrakech, Morocco. Inclusion criteria comprised patients with naïve or previously treated papilla undergoing DASE for bile duct clearance. Technical success was defined as successful balloon placement across the papilla, full inflation to target diameter for >30 seconds, followed by complete stone extraction. Complications were categorized as intraprocedural, early (<24 hours), or delayed (>24 hours).

Results: A total of 57 patients were included (mean age 72.5 ± 12.1 years; 30 females [52.6%], 27 males [47.4%]). Thirty-five patients (61.4%) had a naïve papilla, and 22 (38.6%) had prior EST. Main indications for DASE included large or impacted CBD stones (63.2%), periampullary diverticulum (15.8%), difficult cannulation (12.3%), altered anatomy (5.3%), and other causes (3.5%).

Technical success was achieved in 55 patients (96.5%). Thirteen patients (22.8%) experienced complications: 7 (53.8%) intraprocedural, 4 (30.8%) early, and 2 (15.4%) delayed.

Adverse events included:

- Bleeding in 8 patients (61.5% of all complications): 4 self-limited (50%), 3 endoscopically managed (37.5%), and 1 required radiological embolization (12.5%).
- Post-ERCP pancreatitis (PEP) in 4 patients (30.8%): all mild, resolved with conservative management.
- Perforation in 1 patient (7.7%): managed successfully with endoscopic clipping and supportive care.

Univariate analysis revealed that prior EST was significantly associated with a higher complication rate (p = 0.01).

Conclusion: DASE following EST is a highly effective and relatively safe approach for managing difficult CBD stones, with a high technical success rate and acceptable complication profile. The results support its routine use in therapeutic endoscopy, particularly for cases refractory to EST alone. Prior EST may be associated with a higher risk of adverse events and should prompt careful intra- and post-procedural monitoring.

REDUCING UNNECESSARY ERCP IN BILIARY STONE DISEASE: EFFICACY OF SAME-SESSION FOCUSED EUS IN A LARGE UK TERTIARY CENTER

N. Pantzaris[1], M. Abdalaziz[1], E. Gaunt[1], U. Akbani[1], S. Everett[1], M. Huggett[1], B. Paranandi[1], A. On[1]
[1]Leeds Teaching Hospitals, Leeds, United Kingdom

Contact E-Mail Address: drumairakbani@gmail.com
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is the preferred method for treating common bile duct (CBD) stones. However, in a small number of patients with suspected or confirmed choledocholithiasis on imaging, ERCP results may appear normal. Since the procedure carries considerable risks, such cases should be minimized.
Aims & Methods: This study aimed to analyse the incidence of reported normal ERCPs in cases of biliary stone disease and evaluate the impact of focused EUS in reducing unnecessary procedures.
Data were retrospectively collected from the endoscopy and patient record system, as well as a prospectively maintained database of all ERCP procedures at a UK teaching hospital during a 4.5-year period, from 1/1/2020 to 30/4/2024, with a 30-day additional follow-up period. Variables were assessed by mean with standard deviation (SD) or median with interquartile range (IQR).
Results: There were 3,217 ERCPs performed during the study period, of which 1,636 (50.8%) were performed for biliary stone disease. 124 ERCPs were reported as normal/no stones (7.6%). The most recent imaging was MRCP for 73/124 patients followed by CT for 23/124 and abdominal ultrasound (USS) for 16/124. The median days for imaging-to-ERCP was 8 (4;24). 89/124 patients had a dilated CBD and 11/124 had a confirmed CBD stone on the most recent imaging modality. 90/124 patients had an abnormal ALP and 62/124 had an abnormal bilirubin level. The median days of the most recent liver function tests to ERCP were 2 (1;12).
8/124 patients had a procedural complication. 3 had post-ERCP pancreatitis, 3 a post sphincterotomy bleed, 1 had mild cholangitis and 1 had a small post-sphincterotomy perforation.
From 2020, there has been a gradual increase in the combined single session EUS/ERCP procedures for CBD stones. Figure 1. demonstrates the significant reduction of the reportedly “normal” ERCPs as the number of the combined procedures increased. Around 1/3 of the combined procedures do not proceed to an ERCP.
Conclusion: Current guidelines recommend CBD stone extraction for all patients deemed fit for the procedure. Our findings indicate that performing single-session combined EUS/ERCP in carefully selected cases can reduce unnecessary ERCPs in centres offering both services, thereby minimizing patient risk.

UTILISATION AND OUTCOME OF CHOLANGIOSCOPY IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS – A EUROPEAN COHORT

H. Chi[1], D. Sriranganathan[1], D.M. de Jong[2], J. Reijnders[2], T. Riley[1], S. Phillpotts[1], T. El Menabawey[1], M. Chapman[1], G. Johnson[1], S.P Pereira[1], M.J. Bruno[2], P.J. de Jonge[2], G. Webster[1], European Cholangioscopy in PSC Study Group
[1]University College London Hospital, Pancreaticobiliary medicine, London, United Kingdom, [2]Erasmus MC University Medical Center Rotterdam, Gastroenterology and Hepatology, Rotterdam, Netherlands

Contact E-Mail Address: h.chi@erasmusmc.nl
Introduction: Primary sclerosing cholangitis (PSC) is a progressive disease leading to inflammation and fibrosis of the bile ducts with biliary strictures. New strictures or symptoms should trigger the suspicion of cholangiocarcinoma which may develop in more than 20% of patients. Endoscopic retrograde cholangiopancreaticography (ERCP) is useful in stricture management, but standard tissue acquisition with brush cytology provides poor diagnostic accuracy. Cholangioscopy can aid stricture assessment and stone clearance.
This study investigated the technical success, diagnostic yield and complication rate of cholangioscopy in PSC patients in two large tertiary European hospitals.
Aims & Methods: This retrospective cohort included all consecutive PSC patients who underwent ERCP with cholangioscopy between 2014 and 2024. Exclusion criteria were liver transplantation or confirmed cholangiocarcinoma. Charts were reviewed for patient characteristics, procedure characteristics and outcomes.
Results: A total of 84 cholangioscopies were performed in 55 PSC patients (55% male, mean age 63 years). Most patients were of Caucasian ethnicity (68%). Cirrhosis was present in 29% of patients with 54% also having concurrent inflammatory bowel disease.
Most patients (88%) were discussed in a multidisciplinary meeting prior to ERCP. The primary indications for ERCP were stricture assessment (38%), dominant stricture (21%), cholangitis (19%), suspicion of malignancy (11%), stones (10%). The mean serum alkaline phosphatase and bilirubin were 508 IU/Land 60 umol/L, respectively. Most patients received rectal diclofenac (98%) and antibiotics (96.5%). Fifteen patients (18%) had a native ampulla of whom 5 (33%) were considered as difficult cannulation (per ESGE). No precut was performed. All patients with native ampulla underwent sphincterotomy.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Cholangioscopy was successful in 98% of cases with two failures due to tight stricture and inadequate intraductal view. Electrohydraulic lithotripsy was successful in 76% of cases with a complete stone clearance rate of 82%.

Cholangioscopy-guided biopsies were taken in 44 cases which resulted in histological diagnosis of cholangiocarcinoma in four patients. One patient was diagnosed with cholangiocarcinoma on cholangioscopy-guided biopsies while the cytological brush was non-diagnostic and one patient had cholangiocarcinoma confirmed on both cholangioscopy-guided biopsies and cytological brush. The other two cholangiocarcinoma was diagnosed where only cholangioscopyguided biopsies were done. On the other hand, one patient with normal cholangioscopy-guided biopsies and cytological brush was diagnosed with cholangiocarcinoma on endoscopic ultrasound guided lymph node biopsy.

Seven patients developed a complication (8%): 1 peri-procedural bleeding, 1 hepatic decompensation, 1 gallbladder perforation and pancreatitis, 3 cholangitis and 1 abdominal pain requiring admission. Native papilla was not associated with an increased risk of complications (6.6% vs. 8.7%, p>0.05).

Conclusion: This is one of the largest cohort of cholangioscopies in PSC patients performed in two high volume centre. Cholangioscopy had a high technical success rate. Previous concern that strictures preclude technical success was not seen. Stone clearance using electrohydraulic lithotripsy was also effective.

On the other hand, cholangioscopy-guided biopsies may inform clinical management but more data is needed on the clinical impact of cholangioscopy. Cholangioscopy did not appear to increase the established risk of ERCP in PSC patients.

Disclosure: Nothing to disclose.

ENDOSCOPIC BILIARY DRAINAGE IN MALIGNANT OBSTRUCTION FROM NON-HEPATOBILIARY-PANCREATIC CANCERS: OUTCOMES AND PREDICTORS OF FAILURE

L. Aouragh[1], Y. Dendane[1], O. Elmqaddem[1], H. Koulali[1], G. Kharrasse[1], Z. Abdelkrim[1], Z. Ismaili[1]
[1]Mohammed VI University Hospital,Department of Hepato-Gastroenterology, Faculty of Medicine and Pharmacy, Digestive Disease Research Laboratory, Oujda, Morocco

Contact E-Mail Address: latifa.aouragh97@gmail.com

Introduction: Malignant biliary obstruction (MBO) caused by non-hepatobiliary-pancreatic (non-HBP) malignancies is a rare and underexplored indication for endoscopic retrograde cholangiopancreatography (ERCP). These cases often present a clinical dilemma: while ERCP offers a minimally invasive option, its utility remains uncertain in patients with poor prognosis and advanced disease.

Aims & Methods: We aimed to evaluate the effectiveness of ERCP-guided biliary drainage in this context and identify baseline predictors of clinical failure to help refine patient selection.

We conducted a retrospective analysis of all patients who underwent ERCP for malignant biliary obstruction of non-HBP origin between March 2018 and February 2025. Patients lacking essential clinical or follow-up data were excluded. Technical success was defined as adequate stent placement; clinical success as a ≥50% reduction in bilirubin or resolution of cholangitis within 2 weeks. The predictive role of bilirubin level, stricture location, serum albumin, and ECOG performance status was assessed. A ROC analysis evaluated the discriminative ability of pre-drainage bilirubin.

Results: Forty-eight patients were included (mean age: 55.6 years; 56% women). The most common primary cancers were colorectal (31%, n=15), gastric (18%, n=9), breast (14%, n=7), lung (10%, n=5), and ovarian (8%, n=4). Hilar strictures were observed in 54% (n=26) and mid-to-distal strictures in 46% (n=22). All procedures were performed using plastic stents. In most cases involving hilar strictures, long stents (e.g., 7 Fr / 12–15 cm) were used, and a single biliary sector—usually the most dilated or invaded—was preferentially drained. Technical success was achieved in 85.4% of cases. Clinical success occurred in 54.1% of patients, while early mortality (≤30 days) reached 10.4%, exclusively among individuals with ECOG status 4 and serum albumin <2.8 g/dL. Hilar strictures and total bilirubin levels >200 mg/L were significantly associated with lower clinical success rates (38% vs 65%, p=0.03 and 33% vs 62%, p=0.04, respectively). ROC analysis showed an AUC of 0.72 for bilirubin in predicting failure. Technical failures (14.6%) were mainly due to anatomical distortion or papillary inaccessibility.

Conclusion: Endoscopic biliary drainage in this population is technically achievable but offers limited clinical benefit, especially in cases with hilar involvement, severe hyperbilirubinemia, or poor overall condition. These findings emphasize the importance of using simple, baseline clinical indicators to guide treatment decisions, avoid unnecessary interventions, and adapt care strategies to the realities of resource-limited settings.

Disclosure: I have no conflict of interest.

CBD CLEARANCE USING ENDOSCOPIC PAPILLARY LARGE BALLOON DILATATION (EPLBD) IN PATIENTS WITH DIFFICULT COMMON BILE DUCT(CBD) STONES: A DECADE'S EXPERIENCE OF A TERTIARY CARE CENTRE (CLEAR STUDY)

N. Sirohi[1], S. Srivastava[1], U. Sonika[1], R. Rana[1], V. Vaithiyam Sudharsan[1], S. Sachdeva[1], A. Kumar[1], A. Dalal[1]
[1]GB Pant Institute of Postgraduate Medical Education and Research, Gastroenterology, New Delhi, India

Contact E-Mail Address: nikhilsirohi1994@gmail.com

Introduction: Endoscopic papillary large balloon dilatation (EPLBD) is an established technique for managing difficult common bile duct (CBD) stones. This study evaluates the efficacy and safety of EPLBD in a large cohort from a tertiary care centre.

Aims & Methods: Patients with difficult CBD stones (N = 559) who underwent EPLBD between January 2015 and December 2024 were retrospectively analysed from a prospectively maintained database. The primary outcome was complete CBD clearance. Secondary outcomes included complication rates, number of sessions required, and need for mechanical lithotripsy or surgical intervention. We also identified predictive factors for failed clearance and complications.

Results: The cohort had a mean age of 47.8 ± 14.6 years; 75% were female. The mean diameter of the largest CBD stone was 15.1 ± 4.2 mm, with an average of 2.16 ± 1.7 stones per patient. Mean CBD diameter was 15.1 ± 3.1 mm, and the average balloon size used was 14.8 ± 1.7 mm. Complete clearance was achieved in 84.9% (475/559) of the patients in a single session and in 89.9% (503/559) of the patients overall. Mechanical lithotripsy achieved additional clearance in only 11(2.5%) patients. Complications occurred in 34(6.1%) patients: perforation (n=18,3.2%), bleeding (n=15,2.7%), and pancreatitis (n=1,0.2%). Procedure-related mortality was observed in three (0.5%) patients (perforation, n=2; bleeding, n=1). Regression analysis identified larger stone size as a predictor of clearance failure (OR: 1.10; 95% CI: 1.03–1.17; p = 0.004) and need for repeat intervention as a predictor of complications (OR: 4.49; 95% CI: 1.68–11.99; p = 0.003).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: EPLBD is a safe and effective approach for the management of difficult CBD stones. It offers high success rates with acceptable complication rates, making it a valuable one-stop management for difficult CBD stones, particularly in resource-constrained settings.
Disclosure: Nothing to disclose.

INFLUENCE OF PAPILLARY MORPHOLOGY ON CANNULATION DIFFICULTY AND COMPLICATIONS DURING ERCP: A COHORT FROM A HIGH-COMPLEXITY CENTER IN LATIN AMERICA

R. Pinto-Carta[1], G.A. Reyes Medina[1], M. Vasquez[1], A. Bejarano[2], M.A. Gomez Gutierrez[1], F. Sierra Arango[1]
[1]Fundación Santa Fe Bogota, Bogota, Colombia, [2]Independent Researcher, Bogota, Colombia

Contact E-Mail Address: renzopc77@gmail.com
Introduction: Cannulation of the papilla of Vater is a pivotal step in endoscopic retrograde cholangiopancreatography (ERCP), directly impacting technical success and complication risk. (1) While factors such as endoscopist experience and anatomical variants are known to influence outcomes, (2) the role of papillary morphology remains understudied, particularly in Latin America. Morphology-based risk stratification may aid in anticipating the need for advanced cannulation techniques or expert-level intervention.
Aims & Methods: We prospectively enrolled adults with an intact, naïve major duodenal papilla undergoing ERCP at a high-complexity institution in Bogotá, Colombia. Patients with surgically altered anatomy or periampullary tumors were excluded. Papilla morphology was classified macroscopically according to Haraldsson et al. (3) Difficult cannulation was defined by ESGE criteria: >5 papilla contacts, >5 minutes to cannulate after visualizing the papilla, or ≥2 unintentional pancreatic duct guidewire passes. We recorded clinical and procedural variables, including use of advanced cannulation techniques and complications. Associations were assessed through bivariate comparisons using Fisher's exact test and odds ratios with 95% confidence intervals ($p < 0.05$).
Results: 58 patients were included (mean age 59.9 years; 63.8% female). The most frequent indication for ERCP was choledocholithiasis (81.0%). Papilla types were: type 1 (63.8%), type 3 (27.6%), type 2 (6.9%), and type 4 (1.7%). Difficult cannulation occurred in 8 cases (13.8%), with overlapping criteria: >5 contacts (n=5), >5 minutes (n=3), and ≥2 pancreatic guidewire passes (n=3). Difficult cannulation was more frequent in type 1 (13.5%) and type 3 (12.5%) papillae and occurred in the single type 4 case; none in type 2. The mean number of contacts with the papilla was 2.4 (range 0–16). Use of advanced cannulation techniques was required in 20 cases (34.5%). Cannulation time was significantly longer when advanced techniques were required, with a median of 21.2 minutes and a mean of 27.6 minutes, compared to 0.5 and 0.9 minutes, respectively, in cases managed conventionally. Post-ERCP prophylaxis measures were used in 35 patients (60.3%), including diclofenac (37.9%), aggressive hydration (32.8%), and pancreatic stenting (27.6%). Three patients (5.2%) received all three preventive measures. Complications included pancreatitis (n = 4, 6.9%) and cholangitis (n = 2, 3.4%). Complication rates did not significantly differ according to papilla type ($p = 0.68$). No significant difference in pancreatitis incidence was observed between patients who did and did not receive prophylactic measures ($p = 1.0$; OR 0.64, 95% CI 0.04–9.48). The incidence of post-ERCP pancreatitis was 8.3% in type 1 and 25.0% in type 2 papillae, with no cases observed in type 3 or type 4 papillae. However, the association between papilla morphology and pancreatitis occurrence was not statistically significant ($p = 0.268$).
Conclusion: Type 1 and type 3 papillae were associated with greater cannulation difficulty, though complications did not differ significantly by morphology. These findings support a growing body of evidence linking papillary type to ERCP complexity. While limited by sample size and the absence of endoscopist stratification, the prospective design, standardized use of ESGE criteria, and regional focus contribute valuable insight into procedural risk.
This study provides a foundation for considering papilla morphology in preprocedural planning and for guiding training priorities in high-complexity endoscopy units.

ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY PERFORMED IN THE ENDOSCOPY SUITE IS ASSOCIATED WITH REDUCED IMMEDIATE ADVERSE EVENTS AND TECHNICAL FAILURE RATES

O. Osagiede[1], F. Lukens[1]
[1]Mayo Clinic, Gastroenterology, Jacksonville, United States of America

Contact E-Mail Address: lukens.frank@mayo.edu
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is usually performed in the endoscopy suite which is designed to accommodate staff, endoscopy stack, anesthetic and imaging machines. ERCP in locations outside the endoscopy suite may pose a challenge for the endoscopist in ergonomics and equipment access.
The aim of this study is to compare the technical success and adverse events between ERCP performance in endoscopy suite and non-endoscopy suite locations.
Aims & Methods: Retrospective analysis of 24,122 ERCP procedures in a national sample of the United States over 12 years using the Clinical Outcomes Research Initiative (CORI)/National Endoscopic Database (NED). All patients with ERCP and a description of procedure location (endoscopy suite, radiology, operating room and others) were included. Demographics, patient position, patient tolerance, procedure and fluoroscopy time, visualization and cannulation of main structures, ERCP adverse events, and technical success rates were compared between ERCP endoscopy suite and non-endoscopy suite locations. Categorical variables were compared using Pearson's chi-square test and continuous variables using a standard t-test. Univariate and multivariate regressions were performed adjusting for age, gender, ethnicity, ASA class and clinical setting.
Results: A total number of 11,974 (49.6%) procedures were performed in the endoscopy suite and 12,148 (50.4%) in non-endoscopy suite locations [radiology, 10,435 (43.3%), operating room, 1518 (6.3%) and Others, 195 (0.8%)]. The mean patient age was 57 years, 52% were male. ERCP was performed in the supine position in 12.6% of endo vs. 4.1% of non-endo

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

locations (p<0.001). Patient tolerance was excellent in 39.4% of endo vs 33.9% of non-endo locations (p<0.001). The ampulla was visualized in 97.6% of endo vs. 97.6% of non-endo locations (p = 0.18). The common bile duct (CBD) was visualized and cannulated in 91.4% of endo vs. 90.8% of non-endo locations (p<0.001). The ERCP was incomplete in 5.8% of cases in endo vs. 6% of non-endo locations (p=0.529).

Technical success (aOR: 1.81, p=0.02) was more likely and ERCP adverse events (aOR: 0.47, p = 0.001) less likely to occur in endo-suite. Total procedure time (aOR: 1.00, p=0.67) and fluoroscopy time (aOR: 1.01, p=0.342) were similar between both groups.

Conclusion: ERCP procedures performed in the endoscopy suite is associated with reduced immediate adverse events and technical failure rates. This may reflect the technical difficulty of performing ERCP in non-endoscopy suite locations for the endoscopist, possibly related to ergonomics and equipment access. Our study supports performing ERCP in the endoscopy suite where possible to optimize ERCP safety and success.

Introduction: Endoscopic biliary sphincterotomy is an effective treatment for common bile duct stones. However, its success can be compromised by the presence of large stones or extensive choledochal lithiasis.

The aim of this study was to evaluate the effectiveness of endoscopic retrograde cholangiopancreatography (ERCP) in patients with large obstructive stones (>15 mm) and those with one or two stones or choledochal lithiasis, and to identify factors influencing the success of endoscopic drainage and associated complications in the management of large bile duct stones.

Aims & Methods: This was a retrospective, descriptive, and analytical study conducted over a 19-year period, from April 2006 to February 2025, in our department.

A total of 1,011 patients who underwent ERCP for common bile duct stones were included. Choledochal lithiasis was defined as the presence of more than three stones, and a large stone was defined as an obstructive stone larger than 15 mm. Patients were divided into two groups:

• Group I (n = 143): Patients with a single obstructive stone larger than 15 mm.

• Group II (n = 868): Patients with one or two stones or choledochal lithiasis.

Results: Patients with large stones (Group I) represented 14.1% (n = 143) of the cohort, while Group II included 868 patients (85.9%).

The success rate after a single catheterization was 55.2% in Group I compared to 81% in Group II (p < 0.001). Reintervention was required in 14.7% of Group I patients versus 8% in Group II (p = 0.009). Additional procedures were performed in 46.2% of cases in Group I versus 16.1% in Group II.

The overall success rate after reintervention and/or additional procedures was 88.7% in Group I versus 92.5% in Group II (p = 0.125).

Early complication rates were higher in Group I (10.5%) compared to Group II (5.1%), with a statistically significant difference between groups (p = 0.017).

Univariate analysis identified the following factors as significantly decreasing the overall success rate of endoscopic treatment: older age, acute cholangitis, bile duct stricture, and significant bile duct dilation (diameter >15 mm).

Multivariate analysis, adjusted for age, sex, surgical history, acute pancreatitis, acute cholangitis, periampullary diverticulum, bile duct diameter, and bile duct stricture, showed that only acute cholangitis (OR: 0.295; 95% CI: [0.164 – 0.532]; p < 0.001) and bile duct stricture (OR: 0.53; 95% CI: [0.922 – 1.051]; p = 0.001) were independently associated with a decreased overall success rate of endoscopic treatment.

Conclusion: Our study found no statistically significant difference in the effectiveness of endoscopic treatment between patients with large stones and those with simple lithiasis. However, the presence of acute cholangitis and bile duct strictures appears to be associated with a reduced overall success rate of endoscopic management.

Disclosure: Nothing to disclose.

Introduction: The global trend with increasing incidence of multidrug resistant (MDR) pathogens represents one of the most important medical emergencies. Acute cholangitis is frequently complicated by resistant biliary infections, mostly from the GI tract, chalenging clinical management and outcomes [1].

We aimed to characterize the antimicrobial resistance pattern in a multicentric study, and to identify risk factors for MDR pathogens.

Aims & Methods: The ARISE trial currently takes place in three tertiary endoscopy units from Romania. As of August 2024, a total of 498 adult patients with acute cholangitis were included after disease confirmation by clinical, laboratory, and imaging findings described in the Tokyo guidelines. https://clinicaltrials.gov/study/NCT06197984

Results: Overal, 60.1% of biliary cultures were positive, with 35.2% of them being polymicrobial. Blood cultures were obtained in 76.9% of patients, of which 11.5% were positive. The three most frequently isolated organisms included Escherichia coli (41.4%), Klebsiella pneumoniae (22.6%), and Pseudomonas aeruginosa (16.5%). Among isolated strains, 28.0% demonstrated at least one significant resistance, with extended-spectrum beta-lactamase (ESBL) production (24.9%), methicilin-resistant Staphylococcus aureus (MRSA) (10.6%), and vancomycin resistant enterococci (VRE) (8.8%) topping the resistance patterns. MDR, defined as resistance to three or more antibiotic classes, was detected in 17.4% of positive cul-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tures. Patients with MDR pathogens were older (mean age 71.2 vs. 63.8 years, p<0.01) and more likely to have diabetes melitus (34.2% vs. 18.6%, p<0.05). Tokyo severity grade II (29.5%) or III (19.3%) was significantly associated with MDR involvement (22.0% vs. 9.7%, p<0.01). Prolonged prior antibiotic exposure (over 48 hours) was independently predictive of MDR growth (adjusted odds ratio 2.4, 95% CI 1.6–3.6). In-hospital mortality was higher in patients with MDR isolates (15.8% vs. 4.4%, p<0.01), underscoring the clinical impact of resistance.

Conclusion: Antibiotic resistance in acute cholangitis remains substantial, especially among advanced Tokyo severity cases. Recognizing risk factors, including older age, prior antibiotic use, and severe disease, can guide empiric treatment strategies to mitigate the burden of MDR pathogens and improve outcomes.

ERCP OUTCOMES AFTER ORTHOTOPIC LIVER TRANSPLANTATION: A RETROSPECTIVE ANALYSIS OF A PROSPECTIVE DATABASE

O. Osagiede[1], F. Lukens[1]
[1]Mayo Clinic, Gastroenterology, Jacksonville, United States of America

Contact E-Mail Address: lukens.frank@mayo.edu

Introduction: Biliary complications are well known complications of orthotopic liver transplantation (OLT) and are increasingly recognized in clinical practice, moreso due to the increased volume of liver transplantations performed annually in the United States. Endoscopic retrograde cholangiography (ERCP) has proven to be an effective alternative to more invasive surgical interventions for post-OLT biliary complications.

The aim of this study is to examine the technical performance of ERCP in the liver transplant population presenting with biliary complications post-OLT.

Aims & Methods: Retrospective analysis of prospectively collected clinical data of patients undergoing ERCP in a single large tertiary/academic referral center which is also a liver transplant center. Patients who underwent ERCP for transplant and non-transplant indications between January 2019 and July 2023 were included. The primary outcome was determining ERCP technical success among patients who underwent ERCP post-OLT. Technical success was defined as successful biliary cannulation and achievement of therapeutic goal. Secondary outcomes examined differences in technical success, fluoroscopy time and procedure time based on ASGE-grading system of procedural complexity.

Results: Of a total number of 1289 patients included in the study, 322 (25%) underwent ERCP post-OLT in the study period. The mean age of post-OLT patients was 59.1 years, and 60.9% were males. The ASGE procedural difficulty grading was Grade 1 (63.7%), Grade 2 (23.6%), Grade 3 (8%) and Grade 4 (4.7%) in OLT. Moreover, 39.8% had a native papilla and a spyglass was used in 10.6% of OLT cases. The indications for ERCP post-OLT were biliary stricture (47.5%), abnormal LFTs (20.2%), biliary stone (19%), biliary leak (9.3%), and ischemic cholangiopathy (4%). Technical success was achieved in 98.1% of cases. The average fluoroscopy and procedure times were 4.5 mins and 24.7 mins respectively. There was no difference in technical success based on ASGE grading system, however, fluoroscopy time (-6.1 mins) and procedure time (-27.0 mins) were significantly shorter in Grade 1-2 versus Grade 3-4 respectively.

Conclusion: ERCP is technically successful for biliary complications post-OLT. ASGE-grading system for procedural complexity was a significant predictor of fluoroscopy and procedure durations, but not of technical success.

Disclosure: Nothing to disclose.

Introduction: Hepatic hydatid cyst (HHC) is a parasitic disease caused by the development of the tapeworm Echinococcus granulosus. Fistulization into the biliary tract is one of its most common complications. Endoscopic treatment is preferred due to the risks associated with surgery.

This study aims to evaluate the role of endoscopic retrograde cholangiopancreatography (ERCP) in the diagnostic and therapeutic management of HHC ruptured into the biliary tract.

Aims & Methods: This is a retrospective, descriptive, and analytical study conducted from January 2002 to August 2021, including 50 patients with HHC fistulized into the biliary tract. All patients underwent ERCP combined with endoscopic biliary sphincterotomy. Overall success was defined as complete clearance of the main bile duct. Statistical analysis was performed using SPSS version 24.0.

Results: Among all ERCPs performed during the study period, 4.6% (n=50) were for a hepatic hydatid cyst communicating with the biliary tract. The mean age of patients was 46.1 ± 14.8 years, with a male predominance (66%; male-to-female ratio = 1.94).

ERCP was performed preoperatively in 52.2% of cases and postoperatively in 47.8%.

The main indications were acute cholangitis (44.9%) and persistent external biliary fistula (34%).

The median diameter of the common bile duct was 10 mm [7–14], and the median cyst diameter was 35 mm [27–47].

Sphincterotomy was performed in 96% of cases, allowing hydatid material extraction using a balloon or Dormia basket in 87.8% of cases. A nasobiliary drain was required in 24% of patients, and biliary stent placement was performed in 8%.

The overall success rate was 96% (n=46). Immediate complications occurred in 8% (n=4): one case of hemobilia and three cases of marginal bleeding.

Clinical improvement included jaundice resolution within 5 to 10 days and closure of the external biliary fistula within 10 days.

Conclusion: Our study confirms that endoscopic management of ruptured hepatic hydatid cysts into the biliary tract is an effective therapeutic alternative, with a low rate of immediate complications (8%) and favorable long-term outcomes.

REVISITING CRP THRESHOLDS IN TUMOR-RELATED CHOLANGITIS: TOWARD A CONTEXT-SPECIFIC DIAGNOSTIC APPROACH

Y. Dendane[1], A. Azarkan[1], O. Elmqaddem[1], H. Koulali[1], G. Kharrasse[1], Z. Abdelkrim[1], Z. Ismaili[1]
[1]Faculty of Medicine and Pharmacy/University Hospital Center Mohammed VI, Hepatology and Gastroenterology, Oujda, Morocco

Contact E-Mail Address: dendane.youness@gmail.com

Introduction: The Tokyo Guidelines recommend a CRP cutoff >10 mg/L for diagnosing acute cholangitis. However, this threshold was defined in lithiasic populations and may not be applicable to malignant biliary obstruction, where CRP elevation often reflects tumor-driven inflammation rather than true infection. Applying this universal threshold in oncologic settings risks antibiotic overuse and promotes resistance.

Aims & Methods: This study aimed to reassess the diagnostic value of the current CRP cutoff in tumor-related cholangitis and to identify a more appropriate threshold to enhance specificity and guide targeted antibiotic use.

We conducted a retrospective monocentric study of consecutive patients at a tertiary center between May 2016 and October 2024. Among 571 patients undergoing ERCP, 268 patients with confirmed malignant biliary obstruction and available bile sampling were included. Bacteriological status was defined as positive when either direct bile examination or culture isolated microorganisms. CRP levels, leukocyte counts (hyperleukocytosis >10,000/mm^3), and tumor etiology were recorded. ROC curve analysis was performed to determine the optimal CRP cutoff. Comparative analyses employed Mann-Whitney U, chi-square, and multivariate logistic regression.

Results: The mean age was 65.9 ± 12.4 years, with an equal sex distribution (50% male). Tumor etiologies included pancreatic cancer (56%), cholangiocarcinoma (22%) — 40 hilar and 18 distal cases, gallbladder cancer (13%), ampulloma (7%), and extrinsic or secondary compression (3%). The median CRP was significantly higher in culture-positive patients (47 mg/L [IQR 21–98]) compared to culture-sterile patients (22 mg/L [IQR 11–36]; p<0.001). ROC analysis identified an optimal CRP cutoff of 21 mg/L (AUC = 0.64), achieving a sensitivity of 67% and specificity of 54%. Hyperleukocytosis was present in 66% of culture-positive cases versus 31% of sterile cases (p<0.001).

In multivariate analysis, CRP ≥21 mg/L (OR 2.1; 95% CI [1.3–3.4]; p=0.002) and hyperleukocytosis (OR 3.4; 95% CI [1.9–5.9]; p<0.001) were independently associated with bile bacteriological positivity.

Conclusion: In malignant biliary obstruction, the universal CRP threshold of 10 mg/L lacks specificity and risks antibiotic overuse. A higher threshold around 21–25 mg/L, combined with leukocyte count assessment, improves diagnostic precision. Our findings advocate for a context-specific adaptation of the Tokyo Guidelines to better differentiate tumor-related inflammation from true infection, ultimately enhancing patient safety and antimicrobial stewardship in oncologic care.

FACTORS INFLUENCING INCOMPLETE ERCP PROCEDURES: A SIX-MONTH RETROSPECTIVE ANALYSIS

G. Loy[1], K. Hakeem[1], K. Oppong[1], M. Nayar[1], J. Leeds[1]
[1]Freeman Hospital, HPB Endoscopy Unit, Newcastle Upon Tyne, United Kingdom

Contact E-Mail Address: grace.loy@nhs.net

Introduction: According to the British Society of Gastroenterology (BSG) guidelines on sedation in gastrointestinal endoscopy (2023), minimal to moderate sedation is typically sufficient for level 1/2 endoscopic retrograde cholangiopancreatography (ERCP). However, deep sedation is not routinely available in many centres, potentially affecting patient comfort and procedure completion.

This study investigated factors associated with incomplete ERCP procedures, with a particular focus on patient intolerance.

Aims & Methods: A retrospective review of all ERCP's performed over six months at our tertiary centre was conducted. Data collected included demographics, indication, ERCP grade, sedation used, cannulation rate and completion of procedure (eg complete duct clearance). Achieving the primary therapeutic or diagnostic goal served as the primary outcome. Univariate and multivariable analyses were used to evaluate factors contributing to incomplete procedures.

Results: 475 ERCP's were analysed (median age 67 years; range 18–92; 49.5% female). Successful cannulation was achieved in 458 of 475 procedures (96.4%). Among the 55/475 (11.6%) incomplete ERCPs, 32 (6.7% of all procedures) were abandoned due to patient discomfort—manifested as pain, restlessness, and inability to tolerate the procedure. Univariate analysis showed significantly higher opiate doses (63.8 mg vs. 56.3 mg, p=0.015) and higher midazolam doses (5.0 mg vs. 4.0 mg, p=0.0003) in incomplete procedures.

No significant differences were observed for age, sex, inpatient status, ERCP grade, or use of general anaesthesia. Multivariable analysis revealed no independent risk factors for incompletion. Other contributing factors included prolonged procedures (e.g., EUS prior to ERCP) and challenging anatomy.

Conclusion: Patient discomfort emerged as the primary driver of incomplete ERCPs, highlighting the importance of optimizing sedation strategies and ensuring adequate anaesthetic support. Higher opiate and midazolam doses correlated with incomplete procedures suggesting that deeper sedation may have allowed completion. More detailed research including data from a combination of tertiary and non-tertiary centres is needed to refine sedation practices in line with current BSG guidelines.

Introduction: Precut techniques provide an alternative approach for biliary cannulation during ERCP. While traditionally considered high-risk and typically reserved for high-volume centers, recent evidence supports the safety and efficacy of early precut techniques when performed by experi-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

enced endoscopists. However, data on the safety of precut techniques in the outpatient setting remain limited, particularly in comparison to standard sphincterotomy.

Aims & Methods: We conducted a retrospective analysis of all outpatient ERCP procedures performed at our institution between 2020 and 2024. A total of 304 cases were reviewed. Patients were divided into two groups: Group A, who underwent standard sphincterotomy, and Group B, who required precut techniques following failed standard cannulation attempts.

Results: A total of 159 outpatient ERCPs involving naïve papillae were included: 122 in Group A and 37 in Group B. There was no significant difference in baseline characteristics and indications for ERCP between the 2 groups. Overall cannulation success rate was 97.5% (n=155/159), reaching 89.2% (n=33/37) in the pre-cut group. There was an overall post-procedure complication rate of 6.9% (n=11/159): 7.4% (n=9/122) of patients in Group A and 5.4% (2/37) in Group B, with no significant difference between groups (*p= 0.860*).

Conclusion: In our outpatient ERCP cohort, precut techniques demonstrated a favorable safety profile and comparable outcomes to standard sphincterotomy. These findings support the selective use of precut methods in the outpatient setting.

Introduction: Endoscopic papillectomy (EP) is indicated for papillary adenoma that do not extend into the pancreatic bile duct. There are cases in which en bloc resection or curative resection is expected to be difficult with conventional EP. For such cases, we introduced hybrid EP, in which snaring is performed after peri-lesion incision using a dedicated ESD knife.

Aims & Methods: A total of 13 cases who underwent hybrid EP between 2022 and 2024 were identified from our prospectively maintained database. Hybrid EP involved a circumferential incision with partial submucosal dissection, and subsequent snare resection of ampullary tumors, which was performed by two endoscopists with expertise in ESD or endoscopic retrograde cholangiopancreatography. Demographic data and clinicopathological outcomes were retrospectively evaluated.

Results: En bloc resection was achieved by hybrid EP in all 13cases, with the median procedure time of 118 (range: 65-170) minutes. The median diameters of the resected specimens and tumors were 25 and 15 mm, respectively. All lateral margins were clear, whereas vertical margin was uncertain in one (7.6%), resulting in the complete resection rate of 92.4%. Postoperative bleeding developed in two (15.3%). No tumor recurrence was observed even in that case with uncertain vertical margin, after a median follow-up of 244 (range, 97-678) days.

Conclusion: Hybrid EP is an useful technique for duodenal papillary tumors that are difficult to resect en bloc or curatively by conventional EP.

Disclosure: Nothing to disclose.

Contact E-Mail Address: nrdasu4@gmail.com

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) is caused by increased fat accumulation within hepatocytes. It is primarily associated with Type II Diabetes, obesity, and metabolic syndrome. MASLD has become increasingly prevalent worldwide over the past several decades and is regarded as the most common liver disease in industrialized countries. Our study aimed to identify if MASLD would increase mortality amongst patients undergoing ERCP and to identify positive predictors that lead to increased healthcare utilization.

Aims & Methods: A retrospective analysis was completed utilizing the National Inpatient Sample (2015-2020). Patients were identified based on ICD-10 codes corresponding to those with MASLD undergoing ERCP vs. patients without MASLD undergoing ERCP. Primary outcomes were all-cause mortality and healthcare utilization (mean length of stay (LOS) and total hospital charge (TOTCHG). Secondary outcomes such as the effect of the race and post-procedural complications (sepsis, CVA, Bleeding, AKI, post-procedural bleeding) were analyzed using multivariate analysis.

Results: We identified 2,681,575 total patients with MASLD, of whom 1,104,200 underwent ERCP. After propensity score matching, surprisingly, patients with MASLD undergoing ERCP had decreased mortality (OR .45, 95% CI [0.27- 0.75]). However, LOS and TOTHCG were not statistically significant. Multivariate regression revealed the impact of complications on the primary and secondary outcomes
(listed in Tables 1 and 2 https://media-hosting.imagekit.io/6e3b-9e79c5d24205/ueg2025.png?Expires=1840250284&Key-Pair-Id=K2ZIVPTIP2VGHC&Signature=VEuGD9QcoSy6tVYrHx0H1kKNixXM~yp-pVVTHAz0dY8gj52jh3K1Zc4reiU90cbS1J6HGKn4Uc8gjcJ52x4UpG-2lib-QVI5UlbXdmI91YjAIVtueBaGfCuMpcpth-hJSWWfl4SInfj8Y-Pohy-IA0-SfPe7Gk9PRfeUsy5lJzf36dD1xcwzLUCPfsS10zKeyFN4vEJomZyg-32NQT7Wx8-P43IQgXvHJz0J5WXXD3IyjpTgfoGxJLVhE5ADXUbXaNWuO-eYV5nG2Fb5FvG3HLEzL2q7q0No2xWz3bCmnBC1vsji2zmbkBrRFOEqiaEL-hCL~Z7Ul86Ns9clhnFGpxyl2Iaw__).
Native Americans were found to have a significant increase in mortality (OR 2.47, 95% CI, p-value <0.05). It was also shown that the presence of post-procedural bleeding, AKI, CVA, and sepsis increased mortality, TOTHC, and LOS in patients with MASLD undergoing ERCP.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our study identified positive predictors (sepsis, post-procedural bleeding, CVA, or AKI) for increased LOS, Mortality, and TOTHC in patients with MASLD undergoing ERCP. In addition, high rates of obesity, cardiovascular disease, and Type II Diabetes are more prevalent compared to other racial groups in the US. Further studies are needed to identify whether lack of access to healthcare within the country contributes to disease burden and worsened outcomes in this population.

COMPARISON OF THE EFFICACY AND SAFETY OF METAL STENTS WITH DIFFERENT AXIAL FORCES IN EUS-GUIDED HEPATICOGASTROSTOMY: A MULTICENTRE RETROSPECTIVE STUDY

M. Yamamaura[1], H. Ishiwatari[1], S. Matsubara[2], N. Sasahira[3], M. Ono[4], T. Okuda[5], E. Ishida[6], K. Takada[7], K. Ishikawa[7], T. Okamoto[3], K. Suda[2], M. Ikeda[2], J. Sato[1], A. Oba[1], H. Sakamoto[1], T. Doi[1]

Contact E-Mail Address: shancunchangda@gmail.com
Introduction: Endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) has been performed as an alternative treatment when endoscopic retrograde cholangiopancreatography (ERCP) fails. However, EUS-HGS carries the risk of adverse events (AEs) such as peritonitis and recurrent biliary obstruction (RBO). To lower the risk of AEs, guidelines recommend the use of covered metallic stents (MS) for EUS-HGS. Several studies suggest that MS with high axial force (AF) may lead to a higher incidence of AEs such as pancreatitis and cholecystitis when MS is placed across the major duodenal papilla during ERCP. Studies comparing MS with high and low AF in EUS-HGS are scarce. MS with low AF may lower the incidence of AE in EUS-HGS. This study aimed to compare the efficacy and safety of MS with low AF (EGIS™ biliary (S&G Biotech)) and high AF (Niti-S™ biliary S-type (Taewoong Medical)).
Aims & Methods: We retrospectively reviewed consecutive patients with unresectable malignant biliary obstruction who underwent EUS-HGS with either EGIS or Niti-S across seven institutions in Japan from January 2019 to December 2022. Patients who had undergone prior biliary drainage, such as percutaneous transhepatic biliary drainage, endoscopic nasobiliary drainage, deployment of metal or plastic stents during ERCP, or EUS-HGS using a plastic stent were excluded. A matched cohort of patients was obtained using 1-to-2 propensity score matching: history of cholecystectomy, performance status, ascites, and antegrade stenting. Outcome measures included technical and clinical success, early and late AEs, time to RBO (TRBO), and overall survival (OS). Technical success, clinical success, TRBO, and OS were defined according to the Tokyo criteria 2024. AEs associated with EUS-HGS procedures were evaluated according to the adverse events in gastrointestinal endoscopy (AGREE) classification. Peritonitis was diagnosed when abdominal rebound tenderness and fluid collection on computed tomography (CT) were observed.
Results: Among 162 patients, 123 patients were eligible for the study (39 for Niti-S and 84 for EGIS). After balancing the two groups, the matched cohorts included 27 patients in the Niti-S group and 54 patients in the EGIS group. There were no significant differences in technical success rate (100% vs. 100%, p = 1.00) and clinical success rate (88.9% vs. 98.1%, p = 0.11). The RBO rates were 22.2% and 29.6% (p = 0.60). The median TRBO was 85 days for the Niti-S group and was 213 days for the EGIS group (p = 0.37), and there was no significant difference in median OS (75 vs. 112 days, p = 0.21). Early AE occurred in 10 patients (37.0%) in the Niti-S group and 8 patients (14.8%) in the EGIS group (p = 0.045). In the Niti-S group, there were 8 cases of peritonitis, 4 cases of stent migration, 2 cases of sepsis, 1 case of bleeding, and 1 case of biloma. In the EGIS group, there were 3 cases of peritonitis, 1 case of stent migration, 2 cases of cholangitis, 1 case of pancreatitis, 1 case of sepsis, and 1 case of biloma. Both groups contained cases in which multiple adverse events occurred in a single patient. Late AE were observed in 2 patients (7.4%) in the Niti-S group and 4 patients (7.4%) in the EGIS group (p = 1.00). In the Niti-S group, there were 2 cases of stent migration into the oesophagus. In the EGIS group, there was 1 case of pseudoaneurysm, 2 cases of liver abscess, and 1 case of cholecystitis.
Conclusion: The use of MS with low AF may help reduce the incidence of early AE in patients undergoing EUS-HGS.
Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASOUND-GUIDED GALLBLADDER DRAINAGE. WHICH IS THE BEST WAY TO ACCESS?

S. Stigliano[1], P. Melatti[2], N. Citterio[3], D. Biasutto[4], F. Di Matteo[1]
[1]Fondazione Policlinico Universitario Campus Bio-medico, Endoscopy Department, Roma, Italy, [2]Institute of image-guided Surgery of Strasbourg, Strasbourg, France, [3]Fondazione Policlinico Universitario Campus Bio-medico, Rome, Italy, [4]Fondazione Policlinico Universitario Campus Bio-Medico, Endoscopy Department, Velletri, Italy

Contact E-Mail Address: s.stigliano@policlinicocampus.it
Introduction: Endoscopic ultrasound guided gallbladder drainage (EUS-GBD) with lumen apposing metal stent (LAMS) has become a favourite drainage option for high surgical-risk patients with acute cholecystitis and as rescue treatment for the relief of jaundice in patients with distal malignant biliary obstruction (DMBO) with high technical and clinical success. Both trans-gastric and trans-duodenal drainage are described but which is the best way is still controversial.
Aims & Methods: We aim to compare the two different approaches in term of technical success, rate of adverse events, unplanned readmissions and re-interventions.
Single center retrospective analysis of all consecutive cases of EUS-GBD with LAMS acceding to the Therapeutic Endoscopy Unit of Fondazione Policlinico Universitario Campus Bio-Medico of Rome. Data about LAMS features and procedure were collected.
Results: From January 2019 to September 2024 sixty patients were enrolled (50% male; 77±12 years old). The 60% of them underwent EUS-GBD for acute cholecistitis. In 31/60 (52%) patients the trans-gastric access was performed. In 43/60 (71.7%) patients a Hot-Axios LAMS was used and in the majority of procedure (47/60 78.3%) a calibre bigger than 10 mm was used. Overall technical success was obtain in 98.3% of procedures.
In no case the LAMS was dilated. A naso-cistic tube was placed inside the LAMS in 31/60 patients. Double pig-tail plastic stent was placed in two patients. Regarding the adverse events rate, in one patient distal flange misdeployment occurred. LAMS obstruction occurred in 7/60 patients (11.7%) and need of reintervention in 10/60 (16.7%).
There was no difference in term of drainage indication, technical success rate, type and size of LAMS used, naso-cystic tube or pig-tail stent inser-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tion between the two different EUS-GBD access. However, the trans-gastric access was associated with a higher rate of LAMS obstruction (6/7 vs 1/7 p 0.05) and need of re-intervention (8/10 vs 2/10 p 0.03).

Conclusion: EUS-GBD is a safe technique with high technical success rate. Both trans-gastric and trans-duodenal approaches are effective. However, EUS-GBD with trans-gastric access seems to be associated with a higher rate of late adverse events and when possible another way should be preferred.

Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASOUND GUIDED BILIARY DRAINAGE FOR MALIGNANT BILIARY OBSTRUCTION: FINDING THE BEST ROUTE

P. Melatti[1], N. Citterio[2], D. Biasutto[2], S. Stigliano[2], F. Di Matteo[2]

Contact E-Mail Address: pieramelatti@gmail.com

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) has emerged as a minimally invasive and promising alternative to percutaneous transhepatic biliary drainage (PTBD) and endoscopic retrograde cholangiopancreatography (ERCP) in managing malignant biliary obstruction. Different techniques are available such as choledocoduodenostomy (CDS), gallbladder drainage (GBD) and hepaticogastrostomy HGS). All have been shown to be safe and effective techniques, but which is the most suitable and effective approach is still unknown.

Aims & Methods: We aim to compare the three techniques available in terms of technical success and clinical success, and to assess the adverse events related to the different procedures. Single center retrospective analysis of all consecutive cases of CDS, GBD and HGS acceding to the Therapeutic Endoscopy Unit of Fondazione Policlinico Universitario Campus Bio-Medico of Rome. Data about patients and procedures were collected. Technical success was defined as successful biliary drainage with stent placement. Clinical success was defined as a decrease in total bilirubin level by ⩾30% within 7 days of EUS-BD.

Results: From April 2016 to December 2024 101 patients were included (47.5% male, mean age 74.6 years old), all with malignant biliary obstruction. 52,5% of the subjects (53/101) underwent EUS-CDS, 22,7 % (23/101) underwent EUS-GBD and 24,75% (25/101) underwent EUS-HGS. In 35/101 (34,65%) duodenal stenosis was observed. A total of 7 patients had altered anatomy. The mean procedure time was 26 ± 15,7 minutes.

Overall technical success was 93%, 48/53 (90,5%) in the CDS group, 23/23 (100%) in the GBD group and 23/25 (92%) in the HGS group. Overall clinical success was achieved in 57/79 (72%), 29/38 (76,3%) in the CDS group, 12/20 (60%) in the GBD group and 16/21 (76,1%) in the HGS group.

When considering a reduction in bilirubin level ⩾50%, the overall clinical success was lower (55%). Adverse events occurred in 6/101 (5,9%) of the patients, 3/53 (5,6%) in the CDS group, 0/23 in the GBD group and 3/25 (12%) in the HGS group. There was no difference in terms of sex, age, altered anatomy, presence of duodenal stenosis and the EUS technique performed. The mean time of the procedure was higher in the HGS group, with a difference statistically significant (CDS=22,87±14,78 min, GBD=26±15,73 min, HGS=41±16,09 min, p=0,005).

No difference was observed in terms of technical and clinical success, and adverse events between the three procedures. However, if the reduction in bilirubin level ⩾50% cut-off was used, the HGS was the procedure with the highest rate of clinical success (CDS 59,5% vs GBD 25% vs HGS 76%, p=0,003).

Conclusion: EUS-BD is a safe procedure with high technical and clinical success rate and it s a valid alternative for managing malignant biliary obstruction in high volumes centers. No differences are described between the three approaches. However HGS seems to reduce bilirubin levels more quickly, with longer procedure time.

Disclosure: Nothing to disclose.

PP0999

ENDOSONOGRAPHY TO THE RESCUE - EUS-GUIDED GASTROENTEROSTOMY AS AN URGENT TREATMENT MODALITY IN MANAGING AFFERENT LOOP SYNDROME

Y. Petkova[1], P. Karagyozov[1], D. Kavrakov[1]
[1]Acibadem City Clinic University Hospital Tokuda, Clinic of Gatsroenterology, Sofia, Bulgaria

Contact E-Mail Address: yoanapetkova89@gmail.com

Introduction: Afferent loop syndrome is a rare complication after surgical gastrojejunostomy reconstruction due to mechanical obstruction of the afferent limb. It poses a dismal prognosis, especially in cases of local cancer recurrence. Standard surgical and endoscopic treatment is often unsatisfactory. Due to poor performance status, patients frequently require immediate and less invasive treatment. Transmural stenting with lumen-apposing metal stents/LAMS/ is a new alternative to surgery and transluminal endoscopic treatment. We present our single-center experience in the management of malignant afferent loop syndrome/MALS/ with endoscopic ultrasound-guided gastroenterostomy/EUS GE/.

Aims & Methods: To evaluate the efficacy and safety of EUS GE in malignant afferent loop syndrome in cases of emergency.Methods: Two cases of MALS and severe cholangitis,managed by EUS GE in a single tertiary center.

Results: Patient 1: In the first case, a 39-year-old patient was referred to our center for recurrent episodes of severe cholangitis. He had a previous gastrojejunostomy in a different hospital, as chronic pancreatitis was suspected. After evaluation of the patient, a locally advanced pancreatic cancer with peritoneal carcinomatosis was found. Due to the poor performance status and after multidisciplinary discussion, we performed a single-step EUS GE with HOT AXIOS 15mm/10mm/Boston Scientific Marlborough, Massachusetts, USA /. After the procedure, there was complete resolution of symptoms of cholangitis and the patient started palliative chemotherapy. The patient died 56 days after the procedure due to disease progression.

Patient 2: 57 years old male, who underwent a Whipple procedure due to pancreatic cancer in 2022. During follow - up local recurrence was found. He was admitted with signs of severe cholangitis with renal and respiratory failure. Computed tomography revealed an extremely dilated afferent loop. An EUS GE was performed with,, off - label,, application of HOT SPAX-US 8mm/20mm/Taewoong/. After the procedure, the septic state was resolved, and shortly after discharge, the patient continued with regular courses of systemic chemotherapy. There are no episodes of recurrence during the current follow-up/210 days after the procedure/.

In both cases, there were no events of misdeployment. We found clinical success in both patients with fast resolution of symptoms due to cholangitis. No episodes of recurrence were found during follow-up. We didn't experience any adverse events/AE/ during either procedure, with no AE in the postprocedural period. The mean procedure time was 20 minutes. In both cases, an electro-cautery enhanced lumen apposing metal stent was used, which allowed us to create a single-step endoscopic anastomosis and obtain an internal drainage of the dilated afferent loop into the stomach.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Endoscopic ultrasound-guided gastroenterostomy offers a highly efficient, convenient, and safe alternative for patients presenting with malignant ALS. In our cases, no need for reintervention was found. It could be offered as a fast approach to selected patients, especially those unfit for surgery and with poor performance status.

Disclosure: No conflict of interest.

VALIDATION OF A PREDICTIVE SCORE FOR CLINICALLY SIGNIFICANT FINDINGS IN ENDOSCOPIC ULTRASOUND EVALUATION OF INCIDENTAL COMMON BILE DUCT DILATION

P. Rocha[1], F. Vidal Lima[1], H. Ribeiro[1], M. João[1], M. Ferreira[1], N.P. Almeida[1,2], C. De Jesus Lopes Lérias[1], P. Narra Figueiredo[1,2]
[1]Coimbra University Hospital, Local Health Unit of Coimbra, Gastroenterology Department, Coimbra, Portugal, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Contact E-Mail Address: pedrommrocha113@gmail.com

Introduction: Common bile duct (CBD) dilation can be associated with a wide range of underlying conditions, from benign to significant pathology, including malignancy[1]. A recently proposed score by Raza et al. aims to predict the likelihood of significant findings on endoscopic ultrasound (EUS) in patients with incidental CBD dilation[2], potentially optimizing its use. This study aims to validate this score in a cohort of patients who previously underwent EUS for incidental CBD dilation.

Aims & Methods: Patients with incidental CBD dilation (≥6mm or ≥8mm post-cholecystectomy) who underwent EUS and met the inclusion criteria were retrospectively analyzed. Patient demographics, clinical, laboratory and imaging data were collected to calculate the score: age ≥70 years (1 point), acute non-billiary type abdominal pain (2 points), previous endoscopic retrograde cholangiopancreatography (2 points), CBD diameter ≥15mm or ≥17mm if prior cholecystectomy (2 points). EUS findings were reviewed to identify outcomes.

Results: Sixty-five patients met the inclusion criteria for analysis, 39 females (60%) and 26 males (40%), mean age of 71.5 ± 8.5 years. Overall yield of EUS for significant findings was 21.5%, including 8 patients with choledocolithiasis (12.3%), 4 patients with ampullary adenoma (6.2%), 1 patient with a biliary mass (1.5%) and 1 patient with a pancreatic mass (1.5%). Among the cohort, 23 patients (35.4%) had a score of 0 and none had a significant finding. Thus, a score ≥1 had a sensitivity of 100% and specificity of 45.1%, reliably excluding significant findings. A score ≥3 had a sensitivity of 71.4% and a specificity of 94.1% for identifying meaningful pathology, enabling the identification of high-risk patients with greater precision.

Conclusion: The predictive score effectively stratifies patients with incidental CBD dilation, potentially reducing unnecessary EUS in low-risk individuals while prioritizing high-risk cases. This model enhances resource utilization and targeted care. Further research in larger cohorts may confirm its generalizability.

Introduction: Lymph node (LN) involvement is a well-recognized adverse prognostic factor in gallbladder cancer (GBC), and accurate preoperative nodal staging is critical for improving treatment decisions and thereby optimizing patient management. Cross-sectional imaging has limited accuracy in LN staging. Endoscopic ultrasound (EUS) with tissue acquisition (EUS-TA) offers a minimally invasive method to sample suspicious LNs (1-4).

This study aimed to evaluate the impact of EUS for nodal staging in patients with presumed resectable GBC.

Aims & Methods: In this retrospective, single-center cohort study at the Asian Institute of Gastroenterology, Hyderabad, India, consecutive patients with potentially resectable GBC who underwent preoperative EUS between January 2019 and November 2024 were included. Regional LNs were identified according to the 8th edition of the AJCC staging system as those located at the liver hilum, cystic duct, common bile duct, hepatic artery and adjacent to the gallbladder. Extraregional LN consisted of LNs located distal to the hepatoduodenal ligament. EUS-TA was performed at the discretion of the endosonographer.

The primary outcome was the impact of EUS on clinical decision making, measured as the percentage of patients in whom surgical exploration was precluded due to pathologically confirmed LN metastasis identified by EUS-TA.

The secondary outcome was the incidence of adverse events, classified according to the AGREE classification.

Results: A total of 56 patients were included (median age in years: 58.5, 51.8% female). Preoperative cross-sectional imaging was performed in 94.6% of patients with lymphadenopathy reported in 54.7%. Across 59 EUS procedures, 46 LNs were identified, and EUS-TA was performed in 24 nodes from 21 patients. LN metastases were detected by EUS-TA in 10.7% of patients, in whom surgical resection was waived.

Notably, among patients who underwent subsequent surgical resection, regional LN metastases were identified in nine of 25 patients, indicating that some nodal disease was missed on preoperative EUS. There were no complications reported related to the EUS or EUS-TA.

Conclusion: Preoperative EUS significantly influenced clinical decision making in patients with presumed resectable GBC by identifying LN metastases and thereby altering patient management. Notably, multiple LN metastases were missed at preoperative screening.

Future prospective studies employing standardized EUS protocols or integrating advanced imaging modalities are warranted to improve preoperative nodal staging and optimize management strategies in GBC.

Introduction: Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) with lumen-apposing metal stent (LAMS) for acute cholecystitis is being increasingly performed in high-risk patients instead of laparoscopic cholecystectomy (LC).

Aims & Methods: In our study, we aimed to evaluate the efficacy and safety of EUS-GBD and LC in elderly patients with acute cholecystitis. We conducted a retrospective analysis of 81 patients aged ≥70 years who were admitted at our Hospital between January 2020 and December 2022 with acute cholecystitis, and were treated with either EUS-GBD or LC.

The primary outcomes of our study were the rate of technical success, defined as the correct deployment of the LAMS between the gastrointestinal wall and the gallbladder with evidence of bile or pus drainage; and the rate of clinical success, defined as the clinical and biochemical improvement of acute cholecystitis. Secondary outcomes included the rates of adverse events occurred at 1-30 days, 1-12 months and >12 months, 30-day and overall mortality.

Results: During the study period, 24 patients underwent EUS-GBD and 57 patients underwent LC. The mean age was 83 years (range 70-93) in the EUS-GBD and 77 years (range 70-88) in the LC groups (p=0.0001). The mean American Society of Anesthesiology (ASA) score was significantly higher in the EUS-GBD than in the LC groups (p=0.028). Similarly, the mean Charlson Comorbidity Index (CCI) score was significantly higher in the EUS-GBD than in the LC groups (p=0.03). Technical success was observed in 100% (24/24) and 98.2% (56/57) of EUS-GBD- and LC-treated patients, respectively (p=0.70). Clinical success was observed in 95.8% (23/24) and 98.2% (56/57) of EUS-GBD and LC-treated patients, respectively (p=0.29). The rates of 30-day adverse events were 4.2% (1/24) and 12.3% (7/57) in the EUS-GBD and LC groups, respectively (p=0.25). The rates of adverse events between 1 and 12 months were 16.7% (4/24) and 0% (0/57) in the EUS-GBD and LC groups, respectively (p=0.006). The rates of adverse events occurred after 12 months were 12.5% (3/24) and 0% (0/57) in the EUS-GBD and LC groups, respectively (p=0.023). The 30-day mortality rates were 12.5% (3/24) and 1.7% (1/57) in the EUS-GBD and LC groups, respectively (p=0.042). The overall mortality rates were 12.2% (7/57) and 41.7% (10/24) in the EUS-GBD and LC groups, respectively (p=0.011).

Conclusion: In our study on unselected elderly patients, the clinical success rates of EUS-GBD and LC for acute cholecystitis were similar; however, the mortality rate after EUS-GBD was significantly higher than after LC. These results may be explained at least in part by the higher mean age, ASA and CCI scores observed in the EUS-GBD group compared to the LC group. Our real-life data suggest that preliminary risk-benefit evaluation has directed very high-risk patients with acute cholecystitis towards treatment with EUS-GBD.

EVOLUTION OF PATIENT SELECTION, TECHNIQUE AND OUTCOMES IN EUS-GUIDED GALLBLADDER DRAINAGE: A RETROSPECTIVE ANALYSIS OVER A DECADE

A. La Mantia[1,2], G. Bonato[1], F. Pugliese[1], L. Dioscoridi[1], M. Cintolo[1], M. Bravo[1], A. Palermo[1], C. Gallo[1], M. Mutignani[1], E. Forti[1]

Contact E-Mail Address: marcello.cintolo@ospedaleniguarda.it

Introduction: Acute cholecystitis in high-risk surgical candidates remains a clinical challenge. Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) with lumen-apposing metal stent (LAMS) has emerged as a minimally invasive alternative. Initially reserved for extremely frail patients, EUS-GBD has seen broader application over the past decade. However, the criteria for defining patients as "frail" or "unfit for surgery" remain debated and lack standardization. Furthermore, long-term data remain limited.

Aims & Methods: A retrospective, single-center study was conducted, including all consecutive patients who underwent EUS-GBD between January 2014 and December 2024, with the aim of evaluating changes over time in patient selection, procedural technique, and clinical outcomes. Patients were stratified into two cohorts based on the date of the procedure: Group A (procedures performed up to December 31, 2020) and Group B (procedures performed from January 1, 2021, onward). A comparative analysis was conducted between the groups.

Results: A total of 50 patients were included, of whom 25 (50%) were female, with a mean age of 79.6 (± 12.8) years. The median age-adjusted Charlson Comorbidity Index (a-CCI) was significantly lower in Group B compared to Group A (8.0 vs 9.5, $p = 0.047$). The prevalence of biliopancreatic malignancies decreased from 45.8% in Group A to 23.1% in Group B (p = ns). The use of electrocautery-tip LAMS (Hot AXIOS™, Boston Scientific) increased significantly over time (62.5% vs 100%, $p = 0.001$). Thirty-day survival improved from 83.3% in Group A to 100% in Group B ($p = 0.046$).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Although not statistically significant, 12-month survival showed a trend toward improvement (33.3% vs 56.2%), as did 36-month survival (25.0% vs 60.0%), though the latter was limited by shorter follow-up in the more recent cohort. Technical and clinical success rates remained high across both groups. The overall rate of biliary adverse events (including recurrence and other complications) was 24%, with both early and delayed events remaining infrequent.

	Group A (n = 24)	Group B (n = 26)	p value
Baseline and procedural data			
Mean age, y (± DS)	78 (± 12.3)	81 (± 13.3)	NS
Median age-adjusted CCI, n (IQR)	9.5 (4.5)	8 (5)	0.047
Electrocautery-tip LAMS design, n (%)	15/24 (62.5%)	26/26 (100%)	0.001
Technical success, n (%)	23/24 (95.8%)	26/26 (100%)	NS
Clinical success, n (%)	20/24 (83.3%)	25/26 (96.1%)	NS
Survival outcomes			
30-day survival, n (%)	20/24 (83.3%)	26/26 (100%)	0.046
12-month survival, n (%)	8/24 (33.3%)	9/16 (56.2%)	NS

Conclusion: Our data show that over the past decade, EUS-GBD has evolved from an approach reserved for highly comorbid patients to a more broadly applied therapeutic option, coinciding with reduced baseline comorbidity and oncologic burden among treated patients. This shift was paralleled by increased procedural standardization—most notably, the universal adoption of electrocautery-tip LAMS—and was associated with improved early survival outcomes. Although longer-term survival also trended favorably, further prospective data are needed. The incidence of complications and reinterventions remained infrequent, supporting the safety and durability of the procedure.

THE ROLE OF DETECTIVE FLOW IMAGING- ENDOSCOPIC ULTRASOUND IN THE CHARACTERIZATION OF UNEXPLAINED BILIARY STRICTURES: A RETROSPECTIVE STUDY

L. Babaiyan[1], R. Di Pangrazio[1], M. Marasco[1], F. Panzuto[1], M. Signoretti[1]

Introduction: A biliary stricture is a narrowing of intrahepatic and/or extrahepatic biliary system with upstream dilatation[1]; 70-80% of biliary strictures are malignant[1] therefore histological diagnosis is necessary to distinguish benign from malignant causes and guide management. Strictures without confirmed histology are referred to unexplained biliary strictures[2]. ESGE (European Society of Gastrointestinal Endoscopy) guidelines recommend an integrated diagnostic approach that combines multiple techniques to improve diagnostic accuracy. Endoscopic ultrasound (EUS) has demonstrated high sensitivity for evaluating biliary strictures and unexplained common bile duct (CBD) dilatation, due to its ability to provide high-resolution images of CBD walls and surrounding structures, so is the preferred diagnostic modality for both imaging and tissue acquisition(TA), even in absence of abnormal laboratory test.[1] The introduction of ancillary techniques, as DFI (Detective Flow Imaging), which enables the detection of low-velocity blood flow without the use of contrast media, represents a potential useful addition in the diagnostic algorythm[3].

Aims & Methods: The aim of this single-centre retrospective study is to validate the role of EUS-DFI in characterizing unexplained biliary strictures and CBD dilatation. We included consecutive patients (pts) with unexplained biliary strictures/CBD dilatation who underwent biliopancreatic EUS between January 2024 and April 2025 at the Digestive Diseases Unit of Sant'Andrea University Hospital, Rome. During EUS, biliary stricture (lesions or thickening of CBD wall) were described as hypoechoic or isoechoic. DFI was performed to evaluate strictures: if microvascularization was observed, vascular pattern was classified as regular or irregular[4]. Results were compared with the final diagnosis, defined by histopathology and/or ≥6 months clinical follow-up as gold standard. TA was performed with EUS-FNB (fine needle biopsy) and/or ERCP(Endoscopic Retrograde Cholangiopancreatography) intraductal biopsies/brushing.

Results: Of 13 patients included, 8 (61.5%) were male, median age 72 (range 56-86). All underwent Magnetic Resonance Imaging/Contrast-Enhanced Computed Tomography as first line imaging: 3 (23%) had a perihilar stricture, 9 (69%) a medio-distal, 1 (8%) had "in toto" CBD thickening. Among the 13 strictures, EUS identified 10 (76.9%) lesions, with a mean diameter of 17 mm (median 16 mm; range, 5–35 mm), and 3 (23.1%) CBD wall thickening. Twelve (92%) strictures were hypoechoic, 1(8%) was isoechoic. EUS-TA was performed in all pts, revealing 7 (54%) cases of malignancies, of whome 5 cholangiocarcinoma and 2 pancreatic ductal adenocarcinoma (PDAC), 3 (23%) high-grade dysplasia, and 3 (23%) fibroinflammatory disease on histopatological evaluation. All pts underwent DFI-EUS. Microvascularization was detected in 12 cases (92%), with an irregular pattern observed in 9 pts. Among these, 5 (55.6%) were diagnosed with cholangiocarcinoma, 1 (11.1%) with PDAC infiltrating CBD, and 3(33.3%) with high-grade dysplasia. The 3 benign strictures demonstrated a homogeneous pattern. One case (8%), corresponding to a PDAC, appeared hypovascular on DFI.

Conclusion: In a small cohort of patients with unexplained or indeterminate biliary strictures, the novel DFI-EUS technique proved to be feasible for assessing microvascularization in CBD stenosis and revealed characteristic irregular patterns or hypovascularization in malignant lesions. Further prospective studies with a larger patient population are needed to confirm these preliminary findings.

ASSESSING THE IMPACT OF RADIOFREQUENCY ABLATION ON HILAR CHOLANGIOCARCINOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

H. Khizar[1], J. Yang[2]
[1]The Fourth Affiliated Hospital of School of Medicine, and International School of Medicine, International Institutes of Medicine, Zhejiang University, Department of Surgery, Yiwu, China, [2]HangZhou First People's Hospital, Gastroenterology, Hangzhou, China

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: Hilar cholangiocarcinoma (HC) is a challenging malignancy with limited treatment options. Radiofrequency ablation (RFA) has emerged as a potential palliative treatment, but its efficacy and safety remain controversial. This systematic review and meta-analysis aimed to evaluate the impact of RFA + stent (RFA + S) and stent only (S-only) on HC patients.

Aims & Methods: We conducted a systematic search of PubMed, Embase, and Scopus databases for studies published up to December 2024. Eligible studies reporting RFA outcomes were included.

The primary outcome was overall survival (OS).

Secondary outcomes included stent patency (SP), stent dysfunction, and adverse events. We calculated hazard ratios (HR) and odds ratios (OR) using random-effects models.

Results: This analysis included eleven studies (n = 874 patients) that met the inclusion criteria. The pooled HR for OS was 0.74 (95% CI: 0.61-0.89, p = 0.002), and SP was 0.77 (95% CI: 0.61-0.97; p = 0.03), showing a significant difference in favor of the RFA group. The OR of overall adverse events was 1.48 (95% CI: 0.59-3.72), cholangitis was 1.71 (95% CI: 0.78-3.75), pancreatitis was 1.03 (95% CI: 0.19-5.50), and liver abscess was 0.62 (95% CI: 0.07-5.24), showing no difference (p > 0.05) between the two groups. Patients with chemotherapy showed better survival, indicated by an HR of 0.57 (95% CI; 0.40-0.81). Subgroup analyses also showed that RCT studies had no difference compared to non-RCT studies.

Conclusion: This meta-analysis suggests that application of RFA offer better survival and stent patency benefits with comparable adverse events.

Disclosure: Nothing to disclose.

Introduction: Traditional endoscopic techniques can be used in the treatment of common bile ducts lithiasis. The procedure is considered "difficult", and it is not possible to complete the exctration of the stones when the stone is larger than 2cm, the number of stones is more than 3 and/or when there is a stenosis of the common bile duct. In these cases, the gold standard is the placement of a plastic stent enabling rapid drainage of bile to avoid impaction and eventually a cholangitis. A dissolution rate of 30% -60% (about 1 mm in diameter has been reported by calculation under an optical microscope), even if the initial diameter has been shown to be the most important factor affecting the rate of dissolution.

The aim of this study is to demonstrate that the apposition of the plastic stent in combination with ursodeoxycholic acid therapy is safe and effective in the treatment of difficult choledocholithiasis.

Aims & Methods: In the period between September 2022 and November 2024, 447 patients diagnosed with gallstones of the choledochus treated endoscopically by ERCP were selected. This procedure was successful in 411 patients (92%). The remaining 36 patients (8%) diagnosed with "difficult" choledocholithiasis, were treated with the application of a plastic stent and therapy with ursodeoxycholic acid 10mg / kg / day. ERCP control was established after 3 months.

Results: Four-hundred-eleven patients (92%) had a successful ERCP treatment. Thirty-six 36 patients (8%) diagnosed with "difficult" choledocholithiasis, were treated with the sphincterotomy, the application of a plastic stent , therapy with ursodeoxycholic acid 10mg / kg / day. Bilirubin control was established at 7 and 15 days. The treatment was successful in 100% of cases (36 out of 36). No complications related to the procedure occurred.

At three-months follow-up 31 patients (86%) experienced complete toileting of the main biliary tract. Only 5 patients (14%) needed positioning of a new stent of the main biliary tract, namely one patient had the stent replaced after one month due to obstruction, in three patients the stent became definitive ensuring drainage of the bile in the absence of symptoms, in one patient clearance of the main biliary pathway was possible only after further 3 months.

Conclusion: Insertion of a stent for the treatment of difficult choledocholithiasis is a coded and safe endoscopic technique. It enables fast bile drainage in all cases and complete endoscopic removal of stones at subsequent follow ups in most cases. Ursodeoxycholic acid therapy has also showed to be effective in reducing stones size (<2cm). Permanent stenting of common bile duct is performed only in rare cases, however with satisfactory results.

Disclosure: Nothing to disclose.

Introduction: Metal (MS) or plastic stents (PS) are used for preoperative biliary drainage (PBD) in patients with pancreatic ductal adenocarcinoma (PDAC) undergoing neoadjuvant chemotherapy (NAC) or chemoradiotherapy (NACRT). However, there are no large studies comparing postoperative adverse events(AEs) and postoperative long-term outcomes between patients who received MS and those who received PS for PBD.

Aims & Methods: This multicenter retrospective study compared the safety and efficacy of PBD using MS and PS, including surgery-related adverse events and other clinical outcomes.

This study enrolled patients with resectable or borderline resectable PDAC requiring NAC or NACRT who underwent PBD with MS or PS at 17 tertiary care hospitals in Japan between January 2016 and December 2021. Clinical outcomes, including the incidence of recurrent biliary obstruction (RBO), time to RBO, time from stent placement to surgery, postoperative hospital stay, incidence of postoperative adverse events, and postoperative overall survival, were retrospectively analyzed.

Results: Among the 308 patients with PDAC who received PBD before NAC or NACRT, 251 subsequently underwent pancreatic resection. Of these 251 patients, 122 (48.6%) had PBD with MS, while 129 (51.4%) had PBD with PS. Because there were significant differences in baseline characteristics between both groups, propensity score matching was performed, resulting in 84 matched pairs. RBO occurred significantly less frequently in the MS group than in the PS group (11.9% vs. 59.5%, $p < 0.001$). Time to RBO is significantly longer in the MS group than in the PS group (median 353 days vs. 74 days, $p < 0.001$). The MS group also showed significantly reduced time to surgery from stent placement (median 95 days *vs.* 112 days, $p = 0.010$) and shorter postoperative hospital stays (median 17 days *vs.* 20 days, $p = 0.025$).

Although postoperative AEs occurred less often in the MS group (19.1% vs. 29.8%), the difference was not statistically significant ($p = 0.106$). In both univariate and multivariate models, RBO was identified as the sole independent factor associated with postoperative AEs (odds ratio: 2.36, $p = 0.019$). However, the type of stent used was not significantly associated with the occurrence of postoperative AEs.

Notably, the incidence of postoperative pancreatic fistula was significantly higher in patients who developed RBO compared to those who did not (16.7% vs. 5.6%, $p = 0.027$).

Conclusion: For patients with PDAC undergoing NAC or NACRT, MS placement is preferable to PS placement for PBD. MS placement was associated with a lower incidence of RBO and need for re-intervention, as well as a shorter perioperative hospital stay. Given the reduced frequency of RBO, which is an established risk factor for postoperative AE, MS placement is recommended for PBD in this setting.

Disclosure: Nothing to disclose.

Introduction: Distal malignant biliary obstruction (dMBO) is a frequently occurring condition that requires immediate intervention. The primary treatment for dMBO comprises endoscopic retrograde cholangiopancreatography (ERCP) with biliary stent insertion. The European Society of Gastrointestinal Endoscopy recommends the use of self-expandable metal stents (SEMS) for palliative drainage of dMBO because of their superior patency and reduced incidence of adverse events (AEs), including recurrent biliary obstruction, compared to those of plastic stents. Three types of SEMS are available: uncovered SEMS (UCSEMS), fully covered SEMS (FCSEMS), and partially covered SEMS.

However, the ideal stent type for palliative drainage of dMBO remains undetermined. Several studies have compared UCSEMS with FCSEMS to determine which type is most appropriate for dMBO. In terms of patency, some prospective trials have shown that FCSEMS result in better outcomes; however, others have observed similar results with UCSEMS and FCSEMS.

Most studies have primarily focused on pancreatic cancer cases; however, the pathophysiology of pancreatic cancer and that of nonpancreatic cancer differ significantly, resulting in inconsistent outcomes. Post-ERCP pancreatitis (PEP) is the most common and serious AE associated with the

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

transpapillary placement of SEMS, with an incidence rate of up to 10.8%. Therefore, studies have aimed to identify the risk factors for PEP after SEMS placement. Compared to UCSEMS placement, FCSEMS placement may be more strongly linked to a higher risk of PEP because they block the pancreatic duct orifice more effectively.

Additionally, nonpancreatic cancer has been identified as a potential risk factor for PEP. Therefore, FCSEMS placement for nonpancreatic cancer cases is associated with a significantly higher risk of PEP. We examined the safety of UCSEMS for dMBO caused by nonpancreatic cancer and observed a low PEP rate, even for nonpancreatic cancer cases.

However, a comparison of UCSEMS and FCSEMS is still required because no studies have evaluated their use for dMBO caused by nonpancreatic cancer. Therefore, this study evaluated the efficacy and safety of UCSEMS and FCSEMS for palliative drainage of dMBO caused by nonpancreatic cancer.

Aims & Methods: This retrospective multicenter study included patients who underwent UCSEMS or FCSEMS placement for nonpancreatic cancer-induced dMBO at four centers between January 2010 and April 2024. Propensity score matching (1:1) of the UCSEMS and FCSEMS groups was performed. Technical and clinical success, AEs, recurrent biliary obstruction (RBO), time to RBO (TRBO), and overall survival (OS) of these groups were compared.

Results: No significant differences in technical success (100% for both), clinical success (100% for both), and TRBO (median: 311 days [UCSEMS] vs. 317 days [FCSEMS]; p=0.42) were observed between groups.

Similarly, OS did not differ significantly (median: 432 days [UCSEMS] vs. 190 days [FCSEMS]; p=0.083). The incidence of postendoscopic retrograde cholangiopancreatography pancreatitis (PEP) of the UCSEMS group was significantly lower than that of the FCSEMS group (4.2% vs. 33%; p=0.023).

Conclusion: compared to FCSEMS, UCSEMS provided sufficient patency and reduced AEs associated with dMBO caused by nonpancreatic cancer. The cause of dMBO should be carefully considered when choosing the optimal stent. UCSEMS may be safer and more effective than FCSEMS for the treatment of nonpancreatic cancer cases.

RISK FACTORS FOR OBSTRUCTION OF CHOLEDOCHODUODENOSTOMY BY LUMENAPPOSING METAL STENT AND MANAGEMENT STRATEGIES: RESULTS FROM A PROSPECTIVE COHORT OF 168 PATIENTS

T. Heusse[1], B. Redelsperger[1], T. Beuchard[1], R. Legros[1], H. Lepetit[1], M. Dahan[2], R. Rodrigues[1], R. Collin[1], C. Juglard[1], J. Jacques[1], J. Albouys[1]
[1]CHU Limoges - Hepato-Gastro-Enterology, Limoges, France, [2]Clinique Mutualiste de Pessac, Bordeaux, France

Contact E-Mail Address: thomas.heusse@orange.fr

Introduction: In case of distal malignant biliary obstructions, when ERCP fails, drainage via EUS-CDS using LAMS has become the gold standard.

Identified risk factors include the presence of a duodenal stent (2), duodenal invasion (3), and a bile duct diameter < 15mm (2).

The data regarding stent obstruction during follow-up are heterogeneous and range from 9 to 55% (1).

Aims & Methods: The objective of our study is to identify risk factors for stent obstruction, evaluate the efficacy of obstruction management, and define the best strategy for
managing these stent obstructions.

We conducted a retrospective study of a monocentric prospective database, including all patients treated with EUS-CDS for distal biliary obstruction between 2017 and 2024 in a French university hospital. Obstruction was defined as persistent and/or recurrent jaundice and/or acute cholangitis during follow-up.

Results: A total of 168 patients were included in our study. The overall obstruction rate was 20,4%, with a mean follow-up of 176 days (5.8 months). We confirmed that gastrointestinal obstruction was a risk factor for stent obstruction in both univariate analysis (OR = 4.22 [1.91; 9.31], p = 0.001) and multivariate analysis (OR = 4.67 [2.05; 10.65], p = 0.0002).

Regarding the best management strategy for stent obstruction, placing a new pigtail or metallic stent within the lumen-apposing stent is more effective than simple mechanical desobstruction or antibiotic therapy alone. There was a a higher rate of biliary event-free survival during follow-up (at 6 months 92.3% versus 58.9%; at 12 months 80.8% versus 47.1%).

Conclusion: We confirm that gastrointestinal obstruction is a risk factor for stent obstruction in EUS-CDS procedures.

In cases of cholangitis or persistent jaundice, endoscopic desobstruction by placing a new pig-tail or metallic stent is more effective than simple desobstruction or antibiotic therapy.

CLINICAL OUTCOMES AND PREDICTIVE FACTORS FOR ADVERSE EVENTS IN COMBINED EUS-GUIDED AND ERCP BILIARY DRAINAGE FOR MALIGNANT OBSTRUCTION

N. Shumka[1], P. Karagyozov[1]
[1]Acibadem City Clinic University Hospital Tokuda, Clinic of Gastroenterology, Sofia, Bulgaria

Contact E-Mail Address: shumkanadica97@gmail.com

Introduction: Endoscopic biliary drainage for malignant obstruction can be technically challenging, particularly in patients with high-grade hilar strictures or progressive distal lesions that extend beyond the reach of ERCP alone. While ERCP remains the first-line approach, it may prove inadequate in complex scenarios. Endoscopic ultrasound-guided biliary drainage (EUS-BD) has emerged as an alternative or complementary technique. However, data on outcomes that combine ERCP and EUS-BD in routine clinical practice remain insufficient and limited.

Aims & Methods: This study aims to evaluate the clinical success, stent patency, and complication rates of combined ERCP and EUS-BD in patients with malignant biliary obstruction while identifying factors as-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sociated with complications. We included 40 patients who underwent combined ERCP and EUS-BD for malignant biliary obstruction at a tertiary center from March 2020 to March 2025. The patients were divided into two groups: one-session procedures, in which both techniques were performed during the same session (n=14), and staged procedures, where EUS-BD was followed by at least one prior ERCP (n=26).

Clinical success was defined as resolving jaundice and/or cholangitis without additional drainage. The outcomes assessed included clinical success, stent patency, complications, and reintervention. Univariate analysis was employed to identify predictors of complications.

Results: The cohort included 21 (52.5 %) males and 19 (47.5%) females, with a median age of 65.6 years. The distribution of strictures was as follows: 23 (57.5%) high-grade hilar (Bismuth III/IV), 7 (17.5%) Bismuth I/II, and 10 (25%) distal. Underlying malignancies included 12 (30%) hilar cholangiocarcinoma, 8 (20%) pancreatic adenocarcinoma, and 16 (40 %) liver or hilar metastasis from other tumors.

Clinical success was achieved in 90% of patients (36/40), with no significant difference between one-session and staged groups (85.7% vs. 92.3%, p=0.60). The median procedural time was 39.3 minutes. Overall, 12 patients (30%) experienced complications, including stent-related infections in 10 (25%), post-ERCP pancreatitis in 1(2.5%), and bleeding in 1 (2.5%). Complication rates were similar between the one-session and staged groups (28.6% vs. 31.0%, p=1.00).

Reintervention was required in 3 patients (7.5%). A significant association was observed between undergoing more than two prior ERCPs and the risk of complications (66.7% vs. 22.6%, p=0.038). Neither the presence of hilar strictures (p=0.56) nor procedural timing (one-session vs. staged; p=1.00) was significantly associated with increased complications.

Conclusion: Combining ERCP and EUS-guided biliary drainage is a safe and effective strategy for managing malignant biliary obstruction, including complex hilar and progressive distal strictures. Performing both procedures in a single session does not increase complication rates and may provide comparable clinical success.

The number of prior ERCPs was the only significant predictor of complications, suggesting a potential benefit from earlier use of EUS-BD in selected patients.

Further prospective studies are warranted to confirm these findings and guide treatment algorithms for complex biliary obstruction.

Introduction: Endoscopic Ultrasound Guided Hepaticogastrostomy (EUS-HGS) is one of the Endoscopic Ultrasound Guided Biliary Drainage (EUS-BD) techniques that is frequently performed in specialist endoscopic center throughout the world. At the same time, no consensus exists on effects of individual stent types.

Aims & Methods: We aimed to assess the efficacy and safety profile of plastic stents and individual type of EUS-HGS metallic stents. A random-effects meta-analysis was performed using the PRISMA protocol. Three electronic databases were searched for studies on HGS with plastic or metallic stents from inception until February 2025. The odds ratio (OR) and pooled rates were used for single and two-arm comparisons with 95% confidence intervals (CI).

Results: From twenty-five eligible studies, the OR for adverse events with and without biliary obstruction were OR=1.12 [0.60-2.10], p= 0.648 and OR=2.20 [CI:1.26-3.84], p= 0.017 respectively. The rates for cholangitis, food occlusion, stent hyperplasia was 1% [CI:0-5%], 33% [CI:22-47%] and 1% [CI:0-6%] for plastic stents which differed for different metallic stent types. Lastly, hazard ratio for biliary obstruction was HR= 1.603 [CI:1.211-2.122].

Conclusion: Opting for plastic or metallic stents in EUS-HGS requires a careful consideration between patient's long-term survival, favoring metallic stents and the short-term safety profile, favoring plastic. The type of metallic stent used plays an important role in that decision.

Introduction: The management of malignant hilar biliary obstruction can be done by endoscopic biliary stenting, which is a well-established palliative treatment, improving the quality of life by relieving symptoms.

Aims & Methods: This systematic review and meta-analysis aimed to compare the use of stents placed above and across the sphincter of Oddi in patients with malignant hilar biliary obstruction. We performed a systematic search of the PubMed, Embase, and Cochrane Library databases in April 2025. Article screening was conducted independently by two authors using Rayyan software. Inclusion criteria were randomized controlled trials (RCTs) comparing stent placement above and across the sphincter of Oddi for malignant hilar biliary obstruction, evaluating at least one of the outcomes of interest.

The outcomes were stent migration, stent patency, cholangitis, stent occlusion, and successful placement of the stent. RStudio software was used for statistical analysis, applying a random-effects model to calculate the risk ratio (RR) in binary outcomes and mean differences (MD) in continuous outcomes.

Results: We included three RCTs comprising 161 patients. There was no significant difference between the transpapillary and suprapapillary stents regarding the rates of stent migration (RR 2.03; 95% CI 0.41–10.16; p=0.39; I^2=55%), cholangitis (RR 0.65; 95% CI 0.08–5.07; p=0.68; I^2=0%), technical success (RR 0.99; 95% CI 0.95–1.04; p=0.80; I^2=0%), and stent

occlusion (MD 89.20; 95% CI 16.30–162.10; p=0.02; I^2=78%). However, the mean number of patent stents was significantly lower in the suprapapillary stent group.

Conclusion: The two types of stent seem similar in terms of technique, efficacy, and safety, although the suprapapillary stent seems superior in terms of stent patency.

POST-CHOLECYSTECTOMY MAJOR BILE DUCT INJURY: IDEAL TIME TO REPAIR BASED ON A MULTI-CENTER RANDOMIZED CONTROLLED TRIAL WITH PROMISING RESULTS

M. Omar[1]

[1]South Valley University / Qena Faculty of Medicine, General Surgery Department, Qena, Egypt

Contact E-Mail Address: elqefty@yahoo.com

Introduction: Bile duct injury (BDI) is one of the serious complications of cholecystectomy procedures, which has a disastrous impact on long-term survival, health-related quality of life (QoL), health-care costs as well as high rates of litigation. The standard treatment of major BDI is hepaticojejunostomy (HJ). Surgical outcomes depend on many factors, including the severity of the injury, the surgeons' experiences, the patient's condition, and the reconstruction time. We aimed to assess the impact of reconstruction time and abdominal sepsis control on the reconstruction success rate.

Aims & Methods: We aimed to assess the impact of reconstruction time and abdominal sepsis control on the reconstruction success rate. This is a multicenter, multi-arm, parallel-group, randomized trial that included all consecutive patients treated with HJ for major post-cholecystectomy BDI from February 2014 to January 2022.

Patients were randomized according to the time of reconstruction by HJ and abdominal sepsis control into group A (early reconstruction without sepsis control), group B (early reconstruction with sepsis control), and group C (delayed reconstruction).

The primary outcome was successful reconstruction rate, while blood loss, HJ diameter, operative time, drainage amount, drain and stent duration, postoperative liver function tests, morbidity and mortality, number of admissions and interventions, hospital stay, total cost, and patient QoL were considered secondary outcomes.

Results: Three hundred twenty one patients from 3 centers were randomized into three groups. 44 patients were excluded from the analysis, leaving 277 patients for intention to treat analysis. With univariate analysis, older age, male gender, laparoscopic cholecystectomy, conversion to open cholecystectomy, failure of intraoperative BDI recognition, Strasberg E4 classification, uncontrolled abdominal sepsis, secondary repair, end-to-side anastomosis, diameter of HJ (< 8 mm), non-stented anastomosis, and major complications were risk factors for successful reconstruction. With multivariate analysis, conversion to open cholecystectomy, uncontrolled sepsis, secondary repair, the small diameter of HJ, and non-stented anastomosis were the independent risk factors for the successful reconstruction. Also, group B patients showed decreased admission and intervention rates, decreased hospital stay, decreased total cost, and early improved patient QoL.

Conclusion: Early reconstruction after abdominal sepsis control can be done safely at any time with comparable results for delayed reconstruction in addition to decreased total cost and improved patient QoL.

Introduction: Pancreatic steatosis (PS) is linked to metabolic dysregulation. Magnetic resonance imaging (MRI)-derived proton density fat fraction (PDFF) provides a reliable assessment of intrapancreatic fat. This study investigates the relationship between pancreatic fat, assessed by ultrasound and MRI, and metabolic parameters from the oral glucose tolerance test (OGTT).

Aims & Methods: We analyzed 40 non-diabetic patients with increased pancreatic echogenicity, of whom 29 completed the study (mean age: 54 ± 10.4 years; BMI: 34.8 kg/m^2; waist circumference: 93.8 ± 11.3 cm). Participants underwent OGTT, with assessment of β-cell function indices (Disposition Index, Insulinogenic Index) and insulin sensitivity indices (Matsuda Index, HOMA-IR, Stumvoll Index). Pancreatic fat was evaluated using ultrasound, MRI-PDFF, and two-dimensional shear wave elastography.

Results: The mean pancreatic fat fraction was 13.75 ± 11.22% (median: 7.633%), and mean pancreatic stiffness was 8.1 ± 3.2 kPa. After OGTT, 27.5% of patients exhibited impaired glucose tolerance (IGT). PDFF positively correlated with weight ($r = 0.520$, $p = 0.004$), BMI ($r = 0.505$, $p = 0.005$), and body surface area ($r = 0.509$, $p = 0.005$), but not with liver enzymes, metabolic parameters, or β-cell function. A significant negative correlation was found between pancreatic stiffness and the Potentiation Factor (PFR1), indicating reduced β-cell responsiveness with increasing pancreatic stiffness. Stratification by glucose tolerance status revealed that increased pancreatic fat was associated with greater insulin resistance and compensatory hyperinsulinemia.

Conclusion: In conclusion, our study confirms that increased intrapancreatic fat is an indicator of ectopic lipid accumulation and is correlated with general adiposity. Our study identifies pancreatic fat infiltration as a marker of early metabolic dysfunction, where increasing pancreatic fat triggers β-cell compensatory mechanisms. This underscores the importance of determining a pancreatic fat threshold below which glucose homeostasis may still be restored. Targeted interventions to reduce pancreatic fat are crucial to preventing the progression to irreversible β-cell dysfunction.

Introduction: Exocrine pancreatic insufficiency (EPI) is defined as a reduction in the exocrine pancreatic secretion and/or intraluminal activity of pancreatic enzymes below the level that allows normal digestion of nutrients. Currently, diagnosing EPI presents challenges: the most accurate method requires collecting faecal samples for several days to measure faecal fat excretion following a specific diet, while faecal elastase test, although simpler, has a high incidence of false positives.

The study assesses whether measuring lipase in blood, following the ingestion of a standard high-fat meal could provide a more accessible diagnosis of EPI. The hypothesis is that blood lipase increases proportionally to pancreatic secretion in individuals without EPI, allowing differentiation between patients with and without insufficiency.

Aims & Methods: The study's main objective was to investigate whether blood levels of lipase increase after a fatty meal in normal subjects. If blood lipase and lipase secreted by the pancreas have a correlation, by calculating the area under the curve of several determinations of blood lipase in healthy subjects, we could set a normal pattern of lipase secretion. In the future, this pattern can be compared to patients with EPI to test if it can be a screening tool for EPI.

For the study, 10 healthy volunteers were tested. All participants fasted before receiving a test meal designed to stimulate lipase secretion. Blood samples were then taken every 30 minutes for six hours to measure lipase blood levels and calculate the area under the curve (AUC) using the trapezoid method.

Results: The mean (standard deviation) of the maximum and minimum lipase blood levels was 24 (9) and 19 (8) U/L, respectively. The mean percentage change in lipase was 31% (standard deviation 16%). The area under the curve of blood lipase levels between the baseline sample and the sample at 360 minutes had a mean of 7749 (standard deviation 3129) units per litre per hour.

The median time to peak lipase was 0 minutes, meaning that the expected peak in blood lipase did not occur after the test meal: in 60% of cases, the highest peak of all measurements was the baseline measurement, with no clear peak in response to the meal in the remaining cases, in contrast with pancreatic secretion into the duodenum.

Conclusion: According to our patient sample, lipase does not increase in the blood after stimulation with a test meal, as occurs in pancreatic lipase secretion into the duodenum.

Lipasemia is, therefore, independent of pancreatic secretion and does not seem to be a promising parameter for screening exocrine pancreatic insufficiency.

THE RATE OF CARDIOVASCULAR EVENTS IN PANCREATIC CANCER DOES NOT CHANGE WITH TREATMENT TYPE OR DISEASE STAGE – A SYSTEMATIC REVIEW AND META-ANALYSIS

J. Nemeth[1], J. Lee[1], O. Eperjesi[1], E.-B. Gagyi[2], Z. Bánfalvi[1], V. Lillik[3], I. Creanga-Murariu[1], E. Szalai[1], M. Obediat[1], R. Tóth[1], S. Bunduc[4], P. Hegyi[5]

Introduction: Cardiovascular diseases (CVDs) are often a limiting factor in cancer treatment. In our systematic review and meta-analysis we evaluated the prevalence and incidence of CVDs in pancreatic ductal adenocarcinoma (PDAC).
Aims & Methods: We conducted the systematic search on 5 February 2024 in three databases (PubMed, EMBASE, CENTRAL). Studies reporting the prevalence or incidence of CVDs in PDAC were included. Subgroup analyses based on cancer stage and treatment type were performed.
Pooled proportions with the 95% confidence interval (CI) were calculated using a random effect model. We evaluated the risk of bias using the Joanna Briggs Institute Prevalence Critical Appraisal. (PROSPERO CRD42023482295).
Results: We included 198 articles. The prevalence of CVDs other than thrombotic events at PDAC diagnosis was similar to the one in the general population: hypertension 33 % (95%CI:27-40%), ischemic heart disease 6% (95%CI:3-12%), heart failure, arrhythmia, and stroke affecting each 2-3% of cases. Their incidence during treatment was low (1%-10% overall).
Thrombotic events other than embolism affected 11% (95%CI: 7%-18%) of cases at diagnosis and the incidence during treatment was between 8-10% regardless of cancer stage or treatment type.
Pulmonary embolism affected 3% of cases at diagnosis and occurred in a similar proportion during treatment. The included studies had an overall low-moderate risk of bias.
Conclusion: Thrombotic events affect around 10% of PDAC patients at baseline. A similar proportion develop thrombotic events during follow-up regardless of disease stage or treatment type. The prevalence of CVDs other than thrombotic events is equivalent to the one in the general population.

Introduction: The optimal management of small (≤2 cm) low-grade pancreatic neuroendocrine neoplasms (PNENs) remains a subject of ongoing debate. While surgical resection has traditionally been the standard treatment, its invasiveness and potential for long-term complications, such as pancreatic insufficiency, have driven interest in less invasive alternatives. Recently, endoscopic ultrasonography-guided ethanol injection (EUS-EI) has emerged as a promising treatment option, offering the potential for localized tumor control with minimal impact on surrounding pancreatic tissue.
Aims & Methods: This study was conducted at a single academic center between 2014 and 2024, and the data were retrospectively analyzed. Eligibility criteria included patients with pathologically confirmed grade 1 PNENs ≤2 cm who were either poor surgical candidates or declined surgery. The procedure was carefully planned to minimize complications and improve treatment outcomes. A 25-gauge needle was used to reduce the risk of ethanol leakage. Pure ethanol was injected under EUS guidance until hyperechoic bubbles fully surrounded the tumor margin.
To ensure complete coverage while minimizing ethanol exposure, ethanol was injected from multiple sites if needed. Importantly, the maximum ethanol volume per session was limited to 2 mL to prevent overexposure and reduce adverse events.
To optimize treatment efficacy, contrast-enhanced computed tomography (CE-CT) was performed on postoperative day 3. If residual enhancement was detected, an additional ablation session was scheduled during the same hospitalization, allowing for planned, staged treatment.
Results: A total of 41 patients including four patients with insulinoma underwent EUS-EI, The median tumor size of 10 mm (range: 6–15 mm). The median ethanol volume in the initial session was 0.9 mL (range: 0.3–2.0 mL), and the total median volume was 1.0 mL (range: 0.3–3.2 mL), reflecting the effectiveness of carefully distributed, low-volume injections. Fifteen patients (37%) required an additional planned ablation session based on CE-CT findings. Mild pancreatitis occurred in 6 patients (14%), and the median hospital stay was 5 days (range: 4–8 days), suggesting a favorable safety profile.
Complete ablation was confirmed in 37 patients (90%) at one month post-procedure. All patients with insulinomas experienced an improvement in hypoglycemia-related symptoms.
During a median follow-up of 36 months, local recurrence was observed in only 2 patients (5%), occurring at 22 and 51 months, respectively. Notably, no cases of new-onset diabetes mellitus were reported.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Planned, staged EUS-guided ethanol injection using low per-session ethanol volumes is a safe and effective treatment strategy for patients with small, low-grade PNENs. This approach appears to reduce procedure-related complications while enhancing the rate of complete tumor ablation.

Introduction: Endoscopic ultrasound radiofrequency ablation (EUS-RFA) is a safe and effective therapeutic modality for treating pancreatic neoplasms. While robust data on technical feasibility and safety profile are available and consistent, clinical efficacy and oncological outcomes are still based on low evidence and not standardized methods.

Aims & Methods: We aim to assess current practice in EUS-RFA in terms of indications, prophylaxis for adverse events, generator set-up, follow-up, and lexicon.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

An online survey with 70 questions divided into 5 domains (physicians and center characteristics, indications, procedural details, post-procedural management, and proposed lexicon) was created and shared with 175 international experts at the beginning of 2025; the survey link was open for 5 months and analyzed at the end of April 2025.

Results: Domain 1. 91 physicians (52%) completed the survey; 74.4% from Europe, 13.3% North America and 12.2% Asia; 64.8% declare >10-year EUS experience from high-volume centers (83.3%). 35.6% have formal accreditation as a Center of Excellence for Neuroendocrine Tumors (NET). 41 physicians (45.1%) have performed >20 EUS-RFA procedures, while 20 (22.0%) >50 procedures.

Domain 2. 94.1% physicians perform EUS-RFA for insulinoma, 71.8% non-functioning NET, 57.7% pancreatic metastases, 54.1% other functioning NET, 37.7% pancreatic ductal adenocarcinoma, 31.8% IPMN with mural nodule; very low agreement (<25%) was reached for other indications, (solid pseudopapillary neoplasms, liver tumors, other pancreatic neoplasms, adrenal gland tumors, celiac plexus).

Domain 3. 96% of EUS-RFA are performed under deep sedation or general anesthesia, in inpatient setting (83.1%). Rectal NSAIDs and aggressive hydration are administered for post-RFA pancreatitis prophylaxis in 45.6%, while only rectal NSAIDs in 41.8%. Antibiotic prophylaxis was administered in 57.0%. 50.6% of physicians are concerned about main duct injury for lesions located ≤ 2 mm while 34.2% for lesions closer than 1 mm. In these cases, 43.0% reduce duct damage through changes in power setting, avoiding duct contact, while 24.1% perform ERCP with pancreatic duct stenting. 45.6% avoid performing EUS-RFA in case of ductal infiltration with dilation.

58.4% use the same power-setting for every procedure, and 26.6% the same probe size. 10-mm tip length probe was used by 92.2% of physicians. Low agreement (<50%) for power generator set-up was reached for any indication. 70.9% have no maximum number of applications for each EUS-RFA session and continue ablation until all tissue seems ablated. 56.4% have no maximum time for each application.

Domain 4. 52.6% test serum biochemistry the day after the procedure; 27.0% perform a routine CT scan within 2 weeks. Contrast CT scan (81.0%) and contrast EUS (46.8%) are used for follow-up. A 3-month CT scan was used as the first oncological assessment in 51.3%.

Domain 5. Technical success was defined as “achieving the presumed complete ablation at the end of the procedure” by 88.6%; clinical success as “achieving symptom control for at least 1 year for insulinoma” by 92.2%; disease recurrence as “evidence of vascularized tumor tissue following complete response”. Low consensus (< 50%) was reached on the definition of complete and partial ablation, and post-EUS-RFA pancreatitis.

Conclusion: The results of this study provide clear data on the lack of standardization of EUS-RFA procedures even among experts. An international working group on EUS-RFA methodology is required to address unanswered clinical questions and provide a consensus fostering uniformity in EUS-RFA application.

Introduction: Pancreatic cancer is a highly lethal disease, often diagnosed at an advanced stage due to the lack of early detection methods. Endoscopic retrograde cholangiopancreatography (ERCP) with brush cytology is commonly used to obtain samples from the bile duct (BD) and pancreatic duct (PD), yet its diagnostic accuracy remains debated.

Aims & Methods: This study aimed to assess the pooled sensitivity of BD and PD brushing in detecting pancreatic cancer compared to histology. A systematic search was conducted in three major medical databases on November 05, 2024. We included studies comparing BD and/or PD brushing to a control group of patients diagnosed with pancreatic cancer, mainly based on histology, but radiological follow-up, laparotomy, or other accepted diagnostic methods were included as well. A random-effects meta-analysis was performed to calculate the pooled sensitivity of each technique, with results presented as percentages and 95% confidence intervals (CI).

Results: Our systematic search identified 8375 articles, of which 64 met the inclusion criteria for the final analysis. This included 45 studies assessing BD brushing and 19 studies evaluating PD brushing. The pooled sensitivity for PD brushing was 55.8% (95% CI: 50.3% – 61.2%) with moderate heterogeneity ($Q = 24.84$, $df = 18$, $p = 0.129$). The pooled sensitivity for BD brushing was 40.9% (95% CI: 35.6% – 46.4%) with significant heterogeneity ($Q = 121.03$, $df = 44$, $p < 0.001$). Subgroup analyses were conducted to explore potential variations in diagnostic accuracy. However, data on the safety and adverse events associated with BD and PD brushing were limited among the included studies.

Conclusion: BD and PD brushing during ERCP provide valuable diagnostic yield in detecting pancreatic cancer. Despite BD brushing showing lower sensitivity and high heterogeneity among studies, both methods remain useful diagnostic tools. These findings support the integration of brush cytology in ERCP procedures to improve early pancreatic cancer detection, ultimately aiding in better clinical decision-making.

Disclosure: Nothing to disclose.

SMALL STONES, BIG DECISIONS: REAPPRAISING THE NEED FOR ERCP IN ACUTE BILIARY PANCREATITIS

J. Carlos Goncalves[1,2], M. Souto[1,2], P. Campelo[1,2], T. Cúrdia Gonçalves[1,2], J.L.T.M. Magalhães[1,2], B. Rosa[1,2], J. Berkeley Cotter[1,2]
[1]Unidade Local de Saúde do Alto Ave, Gastroenterology Department, Guimarães, Portugal, [2]Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal

Contact E-Mail Address: joaogoncalves92@gmail.com

Introduction: Biliary stones are a leading cause of acute pancreatitis (AP). Endoscopic Retrograde Cholangiopancreatography (ERCP) is the standard of care when concomitant cholangitis or confirmed choledocholithiasis is present[1].

However, spontaneous migration of biliary stones in the latter occurs in approximately 20% of cases[2], potentially exposing patients to the inherent risks of ERCP without a definitive therapeutic benefit.

Aims & Methods: This study aimed to identify predictors of spontaneous common bile duct stone clearance in patients with acute biliary pancreatitis. We conducted a retrospective cohort study of consecutive patients diagnosed with acute pancreatitis and confirmed choledocholithiasis, who subsequently underwent ERCP. Patients with a prior ERCP or concurrent acute cholangitis were excluded.

Results: Forty-four patients were included, 61.4% female with a mean age of 67±18 years. In 31.8% of cases, no stone was identified at ERCP, suggestive of spontaneous resolution. The median interval from admission to ERCP was 10 days and did not significantly differ between patients with and without stones (p=0.872). Serum levels of total bilirubin (2.5±2.0 vs. 2.3±2.9 mg/dL, p=0.825), AST (160±31 vs. 171±50 U/L, p=0.505), and alkaline phosphatase (267±135 vs. 210±70 U/L, p=0.187) were not significantly different between groups with and without stones at ERCP, respectively.

Neither cholecystectomy status (p=0.722), common bile duct dilation on imaging (p=0.955), nor number of stones (p=0.829) correlated with spontaneous clearance. Interestingly, patients without lithiasis at ERCP had significantly smaller common bile duct stones on imaging compared to those with retained stones (5 ± 3 mm vs. 8 ± 5 mm, p=0.025). Stone size was an independent predictor of spontaneous resolution in the multivariate analysis (OR = 1.24; 95% CI: 1.01–1.52; p = 0.036), with a diameter ≥7 mm yielding a sensitivity of 63% and a specificity of 78.6% for predicting the presence of stones at ERCP.

Conclusion: Spontaneous passage of biliary stones is common in the context of acute biliary pancreatitis, particularly when their size is ≤7 mm. These findings support a risk-adapted strategy, in which Endoscopic Ultrasound may be employed to confirm choledocholithiasis immediately prior to ERCP in patients with small biliary stones.

CLINICAL OUTCOMES OF TARGETED ENDOSCOPIC TREATMENT OF PANCREATIC FISTULAS ACCORDING TO A PANCREATOGRAPHIC MORPHO-FUNCTIONAL CLASSIFICATION: A RETROSPECTIVE SINGLE-CENTER COHORT STUDY

C. Gallo[1], G. Bonato[1], M. Stegagnini[1], E. Forti[1], F. Pugliese[1], L. Dioscoridi[1], M. Cintolo[1], M. Bravo[1], A. Palermo[1], A. La Mantia[1], M. Mutignani[1]
[1]ASST Grande Ospedale Metropolitano Niguarda, Digestive and Interventional Endoscopy Unit, Milan, Italy

Contact E-Mail Address: camilla.gallo1@gmail.com

Introduction: Pancreatic fistulas (PFs) represent a remarkable clinical challenge after abdominal surgery, pancreatitis, or abdominal trauma, with significant morbidity and non-negligeable mortality. Pancreatic endoscopy plays a pivotal role in the setting of recent trend toward aggressive yet minimally invasive surgery-sparing PFs management.

Mutignani et al. recently proposed a morpho-functional pancreatographic classification of PFs aimed at targeting the best suited endoscopic treatment option for each PF type.

Aims & Methods: The primary aim of this study is to evaluate efficacy and safety of endoscopic PFs treatment, according to the Mutignani et al. classification; the secondary aim is the identification of independent variables significantly associated with different treatment clinical success rate.

Monocentric data prospectively collected between March 2011 and July 2024 on patients referred to the Interventional Endoscopic Unit of ASST Grande Ospedale Metropolitano Niguarda who underwent endoscopic treatment of a PF was retrospectively analysed.

Results: A total of 110 patients were included (M 75.5%, median age 61 years [IQR 46-72]). 75/110 (68.2%) were post-surgical (33 after pancreaticoduodectomy, 23 distal pancreatectomy, and 19 other abdominal surgery), 27/110 (24.5%) developed after pancreatitis, and 8/110 (7.3%) were post-traumatic. 17/110 (15.5%) were type I PF [9 (53%) T, 5 (29.4%) H, 3 (17.6%) B], 38 (34.5%) type II [27 (71.1%) O, 11 (28.9%) C], and 55 (50%) type III [35 (63.6%) D, 20 (36.4%) P].

Median treatment delay was 9 days [IQR 5-22]. ERCP was first endoscopic approach in 92 cases (83.6% - of which 6.5% after rendez-vous), EUS-guided in 14 (12.7%), and combined in 4 (3.6%). Mutignani et al classification adherence was 98.2%.

Technical success rate was 100% (91.8% at first approach), clinical success rate was 97/105 (92.4%). Early AEs occurred in 15 cases (14.3% - 33.3% of them infections), late AEs occurred in 8 (7.6% - 100% new pancreatic strictures). 9/105 (8.6%) patients died due to fistula-related causes during follow-up, PF recurrence occurred in 2 cases (2.1%).

At univariate analysis, older age, presence of heart diseases, presence of sepsis at clinical presentation, class C ISGPF fistula, and high-volume PF proved to be significantly more frequent among patients without clinical success compared to those with clinical success (median 72.5 [IQR 54.3-82.7] VS 59 [IQR 46-70.1], p=0.0312; 37.5% VS 2.3%, p=0.0038; 87.5% VS 39.8%, p=0.0199; 57.1% VS 14.3%, p=0.0182; 87.5% VS 42.7%, p=0.0230, respectively).

At multivariate analysis, only the presence of heart diseases confirmed to be significantly associated to the absence of clinical success (OR 2.65, 95%CI: 1.5-3.8, p=0.0217).

Conclusion: High adherence to the Mutignani et al classification system for PFs endoscopic treatment proved to high clinical success and low rate of AEs. Targeted management of PF is not only feasible but also highly effective, basically regardless of patient's and PF's baseline characteristics. Further large-scale prospective multicentric studies are warranted to confirm these findings and refine the optimal treatment strategies.

A DETOUR STENT APPROACH VIA EUS-GJ FOR REINTERVENTION IN BLOCKED BILIARY SEMS

V. Reddy[1], R. Kumar Adi[1]
[1]Yashoda Hospital, Gastroenterology, Hyderabad, India

Contact E-Mail Address: Viswanathdr@yahoo.com
Introduction: Endoscopic reintervention in patients with malignant biliary obstruction and prior stenting can be challenging, particularly when conventional access routes are compromised. While ERCP remains the standard of care, EUS-guided approaches are increasingly being used as alternatives in difficult cases [1,2]. We present a case where a detour stent approach via an existing EUS-GJ provided successful access for biliary stent revision.
Aims & Methods: A 60-year-old male with advanced pancreatic cancer previously underwent percutaneous transhepatic biliary drainage (PTBD), placement of a biliary self-expandable metal stent (SEMS) for malignant biliary obstruction, and an EUS-guided gastrojejunostomy (EUS-GJ) for gastric outlet obstruction. He presented with fever and jaundice, and was diagnosed with acute cholangitis. Imaging suggested stent occlusion.
Endoscopy revealed a patent EUS-GJ but a narrowed and inaccessible duodenal lumen. A therapeutic endoscope was advanced through the EUS-GJ into the afferent limb. Under fluoroscopic guidance, a guidewire was passed through the distal end of the previously placed biliary SEMS. A balloon trawl was performed to clear debris, followed by cholangiography confirming partial stent occlusion. A 10 cm uncovered SEMS was deployed coaxially within the existing stent, restoring biliary drainage.
Results: The procedure was well-tolerated with no immediate complications. The patient showed clinical improvement, with resolution of cholangitis and normalization of liver function tests over the following days. This outcome is consistent with prior reports supporting EUS-GJ as a stable access route for advanced endoscopic interventions [2,6].
Conclusion: The detour stent approach through an existing EUS-GJ is a safe and effective rescue option for biliary reintervention in complex anatomical scenarios, especially in patients with malignant obstruction and prior interventions.

Contact E-Mail Address: marcus.hollenbach@web.de
Introduction: Endoscopic papillectomy (EP) is a standard treatment for ampullary lesions (AL), most of which are small and limited to the papillary mound. Laterally spreading lesions (LSL) of the papilla Vateri represent a rare subtype of AL, characterized by an extensive involvement of the surrounding duodenal mucosa. Data analyzing efficacy and complications of EP for LSL are scarce. In this study, EP for LSL were compared with non-LSL AL in thoroughly matched cohorts.
Aims & Methods: The ESAP study encompassed 1422 endoscopic papillectomies (EPs). Propensity-score matching used the nearest-neighbor method for age, gender, comorbidity, and histologic subtype as cofactors. The main outcomes were complete resection (R0), technical success, complications, and recurrences.
Results: Propensity-score-based matching identified 232 patients (116 non-LSL and 116 LSL AL) with comparable baseline characteristics. LSL sizes were significantly larger compared to non-LSL (median 27.0mm vs. 16.5mm, p<0.001). After first intervention, the R0-rate was significantly lower in the LSL group (54.3% vs. 69.0%, p=0.002). Following repeated endoscopic interventions (such as EP, radiofrequency ablation (RFA) or argon plasma coagulation (APC)), the technical success was comparable in both groups (82.8% vs 82.8%; p=1.00). After a median FU of 22 months, there were significantly more recurrences in the LSL group (41.3% vs. 15.0%, p<0.001). Complication rates did not differ significantly between the two groups (p=0.756).
Conclusion: LSL can be safely resected by EP, though repeated interventions are necessary to achieve complete resection. The higher risk of recurrence in LSL necessitates a vigilant surveillance strategy.
Disclosure: FUJIFILM Honoraria.

SINGLE-CENTER EXPERIENCE WITH ENDOSCOPIC MANAGEMENT OF DEMARCATED PANCREATIC WALLED-OFF PANCREATIC NECROSIS (WOPN)

P.J. Hegyi[1], B. Eross[2]
[1]Semmelweis University, Institute of Pancreatic Diseases/Centre for Translational Medicine, Budapest, Hungary, [2]Semmelweis University, Institute for Translational Medicine, Budapest, Hungary

Contact E-Mail Address: drdunajskastreda@gmail.com

Introduction: The revised Atlanta Classification delineates the local complications of acute pancreatitis, categorizing them as acute (peri) pancreatic fluid collections (PFCs), acute necrotic collections, pancreatic pseudocysts, and walled-off pancreatic necrosis (WOPN). Various endoscopic interventions are employed for the management of WOPN, notably including direct transluminal endoscopic necrosectomy (DEN) following the placement of an endoscopic ultrasound-guided (EUS) lumen-apposing metal stent (LAMS).

This study aims to assess the clinical outcomes and safety profile of DEN in patients diagnosed with pancreatic WOPN.

Aims & Methods: This single-center retrospective analysis encompasses patients with pancreatic WOPN who underwent DEN at Semmelweis University between October 1, 2021, and October 1, 2024. The procedures were performed by three seasoned specialists in EUS and endoscopic retrograde cholangiopancreatography (ERCP).

Comprehensive data on patient demographics, procedural specifics, and follow-up outcomes were collected, with adverse events classified according to the AGREE criteria.

Results: We successfully placed LAMS in 31 patients (61% female, mean age 66.3 years, SD 9.4). The primary indications for intervention included the dimensions of WOPN, exacerbation of gastric outlet obstruction, and signs of infection. The mean dimensions of WOPN were recorded as 98 mm in the anteroposterior direction (SD 35.6), 90 mm laterolateral (SD 44), and 88 mm craniocaudal (SD 27.4), with a predominant occurrence in the head of the pancreas (60%). Alcohol consumption emerged as the leading etiological factor for WOPN in 92% of male patients, whereas biliary causes were identified in 67% of female patients.

In total, we conducted 83 DEN procedures across the 31 patients (51 males and 32 females). The average number of DEN sessions was three for both male and female groups (range: 2-6). The technical success rate achieved was 100%, accompanied by a clinical success rate of 97%. One patient succumbed to the condition; however, three of the surviving 30 required intensive care due to multiorgan failure.

To enhance the resolution of infection between DEN sessions, we employed 7 Fr/250 cm nasocystic tubes for irrigation of the WOPN with a saline solution in all patients, with no adverse events reported as a result of this intervention.

Conclusion: DEN can be performed safely in experienced medical centers and demonstrates a high success rate in the treatment of infected WOPN, effectively alleviating symptoms and decreasing enzyme levels. The predominant etiology of WOPN formation in male patients is attributed to alcohol consumption, while biliary factors are more prevalent in female patients.

Disclosure: Nothing to disclose.

Contact E-Mail Address: germanadenucci1@gmail.com

Introduction: EUS-guided drainage using lumen-apposing metal stents (LAMSs) and direct endoscopic necrosectomy (DEN) are primary treatment modalities for symptomatic pseudocysts and walled-off pancreatic necrosis (WOPN). However, bleeding is a frequent and serious adverse event associated with these procedures, often requiring radiological or surgical interventions also due to the limitations of conventional endoscopic hemostatic techniques. PuraStat is a novel topical hemostatic agent that has demonstrated excellent results in managing gastrointestinal bleeding.

Aims & Methods: Our aim was to evaluate the efficacy and safety of PuraStat in managing bleeding secondary to EUS-guided drainage and DEN of pancreatic fluid collections (PFCs). In this multicenter, retrospective, observational study we described 27 patients who underwent PuraStat treatment because of active bleeding during or after EUS-guided drainage or DEN sessions of pseudocysts or WOPN between 2017 and 2024.

Results: 38 bleeding episodes were recorded (10 patients with WOPN experienced multiple bleeding events). The bleeding type was oozing in 36 cases and spurting in 2 cases. PuraStat was successfully applied in 100% of patients and achieved successful hemostasis in 96.5% of cases. No re-bleeding occurred. No PuraStat-related adverse events were recorded.

Conclusion: PuraStat is a safe, effective, and easy-to-use hemostatic agent for managing oozing hemorrhages related to PFCs EUS-guided drainage or DEN. Prospective and comparative studies are needed to confirm these preliminary data.

Introduction: Pancreatic neuroendocrine tumors (pNETs) are a heterogeneous group of tumors with different treatment options depending on pathological grading, clinical staging, and presence of symptoms related to hormonal secretion. Their classification is made on mitotic count and Ki-67 index.

The current standard for Grading assessment is analysing the material obtained from EUS-guided fine needle aspiration/biopsy (EUS-FNA/FNB). However this technique is not free from adverse events and could be challenging for NETs localization.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The evidence of high grade of fibrosis and microvascular density decrease (MVD) on tumor pathological specimens has led many authors to search for undirected malignant features of pNET extrapolated from non-invasive techniques. The introduction of ancillary techniques, such as second-generation contrast agents (CH-EUS), has improved study of pNET. Particularly, at CH-EUS examination contrast pattern well correlates with behaviour and grading of NETs. However, the use of contrast agents entails a prolongation of procedure time and additional costs. An innovative ultrasound Doppler technique, Detective Flow Imaging EUS (DFI-EUS), involves no additional time or cost as it doesn't require the administration of contrast agent. There is still no standardisation of this technique and few studies have validated its use.

Aims & Methods: The aim of this study is to evaluate the DFI role in defining NET vascularization and its correlation with CH-EUS. The second aim of the study is to assess DFI role in predicting histological grading.

Single center retrospective analysis on consecutive patients with solid pancreatic lesions who underwent EUS at Therapeutic Digestive Endoscopy Unit of the Fondazione Policlinico Universitario Campus Bio-Medico in Rome.

After activation of DFI, each lesion was observed for at least 30 seconds. Lesions was classified into three grades, according to the degree of vascularisation at DFI: (grade 0 absence of microvascularization of the tumor; grade 1 minimal/isovascularization of the tumor; grade 2 markedly increased microvascularization).

All lesion with final hystological diagnosis of NET were enrolled.

Grading and Ki-67 index of tumors were reported.

Data about lesion's features and procedure were collected.

Results: From April 2024 to February 2025, 17 patients were enrolled (58.8% male; mean age 57±12 years old). The majority of lesion (53%) were localized in the body of the pancreas and the mean lesion' s size was 28±20 mm. The final histological diagnosis classified 50% lesions as G1, 38.8% G2 and 5.5% G3.

At the CEH-EUS the 70.6% of lesion showed hyper-enhancement. About the DFI evaluation the 17.6% of lesion was hypo-vascular, 17.6% Iso-vascular and 64.7% was hyper-vascular. There was excellent correlation between DFI characterization of the lesion and the CH-EUS (ICC 0.9)

Among the NET G1, 66.7% were Hypervascular at DFI and 33.3% Isovascular. Among the G2, 71.4% were Hypervascular at DFI and 28.6% Hypovascular. The only G3 lesion was Hypovascular.

There was inverse correlation between the NET grade and the DFI grade (Pearson coefficient -0.56; p 0.02).

Conclusion: DFI-EUS can provide a fast evaluation of the micro-vascularization of pNET with excellent correlation with CH-EUS. Hyper-vascular pattern at DFI correlates with low Ki-67 index.

Disclosure: Nothing to disclose.

Contact E-Mail Address: spencervaiciunas@hotmail.com

Introduction: Pancreatic neuroendocrine tumors (NETs) are rare neoplasms that are classified as functional (F-NET) or nonfunctional (NF-NET) depending on the presence or absence of excess hormone production. Endoscopic Ultrasound guided fine needle aspiration (EU-FNA) is often used to diagnose NETs but there are limited data on its sensitivity for this purpose.

Aims & Methods: To determine the sensitivity of EUS-FNA for the diagnosis of a NET.

A prospective randomized trial study, from May 2013 to Abril 2025 was performed in a referred Gastrointestinal hospital in Brazil. A total of 184 patients underwent EUS for suspected NETS and collected materials from fine needle aspiration and sent to histopathology analyzes.

The diagnosis of a NET was confirmed by:

1. EUS-FNA with or without confirmatory immune chemistry (ICC) with synaptophysin and chromogranin form pancreatic mass or metastatic site, or;
2. An alternative biopsy method and/or surgical resection of the pancreas or other metastatic site

Results: 184 patients (112 male; median age: 54 yrs, range: 21-78 yrs) with 68 (37%) F-NETs and 116 (63%) NF-NETs were identified. By EUS, the tumors were located in the pancreas head, body, tail or were multifocal in 76 (41%), 54 (29%), 38 (21%) and 16 (18%), respectively.

Of these 184, 152 (83%) underwent EUS-FNA of a pancreatic mass, 72 (47%) of whom also had a EUS-FNA of an alternative (nonpancreatic) site including liver (n=30; 16%), another lesion in the pancreas (n=14; 8%), or lymph node (n=18; 10% peripancreatic in 10, celiac in 6 and mediastinal in 2).

Immunohistochemistry was performed in 102/152 (67%) EUS-FNA specimens and the result were: ICC-positive (n=88), ICC-negative (n=10), not interpretable (n=2) or inadequate for interpretation (n=2), Surgery was performed in 82 (54%): distal pancreatectomy (n=32), Whipple procedure (n=20), enucleation (n=20) and subtotal (n=4) and total pancreatectomy (n=2).

The remaining four who underwent surgery had an exploration laparotomy only. 132 patients had a confirmed diagnosis of NET and the sensitivity of EUS-FNA was respectively: all patients 84%, F-NET 78%, NF-NET (89%) and lesions less than or equal to 13 mm (62%). The results of the false-negative EUS-FNA biopsies of pancreas (n=24) were interpreted as: normal in 4; suspicious in 4, nondiagnostic in 10, adenocarcinoma in 4, and a solid pseudopapillary tumor in 2.

Conclusion: EUS-FNA is a sensitive method for the diagnosis of pancreatic NETS but yield is lower in tumor smaller than 13mm in diameter.

Disclosure: Nothing to disclose.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. PP1027

IMPACT OF MACROSCOPIC ON-SITE EVALUATION (MOSE) ON ACCURACY OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE BIOPSY (EUS-FNB) OF SOLID LESIONS: A RANDOMISED CONTROLLED TRIAL.

K. Amalou[1], N. Kecili[1], R. Rekab[1], A. Belloula[1], K. Saidani[1]
[1]HCA, Gastroenterology, Algiers, Algeria

Contact E-Mail Address: amalou_kh@yahoo.fr

Introduction: Endoscopic ultrasound (EUS) tissue acquisition requires rapid on-site evaluation (ROSE) to improve diagnostic yield with less needle passes; however, ROSE requires the presence of a cytopathologist and additional cost and time for slide staining and interpretation. Macroscopic on-site evaluation (MOSE) is the direct assessment of the tissue sample provided by EUS-guided fine needle biopsy (EUS-FNB) macroscopically, to detect whether it is sufficient or not.

Aims & Methods: Aim of this study was to evaluate the efficacy of MOSE in terms of tissue acquisition and diagnostic accuracy for abdominal solid lesions

This is a prospective and comparative study including 148 consecutive patients performing EUS-FNB for pancreatic and extrapancreatic solid lesions, randomized by alternate allocation to macroscopic on-site evaluation (MOSE) (74 patients) or to a conventional technique (74 patients), with two passes each. MOSE samples were differentiated into score 0: no visible material, score 1: only necrotic or haematic material, score 2: white core tissue ≤ 2 mm, or score 3: white core tissue > 2 mm.

The conventional technique consisted in pushing all the needle content into a test tube for evaluation by the pathologist. In both groups, a 22 Gauge Franseen-tip needle biopsy was used.

Results: The overall diagnostic adequacy was 92.5% (137/148) and accuracy was 86.4% (128/148). The diagnostic accuracy was similar in the two groups: MOSE 87.8% (65/74 lesions), vs. conventional 81.0%, 60/74 lesions, $p = 0.34$). Regarding diagnostic adequacy, the MOSE technique was 95.9% (71/74 passes) compared to 91.8% (136/148 passes) with the conventional technique, $p = 0.04$.

The accuracy increased according to the MOSE score evaluation: it was 49.3%, 68.9% and 81.3% in patients with score 1, score 2, and score 3, respectively. There was no statistically significant difference between the two groups with conclusive and inconclusive cytopathological results regarding size of the needle, number of needle passes, type of the needle and the specimen acquisition method.

Conclusion: The MOSE score showed a comparable diagnostic accuracy to the conventional technique. However, MOSE allows endoscopists to perform an inspective evaluation of the material, tends to perform better than the conventional technique in terms of diagnostic adequacy, and may potentially reduce the number of passes.

Disclosure: Nothing to disclose.

Introduction: Tuberculous lymphadenopathy represents a challenging diagnostic scenario, particularly in regions with high TB prevalence. Its diagnosis is challenging due to the nonspecific clinical and radiological findings. Blood and skin tests for TB have variable sensitivities and specificities, so histopathologic diagnosis and molecular tests for diagnosis of TB in tissue samples may be more accurate than blood tests. Obtaining tissue samples under ultrasonography or CT guidance is sometimes very difficult and risky especially in the intra-abdominal and mediastinal regions.

Endoscopic ultrasound (EUS) with EUS fine needle biopsy (EUS-FNB) is a safe technique in obtaining tissue samples for diagnosis of abdominal and mediastinal TB. EUS introduces a critical advantage of real-time imaging and precise tissue sampling. Many studies found that EUS-FNB yielded significantly higher diagnostic yield in complex TB presentations, with detection rates ranging from 78-92% across various anatomical sites.

Comparative analysis with Gene X-pert MTB/RIF assay and Polymerase Chain Reaction (PCR) techniques demonstrated nuanced diagnostic capabilities. Gene X-pert provides rapid molecular detection with high specificity for rifampicin resistance while PCR offers molecular amplification of bacterial DNA.

Aims & Methods: In this prospective cross-sectional study, we explored the diagnostic efficacy of molecular techniques, specifically PCR and Gene X-pert MTB/RIF assay, in detecting Mycobacterium tuberculosis in tissue samples obtained through EUS-FNB. We also aim to evaluate the sensitivity, specificity, and rapid detection capabilities of these molecular methods compared to traditional diagnostic techniques.

Patients and Methods: This study included 56 patients, 28 males and 28 females with mean age of 50 ±16 years. TB PCR or Gene X-pert was done in tissue samples including mediastinal and intra-abdominal lymphadenopathy in 75% of cases, obtained by EUS-FNB. Results: PCR or Gene X-pert for TB were true-positive in 7 cases and false negative in one case with sensitivity of 88%, specificity of 100%, positive predictive value of 100% and negative predictive value of 98%.

Results: PCR or Gene X-pert for TB were true-positive in 7 cases and false negative in one case with sensitivity of 88%, specificity of 100%, positive predictive value of 100% and negative predictive value of 98%.

Conclusion: We concluded that PCR and Gene X-pert of TB in tissues obtained by EUS-FNB are of great value in diagnosis of extrapulmonary TB.

Introduction: There has been a shift from percutaneous drainage towards endoscopic ultrasound (EUS)-guided drainage for management of post-operative pancreatic fluid collections (POPFC). However, available series have been limited by sample size and little is known about the factors that may influence clinical success.
Aims & Methods: Our aim was to evaluate the outcomes of EUS-guided drainage of POPFC following pancreatic surgery and identify predictors of clinical success.
We performed a retrospective review of patients who underwent EUS-guided drainage of POPFC between 2014 and August 2024 at three academic centers. Primary outcome was clinical success, defined as the complete radiological regression of the collection and resolution of symptoms without the need for additional drainage procedures.
Results: In total, 265 cases were included (mean age 64 [SD±13.9] years, 37% pylorus-resecting pancreatoduodenectomy). Early drainage (≤14 days) was performed in 52% of cases (n=138) and DPPS were used in 209 cases (79%).
Clinical success with a single EUS drainage procedure was achieved in 160 cases (60.4%). Step-up interventions were required in 67 patients (25.3%), 37 of which required endoscopic revision only. Technical success was achieved in 90% (n=238) and adverse events occurred in 43 cases (16%).
Stent type, drainage timing, splenectomy and drainage route did not seem to significantly influence clinical success. Multivariate analysis including stent type and surgical history, showed that distal pancreatectomy was an independent risk factor for clinical failure.
Conclusion: EUS-guided drainage of POPFC was effective in the majority of cases with a single procedure, although distal pancreatectomy was suggested as an independent risk factor for clinical failure. These results further support the use of EUS-guided drainage for the management of postoperative collections.

Introduction: The use of contrast-enhanced endoscopic ultrasound (CE-EUS) for characterizing solid pancreatic masses has improved diagnostic capabilities. We aimed to evaluate the performance of an artificial intelligence (AI)-powered system for differential diagnosis of pancreatic adenocarcinoma using CE-EUS.
Aims & Methods: The methodology integrates advanced imaging analysis and machine learning (ML) to develop an automated framework for pancreatic tumor characterization using EUS. A convolutional neural network (CNN) is first trained on labeled non-contrast EUS images to detect and segment the pancreas and tumor regions accurately. Once trained, the CNN is applied to new cases, identifying regions of interest (ROIs) in the non-contrast images, which are subsequently mapped onto the corresponding contrast-enhanced images for further analysis. Time-Intensity Curve (TIC) analysis was performed on the mapped ROIs, extracting a comprehensive set of quantitative parameters describing contrast enhancement dynamics.
These parameters include temporal metrics (e.g., time to peak, rise time), intensity measures (e.g., peak intensity, wash-in intensity), slopes (e.g., wash-in and wash-out rates), area-based metrics (e.g., area under the curve), and perfusion-related characteristics (e.g., perfusion index, blood flow). The extracted TIC parameters are then used to train a feedforward neural network (FNN), which learns to differentiate diagnostic categories based on the perfusion characteristics of the lesions.
In the final integrated model, the CNN detects pancreas and tumor regions, maps them to contrast-enhanced images, computes TIC parameters, and feeds these into the FNN to provide automated diagnostic predictions.

Results: Retrospective analysis was performed on a prospectively collected dataset of 120 CE-EUS videos obtained from patients with solid pancreatic masses in 3 tertiary referral centers. The dataset included 88 pancreatic adenocarcinomas, 1 lymphoma, 4 metastatic lesions, 10 neuroendocrine neoplasms (G1/G2), 15 cases of chronic pancreatitis, and 2 solid pseudopapillary neoplasms (SPNs).

Diagnostic performance was evaluated by calculating sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy. Based on CNN analysis, both precision and recall were also calculated.

The AI-powered CE-EUS system achieved high diagnostic performance, with an accuracy of over 95% for the diagnosis of pancreatic adenocarcinoma. Precision and recall were also excellent for differentiating adenocarcinoma from other pancreatic lesions based on CNN analysis.

Conclusion: This novel AI-based approach using CE-EUS reliably distinguished pancreatic adenocarcinoma from other solid pancreatic masses. Real-time analysis of time-intensity curve parameters enhances diagnostic accuracy and offers a promising adjunct to traditional EUS methods. Further prospective validation is warranted to confirm these findings and explore clinical applicability.

Introduction: Contrast-enhanced endoscopic ultrasound (CE-EUS) is a valuable tool for evaluating gastrointestinal lesions, providing real-time insights into vascular patterns and tissue perfusion. It is increasingly utilized to differentiate solid and cystic lesions, particularly in pancreaticobiliary diseases.

However, CE-EUS interpretation remains operator-dependent, with variability influenced by observer expertise and a lack of standardized criteria.

Previous studies on interobserver agreement (IOA) in CE-EUS interpretation have yielded inconsistent results, underscoring the need for further investigation into dynamic contrast features such as enhancement patterns and wash-in/wash-out phases.

Aims & Methods: This study aimed to evaluate IOA among endosonographers with varying levels of expertise in interpreting CE-EUS videos, focusing on lesion classification, dynamic contrast features, and video quality. This multicenter retrospective study involved 24 endosonographers (15 experts, 9 non-experts) from 16 European centers. Participants completed an initial survey capturing their experience and institutional characteristics.

Subsequently, they independently reviewed 60 CE-EUS videos (~1 minute each), recorded between 2021 and 2023, comprising 40 solid, 15 cystic, and 5 mixed lesions. Videos varied in quality. Observers assessed lesion type (solid or cystic), arterial and venous enhancement patterns (hyper-, hypo-, or non-enhancing), wash-in and wash-out timing (rapid or late), contrast distribution (homogeneous or inhomogeneous), and video quality. Fleiss' kappa (κ) was used to calculate IOA for each parameter.

A multivariate analysis was conducted to identify factors influencing IOA.

Results: Moderate agreement was found for lesion classification (κ = 0.47). IOA for arterial phase enhancement was slight (κ = 0.38), as was agreement for arterial wash-in timing (κ = 0.27), venous wash-out timing (κ = 0.21), and contrast distribution homogeneity (κ = 0.24). No agreement was reached for video quality assessment (κ = 0.14). Operator experience was not significantly associated with IOA.

Multivariate analysis revealed that IOA for wash-in timing was influenced by procedural volume at the observer's center and the type of endoscopic equipment used (p = 0.004 and p = 0.034, respectively).

Additionally, center volume significantly affected perceived video quality assessment (p = 0.035).

Conclusion: This study demonstrates considerable variability in CE-EUS interpretation among observers, particularly for dynamic contrast features, where agreement was slight. Lesion classification showed moderate reproducibility, but standardized evaluation criteria are needed for other parameters. Procedural volume at the observer's center significantly influenced IOA, emphasizing the importance of institutional experience. These findings highlight the need for improved training programs and interpretation frameworks to enhance the diagnostic consistency and clinical utility of CE-EUS.

Introduction: Endoscopic ultrasound (EUS) elastography has emerged as a valuable tool for assessing pancreatic tissue stiffness, aiding in the differentiation of normal pancreas, chronic pancreatitis (CP), and solid pancreatic masses, including pancreatic adenocarcinoma (PDAC) and cholangiocarcinoma (CC). The newly developed two-dimensional shear wave elastography (2D-SWE) provides real-time, quantitative elasticity maps with improved reproducibility.

This study aims to evaluate the performance of 2D-SWE during EUS for differentiating normal pancreas, CP, and solid pancreatic tumors.

Aims & Methods: This prospective study included patients undergoing EUS for pancreatic evaluation. All 2D-SWE measurements were made using the Aplio i800 EUS ultrasound machine. Four groups were analyzed: (1) individuals with a normal pancreas, (2) patients with CP (based on Rosemont criteria), (3) patients with PDAC, and (4) patients with CC (all diagnoses confirmed histopathologically). 2D-SWE was performed during EUS using a linear-array echoendoscope. Quantitative elasticity values (kPa) were recorded for the normal pancreas, CP-affected tissue, and tumor lesions. The diagnostic performance of 2D-SWE was assessed using intraclass correlation coefficient (ICC), receiver operating characteristic (ROC) analysis, and pairwise statistical comparisons.

Results: A total of 30 patients were included (6 normal, 5 CP, 17 PDAC, 2 CC). The intra-observer reproducibility of SWE measurements was excellent (ICC = 0.89). Mean elasticity values significantly differed among groups, with PDAC showing the highest variability (mean SWE = 54.1 ± 45.7 kPa, median = 33.1), CC presenting elevated stiffness (mean SWE = 77.4 ± 11.0 kPa), CP showing heterogeneous values (mean SWE = 57.5 ± 52.3 kPa, median = 43.6), and normal pancreas showing the lowest stiffness (mean SWE = 7.5 ± 3.9 kPa, median = 6.2).

ROC analysis for distinguishing malignant solid tumors (PDAC + CC) from normal pancreas showed excellent diagnostic performance (AUC = 0.93). The optimal cutoff of 17.0 kPa yielded a sensitivity of 84.2%, specificity of 100%, positive predictive value (PPV) of 100%, negative predictive value (NPV) of 66.7%, and overall accuracy of 88%.

Pairwise t-tests confirmed a statistically significant difference between PDAC and normal pancreas (p = 0.0007), with trends observed for CC vs normal (p = 0.0605) and CP vs normal (p = 0.099). No statistically significant differences were observed among solid tumor subtypes (PDAC vs CC, PDAC vs CP, CC vs CP).

Conclusion: 2D-SWE during EUS provides highly reproducible and quantitative elasticity values that reliably differentiate normal pancreas from solid pancreatic tumors. This method demonstrates excellent diagnostic performance, particularly in identifying PDAC, and shows promising trends for distinguishing CP and CC, supporting its clinical integration in EUS evaluation protocols.

Introduction: Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is the primary diagnostic tool for assessing solid pancreatic lesions. In case of pancreatic neoplasia, the time taken to obtain an accurate diagnosis is critical; therefore, it is essential to acquire an efficient histological sample. Techniques such as Rapid On-Site Evaluation (ROSE) and Macroscopic On-Site Evaluation (MOSE) may enhance the diagnostic accuracy of EUS-FNB and increase the proportion of histologically adequate samples. However, the necessity of these on-site evaluation techniques remains a topic of debate.

Aims & Methods: This study aims to determine whether these techniques should be incorporated into routine practice.

Five medical databases (PubMed, EMBASE, CENTRAL, Scopus, and Web of Science) were searched comprehensively for studies comparing the diagnostic accuracy and sample adequacy data of EUS-FNB ± ROSE and/or MOSE in solid pancreatic lesions. In the meta-analysis, pooled proportion rates with 95% confidence intervals (CIs) were calculated. The comparative analysis part of this study is still ongoing. PROSPERO registration number: CRD42024613021.

Results: Altogether, we included 4562 patients from 31 articles in our quantitative and qualitative synthesis. The pooled diagnostic accuracy and sample adequacy rate for EUS-FNB without ROSE and/or MOSE were 90% (95%CI: 86-93) and 94% (95%CI: 82-98), respectively. Using ROSE, these values were 95% (95%CI: 93-97) and 97% (95%CI: 90-99), while in the case of the MOSE technique, these values were 93% (95%CI: 92-94) and 98% (CI: 95-99), respectively. In the MOSE group, diagnostic accuracy using 22G needles was significantly higher (94% [95%CI: 92-96] vs 91% [95%CI: 89-94], [p = 0,027]) compared with other needle types.

Conclusion: In conclusion, on-site evaluation techniques may enhance diagnostic accuracy and improve EUS-FNB sample adequacy rates. The findings from the ongoing comparative analysis are crucial in determining the potential adoption of these techniques.

Disclosure: Nothing to disclose.

PP1034

IMPROVING POST-TEST PROBABILITY FOR DIAGNOSIS OF PANCREATIC DUCTAL ADENOCARCINOMA USING A MULTIMODAL ENDOSCOPIC ULTRASOUND APPROACH: A SINGLE CENTER RETROSPECTIVE STUDY INTEGRATING CONTRAST-ENHANCED ENDOSCOPIC ULTRASOUND, STRAIN RATIO ELASTOGRAPHY AND DETECTIVE FLOW IMAGING

Introduction: Pancreatic cancer is one of the most aggressive malignancies, with a poor five-year survival rate. Therefore, optimizing diagnostic strategies is a critical priority. Endoscopic ultrasound (EUS) plays a key role in characterizing focal pancreatic masses (FPM). The development of ancillary EUS techniques including contrast-enhanced EUS (CH-EUS), strain ratio elastography (SRE) and Detective Flow Imaging (DFI) has enhanced the assessment of vascularization and tissue stiffness, potentially improving the differentiation between benign and malignant lesions. Emerging evidence suggests that these parameters may provide valuable insights into the malignant potential of FPM [1,2,3].

This study evaluates whether the combined use of CH-EUS, SRE, and DFI improves diagnostic accuracy in predicting pancreatic ductal adenocarcinoma (PDAC).

Aims & Methods: Single-center, retrospective study including consecutive patients who underwent biliopancreatic EUS for FPM between October 2023 and April 2025 at the Digestive Diseases Unit of Sant'Andrea University Hospital, Rome. During EUS evaluation, CH-EUS, SRE, and DFI were performed to characterize lesions.

The final diagnosis was confirmed by histopathology (EUS fine-needle biopsy) and/or radiological workup (Computed Tomography, Magnetic Resonance Imaging, Positron Emission Tomography), with a follow-up of at least 6 months.

For CH-EUS, lesions were categorized as hypoenhanced, isoenhanced or hyperenhanced compared to surrounding parenchyma in the early arterial phase after injection of 8 mL of sulphur hexafluoride microbubbles, a second-generation ultrasound contrast agent. Hypoenhanced lesions were considered predictive of PDAC [4].

SRE was assessed using the ultrasound system's embedded software, comparing a region of interest (ROI) in the FPM with the intestinal wall. A strain ratio>10 was considered predictive of PDAC [5,6].

DFI was employed to evaluate the microvascularization, classifying lesions as hypovascular or hypervascular, with hypovascularity considered predictive of PDAC [7,8].

Results: Overall, 59 patients were included, 27 (45.8%) females, with a median age of 69 years (27–88). About lesions 37 (62.7%) were in the head, 14 (23.7%) in the body, and 8 (13.6%) in the tail, with a median diameter of 25 mm (8–63 mm).

Among these, 41 (69.5%) were PDAC, 3 (5.1%) were inflammatory lesions, 2 (3.4%) were metastasis and 13 (22%) were neuroendocrine tumors (G1-G2). CH-EUS was performed in 34 cases (57.6%), SRE in 29 (49.2%), and DFI in 37 (62.7%).

All three modalities were applied in 20 (33.9%) cases and combinations of DFI with another technique were used in 13 (22.1%).

The sensitivity, specificity, accuracy, positive predictive value (PPV) and negative predictive value (NPV) for PDAC of each modality, alone and in combination, are summarized in Table 1.

Modality	Sensitivity (%)	Specificity (%)	Accuracy (%)	PPV (%)	NPV (%)
CH-EUS (hypoenhanced)	63.2	86.7	73.5	85.7	65.0
SRE (strain ratio >10)	88.2	75.0	82.8	83.3	81.8
DFI (hypovascularization)	83.3	84.6	83.8	90.9	73.3
CH-EUS + DFI (n = 27)	62.5	90.9	74.1	90.9	62.5
SRE + DFI (n = 24)	66.7	100.0	79.2	100.0	64.3
CH-EUS + SRE + DFI (n = 20)	63.6	100.0	80.0	100.0	69.2

Table 1: Diagnostic performance of ancillary techniques and their combination for PDAC detection.

Conclusion: Multimodal approaches by using ancillary EUS techniques (CH-EUS, SRE and DFI), particularly combinations including DFI, showed a high specificity and PPV in predicting malignant FPM. Therefore, a multimodal EUS approach may improve post-test probability for PDAC.

ADEQUACY OF EUS-FNA AND FNB SAMPLES FOR GRADING PANCREATIC NEUROENDOCRINE TUMORS ≤ 20 MM: A SYSTEMATIC REVIEW AND META-ANALYSIS

F. Valverde-López[1], R. Jiménez-Rosales[1], R. Mendoza-Rodriguez[2], J.G. Martínez-Cara[1], E. Redondo-Cerezo[1]
[1]Hospital Universitario Virgen de las Nieves, Gastroenterology and Hepatology, Granada, Spain, [2]Hospital Universitario Virgen de las Nieves, Gastroenterology and Hepatology, GRANADA, Spain

Contact E-Mail Address: fcovalverde89@gmail.com

Introduction: In recent years, both the incidence and early-stage diagnosis of pancreatic neuroendocrine tumors (pNETs) have increased, likely due to advancements in cross-sectional imaging techniques (1). Management strategies are size-dependent, with observation generally preferred

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

for lesions <10 mm and surgical resection for those >20 mm. However, there is no consensus regarding the optimal approach for tumors between 10 and 20 mm, highlighting the need for multidisciplinary decision-making (2).

In this setting, endoscopic ultrasound (EUS) with fine-needle aspiration (FNA) or fine-needle biopsy (FNB) plays a crucial role not only in diagnosis but also in tumor grading (3).

However, samples obtained through EUS-FNA or FNB may not provide sufficient histological material to determine tumor grade in pNETs smaller than 20 mm. This study aims to summarize the current evidence regarding the adequacy of histological samples obtained via EUS-FNA/FNB for tumor grading.

Aims & Methods: This study followed the PRISMA guidelines for Systematic Reviews and Meta-Analyses. MEDLINE, EMBASE, and SCOPUS databases were searched up to December 2024 for studies reporting on the sample adequacy of EUS-FNA or FNB for grading pNETs ≤ 20 mm. Sample adequacy was defined as the proportion of samples in which the Ki-67 index was successfully obtained for tumor grading among all samples collected. Pooled estimates were calculated using random-effects models. Heterogeneity was assessed using the I^2 statistic. Subgroup analyses were conducted based on needle type (FNA vs. FNB).

Results: 17 studies were included, analyzing a total of 1414 patients. The pooled adequacy rate was 71.6% (95% CI: 0.592–0.841), with substantial heterogeneity across studies (I^2 = 98.69%). The risk of publication bias was considered low based on Egger's test (p = 0.162). When considering only studies that used FNA, adequacy rates were lower, with a pooled estimate of 52.5% (95% CI: 0.302–0.748; I^2 = 97.99%).

In contrast, studies employing FNB showed higher adequacy rates, with a pooled estimate of 79.8% (95% CI: 0.605–0.991), although heterogeneity remained high (I^2 = 87.32%). In this subgroup, there was also evidence of publication bias, as suggested by Egger's test (p = 0.017) and visual asymmetry in the funnel plot.

Conclusion: Our study found that EUS-FNA/FNB provides adequate histological specimens for tumor grading in pNETs < 20 mm, although significant heterogeneity was observed. As expected, FNB demonstrated considerably better performance than FNA in establishing tumor grade, suggesting it should be preferred for pNET sampling.

However, even with FNB, tumor grade could not be determined in up to 20% of cases, indicating that it remains a suboptimal tool for grading and may offer limited additional value beyond diagnostic confirmation in some patients.

Notably, our study did not distinguish between first-, second-, and third-generation FNB needles; therefore, results from newer-generation FNBs may show improved sample adequacy rates.

Furthermore, the observed heterogeneity highlights the need for studies specifically evaluating the ability of EUS-FNB to obtain high-quality tissue for grading, thereby supporting the role of EUS in clinical decision-making for these small tumors.

Introduction: Symptomatic walled-off necrosis (WON) after acute pancreatitis (AP) can be treated endoscopically through an endoscopic ultrasound (EUS) guided transmural drainage. It is still not clear whether the use of lumen-apposing metal stents (LAMSs) instead of plastic stents might lead to better clinical outcomes.

Aims & Methods: Our aim was to perform a meta-analysis of the existing randomized controlled trials (RCTs) comparing these two techniques. Following PRISMA statement after PROSPERO registration, a literature search was performed on Embase, PubMed, Scopus and Google scholar, inception date in October 2024, including only RCTs (with full-text available) directly comparing EUS-guided LAMSs vs plastic stents in the treatment of WON after AP. Exclusion criteria included studies other than RCT, not directly comparing the 2 techniques, not on humans and not in English. Quality of the studies was assessed through the Risk of Bias 2 (Rob2) tool. The primary outcome was the long-term (>1 month) clinical success. Secondary outcomes included short-term (<1 month) clinical success, technical success, total number of direct endoscopic necrosectomies (DEN), total number of interventions, need for surgery, mortality, bleeding, stent migration, procedure duration, length of hospital stay, overall adverse events, stent-related adverse events, sepsis, recurrence, percutaneous drainage (PCD) placement. A trial sequential analysis was performed to identify the required information size (RIS) for the primary outcome and for the number of DEN.

Results: A total of 3456 articles were screened, and 6 RCTs were included in the final analysis, with a total number of 352 patients, of which 177 patients in the metal stent (LAMS) group and 175 patients in the plastic stent group. Post-procedural sepsis resulted significantly lower in the metal stents (LAMS) group (RR 0.45, 0.24-0.84; p= 0.01; I^2= 0%) and procedure duration resulted significantly shorter in the metal stent (LAMS) group (mean difference -12.20, -19.30 to -5.10; p= 0.0008; I^2= 96%).

No significant differences were found in all the other primary and secondary outcomes. At trial sequential analysis, RIS for long term clinical success was 23609 patients, while RIS for DEN was 4412 patients.

Conclusion: Except for post-procedural sepsis and procedure duration, there was no difference in terms of clinical outcomes between the use of metal (LAMS) or plastic stents for EUS-guided drainage of WON. Advantages of shorter procedural duration could translate to the preferential use of metal stents in sicker, infected cohort of WON patients.

HARNESSING THE ROLE OF ENDOSCOPIC ULTRASOUND IN PEDIATRICS: A TERTIARY REFERRAL CENTER EXPERIENCE IN PAKISTAN

A. Yaseen[1], S.K. Niaz[1], N. Zakaria[1], S. Qureshi[1], S. Kadir[1]
[1]Sindh Institute of Advanced Endoscopy and Gastroenterology, Endoscopy and Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: asmayaseen97@hotmail.com

Introduction: Endoscopic ultrasound (EUS) emerged as a revolutionary intervention in gastroenterology, it has been extensively utilized among adult patients, however EUS utility in pediatric patients has remained limited due to EUS endoscope design which includes rigidity, diameter, traumatic distal tip, further more complicated by need of Monitored Anesthesia Care (MAC) or General Anesthesia (GA) for intervention which require specialized pediatric anesthesia team[i].

Fewer studies have been conducted so far regarding EUS utility, effectiveness and safety among children, most of the studies have smaller data. Recently, the European Society for Pediatric Gastroenterology Hepatology and Nutrition (ESPGHAN) and the European Society of Gastrointestinal Endoscopy (ESGE) have published joint guidelines for EUS in children which highlights the various indications for EUS in children[ii].In Pakistan, only few endoscopy centers are performing pediatric EUS.

Aims & Methods: This article aims to describe the safety along with technical and clinical success of EUS for both diagnostic and therapeutic purposes among children at a tertiary referral endoscopy center in Pakistan.

Retrospective charts review of patients ≤ 18 years of age who underwent EUS for disgnostic or therapeutic purpose over 10 years, from 2015 to 2024, at Sindh Institute of Advanced Endoscopy and Gastroenterology. This institute was initially working under Civil Hospital Karachi as Endoscopy Suite of S4 Unit. Since May 2023, it has been working as a separate endoscopy unit. This endoscopy center is a referral unit located in the largest city of Pakistan.

Results: A total of 130 patients ≤ 18 years age had EUS, the youngest was 5 years old and 54.3% were male gender. Primary indication for EUS examination included: 35 chronic pancreatitis, 39 pancreatic pseudocyst, 12 pancreatic mass, 3 biliary obstruction with suspected choledochal cyst, 2 liver biopsy, 21 gastrointestinal tract lesions, 6 lymph nodes and 12 other causes. 96 EUS were performed for diagnostic purpose, in which 20 patients underwent fine needle biopsy and 6 underwent fine needle aspiration.

Among therapeutic EUS, patients underwent 21 EUS guided pseudocyst drainage, one patient had EUS guided walled off necrosis drainage, 4 patients underwent celiac plexus block referred for pain management of chronic pancreatitis,one patient underwent EUS guided pancreatic duct cannulation and stent placement and one patient had EUS guided randezvous procedure. All therapeutic procedures were performed under general anesthesia whereas diagnostic EUS were performed under monitored anesthesia care. No immediate or early complications were seen.

Conclusion: In this modern era of advanced diagnostic tools and minimally invasive interventions, EUS related procedures are safe and effective in pediatric group of patients too. However, this procedure should be standardized and performed at centers with trained endoscopists and an experienced pediatric anesthesia team.

PREDICTING EUS-FNB ADEQUACY WITH VISUAL ON-SITE EVALUATION (VOSE): TOWARD SMARTER PANCREATIC BIOPSIES

O. Nacir[1,2], F.E. Lairani[1,2], A. Ait Errami[1,2], S. Oubaha[1,3], Z. Samlani[1], K. Krati[1,2]
[1]Mohammed VI University Hospital, Department of GastroEnterology and Hepatology, Marrakech, Morocco, [2]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Biosciences and Health Laboratory, Marrakech, Morocco, [3]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Department of Physiology, Marrakech, Morocco

Contact E-Mail Address: o.nacir@uca.ac.ma

Introduction: Endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) is widely recognized as the preferred diagnostic method for pancreatic lesions, achieving diagnostic accuracy rates between 78% and 95%. Rapid on-site evaluation (ROSE) improves adequacy rates but remains unavailable in many centers. In this context, we evaluated a simplified method, Visual On-Site Evaluation (VOSE), based on macroscopic evaluation of the biopsy sample, to predict histo-cytological adequacy without needing ROSE.

Primary aim: assess the accuracy of VOSE in predicting sample adequacy. Secondary aims: evaluate the diagnostic yield of FNB and the potential reduction in unnecessary needle passes.

Aims & Methods: This prospective single-center study enrolled patients undergoing EUS-FNB for pancreatic lesions between January 2020 and February 2024.

VOSE parameters included the presence of a macroscopic visible core (MVC), number of specimens, and specimen length. Associations between VOSE findings and final histo-cytological adequacy were analyzed using Fisher's exact test and Student's t-test. A p-value < 0.05 was considered statistically significant. Study conducted at a university hospital center.

Results: Fifty-nine patients (57.6% male; mean age 67.9 ± 9.8 years) were included, contributing to a total of 59 pancreatic lesions. Across 218 passes performed, the overall sample adequacy rate was 91.5%.

Adequacy was significantly higher when using 22-G needles compared to 25-G needles (95.7% vs. 86.2%, p = 0.018). VOSE criteria (presence of MVC, multiple fragments, and long specimen) demonstrated a sensitivity of 52.3%, a specificity of 61.1%, and a positive predictive value (PPV) of 93.1% for predicting sample adequacy. Applying VOSE led to a 45% reduction in unnecessary additional passes.

Conclusion: EUS-FNB provides excellent diagnostic adequacy for pancreatic lesions, particularly with 22-G needles. The use of VOSE, a simple and reproducible macroscopic evaluation method, can reliably predict histo-cytological adequacy and substantially reduce the number of passes, offering a practical alternative in centers without ROSE availability.

Introduction: Pancreatic fibrosis (PF), a pathological hallmark of chronic pancreatitis, serves as a critical mediator in the progression of numerous pancreatic disorders. Early identification of fibrotic changes presents a strategic opportunity to intervene in disease pathways, potentially curbing the advancement of pancreatic pathologies. It makes research of non-invasive radiological PF assessment perspective.
Aims & Methods: Aim of our study was to evaluate the possibility of multidetector computed tomography (MDCT) post-processing parameters in PF grade assessment.
Methods. Results of contrast-enhanced 128-row MDCT from 165 patients (mean age 57.9±13.5) who underwent surgery from April 2022 to February 2024 due to pancreatic tumors and advanced chronic pancreatitis were analyzed. We calculated contrast enhancement ratio (CR) between venous phase (VP) and non-contrast MDCT, and normalized CR (NCR) during the pancreatic phase (PP) and VP, also we measured pancreas attenuation during MDCT examination. PF morphological grade was assessed according to Klöppel & Maillet's scoring system [1] and scaled into three grades: mild, moderate and severe PF.
This study was conducted within the healthcare research project "Assessment of pancreatic fibrosis as a prognostic factor for its diseases course" funded by Autonomous non-profit organization "Moscow Center for Innovative Technologies in Healthcare" administered by the Moscow Healthcare Department.
Results: The values of post-processing CT results were compared in groups with different degrees of PF. Mean CR were significantly higher (p=0.001) in patients with severe PF (CR 1.16±0.65 HU) than in patients with mild PF (CR 0.78±0.31 HU). CR significant increase (p=0.03) was found in patients with signs of inflammatory changes in the pancreas tissue (CR 1.14±0.6 HU) than in those without them (CR 0.81±0.3 HU). There were no significant differences between the NCRPP and NCRVP, and the degree of PF, which we had shown in publications of our preliminary results. We suppose the main reason of this fact is study groups enlargement as well as measurement technique improvement, led to results clarification.
Conclusion: The CR value increased in patients with severe degree of PF and decreased in patients with mild PF. Also, there was a significant relation between CR increase and presence of early signs of pancreatic inflammatory changes. Thus, there was a relationship between MDCT post-processing results and morphological signs of PF, which can be used for pancreatic fibrosis non-invasive diagnosis and identification of additional signs of early chronic pancreatitis.

PANCREATIC STEATOSIS AND EXOCRINE PANCREATIC INSUFFICIENCY: A SYSTEMATIC REVIEW AND META-ANALYSIS

B. Cerbino[1], M. Tomé[2]
[1]Pró-Cardíaco Hospital, 22030040, Brazil, [2]Federal University of Campina Grande, Cajazeiras, Brazil

Contact E-Mail Address: brunacerbino@yahoo.com.br
Introduction:
Pancreatic steatosis (PS) has been increasingly recognized and associated with some relevant metabolic implications. However, data on its correlation with exocrine pancreatic function remain limited. We conducted a systematic review and meta-analysis to evaluate whether PS is associated with exocrine pancreatic insufficiency (EPI).
Aims & Methods: This study aimed to investigate whether imaging-detected PS is related to exocrine pancreatic dysfunction, assessed by fecal elastase-1 (FE-1) levels. We searched PubMed, EMBASE, and Cochrane Central for studies including adults with and without PS identified on imaging, and reporting FE-1 concentrations. Data were pooled using random-effects models.
Results: Three studies evaluating a total of 1,864 patients were included. Fecal elastase levels were significantly lower in patients with PS compared to controls, indicating worse exocrine pancreatic function in this group (MD -199.78; 95% CI -303.66 to -95.91; $p < 0.05$; $I^2 = 97\%$). Moreover, PS was associated with a significantly increased risk of exocrine pancreatic insufficiency (RR 3.13; 95% CI 1.17–8.40; $p = 0.023$; $I^2 = 81\%$), reinforcing the link between fat accumulation in the pancreas and impaired exocrine function.
Conclusion: This meta-analysis demonstrates a significant association between PS and impaired pancreatic exocrine function, compared to individuals without known pancreas disease. These findings underscore the importance of a comprehensive metabolic assessment in patients with PS, given its potential role in pancreatic dysfunction.

STENT CHOICE IN EUS-GUIDED DRAINAGE OF WALLED-OFF NECROSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE RANDOMIZED CONTROL TRIALS

H. Khizar[1], H. Zhou[2], J. Yang[3]
[1]The Fourth Affiliated Hospital of School of Medicine, and International School of Medicine, International Institutes of Medicine, Zhejiang University, Surgery, Yiwu, China, [2]Hangzhou First People Hospital, Department of Gastroenterology, Hangzhou, China, [3]Hangzhou First People's Hospital, Gastroenterology, Hangzhou, China

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: Safe and effective treatment of walled-off necrosis (WON) is challenging. Plastic stents (PS) and lumen-apposing metal stents (LAMS) have been used for endoscopic ultrasound-guided (EUS-guided) drainage of WON. This study evaluated LAMS and DPS results.

Aims & Methods: A database search was conducted until March 2024, and studies which met the criteria were selected. We assessed technical and clinical efficacy and other secondary outcomes using the RevMan software.

Results: The final analysis included five randomized control trials (RCTs), involving a total of 318 patients (161 in the LAMS and 157 in the PS group). There was no indication of any risk of bias and basic characteristics of the patients between the two group. The risk ratio (RR) for technical and clinical success were 1.00 (95% confidence interval (95%CI 0.97, 1.03) and 1.04 (95%CI 0.93, 1.16), respectively, indicating no significant difference ($p > 0.05$) between the two groups.

There was a significant difference in procedure time of -20.23 minutes (95% CI -31.61, -8.85) and the number of procedures sessions by -0.01 (95%CI -0.51, 0.48). However, there was no significant difference in hospital stay of 1.38 days (95% CI -5.57, 8.33) and adverse events (RR 0.79, 95%CI 0.43, 1.46).

Conclusion: There is no significant difference in the clinical efficacy and safety of PS and LAMS for treating patients with WON.

Disclosure: Nothing to disclose.

Introduction: Pancreatic fluid collections (PFCs) are significant local complications that can arise from acute pancreatitis, and its management often involves drainage, although the benefits of metal stents over plastic stents remain uncertain.

This meta-analysis compared the efficacy and safety of metal stents versus plastic stents for endoscopic ultrasound (EUS)-guided drainage of PFCs.

Aims & Methods: We searched PubMed, Embase, and Cochrane Library for randomized controlled trials (RCTs) comparing metal with plastic stents for drainage of PFCs. The odds ratio (OR) was used for binary outcomes and the mean difference (MD) for continuous outcomes with their respective 95% confidence interval (CI).

Results: This study included eight RCTs and over 500 patients. Procedure duration was shorter in the metal stent arm compared with the plastic stent arm (MD -10.63; 95%CI -16.12 to -5.15, $p<0.001$). However, there was no statistically significant difference between metal and plastic stents in clinical success ($p=0.78$), technical success ($p=0.65$), overall mortality ($p=0.48$), recurrence ($p=0.23$), number of interventions ($p=0.85$), need of necrosectomy ($p=0.35$), need of surgery ($p=0.35$), length of hospitalization ($p=0.86$), exocrine insufficiency ($p=0.54$), endocrine insufficiency ($p=0.77$), and AEs ($p=0.36$).

Conclusion: Metal stents for EUS-guided drainage of PFCs are associated with a shorter procedure duration. Besides that, it did not improve other clinically relevant outcomes in comparison with plastic stents.

Disclosure: Nothing to disclose.

A SYSTEMATIC REVIEW ON THE SAFETY AND EFFICACY OF CHOLECYSTECTOMY - DURING PREGNANCY IN THE CONTEXT OF ACUTE PANCREATITIS

T. Haziri[1]
[1]Klinika E Gastroenterologjise, Gastroenterology Resident, Prishtine, Kosovo

Contact E-Mail Address: taibe_haziri@hotmail.com

Introduction: Acute pancreatitis (AP) during pregnancy is a rare but potentially life-threatening condition for both mother and fetus. The most common cause is gallstone disease, followed by hypertriglyceridemia and, less frequently, alcohol use. The physiological changes of pregnancy can mask the clinical presentation, delaying diagnosis and intervention. This review aims to synthesize current evidence on the diagnosis, management, and maternal-fetal outcomes of AP in pregnancy, with special attention to the role and timing of cholecystectomy during an acute episode.

Aims & Methods: A comprehensive literature search was conducted using PubMed, Scopus, and the Cochrane Library for studies published between 2000 and 2024. Inclusion criteria involved clinical trials, cohort studies, systematic reviews, and relevant guidelines discussing AP in pregnancy and cholecystectomy

Results: The majority of AP cases in pregnancy occur in the third trimester or early postpartum period. Gallstones account for 65–100% of cases. Conservative management remains the first-line approach, particularly in the first trimester. However, recurrence rates up to 70% with conservative therapy alone have prompted a reevaluation of surgical timing. Recent studies support the safety of cholecystectomy during the second trimester and even during stabilized mild to moderate AP. In the third trimester, ERCP with endoscopic biliary sphincterotomy is preferred, with cholecystectomy deferred postpartum. Multidisciplinary management has significantly improved maternal and neonatal outcomes in recent years.

Conclusion: Acute pancreatitis in pregnancy remains a rare but serious condition requiring timely diagnosis and multidisciplinary care. Recent innovations support the safety and efficacy of cholecystectomy laparascopyce during the second trimester and even in selected stabilized cases

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Introduction: Pancreatic necrosis is a devastating disease that leads to a high mortality and morbidity rates. Necrosectomy is the golf standart treatment for infected pancreatic necrosis. Percutaneous and endoscopic approaches has been widely accepted in selected cases. Endoscopic necrosectomy in early complicated pancreatic necrosis were performed as a first intent to treat and retrospectively evaluated regarding to morbidity, efficacy, recurrence and length of hospital stay.

Aims & Methods: Report our experience on endoscopic manage of pancreatic necrosis using a daily transmural and transpapillary drainage in 25 patients.

Records of all patients who underwent EN from January 2023 to January 2025 Endoscopic manage of acute pancreatic necrosis using a daily transmural and transpapillary drainage in 25 patients. The Apache classification and CCT score is used. Diagnostic ERP to search communications between pancreatic duct and the collection were performed in selective cases and in cases that communication exists; prothesis can be inserted through the minor or major papilla to plug it. The transmural drainage was performed in 25 patients (05 Duodenal and 20 gastric) and transpapillary and transmural in 07 patients, after identification of the most proeminent or bulging part of the stomach or duodenum. All patients were followed with CT scans, IRM to ensure clinical resolution.

Results: 25 patients (14 women, 09 men) could be treated. The Apache classification is used 0 a 9 score in 14 patients (56,%) and 11 (44%), CT severity index was 30-50% in 05, > 50% in 20. Pancreatic necrosis were located in the pancreatic head in 03 patients, the head/body in 02, body in 6, body/tail 04, head/body/tail 10. ERP demonstrated the ductal communication of the colection with the main pancreatic duct in 07 patients, rupture in 03, disconnect syndrome in 03 and normal in 02. Drainage was successful in 25 (100%). 07 (28%) combined treatment (transpapillary and transmural), 18 (72%) transmural. The median number of endoscopic session for each patients was 4 (range 2 to 8). The median hospital stay for in the all patients was only endoscopic therapy was 9. The range follow –up was 18 months (range 6 to 24) with mean number of ERCPs was 4 (range 2 to 8). Two patients required concurrent radiology procedure, recurrence of fluid collection (n=1), flank abscess (n=1). There were 2 (16,6%) pseudocyst recurrences during this period, and were managed clinically and/or endoscopically. There was no mortality related to the procedure.

Conclusion: The early and aggressive endoscopic treatment with daily necrosectomy can be performed and show promising results same in early complications of pancreatic necrosis. Combined approaches with radiology and conventional surgery can also be applied in selected cases.

Disclosure: No conflict of interest.

LENTINAN PROTECTS AGAINST ACUTE PANCREATITIS IN AN ATP CITRATE LYASE-DEPENDENT MANNER

Y. Hong[1,2], X. Yan[1,2], Q. Ding[1,2], S. Weng[1,2], Z. Zhang[1,2]
[1]The First Affiliated Hospital of Fujian Medical University, Department of Hepatopancreatobiliary Surgery, Fuzhou, China, [2]The First Affiliated Hospital of Fujian Medical University, Fujian Abdominal Surgery Research Institute, Fuzhou, China

Contact E-Mail Address: hongyupu@fjmu.edu.cn

Introduction: Acute pancreatitis (AP) is a common acute inflammatory disease of the abdomen. ATP citrate lyase (ACLY) has been shown to play a critical role in mitigating acute pancreatitis-associated injury. Lentinan, a multifunctional polysaccharide derived from shiitake mushrooms, exhibits biological activities such as anti-inflammatory, antioxidant, and immunomodulatory effects, and is widely used in clinical settings. However, the role of Lentinan in acute pancreatitis remains unclear.

Aims & Methods: This study aimed to investigate the protective effects of Lentinan against acute pancreatitis and whether this protection depends on ATP citrate lyase. Adult healthy male C57BL/6 mice were randomly divided into control group, acute pancreatitis group, and Lentinan + acute pancreatitis group. The cerulein-LPS induced AP model was established by intraperitoneal injection of cerulein solution (100 μg/kg body weight) 10 times at hourly intervals, followed by a single injection of lipopolysaccharide (5 mg/kg) immediately after the last cerulein injection. In the lentinan + acute pancreatitis group, mice were pretreated with intraperitoneal injections of of Lentinan solution (50 mg/kg, 100 mg/kg, or 200 mg/kg) for three consecutive days before AP induction.

The severity of pancreatitis was assessed by comparing plasma activities of amylase, lipase, alanine aminotransferase, aspartate aminotransferase, and plasma levels of urea, and creatinine, as well as pancreatic histopathological scores.

Systemic inflammatory response was evaluated by measuring plasma IL-1β and TNF-α levels through enzyme-linked immunosorbent assay. Pancreatic infiltration of macrophages and neutrophils was detected by immunofluorescence, and protein levels of ACLY, NLRP3, and IL-1β in

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pancreatic tissues were measured by Western blot. To further validate the critical role of ACLY, AP was induced in mice with pancreas-specific ACLY knockout, with Lentinan pretreatment.

Results: Lentinan significantly alleviated pancreatic histopathological damage caused by AP, including edema, necrosis, and inflammatory cell infiltration. It also reduced plasma aminotransferase activity, creatinine, and urea levels, but did not significantly decrease plasma amylase or lipase activity. A higher dose of Lentinan (200 mg/kg) was less effective than lower doses in reducing plasma aminotransferase, creatinine, and urea in AP mice, possibly due to greater hepatorenal toxicity. Therefore, a moderate dose of Lentinan (100 mg/kg) provided effective protection against acute pancreatitis and was therefore selected for subsequent experiments.

Additionally, Lentinan reduced pancreatic infiltration of macrophages and neutrophils, decreased plasma pro-inflammatory cytokine levels, upregulated pancreatic ACLY protein expression, and downregulated the levels of NLRP3 inflammasome and IL-1β proteins in pancreatic tissues. In mice with pancreas-specific ACLY knockout, both local pancreatic injury and systemic inflammation caused by AP were significantly exacerbated, and the protective effect of Lentinan against acute pancreatitis was diminished.

Conclusion: Lentinan exerts protective effects against acute pancreatitis by improving local and systemic inflammatory responses. The expression of pancreatic ACLY is indispensable for mediating this protective effect, which was partially achieved through the inhibition of the NLRP3 inflammasome pathway. The present study establishes a novel mechanism for this clinically available immunomodulator, which could have potential therapeutic implications in acute pancreatitis.

SIMPLE ELECTROLYTE SCORING SYSTEM FOR PREDICTING DISEASE PROGRESSION IN ACUTE PANCREATITIS PATIENTS : A RETROSPECTIVE STUDY

Y. Lei[1], X. Li[1], Y. Zou[1], S. Chen[1], Y. Zhu[1]
[1]The First Affiliated Hospital of Nanchang University, Digestive Department, Nanchang, China

Contact E-Mail Address: zouyaoyu1997@163.com

Introduction: Acute pancreatitis (AP) is closely intricately linked to electrolyte disturbances. Such imbalances can exacerbate the instability of the intracellular environment, subsequently accelerating the progression of AP. This study aimed primarily to develop a simplified electrolyte scoring system (CC score) to determine AP exacerbation.

Aims & Methods: A new CC score was established in this study using the Medical Information Mart for Intensive Care IV (MIMIC-IV) v3.1 database, and it was validated using the digestive department database of the First Affiliated Hospital of Nanchang University. The primary endpoint considered was the exacerbation of the disease post-admission in AP patients. Receiver operating characteristic (ROC) curves and decision curve analysis (DCA) plots were used to assess the predictive value and clinical applicability of the new CC score. Improvements were implemented on the acute physiology and chronic health evaluation II (APACHE II) and systemic inflammatory response syndrome (SIRS) scoring systems, and their performance was compared with that of traditional predictive scoring systems.

Results: This study incorporates data from 1413 AP patients drawn from the MIMIC-IV database, supplemented by a further 1040 AP patients in an external validation group. Of these, 178 and 70 AP patients were respectively transferred to the Intensive Care Unit (ICU). The multivariate adjustment model indicates that a significant negative correlation between serum Ca^{2+} levels and severe progression in AP patients, while serum Cl^- levels showed a J-shaped association with severe progression. Through node analysis of the restricted cubic splines (RCS) model, combined with the clinical grading standards for hyperchloremia and hypocalcemia, the critical values for Cl^- and Ca^{2+} were determined to be 110 mmol/L and 1.77 and 2.1 mmol/L, respectively.

Based on these findings, we established a new CC score and optimized the APACHE II and SIRS scoring systems. The results indicated that the predictive power of the optimized APACHE II score (AUC=0.83) and SIRS score (AUC=0.87) for severe progression in AP patients surpassed that of the original APACHE II score (AUC=0.74) and SIRS score (AUC=0.71).

Conclusion: The new CC score not only effectively predicts the risk of severe progression in AP patients but also enhances the predictive performance of both SIRS and APACHE II scores for assessing severe progression risk in these patients.

COMPARISON OF USING LUMEN-APPOSING METAL STENTS VERSUS PLASTIC STENTS FOR DRAINAGE OF PANCREATIC WALLED-OFF NECROSIS ： A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Y. Lei[1], S. Xiong[1], J. Wan[1], Y. Zou[1], Y. Zhu[1]

Introduction: In the late stage of acute pancreatitis, the occurrence of pancreatic walled-off necrosis (WON) can be life-threatening, especially in the presence of infection. EUS-guided transgastric drainage is currently a minimally invasive treatment modality for the clinical treatment of WON. However, there is no consensus in international guidelines on the choice between lumen-apposing metal stents (LAMS) and traditional double-pigtail plastic stents (DPT).

Aims & Methods: Objective To investigate the differences in drainage effectiveness and complications among different stents, we included currently published randomized controlled trials (RCTs) for a meta-analysis. Methods We systematically searched the PubMed, Embase, and Cochrane Library databases for studies published between 1 January 2010 to 1 March 2023, and updated the search on March 1, 2025. The observed indicators included: primary outcome indicators (clinical success rate, re-intervention), other observation indicators (total adverse events, mortality, adverse events, procedural duration). Binary variables were analyzed using relative risk (RR) and 95% CI, while continuous variables were analyzed using mean difference (MD). The selection of a random effects model or fixed effects model depended on the situation.

Results: Six RCTs with a total of 325 patients were included for analysis, with 177 patients in the LAMS group and 175 patients in the DPT group. There was similar in the primary outcome indicators of clinical success rate (RR=1.05; 95% CI 0.93 - 1.17; *P*=0.46), the number of patients requiring debridement of necrotic tissue (RR=0.95; 95% CI 0.62 - 1.47; *P*=0.83), and percutaneous drainage (RR=0.98; 95% CI 0.27 - 3.5; *P*=0.97).

There were also no significant differences in terms of mortality rate (RR=0.86; 95% CI 0.32 - 2.33; *P*=0.77), total adverse events (RR=0.87; 95% CI 0.59 - 1.29; *P*=0.48), adverse events related to bleeding (RR=1.48; 95% CI 0.67 - 3.28; *P*=0.34), procedural time (MD=-9.44; 95% CI, -15.27 - -3.61, *P*=0.002).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In comparison to DPT, LAMS could shorten procedural duration. However, there was no significant difference clinical success rate, re-intervention and adverse events. Therefore, future studies with large samples and high quality are needed for further confirmation.
Meanwhile, due to the high heterogeneity among studies, conclusions should be considered with caution. Clinicians need to make the most suitable treatment decisions based on the actual situation to ensure patients get the best treatment effect and prognosis.

THE ROLE AND UPTAKE OF DRUG AND ALCOHOL SERVICES AMONG PATIENTS WITH ALCOHOL-ASSOCIATED ACUTE PANCREATITIS ADMITTED TO A TERTIARY HEALTH SERVICE

C. Ho[1], A. Mitropoulos[1], J. Tse[1], B. Xia[1], B. McLeod[1], O. Slifirski[1], D. Jacka[2], S. Hew[1]
[1]Monash Health, Gastroenterology and Hepatology, Melbourne, Australia, [2]Monash Health, Addiction Medicine Unit, Melbourne, Australia

Contact E-Mail Address: cindyhalanho@gmail.com
Introduction: Alcohol is a common cause of acute pancreatitis, and ongoing consumption increases the risk of recurrent episodes. There are no international guidelines to direct behavioural or pharmacological interventions to reduce recurrence of alcohol-associated acute pancreatitis (AAP). Studies exploring the role of addiction medicine in patients with AAP are limited.
Aims & Methods: This study describes the uptake and role of the Addiction Medicine Unit (AMU), a specialist consultative service, in patients admitted with AAP. We conducted a retrospective cohort study including all inpatients diagnosed with AAP at a large multisite tertiary health service in Melbourne, Australia between May 2022 to May 2024. Patient demographics, diagnosis of alcohol use disorder (AUD) and pharmacological and non-pharmacological interventions provided by the AMU were obtained from the patient's medical records.
Results: A total of 231 patients with 314 admissions with AAP were identified. Most were males (77.9%) with a median age of 44 years (IQR 21), with median bedside index of severity in acute pancreatitis (BISAP) score of 1 (IQR 1). Of the patients, 35 (11.1%) had necrotising pancreatitis, 30 (9.6%) required admission to the intensive care unit (ICU), and 1 patient died from AAP. The prevalence of AUD was 82.3%. Referral to the AMU occurred in 56.7% of admissions, predominantly among those with AUD (87.6%).
Patients referred to the AMU had a higher median number of standard drinks per week (70 standards, range 6-385 standards) compared to those who were not referred (49 standards, range 1-301 standards) (p=0.024). The AMU recommended outpatient services alone in 40.4%, both pharmacological and outpatient interventions in 37.6%, and medications alone in 21.9%.
Outpatient services included either a service for community-based assessment and counselling (86.4%), residential rehabilitation programs and/or detox services (5.8%), follow up in the AMU outpatient clinic (3.9%) or a combination of these outpatient services (3.9%). There were 137 (43.6%) admissions in which patients were commenced on medications for AUD.
Topiramate (42.6%), and naltrexone (42.6%) were the most prescribed pharmacological agents by the AMU, followed by baclofen (9.8%), acamprosate (4.1%) and disulfiram (0.8%). Over the 2-year period, 54 (23.4%) were readmitted with AAP. Most patients were not readmitted within 30 days of discharge (73.2%) however there were 33 (10.5%) patients readmitted for pancreatitis or pancreatitis-related complications including pain or infection, and 18 (5.7%) readmitted to hospital for non-pancreatitis related reasons. Patients who were older (median 49 years) were more likely to be readmitted with AAP compared to those who were younger (median age 43 years) across the study period (p=0.05). There were six patients re-admitted with AAP with their index admission deemed related to an alcoholic binge without suspected underlying AUD. Of these six patients, only two were referred and reviewed by the AMU, with the other four patients not referred.
Conclusion: Our study highlights the critical role of the AMU in managing AAP, particularly given the high prevalence of concurrent AUD in this population. Despite this, significant gaps remain in screening for AUD and initiating referrals, resulting in only half of AAP patients being referred.
Considering the substantial morbidity and healthcare cost associated with alcohol, efforts to improve referral practices during index admissions may be key to reduce readmissions for AAP and improve patient outcomes.
Disclosure: Nothing to disclose.

UNDER-RECOGNIZED BURDEN OF HYPERTRIGLYCERIDEMIA-INDUCED ACUTE PANCREATITIS: A RETROSPECTIVE SINGLE-CENTER ANALYSIS AND THERAPEUTIC OUTCOMES

F. Dakhlalaa[1], M.S. Alkhatry[2], B. Almasri[3], L. Kadir[1], K. Yadav[4]
[1]IBHO EHS UAE, Medical Gastroenterology Unit, Ras Alkhaimah, United Arab Emirates, [2]IBHOH, Dept. of Gastroenterology, Ras Al-Khiemah, United Arab Emirates, [3]IBHO EHS UAE, GI Endoscopy Department, Ras Alkhaimah, United Arab Emirates, [4]IBHO, RAS ALKHIAMAH, United Arab Emirates

Contact E-Mail Address: fedadakhlala@yahoo.com
Introduction: Hypertriglyceridemia (HTG) is an underdiagnosed etiology of acute pancreatitis (AP), traditionally reported in 1–7% of cases. However, emerging evidence suggests that its true prevalence may be significantly higher. Prompt identification and effective management of HTG-induced AP are essential, yet standardized treatment approaches remain limited.
This study aimed to assess the prevalence of HTG-induced AP and evaluate insulin infusion as a first-line therapeutic strategy.
Aims & Methods: We retrospectively analyzed 200 adult patients admitted with AP at [Hospital Name] between January 2023 and December 2024. Patients with serum triglyceride levels ≥11.3 mmol/L (≥1000 mg/dL) and no other identifiable causes of AP (e.g., gallstones, alcohol use) were included. Demographic data, comorbidities, treatment modalities, and outcomes were reviewed. A favorable response to insulin therapy was defined as a ≥50% reduction in serum triglyceride levels within 72 hours. Statistical analysis was performed using SPSS; p<0.05 was considered statistically significant.
Results: HTG was identified as the primary cause of AP in 40 out of 200 patients (20%). Among these, 60% had type 2 diabetes mellitus, 50% were obese (BMI ≥30 kg/m^2), and 35% reported regular alcohol use. All patients were initiated on insulin infusion. Thirty-four patients (85%) responded favorably, while six (15%) required plasmapheresis. The mean hospital stay was significantly shorter in the insulin-only group compared to those requiring plasmapheresis (5 vs. 8 days, p<0.01), with a lower complication rate as well (10% vs. 25%, p<0.05). No in-hospital mortality occurred.
Conclusion: HTG-induced AP may be substantially more prevalent than previously recognized. Routine triglyceride screening should be considered in AP cases with no obvious cause. Insulin infusion is a safe, effective, and widely accessible first-line therapy that may reduce complica-

Introduction: Abdominal pain is a prominent symptom in acute pancreatitis (AP) and has been linked to disease severity.

Aims & Methods: We aimed to examine associations between pain intensity and the outcome of AP and the discriminatory ability of pain intensity to predict these outcomes. For this, we conducted a post-hoc analysis using data from the PAINAP database of patients admitted with AP across 118 centres in 27 countries. Based on the pain intensity on admission using a numeric rating scale (NRS) of 0 to 10, patients were categorised as having no/mild (NRS 0-3), moderate (NRS 4-6) or severe pain (NRS 7-10). Demographic details and AP outcomes were compared across these three groups, and associations were explored using multivariable regression analyses.

Finally, the influence of pain intensity on the probability of AP outcomes was assessed by calculating AUC-ROCs, sensitivity, specificity, positive/negative predictive values, and likelihood ratios.

Results: We included 1,727 patients, of whom 183 (11%) reported no/mild pain, 503 (29%) moderate pain, and 1,041 (60%) severe pain. Severe pain was associated with more severe AP (OR 1.66 (95% confidence interval (95%CI), 1.09-2.52), P=0.02), renal failure (OR 3.04 (95%CI, 1.35-6.87) and pancreatic necrosis (OR 2.37 (95%CI, 1.22-4.59), P=0.01) compared to no/mild pain. Severe pain had a low discriminatory ability for predicting outcomes of AP, with AUC-ROCs ranging from 0.53 to 0.61.The sensitivity was moderate for all outcomes, with the highest value (81% (95%CI, 72-88)) for renal failure. The specificity was lower across all outcomes, ranging from 41 to 42%. Positive predictive values were low (9-30%), whereas negative predictive values were higher (77-97%). The highest negative predictive value was observed for renal failure. Pain intensity (cutoff NRS ≥ 7) did not affect the post-test probability of outcomes compared to pre-test probability, suggesting that pain intensity alone is insufficient for evaluating prognosis in AP.

Conclusion: Pain intensity was associated with worse outcomes in AP, but the discriminatory performance of pain intensity for predicting AP outcomes was poor. Future research is warranted to refine the assessment of AP pain and clarify the underlying mechanisms. A more comprehensive understanding of pain in AP could improve its prognostic value, guide more personalised treatment strategies, and optimise pain management.

A TRANSFORMER-BASED PREDICTION MODEL FOR ACUTE PANCREATITIS SEVERITY

J. Cao[1], Y. Liu[1], H. Liu[1]

[1]The Second Affiliated Hospital of Guilin Medical University, Gastroenterology, Guilin, China

Contact E-Mail Address: lskacj2018@163.com

Introduction: Acute pancreatitis (AP) is a common gastrointestinal disorder with significant morbidity and mortality, particularly in severe cases (SAP). Early prediction of SAP is crucial for timely intervention and improved patient outcomes. Traditional scoring systems like Ranson, BISAP, and APACHE II have limitations in accuracy and timeliness.

Machine learning (ML) has shown promise in enhancing SAP prediction, but the potential of advanced architectures like Transformer models remains unexplored. This study aims to develop a Transformer-based model for SAP prediction and compare its performance with traditional ML methods.

Aims & Methods: The primary aim of this study was to develop a Transformer-based prediction model for acute pancreatitis severity and evaluate its performance compared to traditional machine learning models. Retrospective data from 722 AP patients admitted to the Second Affiliated Hospital of Guilin Medical University between January 2020 and June 2024 were analyzed. Patient data included 24-hour admission laboratory indicators such as electrolytes, liver function, renal function, and inflammatory markers.

To construct the prediction model, a comprehensive workflow was designed. Data preprocessing involved feature vectorization using One-Hot encoding, missing value imputation using the K-Nearest Neighbor (KNN) algorithm, normalization of feature values to a [0, 1] range, and handling class imbalance using Synthetic Minority Over-Sampling Technique (SMOTE).

Feature selection was performed by dividing patients into SAP and MAP groups, identifying features with significant differences using non-parametric tests, and ranking features by their relevance through correlation analysis. Features causing a decline in AUC during incremental addition were removed to optimize the feature set.

The Transformer model, leveraging self-attention mechanisms to process sequential data, was trained alongside traditional ML models (Logistic Regression, Decision Tree, Random Forest, and XGBoost). Five-fold cross-validation was used to prevent overfitting, and model performance

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

was evaluated using metrics such as AUC, accuracy, precision, recall, F1 score, and specificity. SHAP analysis was employed to interpret the Transformer model's predictions, providing insights into the contribution of each feature to the model's output.

Results: The Transformer model outperformed traditional ML models (Table 1), achieving an AUC of 0.9662 and exceeding 0.90 in all metrics. It maintained robust performance even with minimal training data (AUC: 0.8437 at 5% training). SHAP analysis highlighted key predictors (calcium, amylase, basophil percentage, CO2 binding capacity), aligning with clinical relevance.

Model	AUC	Accuracy	Precision	Recall	F1 Score	Specificity
Transformer	0.9662	0.9028	0.9095	0.9004	0.9047	0.9059
Random Forest	0.9224	0.8433	0.8788	0.8056	0.8406	0.8830
XGBoost	0.9075	0.8034	0.8033	0.8167	0.8099	0.7895
Logistic Regression	0.8910	0.8405	0.8780	0.8000	0.8372	0.8830
Decision Tree	0.8684	0.8433	0.8655	0.8222	0.8433	0.8655

Table 1. Performance metrics comparison of different models.

Conclusion: The Transformer model demonstrated superior accuracy, generalizability, and interpretability for SAP prediction, particularly in small datasets. Its clinical utility is enhanced by SHAP-driven insights into key predictors. Retrospective design limits prospective validity; future work should validate the model in larger cohorts and integrate additional biomarkers. This study supports the potential of transformer in medical prediction to improve patient outcomes through timely interventions.

Introduction: Sphincter of Oddi dysfunction (SOD) is considered one of the possible underlying causes of unexplained biliary pain and idiopathic acute pancreatitis. According to the Rome IV criteria, sphincter of Oddi manometry (SOM) is required for the diagnosis of pancreatic-type SOD (PSOD); however, SOM is highly invasive and carries a significant risk of post-procedural pancreatitis. Therefore, a non-invasive and simple method to evaluate sphincter (papillary) pressure is critically needed. We hypothesized that cine-dynamic magnetic resonance cholangiopancreatography (MRCP) may serve as a useful tool for the functional assessment of papillary pressure in patients with suspected SOD.

Aims & Methods: In this prospective observational study, cine-dynamic MRCP was performed on 40 subjects: 10 healthy controls, 7 with suspected biliary-type SOD (BSOD), and 12 with suspected PSOD. Eleven additional cases were excluded for not meeting the Rome IV criteria for SOD. Cine-dynamic MRCP involved generating a 2D MRCP image and applying a 20 mm spatially selective inversion recovery (IR) pulse to suppress water signals at the level of the Sphincter of Oddi. Sequential images (20 frames over 5 minutes) were obtained to visualize the dynamic inflow of bile and pancreatic juice. Two quantitative indices were evaluated: the frequency of inflow events and the secretion grade of bile or pancreatic juice. The secretion grade was defined based on the distance that the fluid moved within the common bile duct or main pancreatic duct, using a standardized 5-point scale. A subset of patients underwent EST, and changes in MRCP parameters were compared before and after the procedure.

Results: Bile flow frequency (times; median [range]) was significantly reduced in both the BSOD group (2 [1–17]; p = 0.006) and the PSOD group (8 [3–14]; p = 0.008), compared with controls (13.5 [6–19]).The secretion grade of bile flow (median [range]) was also significantly lower in the BSOD group (0.2 [0.1–1.3]; p = 0.012) and PSOD group (0.5 [0.15–1.75]; p = 0.021), compared with controls (1.6 [0.3–2.05]).

For pancreatic juice flow, frequency was significantly lower in the PSOD group (9.5 [4–17]; p = 0.037) than in controls, whereas the BSOD group showed no significant difference (11 [3–18]; $p = 0.262$).

Similarly, the secretion grade of pancreatic juice was significantly reduced in the PSOD group (0.98 [0.25–2.9]; p = 0.040), but not in the BSOD group (1.15 [0.3–2.7]; $p = 0.154$). Endoscopic sphincterotomy was performed in seven patients, and follow-up cine-dynamic MRCP was available in six of them. All six showed improvement in flow parameters, and none of the seven patients experienced symptom recurrence for over one year after treatment.

Conclusion: Cine-dynamic MRCP can be a non-invasive imaging biomarker for evaluating Sphincter of Oddi function by visualization and quantification of bile and pancreatic juice flows.

COMBINING BEDSIDE INDEX OF SEVERITY IN ACUTE PANCREATITIS (BISAP) AND CHARLSON COMORBIDITY INDEX IMPROVES EARLY RISK STRATIFICATION IN BILIARY ACUTE PANCREATITIS

J. Prosenz[1,2], M. Birkl[1,2], T. Hadrigan[1,3], L. Brandl[1], A. Wittmann[1,4], F. Koutny[1,2], A. Maieron[1,2]

Contact E-Mail Address: moiramelina.birkl@stpoelten.lknoe.at

Introduction: Acute biliary pancreatitis (ABP) has been shown to be associated with increasing incidence and health-care costs, and possibly higher mortality than other etiologies. Despite the existence of various scoring systems, early and accurate risk stratification remains difficult. Due to heterogeneity of populations, focusing on one etiology might reveal important insights concerning predictors of outcome.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: We conducted a retrospective, multicenter cohort study including all patients admitted with ABP between 2018 and 2021 at two hospitals. Epidemiological, clinical, and outcome data were analyzed.
The main clinical outcome of interest was a hierarchical composite endpoint of five mutually exclusive clinical states:
i. Death (90-day all-cause mortality),
ii. Severe AP and/or admission to the intensive care unit (ICU),
iii. Endoscopic, interventional radiological, or surgical interventions,
iv. Moderately-severe AP,
v. Mild AP.
Univariable logistic regression identified parameters associated with worse outcomes, which were then tested in multivariable models. Emphasis was placed on early availability and clinical practicality of predictors. We aimed to stratify patients into outcome trajectories reflecting both health impact and healthcare resource utilization.
Results: Out of 569 total acute pancreatitis cases, 217 (38.1%) patients had ABP (mean age 65.9 ±17.4 years; median length of stay (LOS) 7 days, IQR 4;11) Mild, moderately-severe, and severe disease occurred in 62.2%, 30.0%, and 7.8% of patients. All-cause 90-day mortality was 2.3%. Several parameters were significantly ($p<0.05$) associated with worse outcomes, including BISAP and the Charlson comorbidity index (CCI) ($p<0.001$). Individually, BISAP and CCI classified patients reasonably, however, wide prognostic uncertainty persisted.
When combining BISAP and CCI (BISAP-C), 5 discrete risk groups were identified, ranging from low (group 1, BISAP 0-2 & CCI 0-2) to very-high risk (group 5, BISAP 3-5 & CCI ≥6) (see Table 1). The prevalence of severe outcomes (i–iii) increased across these strata: 2.4% (Group 1), 9.5% (Group 2), 27.3% (Group 3), 60% (Group 4), and 62.5% (Group 5), with LOS also significantly longer in higher-risk groups ($p<0.001$).
Mortality was 50% in group 5, while, importantly, 97.6% of patients in group 1 experienced mild-to-moderate AP without ICU admission, persistent organ dysfunction, surgical or endoscopic interventions, and no fatality, supporting potential early discharge. This also occurred in 90.5% of group 2.
Notably, Groups 1 and 2 together comprised nearly 80% of the cohort.

	Outcome groups*				
	Group 5 Very-high	Group 4 High	Group 3 Mod.-high	Group 2 Mod.-low	Group 1 Low
BISAP CCI	3-5 ≥6	3-5 ≤5	0-2 ≥6	0-2 3-5	0-2 ≤2
Cases, n (% of cohort)	8 (4.0%)	5 (2.5%)	22 (10.9%)	84 (41.6%)	83 (41.1%)
LOS, median (IQR)	5 (3;10)	15 (9;106.5)	10 (6;14.25)	7 (4;11)	5 (3;9)
Mortality, 90d all-cause	4 (50%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
Severe pancreatitis or ICU admission	0 (0%)	3 (60%)	6 (27.3%)	6 (7.1%)	2 (2.4%)
Intervention (endosc., IR, surgical)	1 (12.5%)	0 (0%)	0 (0%)	2 (2.4%)	0 (0%)
Moderately-severe pancreatitis	2 (25.0%)	2 (40%)	7 (31.8%)	18 (21.4%)	24 (28.9%)
Mild pancreatitis	1 (12.5%)	0 (0%)	9 (40.9%)	58 (69.0%)	57 (68.7%)

Table 1. Outcome trajectories.

Conclusion: Comorbidity seems to play a major role concerning worse outcomes in ABP. The combination of CCI and BISAP (BISAP-C), both comprised of early-on and easily available parameters, offers improved early prognostic discrimination and may provide tailored, individualized management and healthcare resource utilization.

SHOULD GASTROINTESTINAL BLEEDING AND IMPAIRED MENTAL STATUS BE CONSIDERED ORGAN FAILURE IN PATIENTS WITH ACUTE PANCREATITIS?

L. Guilabert[1], K. Cárdenas-Jaén[1], L.M. Bernal-Luján[1], J.A. Andreu Viseras[1], S. Pérez Brotons[1], A. Vaillo-Rocamora[1], L. Sempere Robles[1], E. De-Madaria[1,2]

Contact E-Mail Address: lucia.guilabert@gmail.com

Introduction: The Revision of the Atlanta Classification (RAC) defines severe acute pancreatitis (AP) by the presence of persistent organ failure (OF), limited to respiratory, renal, or cardiovascular systems, this being associated with a high mortality rate. Whether gastrointestinal bleeding (GIB) and impaired mental status (IMS) should be considered as OF remains unclear. We aimed to assess the association of GIB and IMS with mortality and other outcomes.
Aims & Methods: We performed a retrospective analysis of a prospective database including 1,612 AP patients. GIB was defined as bleeding >500 mL. IMS was defined as a Glasgow score ≤14 at baseline. Multivariate logistic regression models were used to assess associations with mortality, controlling for comorbidity and RAC- defined OF. Two models were used: one including all OF (any duration), and another including only persistent OF.
Results: GIB occurred in 1.5% and IMS in 3% of patients. Both were associated with worse outcomes in bivariate analysis. In multivariate models, GIB was not independently associated with mortality. IMS was independently associated with mortality (aOR 4.0, 95% CI 1.2–13.4) only when adjusting for persistent OF, but not when adjusting for OF of any duration. Renal, respiratory or cardiovascular OF of any duration, as well as persistent OF, had an independent and very strong association with all the outcome variables including mortality, clearly differentiating them from GIB and IMS.
Conclusion: GIB and IMS are markers of disease severity but do not show a consistent independent association with mortality comparable to the current RAC definition of OF.
Disclosure: Nothing to disclose.

Contact E-Mail Address: chicol87@hotmail.it

Introduction: The aim of this study is to evaluate the volume of biliopancreatic diseases at AUSL Romagna and assess their burden on healthcare system from emergency care to subsequent hospitalization in dedicated departments.

Aims & Methods: We designed a longitudinal, retrospective, descriptive study, considering patients who accessed the Emergency Departments (ED) in all first and second-level centers of AUSL Romagna from January 2018 to December 2024, having blood lipase levels above the upper limit (≥60 U/L).

We divided these patients into two groups: the first one (identified as "acute pancreatitis" (AP)) with lipase levels above three times upper limit (≥180 U/L), and the second group (identified as "other biliopancreatic (BP) diseases") including patients with high lipase level associated to other gastrointestinal conditions, evaluating their care pathways.

Results: The total number of emergency admissions to AUSL Romagna with lipase levels ≥ 60 U/L was 29011, accounting for 1% of annual emergency admissions, with the majority triaged as green (minor urgency). Of these, 9204 patients (32%) were discharged with a diagnosis compatible with AP (13%, N= 3669) or other BP diseases (19%, N= 5535), with consistent rates over the years. Male sex was predominant for BP group with a median age of 63 years, female sex for the AP group and median age of 66 years.

Nearly all patients with AP (94%) required subsequent hospitalization, primarily in the gastroenterology department (32%), followed by general medicine (25%) and general surgery (15%). In the other BP diseases group, fewer than half (40%) required subsequent hospitalization.

The discharge diagnoses from specialized departments showed an increase in diagnostic accuracy compared to initial assessments, reflecting initial missed diagnoses, appropriate re-evaluations during hospitalization, complications, etc.

From an economic perspective, hospital stays in specialized departments lasted an average of 9.5 days, with an average cost of €3,784 per stay. Specifically, hospitalizations in the gastroenterology department for AP had an average duration of 9.3 days, with a total cost of €4129740 for 1181 admissions.

For other BP diseases, the costs for a total of 522 hospitalizations amounted to €1808899, with an average stay of 9.3 days. Most hospitalizations ended in discharge to home (84%), with an in-hospital mortality rate of 4%.

Conclusion: Our study provided a detailed roadmap of patients with biliopancreatic diseases in AUSL Romagna (an area covering 1.2 millions of inhabitants), from their admission in ED to their discharge by different departments. BP diseases account for 1% of all ED accesses and most of the cases are characterized by medium-high complexity, with an economic annual burden of €2.8 million. These results may support the healthcare policy towards an optimization of economic and human resources to improve patient's management and outcomes.

Disclosure: Nothing to disclose.

CRUCIAL IMPACT OF WEIGHT LOSS IN AN ACUTE PANCREATITIS COHORT: RISK FACTORS AND CLINICAL CONSEQUENCES

O.J. Zahariev[1,2], L. Havelda[1,2], K.L. Vámossy[2], G. Soós[2], B.C. Budai[1,3], R.J. Reszketö[2], D. Tarján[1,2], M. Lipp[1,2], E.R. Fürst[1,2], S. Váncsa[1,2], Z.I. Bánfalvi[2,1], B. Barna[2], I. Rajci[2], B. Lázár[2,1], P.J. Hegyi[1,2], B. Eross[4,2], P. Sahin[2], P. Hegyi[5,2]

Introduction: Acute pancreatitis (AP) presents a risk for malnutrition due to its hypermetabolic state and impaired nutrient absorption. Identifying patients at risk of weight loss during hospitalization is crucial for timely interventions, resource allocation, and improved clinical outcomes.

However, no studies to date have focused on inpatient weight loss in AP patients.

Aims & Methods: This study aimed to determine which AP patients are at risk of weight loss during hospitalization.

We conducted a prospective cohort study of patients presenting with AP at a national tertiary care center (Semmelweis University Institute of Pancreatic Diseases) from 4th October 2021, to 30th September, 2024. Body weight was measured on admission and at discharge. Weight stability was defined as a change of -2.5% to +2.5%; changes outside this range were classified as weight loss or gain.

We explored associations with demographic factors, pre-existing exocrine and endocrine pancreatic damage, etiology, AP severity, and length of hospital stay.

Results: Of 1,795 patients admitted to the unit, 1,018 had data on body weight change. The average age was 56 ± 17 years, and 56% of the cohort was male. Weight loss was observed in 26.2% of patients, while 8.1% gained weight. Men were more likely to lose weight (30%) compared to women (22%). The most common etiologies were biliary (n=432), alcoholic (n=242), and idiopathic (n=159). The highest proportion of weight loss (7/20, 35%) was observed in AP triggered by pancreatobiliary tumors, followed by biliary etiology (128/432, 30%) and hypertriglyceridemia (12/43, 28%).

Patients with no prior AP attacks experienced weight loss more often (180/620, 29%) than those with recurrent AP episodes or severe pre-existing pancreatic exocrine damage (chronic pancreatitis, 34/162, 21%). Weight loss was observed in 34% of diabetic, 28% of prediabetic, and 22% of healthy patients. AP severity was directly proportional to both the likelihood and degree of weight loss.

In severe pancreatitis 49% of patients lost weight, which was double the rate observed in mild pancreatitis (23%). Weight loss also increased in parallel with the length of hospital stay. Among those requiring hospitalization longer than a week, more than half (104/188, 55%) experienced weight loss.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Male gender, AP severity, prolonged hospitalization, and pre-existing endocrine pancreatic damage (but not exocrine pancreatic damage) are associated with a higher risk of weight loss during hospitalization. AP triggered by pancreatobiliary tumors, biliary etiology, or hypertriglyceridemia carries a greater risk of weight loss compared to other etiologies.

Disclosure: There are no conflicts of interest.

Contact E-Mail Address: fcovalverde89@gmail.com

Introduction: Acute pancreatitis (AP) is a major cause of digestive-related hospitalizations. Systemic inflammatory response syndrome (SIRS) is present in 20–60% of cases and is associated with severe AP, multiorgan failure (MOF), or in-hospital mortality. This study aims to assess the clinical impact of transient and persistent SIRS on mortality and MOF, compared with the BISAP score.

Aims & Methods: A retrospective study was conducted on a prospective cohort of patients admitted with AP to a tertiary hospital between March 2017 and June 2019. Blood tests were recorded at admission and at 48 hours. Severity was defined using the 2012 Atlanta classification. MOF was defined as dysfunction of two or more organ systems lasting over 48 hours. Transient SIRS was present only at admission, while persistent SIRS lasted >48h. Univariate analysis and ROC curves were conducted using SPSS. Fagan nomograms estimated post-test probabilities of mortality and MOF using pre-test prevalence from the cohort.

Results: A total of 467 patients were included; 84 (18.41%) had SIRS at admission, of whom 32 (37.52%) had persistent SIRS. ROC analysis showed similar AUCs for persistent SIRS and BISAP ≥2, while transient SIRS had poor predictive value. Fagan nomograms showed persistent SIRS had the highest positive and negative likelihood ratios, and greater post-test probability for mortality and MOF, compared to BISAP ≥2 and transient SIRS.

Predictor	Pre-test probability	Probability ratio + (IC 95%)	Post-test probability +	Probability ratio – (IC95%)	Post-test probability -
MORTALITY					
TRANSITIONAL SIRS	4%	0.46 (0.07-3.16)	2% (0-12%)	1.07 (0.96-1.20)	4% (4-5%)
PERSISTENT SIRS		16 (4.90-27)	41% (29-53%)	0.33 (0.17-0.64)	1% (1-3%)
BISAP ≥ 2		2.92 (2.40-3.55)	12% (10-14%)	0.14 (0.04-0.52)	1% (0-2%)
MULTIORGAN FAILURE					
TRANSITIONAL SIRS	5%	1.18 (0.4-3.49)	6% (2-15%)	0.98 (0.83-1.15)	5% (4-6%)
PERSISTENT SIRS		13 (7.36-23)	40% (28-54%)	0.45 (0.28-0.72)	2% (1-4%)
BISAP ≥ 2		2.74 (2.18-3.45)	13% (11-16%)	0.24 (0.10 – 0.59)	1% (1-3%)

Table 1: Pre-test and post-test probability of developing multiorgan failure in relation to mortality and the type of SIRS developed during admission, as well as the presence of a BISAP score ≥ 2.

Conclusion: Persistent SIRS was associated with higher risk of mortality and MOF, while transient SIRS had limited prognostic value. Persistent SIRS and BISAP ≥2 had comparable ROC performance, but Fagan nomograms demonstrated the superior clinical predictive utility of persistent SIRS. It showed post-test probabilities up to 40%, compared to 12–13% for BISAP ≥2.

These results highlight the importance of monitoring SIRS persistence in AP for better risk stratification and early intervention.

Contact E-Mail Address: fcovalverde89@gmail.com

Introduction: Acute pancreatitis (AP) is one of the most common diseases leading to admission in Gastroenterology departments. The aging population is contributing to an increasing number of hospitalizations among elderly patients.

Our study aims to evaluate different clinical outcomes in patients across different age groups.

Aims & Methods: A retrospective analysis was conducted using a prospective database consisting of a cohort of patients with AP consecutively enrolled from March 2017 to June 2019 at a tertiary care hospital.

Clinical management followed standard clinical practice guidelines, including routine abdominal ultrasound upon admission and CT scans in cases of diagnostic uncertainty or clinical deterioration. Diagnosis and classification were based on the revised 2012 Atlanta classification.

Patients were divided into three age groups: <50 years, 50–75 years, and >75 years. Initially, a univariate analysis using the chi-square test was performed, followed by binary logistic regression to assess the influence of age on different clinical aspects of the disease.

Results: 465 patients with AP were recruited. Overall, 48.6% of the patients were women; however, in the >75 age group, up to 64% were female. Older patients presented with more comorbidities, a greater need for antibiotic therapy, higher rates of severe AP, and an increased likelihood of mortality. These associations were confirmed in the multivariate analysis.

Notably, patients over 75 years old had a higher risk of requiring antibiotic therapy (OR 2.73) and death (OR 7.42), while those aged 50–75 years had a higher risk of developing severe AP compared to younger patients (OR 8.05). No significant differences were found between age groups regarding the occurrence of necrotizing pancreatitis.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Age group	<50 (reference)	50-75 (OR: CI 95%)	p	>75 (OR: CI 95%)	p
Female sex	-	1.10 (0.66-1.82)	n.s	2.96 (1.77-4.96)	< 0.001
Necrotizing pancreatitis	-	0.76 (0.26-2.22)	n.s	0.62 (0.20-1.90)	n.s
Antibiotic use	-	1.33 (0.76-2.33)	n.s	2.73 (1.58-4.74)	<0.001
Severe acute pancreatitis	-	8.05 (1.04-61.95)	0.04	16.29 (2.17-122.07)	0.007

Table 1. Binary logistic regression analysis showing the increased risk of each variable by age group, using the youngest group (< 50 years old) as the reference category.

Conclusion: Our study presents the distribution of epidemiological and clinical variables across different age groups (<50 years, 50–75 years, and >75 years). We found that women over 75 years had a higher risk of developing AP compared to men, which could be influenced by an increased prevalence of biliary etiology with advancing age.

Interestingly, patients over 75 years required antibiotic therapy more frequently, although the rates of necrotizing pancreatitis did not differ between age groups. This may suggest a higher incidence of other types of infections in older patients.

Notably, patients over 75 years accounted for 80% of the deaths in our cohort, while no clear increase in mortality risk was observed in the 50–75 age group compared to younger patients.

Finally, the risk of severe AP increased progressively with age, peaking in patients over 75 years. In conclusion, female sex was predominant among patients over 75 years, who also showed a significantly higher risk of severe AP and mortality, as well as a greater need for antibiotic therapy.

Disclosure: Nothing to disclose.

Introduction: Acute pancreatitis (AP) is associated with an intense catabolic, local-regional and systemic inflammatory state, which can lead to changes in body composition, with prognostic implications.

Aims & Methods: Aims: To evaluate the body composition by anthropometry, bioelectrical impedance analysis (BIA) and computed tomography (CT) and its influence in AP severity, endocrine insufficiency (EnPI-AP), pancreatic exocrine (EPI-AP) and post-pancreatic enzyme replacement therapy (PERT).

Methods: Prospective longitudinal study of consecutive adult patients diagnosed with first AP episode. EPI-AP patients were randomized to receive PERT (4000IU/meal+20000IU/snack) vs. placebo (clinicaltrials.gov:NCT05480241). Body composition was assessed using anthropometry, BIA (InBody 570) and CT (cross-sectional areas L1/L3). Obesity was diagnosed for body mass index (BMI)≥30Kg/m^2, waist-to-hip ratio (WHR)>0.9(men)/0.85(women) and percentage total fat mass (TFM)>20%(men)/28%(women).

Visceral obesity was defined by abdominal circumference (AC)>94(men)/80(women)cm, visceral fat area (VFA)≥100cm^2 and visceral/subcutaneous fat ratio (VSFR)≥0.4. Sarcopenia was diagnosed by skeletal muscle mass (SMM)<20(men)/15(women)Kg, SMM index (SMMi)<7.0/5.5Kg/m^2 and skeletal muscle area index (SMAi)<41(men)/38.5(-women)cm^2. The three methods were correlated using spearman test and Bland-Altman plots.

Results: A total of 105 patients (65.7%(n=69) males; mean age:63.8 ±17.1yo) were enrolled and followed-up. AP was moderately-severe/severe in 32.4%/16.2%. EPI-AP and EnPI-AP occurred in 47.6% (n=50) and 17.1% (n=18). EPI-AP was persistent (≥6months after AP diagnosis) in 58%. After 6-month post-randomization, 44% (n=11/25) under PERT and 40% (n=10/25) under placebo resolved EPI-AP (p=0.598).

Obesity was diagnosed in 19.0% (n=20) by BMI, 97.1% (n=102)/72.4% (n=76) by WHR in antropometry/BIA, and 57.1% (n=60) by TFM. Visceral obesity was diagnosed in 78.1% (n=82) by AC, in 41.9% (n=44)/ 97.2% (n=103) by VFM in BIA/CT and in 90.5% (n=95) by VSFR. Sarcopenia was diagnosed in 1.0% (n=1) by MMS.

Considering outcomes, moderately-severe/severe AP was strongly associated with WHR by BIA (OR=10.2; p=0.034) and VFA by BIA (OR=1.08; p=0.029) and CT (OR=1.003; p=0.038). EPI-AP was statically associated with WHR by BIA (OR=11.6; p=0.048) and SMMi by BIA (OR=77.4; p=0.048) and TFM (OR=2.3; p=0.048). Severe EPI-AP was strongly associated with VSFR (OR=20;95%CI; p=0.048) and SMMi by BIA (OR=23.2; p=0.003) and CT (OR=2.3; p=0.041). SMMi by BIA (OR=14.1; p=0.030) and CT (OR=1.6; p=0.031) predicted EnPI-AP.

For obesity, TFM by BIA had a strong correlation with BMI (r=0.61; p<0.001) and a weak correlation with WHR by anthropometry (r=0.37; p<0.001). Regarding visceral obesity, VFA by BIA was weakly correlated with WHR by anthropometry (r=0.29; p=0.004) and VFA by CT (r=0.20; p=0.045). For sarcopenia, SMM by BIA was strongly correlated with SMM by CT (r=0.78; p<0.001).

In EPI-AP patients, a significant decrease of WHR (t(52)=2.262; p=0.028) and TFM (t(53)=1.695; p=0.046) by BIA was observed after 6months of PERT.

Conclusion: Body composition is significantly changed in AP, with >2/3 of patients with obesity, especially the visceral component. Obesity, including visceral obesity, correlates with AP severity. Obesity, including visceral obesity and sarcopenia are correlated with the EPI-AP and its severity, while sarcopenia is correlated with EnPI-AP. PERT has led to a significant reduction in obesity markers. Body composition assessment by BIA (TFM, VFA and SMM) and CT (VFA and SMM) were of clinical value and comparable.

RATE AND RISK FACTORS FOR PROGRESSION FROM ACUTE TO RECURRENT AND CHRONIC PANCREATITIS IN CHILDREN: SYSTEMATIC REVIEW AND META-ANALYSIS

E.-B. Gagyi[1]
[1]Semmelweis University, Center for Translational Medicine, Budapest, Hungary

Contact E-Mail Address: endre.gg@gmail.com

Introduction: Most children recover after an initial acute pancreatitis (AP) episode, yet some progress to recurrent AP (RAP) or chronic pancreatitis (CP).

Aims & Methods: We aimed to quantify progression rates and identified exposures consistently associated with these transitions. MEDLINE, Embase and Cochrane were searched on 19th of December 2024 for paediatric studies reporting AP patients progression into RAP or CP. Random-effects model was used to pool proportions and odds ratios (OR) with 95 % confidence intervals (CI). Heterogeneity was assessed using the I2 statistics.

Results: Fifty-seven studies (5 642 children) met the eligibility criteria. After the first AP attack, RAP developed in 18 % (CI 16–22) and CP in 10 %. Among children with RAP, 35 % progressed to CP. RAP risk varied by aetiology: hypertriglyceridaemia 33 %, idiopathic 28 %, biliary 19 %, traumatic 16 %, drug-induced 14 %, virus-associated 3 %.

Structural abnormalities were linked with higher odds of RAP (OR 3.15, CI 1.51–6.56). Pancreas divisum (OR 2.64, CI 1.51–4.63) and PRSS1 mutation (OR 4.56, CI 3.06–6.80) correlated with CP.

Conclusion: Approximately one in five paediatric AP episodes recur, and more than one-third of RAP cases evolve into CP. Aetiology strongly modulates RAP risk, whereas structural and genetic factors relate to later progression. Early cross-sectional imaging for anatomical variants and targeted genetic testing after the inaugural attack may refine prognostication, counselling and surveillance.

These findings inform future international therapeutic trials.

Disclosure: Nothing to disclose.

Introduction: Early identification of severe acute pancreatitis (SAP) enables the prompt initiation of aggressive resuscitation strategies and improves patient outcomes.

The aim of the present study is to assess the clinical differences between patients with SAP and those with mild or moderate acute pancreatitis, as well as the distribution of organ failure in severe cases.

Aims & Methods: A retrospective analysis was conducted on a prospective database comprising a cohort of 526 patients with acute pancreatitis, consecutively included from March 2017 to June 2019 at a tertiary care hospital. All included patients underwent systematic blood testing at admission and at 48 hours. Clinical management adhered to current clinical practice guidelines. Diagnosis and classification were based on the revised 2012 Atlanta classification. The analysis included the need for antibiotic therapy, development of local complications, organ failure patterns, and infectious complications

Results: Table 1 summarizes the clinical characteristics and outcomes associated with severe acute pancreatitis (SAP). Regarding infectious complications, patients with SAP showed higher rates of infected necrosis and extrapancreatic infections, although no significant differences were observed in the incidence of acute cholangitis. Patients with SAP were more likely to develop necrotizing pancreatitis and local complications. Moreover, they accounted for the vast majority of ICU admissions and deaths. In terms of persistent organ failure, renal failure was the most frequent (80%), followed by respiratory failure (45%). A high proportion of patients who developed SAP presented with SIRS at admission (64%) and at 48 hours (55%).

	Mild/Moderately severe AP (n = 399 / 90.7%)	Severe AP (n = 41 / 9.3%)	p-value
Necrotizing pancreatitis	8 (2.1%)	13 (34.2%)	0.001 **
Infected necrosis	4 (1%)	6 (16.2%)	0.001 **
Antibiotic therapy	129 (32.9%)	29 (74.4%)	0.001 **
Extrapancreatic infection	35 (12.5%)	10 (28.6%)	0.011 **
Mortality	2 (0.5%)	18 (43.9%)	0.001 **
Cholangitis	145 (36.3%)	18 (43.9%)	0.340
ICU admission	3 (0.3%)	12 (29.3%)	0.001 **
SIRS at admission	56 (14.1%)	26 (63.4%)	0.001 **
SIRS at 48 hours	17 (4.3%)	22 (55%)	0.001 **

Table 1.

Conclusion: Early identification of severe acute pancreatitis (SAP) is not always straightforward and requires close monitoring. Nevertheless, recognizing these patients is critical, as prognosis is intrinsically linked to the timeliness of diagnosis and the implementation of supportive measures necessary to maintain organ stability.

Patients with SAP are at higher risk of developing organ failure. In our cohort, we observed increased use of antibiotic therapy among SAP patients, likely due to the higher incidence of infected necrosis and extrapancreatic infections. Conversely, the incidence of acute cholangitis, based on the 2018 Tokyo criteria, was similar between SAP and mild/moderate AP cases.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Regarding organ failure, renal failure was the most frequent in our cohort, although other series have reported respiratory failure as the most common. The presence of SIRS at admission and at 48 hours was associated with subsequent development of SAP; however, a significant number of patients with SIRS did not ultimately develop a severe course. Its predictive value may be enhanced when combined with other prognostic factors.

ETIOLOGY-SPECIFIC PATTERNS OF INFECTIOUS COMPLICATIONS IN ACUTE PANCREATITIS

R. Mendoza-Rodriguez[1], F. Valverde-López[2], A. Lancho Munoz[1], E. López-González[1], J.G. Martínez-Cara[1], E. Redondo-Cerezo[2]

Introduction: Infections in acute pancreatitis are associated with increased morbidity, mortality, and healthcare costs. Early diagnosis is essential to improve prognosis and reduce mortality. The aim of the present study is to evaluate the distribution of infectious complications according to the underlying etiology.

Aims & Methods: A retrospective analysis was conducted on a prospective database comprising a cohort of 526 patients with acute pancreatitis, consecutively included between March 2017 and June 2019 at a tertiary care hospital. All patients underwent systematic blood testing at admission and at 48 hours. Clinical management adhered to standard clinical practice guidelines. Diagnosis and classification were based on the revised 2012 Atlanta classification. Infectious complications were analyzed in patients with biliary and alcohol-related acute pancreatitis.

Results: The distribution of infectious complications occurring during hospitalization is shown in Table 1.

Variable	Overall (n = 526)	Biliary (n = 304)	Alcohol-related (n = 39)	p-value
Acute cholangitis (Tokyo-18)				
Suspected and/or confirmed	173 (37.6%)	140 (53.8%)	8 (20.4%)	0.001 **
Confirmed cases only	49 (29.2%)	43 (30.7%)	0	0.059
Antibiotic therapy	165 (36.1%)	123 (41.3%)	9 (23.7%)	0.037 **
Extrapancreatic infections (Total)	48 (14.3%)	34 (15.2%)	3 (13%)	1.000
Pneumonia	16 (4.8%)	8 (2.6%)	1 (2.6%)	1.000
Urinary tract infection	28 (8.4%)	25 (8.2%)	1 (2.6%)	0.335
Phlebitis / Catheter-related infection	4 (1.2%)	1 (0.3%)	1 (2.6%)	0.215
Infected pancreatic necrosis	11 (2.4%)	6 (2.1%)	2 (5.3%)	0.230

Table 1.

Up to 53.8% of patients with biliary acute pancreatitis presented with acute cholangitis according to the Tokyo-18 criteria, whereas this occurred in only 20.4% of alcohol-related cases. All cases of cholangitis in the alcoholic pancreatitis group, as well as the majority of those in the biliary group, met only the criteria for suspected acute cholangitis (100% vs. 53.8%, respectively). Antibiotic therapy was used in 41.3% of biliary pancreatitis cases, with a statistically significant difference compared to alcohol-related pancreatitis (23.7%).

No significant differences were observed in the rates of extrapancreatic infections between the two groups, occurring in 15.2% and 13% of biliary and alcohol-related cases, respectively.

Conclusion: Extrapancreatic infections play a key role in the clinical course of acute pancreatitis, particularly in moderate and severe cases. The most frequent sites of infection include the respiratory and urinary tracts, as well as bloodstream infections. These infections are associated with an increased risk of complications, prolonged hospital stays, and higher mortality.

The characteristics of infections vary according to the etiology of pancreatitis. In our cohort, biliary pancreatitis was significantly more often associated with acute cholangitis, which is consistent with the pathophysiology of biliary-origin pancreatitis. Among patients with alcohol-related pancreatitis, up to 20% met criteria for suspected cholangitis; however, none fulfilled the criteria for confirmed cholangitis.

This may be explained by the presence of acute-phase reactants and transient cholestasis, potentially leading to the administration of unnecessary antibiotic therapy.

Although previous studies have reported higher rates of respiratory infections in alcohol-related acute pancreatitis, our data showed no significant differences in these infections—or in infectious complications overall—between the two etiologies.

PP1063

ACUTE PANCREATITIS: HAS THE EPIDEMIOLOGICAL PROFILE CHANGED OVER THE PAST TEN YEARS?

R. Mendoza-Rodriguez[1], F. Valverde-López[1], A. Lancho Munoz[1], E. López-González[1], J.G. Martínez-Cara[2], E. Redondo-Cerezo[3]
[1]Hospital Universitario Virgen de las Nieves, Granada, Spain, [2]Hospital Virgen de las Nieves, Endoscopy Unit, Granada, Spain, [3]Hospital Universitario Virgen de las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: rmendozar770@gmail.com

Introduction: The available evidence on the epidemiology of acute pancreatitis (AP) is primarily based on older studies conducted in other countries, limiting its applicability to local settings. This study aims to provide updated data on the clinical characteristics and outcomes of patients with AP in our region thereby improving understanding and management of the disease.

Aims & Methods: A retrospective analysis was conducted on a prospective database comprising a cohort of 526 patients with acute pancreatitis (AP), consecutively included between March 2017 and June 2019 at a tertiary care hospital. Systematic laboratory testing was performed at admission and again at 48 hours. Clinical management followed standard practice guidelines, including routine abdominal ultrasound after admission and abdominal CT scan in cases of diagnostic uncertainty, clinical deterioration, or lack of improvement. Diagnosis and classification were based on the revised 2012 Atlanta classification.

Results: The most frequent etiology of AP in our setting was biliary lithiasis (65.9%), followed by idiopathic (15.4%) and alcohol-related causes (8.4%). Severe AP accounted for 9% of cases, while 14.3% were classified as moderately severe. Up to 20.2% of patients developed local complications; however, only 4.9% presented with pancreatic necrosis.

SIRS was observed in 18.7% of patients at admission, decreasing to 8.7% at 48 hours. Only 3.7% of patients required ICU admission (Table 1). Factors such as smoking, ERCP, antibiotic therapy, acute cholangitis, and SIRS showed significant differences across different etiological groups.

	Biliary	Alcohol	Hypertriglyceridemia	Pot-ERCP	Idiopathic	Total
Frequency	304 (65.9%)	39 (8.5%)	8 (1.7%)	5 (1.1%)	71 (15.4%)	461
Severe pancreatitis	28 (9.2%)	2 (5.1%)	0	1 (20%)	8 (12.7%)	42 (9%)
Local complications	24 (7.9%	6 (15.4%)	2 (25%)	1 (20%)	11 (15.5%)	106 (20.2%)
Transient organ failure (<48h)	46 (16.2%)	3 (8.1%)	2 (28.6%)	1 (20%)	14 (20.3%)	72 (16.3%)
Persistent organ failure (>48h)	28 (9.2%)	3 (7.7%)	0	0	9 (12.7%)	42 (9%)
SIRS at admission	46 (15.2%)	12 (30.8%)	1 (12.5%)	1 (20%)	16 (22.5%)	86 (18.5%)
Acute cholangitis (suspected and/or confirmed)	138 (45.5%)	7 (15.4%)	0	3 (60%)	17 (23.9%)	173 (37.6%)
Antibiotic therapy	123 (41.3%)	9 (23.7%)	1 (12.5%)	4 (80%)	19 (27.1%)	165 (36.1%)
ERCP performed	42 (14.1%)	0	0	2 (40%)	2 (2.9%)	49 (10.9%)

Conclusion: Acute pancreatitis (AP) is a common condition that imposes a significant healthcare burden. Determining the etiology of AP at admission is important not only from an epidemiological standpoint but also due to its profound implications for patient prognosis.

Contrary to what has been reported in the literature, the second most frequent cause of AP in our cohort was idiopathic, surpassing alcohol-related cases. In line with other studies, we observed significant differences between biliary and alcohol-related etiologies regarding smoking habits, development of acute cholangitis, need for ERCP, and use of antibiotic therapy. Patients with alcohol-related AP were significantly more likely to present with SIRS at admission. However, we did not find statistically significant differences in other key clinical outcomes, although patients with alcohol-related AP appeared to have a higher, but not statistically significant, risk of developing local complications, pancreatic necrosis, and SIRS at 48 hours.

This study highlights the importance of tailoring management strategies according to etiology to optimize clinical outcomes.

Introduction: Acute pancreatitis (AP) is a common gastrointestinal disorder with significant morbidity and mortality in severe cases. Pre-existing comorbidities and newly developed complications, like heart failure may influence outcomes in AP patients.

Aims & Methods: This study aimed to evaluate the impact of pre-existing and newly developed cardiac conditions on in-hospital and post-discharge mortality in patients with acute pancreatitis. A single-center registry analysis of the Hungarian Pancreatic Study Group Acute Pancreatitis Registry was conducted at Semmelweis University, Budapest, Hungary, involving 1,316 patients diagnosed with acute pancreatitis between 2021-2024. Data on pre-existing chronic heart failure (CHF), atrial fibrillation (AF), stroke history, and newly developed acute heart failure (AHF) were collected.

Electrocardiogram (ECG) findings, including QTc prolongation, were also analyzed. In-hospital mortality and post-discharge mortality within one year were assessed. Odds ratios (OR) with 95% confidence intervals (CI) were calculated to quantify the strength of associations.

Results: Of the 1316 patients, 45% were female, the average age was 55.8 (range: 18-95) years, 8% had severe, 25% had moderate, and 65% had mild AP. Regarding cardiovascular background, pre-existing CHF and stroke history did not show a significant association with increased in-hospital mortality in AP (OR: 1.85, 95% CI: 0.63-5.44 and OR: 1.21, 95% CI: 0.36-4.02, respectively). Although AP patients with pre-existing AF had four-fold higher odds of in-hospital mortality (OR: 4.01, 95% CI: 1.92-8.34).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Assessing in-hospital cardiovascular alterations, newly discovered AF was not significantly associated with increased in-hospital mortality (OR: 4.40, 95% CI: 0.97-20.02).

Moreover, QTc prolongation on ECG was not significantly associated with in-hospital mortality (OR: 2.10, 95% CI: 0.61-7.25) or post-discharge mortality within one year after AP (OR: 1.65, 95% CI: 0.20-13.74). However, AP patients with newly developed AHF had a 25-times higher odds of in-hospital mortality (OR: 25.81, 95% CI: 12.13-54.98) and a 4-times higher odds for post-discharge mortality within one year (OR: 4.93, 95% CI: 1.01-24.26).

Conclusion: Pre-existing AF and newly developed AHF are significantly associated with increased in-hospital mortality in patients AP, moreover, newly developed AHF is also associated with increased post-discharge mortality within one year. These findings highlight the importance of cardiac monitoring and management in AP patients to improve outcomes.

Contact E-Mail Address: fehertibordaniel@gmail.com

Introduction: Depression and anxiety are common yet underrecognized comorbidities in patients with pancreatitis. While evidence suggests a significant psychological burden in these patients, the underlying mechanisms remain unclear, and psychological management is not routinely implemented in clinical care.

This study aims to assess the prevalence of these conditions and highlight the need for their integration into pancreatitis treatment.

Aims & Methods: Our protocol was registered on PROSPERO (CRD42023481739). We conducted a comprehensive search on November 10, 2023, across three databases - MEDLINE, Embase, and CENTRAL - to identify studies reporting on the prevalence of depression and anxiety symptoms in patients with pancreatitis. We used a random-effects model to calculate the pooled proportion rate and mean differences (MD) with 95% confidence intervals (CI), as well as a pooled single-mean analysis of the psychological questionnaire data.

Results: In total, 43 studies were included in our meta-analysis. Among patients with acute pancreatitis (AP), anxiety was reported in approximately 23% of cases (CI: 7-54), whereas in chronic pancreatitis (CP), the prevalence was higher at 31% (CI: 23-39). Depressive symptoms were identified in approximately 29% of AP patients (CI: 14-51) and 39% of CP patients (CI: 30-48). The pooled single-mean analysis of questionnaire data further underscored the severity of these psychological symptoms, with scores exceeding established clinical cut-off points. For depressive symptoms, mean scores were as follows: CESD-10 (14.30 [CI: 6.69-21.92]), HADS (8.23 [CI: 4.53-11.94]), and SES (49.29 [CI: 44.01-54.57]). Similarly, anxiety symptom severity was reflected in the following measures: HADS (8.67 [CI: 4.53-11.94]) and SAS (47.75 [CI: 35.05-60.45])

Conclusion: There is a significant prevalence of both anxiety and depression in patients with pancreatitis. There is a need to integrate psychological interventions into the treatment of pancreatitis to potentially improve clinical outcomes.

Disclosure: Nothing to disclose.

Introduction: Depressive and anxiety symptoms may influence the severity of acute pancreatitis episodes; however, their impact, particularly in pancreatic units, remains poorly understood.

Aims & Methods: Our study aimed to identify risk factors associated with poorer psychological assessment scores in patients with acute and chronic pancreatitis (AP, CP) and their impact on clinical outcomes.

Patients admitted to a tertiary pancreatic unit were assessed for depressive and anxiety symptoms upon admission, with follow-ups every seven days during hospitalization. Psychological states were measured using the Hospital Anxiety and Depression Scale (HADS).

Results: Of the 1,397 admitted patients (median = 54, range = 17–97), 1,237 completed the questionnaire (42.98% female). At admission, 56.5% of patients had normal scores (0-7 points), 23.4% had borderline abnormal scores (8-10 points), and 20.3% had abnormal scores (11-21 points). The prevalence of abnormal cases at intervention, i.e. before intervention, was 20.15% in AP, 23.15% in early chronic pancreatitis (ECP), and 24.15% in acute-on-chronic pancreatitis (ACP). Borderline abnormal cases were observed in 22.25%, 24.15%, and 19.15% of cases, respectively.

Abnormal cases varied by etiology: hypertriglyceridemia (13.9%), biliary (16.9%), alcohol-related (26.3%), and tumor-related pancreatitis (26.6%). The prevalence also differed by AP severity: mild AP (17.76%), moderate AP (23.94%), and severe AP (35.05%). Following psychological intervention, the number of patients with abnormal scores decreased (67.6%, 19.6%, and 12.8%, respectively).

Conclusion: Depressive and anxiety symptoms are common in patients with acute and chronic pancreatitis, with more severe AP already associated with worse psychological scores at admission. Psychological interventions are essential to improve clinical outcomes.

Disclosure: Nothing to disclose.

PP1067

CONTRIBUTION OF ENDOSCOPIC ULTRASOUND TO THE AETIOLOGICAL DIAGNOSIS OF UNEXPLAINED ACUTE PANCREATITIS

S. Hdiye[1], S. Mrabti[1], A. Benhamdane[1], F. Ait iken[1], M. Amine[1], A. Achemlal[1], S. Oualaalou[1], S. Azammam[1], I. Karam[1], S. Akir[1], T. Addajou[1], R. Berraida[1], E. Ilham[1], R. Fedoua[1], H. Seddik[1]
[1]Mohammed V Military Hospital, Faculty of Medicine and Pharmacy of Rabat, Department of Gastroenterology II, RABAT, Morocco, Rabat, Morocco

Contact E-Mail Address: shdiye@gmail.com

Introduction: The aetiology of acute pancreatitis remains elusive in 10-30% of patients after clinical, biological and morphological investigations. Endoscopic ultrasound has shown promise and is particularly effective in exploring the bilio-pancreatic region.

Aims & Methods: The aim of our study was to evaluate the contribution of endoscopic ultrasound to the aetiological diagnosis of unexplained acute pancreatitis.

This is a retrospective descriptive study of 89 patients who underwent endoscopic ultra sound for unexplained acute pancreatitis between January 2010 and January 2025.

Results: The mean age of our patients was 55 +/- 16.3 years, with extremes ranging from 17 to 89 years. The sex ratio (M/F) was 0.81, with a slight female predominance of 55.1%. A history of previous acute pancreatitis was found in 31.9% of cases, and 16.3% of patients had undergone cholecystectomy. The diagnostic yield in our study was 68%. Biliary origin was retained in 40.4% (n=36) of patients, 19 of whom underwent complementary ERCP at the same anaesthetic time. Neoplastic pathology was found in 32.5% of cases (n=30). Chronic pancreatitis was reported in 22.4% of patients (n=20). Two cases of pancreas divisum, one case of sphincter of Oddi dysfunction and one case of choledocele were found. In the remaining 32% of cases, the endoscopic ultrasound was normal and no cause could be found.

Conclusion: Endoscopic ultrasound is currently an indispensable tool in the etiological investigation of unexplained acute pancreatitis. In our study, the diagnostic efficiency was around 68%.

GENOME-WIDE ASSOCIATION STUDY IDENTIFIES FUT2 RS601338 POLYMORPHISM LINKING INTRA-PANCREATIC FAT DEPOSITION TO CHRONIC PANCREATITIS

J. Mi[1], X. Bai[2], H. Chen[1]
[1]Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Department of Gastroenterology, Hangzhou, China, [2]Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Department of Gastroenterology, Beijing, China

Contact E-Mail Address: jiarui.mi@zju.edu.cn

Introduction: Pancreas fat deposition has emerged as a critical area of research within the metabolic field. However, its genetic basis and how genetic predisposition impacts on the pancreatic disorders are not well understood.

Aims & Methods: This study used UK Biobank data, including MRI scans of 20,040 European individuals with pancreatic proton density fat fraction measurements (excluding those with acute/chronic pancreatitis or pancreatic cancer). We conducted a genome-wide association study (GWAS) and subsequent post-GWAS analyses to identify genetic loci and prioritize genes enriched in pancreatic tissue. Regression models and interaction analyses were used to assess the impact of these candidates on the risk of pancreatic disorders.

Results: Our analyses identified 44 independent significant genetic variants near 14 protein-coding genes, including FUT2, CBFA2T2, FAF1, MAMSTR, SGMS1, CSNK2A1, CEBPB, and CEBPG. Genetic colocalization and transcriptome-wide association studies (TWAS) confirmed the essential roles of FUT2 and CBFA2T3 in the pancreas. Single-cell transcriptomics showed high FUT2 expression specifically in the exocrine pancreas (acinar and ductal cells).

Notably, the missense polymorphism rs601338 in the FUT2 exon region causes a stop gain in protein translation. Regression analysis revealed that the rs601338 AA genotype was significantly linked to increased chronic pancreatitis (CP) risk across all populations in full adjustment model (OR 1.26, [95% CI 1.07-1.48], $p < 0.001$; HR 1.24, [95% CI 1.03-1.50], $p < 0.001$). Subgroup analyses revealed population-specific patterns: in Europeans, the AA genotype showed significant associations in logistic regression, while in non-Europeans, both GA and AA genotypes exhibited positive trends, with AA achieving significance (OR 1.20, [95% CI 1.01-1.41], $p = 0.034$). Sex-stratified analyses showed significant associations in males (OR 1.33, [95% CI 1.08-1.62], $p = 0.006$; HR 1.31, [95% CI 1.04-1.67], $p = 0.025$) but not females with full adjustment. Interaction analysis indicated a synergistic risk effect of current smoking and the rs6031218 AA genotype on CP, while COX-2 inhibitor treatment might reduce CP risk in rs6031218 AA individuals.

Conclusion: This study offers genetic insights into pancreatic fat deposition and its systemic health impacts. The findings emphasize the need for regular surveillance of pancreatic fat deposition in certain population with a high genetic risk from FUT2 polymorphism and provide evidence for developing therapeutic strategies for the primary prevention of CP.

PP1069

TRANS PAPILLARY DRAINAGE IS THE WAY TO DRAIN PSEUDOCYSTS COMPLICATING CHRONIC PANCREATITIS- A TERTIARY CARE CENTRE STUDY

P. Desai[1], C. Patel[1], M.V Kabrawala[1], R. Prajapati[1], N. Patel[1], M. Sethia[1]
[1]SIDS Hospital & Research Institute, Surat, India

Contact E-Mail Address: drp_desai@hotmail.com

Introduction: To assess whether trans papillary drainage is the way to go for pseudocysts complicating patients with chronic pancreatitis. With our previous experience we used the technique of no injecting contrast during ERP in case of leaks complicating chronic pancreatitis causing either pseudocysts, pleural effusions or ascites.

Here we are presenting a retrospective analysis of our management of pseudocysts in chronic pancreatitis.

Aims & Methods: We retrospectively analysed all cases of chronic pancreatitis having ascites, effusions and pseudocysts. We performed magnetic resonance cholangiopancreatography (MRCP) followed by therapeutic endoscopic retrograde pancreatography (ERP) without contrast. Results were observed confirming a leak from the MPD, possibility of wire crossing the leak or not and resolution of the pseudocysts. Patients with only pseudocysts were included in this analysis.

Results: We performed ERP in 1522 patients from 2000 till date. Ductal disruptions noted in 509/1522 (33.44%) out of which pseudocyst was observed in 330 cases (64.83%).

311 patients (94.2 %) experienced successful cannulation of PD. In 19 (5.8%) PD could not be cannulated. Non cannulated cases treated with EUS guided transmural drainage 14 (73.7%) and surgery 5(26.3%)

Of these 311, 24 (8.3%) had pancreas divisum and MPD was cannulated from minor papilla.

Leak did not cross but stents put in cyst (236, 75.9 %). Cyst resolution – 228 (96.6%). Cyst Not resolved 8 (3.4%). Leaks were crossed in 75 (24.1 %); Cyst resolution 69 (92%). Cyst not resolved 6 (8%).

Unresolved cysts 14 (4.5%) were treated with EUS Aspiration- 5 (35.7%), EUS Transmural drainage 8 (57.1%), Surgery -2 (14.2%).

Discussion: In chronic pancreatitis the cause of pseudocysts is ductal rupture and very minimal inflammation as compared to acute pancreatitis where the major cause is inflammation with ductal leak and necrosis of the pancreas.

There is hardly any necrosis in chronic pancreatitis pseudocysts. Hence the management of both should be individualised. Transpapillary drainage in pseudocysts complicating chronic pancreatitis offers a less morbid and a simpler alternative to transmural drainage or surgery.

Conclusion: Pseudocysts complicating chronic pancreatitis can be managed very effectively using transpapillary drainage in majority of cases and should be attempted before considering transmural or surgical drainage. It saves the patient significant morbidity

Disclosure: Nothing to disclose.

Introduction: Chronic pancreatitis (CP) may have differences in causes, presentations and progression related to sex. There are few studies describing the sex related phenotype of CP.

Aims & Methods: We aimed to study sex differences in etiology, complications and treatment of CP in a large, North-European CP cohort. Data were extracted from the Scandinavian Baltic Pancreatic Club (SBPC) database. The collected data included sex, age, etiology, anthropometric measures, data for smoking and alcohol exposures and data on treatment and complications from CP. Differences between sexes were compared with multiple logistic regression models.

Results: We included 1922 patients in the analyses, of whom 1264 were men. Mean age of CP onset was 52.5 (SD 15.0) years in men and 51.5 (SD 16.4) years in women (p=0.2). In univariate analysis alcohol etiology and smoking was associated with male sex, whereas hereditary pancreatitis, efferent duct obstruction, autoimmune pancreatitis were associated to female sex. Numbers of men and women with non-alcoholic etiology were almost equal (461 and 422, respectively).

In multivariate analysis including all etiologies, time with disease and age; alcohol etiology remained strongly associated to male sex (OR 2.92 (2.29-3.71), p<0.001), whereas duct obstruction etiology was associated with female sex (OR 0.62 (0.44-0.89), p=0.01).

Significantly more women were underweight (p<0.001), and more men were overweight (p<0.001). Concerning other complications, diabetes mellitus (DM) was strongly associated with men (OR 1.62 (1.27-2.07), p<0.001), whereas osteoporosis was strongly associated with women (OR 0.47 (0.32-0.70), p<0.001). Recurrent acute pancreatitis and exocrine insufficiency were equally distributed between the sexes. There were no differences between sexes for medical, endoscopic or surgical treatment options.

Conclusion: More men than women had alcohol induced CP, but there was almost no difference in absolute numbers of men and women with non-alcoholic CP. Among the CP patients, DM was associated with men, while osteoporosis was associated with women.

Disclosure: Nothing to disclose.

PP1071

QUALITY OF LIFE AND PATIENT SATISFACTION IN CHRONIC PANCREATITIS PATIENTS IN SRI LANKA: A CROSS SECTIONAL STUDY

D. Safeer[1], D. Senanayake[1], G.H. Wimalasena[1], S. Seneviratne[1,2], S. Sivaganesh[1,2], D. Subasinghe[1,2], N. Fernandopulle[1,2]
[1]University of Colombo, Surgery, Faculty of Medicine, Colombo, Sri Lanka, [2]University Surgical Unit, National Hospital of Sri Lanka, Colombo, Sri Lanka

Contact E-Mail Address: deedatsafeer@gmail.com

Introduction: Chronic pancreatitis (CP) is a debilitating condition characterized by persistent abdominal pain, malabsorption, and endocrine dysfunction, significantly impacting patients' quality of life (QoL) and satisfaction with care. This study aimed to assess QoL and patient satisfaction among CP patients in a low-resource setting and identify associated clinical and demographic factors.

Aims & Methods: A cross-sectional study was conducted at the University Surgical Unit of the National Hospital of Sri Lanka between May 2024 and February 2025. A total of 106 patients with confirmed CP were recruited. QoL was assessed using the EORTC QLQ-C30 and its pancreas-specific module PAN26. Patient satisfaction was evaluated using the Short Assessment of Patient Satisfaction (SAPS) questionnaire. Clinical and demographic data were collected. Associations between variables were analyzed with Pearson correlations, t-tests, and ANOVA. A p-value < 0.05 was considered statistically significant.

Results: The mean global QoL score was 47.99 (SD = 28.29), indicating a moderate impairment. Among symptoms, fatigue (mean = 44.7), pain (44.8), and financial difficulties (48.7) were most burdensome. Functioning scores were highest in social (72.3) and physical (69.1) domains. From the PAN26 module, pancreatic pain (44.28), digestive symptoms (42.97), and impaired body image (33.82) were common concerns. The mean SAPS score was 20.0 (SD = 3.5), with 64.4% of patients reporting being satisfied or very satisfied with care.

A moderate positive correlation was observed between QoL and patient satisfaction ($r = 0.348$, $p < 0.05$), suggesting that improved well-being was associated with higher satisfaction. Factors significantly associated with poorer QoL included diabetes secondary to CP ($p < 0.05$), alcohol consumption, smoking, and lower BMI ($p < 0.05$).

Interestingly, patients who underwent ERCP reported lower QoL scores ($p < 0.05$), likely reflecting that more severe cases were selected for intervention. Higher education level showed a trend toward improved QoL. Lower-income patients reported worse QoL, underscoring the role of financial hardship in disease burden.

Conclusion: This study highlights that CP patients in Sri Lanka face considerable challenges to their quality of life, largely driven by persistent pain, comorbidities, and economic constraints. A clear link exists between clinical severity and reduced QoL, but invasive procedures such as ERCP do not always translate to better patient-reported outcomes, possibly due to selection bias. Conservative management, when coupled with adequate pain relief, nutritional support, and patient-centered follow-up, may be equally effective in select patients.

Interventions aimed at improving nutritional status, optimizing diabetes and pain control, and addressing financial toxicity are critical for improving both QoL and patient satisfaction.

Disclosure: Nothing to disclose.

Contact E-Mail Address: nemethjazmin222@gmail.com

Introduction: Pancreatic calcification is the most frequent structural change in chronic pancreatitis (CP), but the factors associated with its development are not well understood.

Aims & Methods: We aimed to investigate the risk factors of calcification development in patients with chronic pancreatitis. The study protocol was registered on PROSPERO (CRD42024591837). On September 18, 2024, we conducted a systematic search across three databases (PubMed, EMBASE, and CENTRAL) for studies reporting factors associated with calcification in chronic pancreatitis (CP). Pooled proportions and odds ratios (OR) with 95% confidence intervals (CI) were calculated using a random effects model.

Results: The systematic search resulted in 10,893 articles, from which 85 eligible studies were identified, covering a total of 34568 participants. The odds of calcification were 45% higher in alcoholic compared to idiopathic CP (OR=1.45, CI: 1.00–2.11). Alcohol consumption (OR=2.31, CI: 1.8–2.98) and smoking (OR=2.22, CI: 1.61–3.06) were associated with a two times higher risk of calcification in CP, when compared to non-smokers and non-drinkers. In contrast, the presence of CFTR mutations did not increase the risk of calcification in CP (OR=0.43, CI: 0.11–1.66) compared to patients without CFTR mutations.

Conclusion: Alcohol consumption and smoking were significantly associated with the presence of calcification in CP, making it essential to identify these risk factors and incorporate smoking cessation and alcohol reduction programs into standard care.

Disclosure: Nothing to disclose.

Introduction: Recurrent abdominal pain is the predominant symptom of chronic pancreatitis (CP), contributing to significant morbidity and reduced quality of life. Medical management includes analgesics, antioxidants, neuromodulators, and pancreatic enzyme replacement therapy (PERT).

While PERT is used for pancreatic exocrine insufficiency (PEI), it is also thought to reduce pain by suppressing pancreatic secretion via negative feedback. However, previous meta-analysis did not show pain reduction,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

though subgroup analysis suggested potential pain relief with non-enteric (NE) coated enzymes1. Unlike currently available enteric-coated formulations, high in lipase but low in proteas, non-enteric coated enzymes with high protease content dissolve rapidly and may more effectively suppress cholecystokinin-mediated pancreatic stimulation, potentially improving pain outcomes.

Aims & Methods: To primarily assess the effect of a high-protease, non-enteric-coated pancreatic enzyme preparation on pain in patients with painful chronic pancreatitis. The study was registered under ClinicalTrials.gov (NCT05042284).

We conducted a randomized, double-blind, placebo-controlled trial where we randomly assigned participants to a high protease (30,000 U)-containing, non-enteric-coated enzyme preparation (n=54) and a placebo (n=53) group. The study duration was 24 weeks. Patients with painful CP (per Mayo Clinic criteria) with chronic pain were enrolled.

The primary outcome was to see a difference in mean Izbicki pain score at 12 and 24 weeks and a change in pain scores (VAS 0-10) using pain diaries. Secondary outcomes were changes in the number of painful days, analgesic requirements, patient's global impression of change (PGIC), quality of life, and adverse effects. Weekly pain data were collated. Repeated measures, linear, and mixed-effects models were used to analyze the primary outcome. Analysis was intention-to-treat.

Results: 107 out of 256 screened patients fulfilled enrollment criteria. The mean age was comparable between groups (35.1±10.6 vs. 33.6±12.3 years; p=0.51), and baseline characteristics were similar. The primary outcome using mixed model analysis showed no significant differences in the change in Izbicki pain scores between the two groups at 12 and 24 weeks (Table: Results). The mean difference in VAS pain score was -3.7(95%CI: -4.3to-3.1) in enzyme group vs. -3.5(95%CI: -4.2to-2.9) in placebo group (p=0.64) at 12 weeks. The changes were -4.2(95%CI: -4.7to-3.6) vs. -4.1(95%CI: -4.7to-3.5), respectively (p=0.79), at 24 weeks indicating no significant difference. The median number of painful days was also similar, at 12 weeks, 16 (IQR: 9–35) in the enzyme group vs. 16 (IQR: 4–36.5) in placebo (p=0.31); at 24 weeks, 3(IQR: 0–8.5) vs. 3(IQR: 0–7)(p=0.30) respectively.

Analgesic use was higher in the enzyme group at 12 weeks (45(83.3%) vs. 37(69.8%); p=0.11) and 24 weeks (42(77.8%) vs. 35(66%); p=0.20). Differences in the change in global health status, quality of life, PGIC, and adverse effects at both time points were also non-significant.

			Estimated mean difference from baseline (95% CI)			
Mean (SD) Izbicki score	Placebo (n=53)	NEPERT (n=54)	Placebo	NEPERT	Mean difference in change	P value
Baseline	42.8 (17.0)	46.2 (14.6)				
12 weeks	23.5 (18.6)	29.4 (20.3)	-19.3 (-24.1 to -14.7)	-16.8 (-21.6 to -11.9)	-2.5 (-9.3 to 4.2)	0.49
24 weeks	9.6 (11.8)	12.8 (16.0)	-33.2 (-38.1 to -28.4)	-33.4 (-39.2 to -27.6)	0.2 (-7.2 to 7.6)	0.96

Results: Primary endpoint (Izbicki pain score).

Conclusion: Despite the high protease content, Non-enteric coated enzyme preparations did not improve pain and quality of life in patients with painful chronic pancreatitis. Further RCTs are needed to evaluate benefits in distinct subgroups.

Introduction: Pancreatic fibrosis (PF) is a prominent histological feature of chronic pancreatitis and influences on vast majority of pancreatic disorders. So, PF early diagnosis gives a great opportunity to be a part of the strategy for preventing pancreatic diseases progression. It makes non-invasive PF assessment especially via biomarkers level measurement research perspective.

Aims & Methods: Aim was to evaluate the possibility of biomarkers levels measurement in PF grade assessment.

Methods. We measured interleukin-10 (IL-10) and interleukin-36 (IL-36), matrix metalloproteinase-1 (MMP-1) and matrix metalloproteinase-9 (MMP-9), fibronectin (FN) and hyaluronic acid (HA) plasma levels from 165 patient who underwent surgery from April 2022 to February 2024 due to pancreatic tumors and advanced chronic pancreatitis. We included 69 (41.8%) male and 96 (58.2%) female patients, mean age was 57.91±13.5 (25-89). Serum levels of specified biomarkers were determined by enzyme immunoassay using commercial kits; data registration performed was carried out on a semi-automatic analyzer. PF morphological grade was assessed according to Klöppel & Maillet's scoring system [1] and scaled into three grades: mild, moderate and severe PF.

This study was conducted within the healthcare research project "Assessment of pancreatic fibrosis as a prognostic factor for its diseases course" funded by Autonomous non-profit organization "Moscow Center for Innovative Technologies in Healthcare" administered by the Moscow Healthcare Department.

Results: Plasma FN (pFN) level was significantly (p=0.029) higher in patients with mild PF (pFN=110.7±72.7 μg/mL), than in patients with severe PF (pFN=74.9±32.8 μg/mL). The median pFN levels were significantly varied in groups with different grades of intralobular PF (p<0.05), but not in groups divided by perilobular PF grade (p>0.05).

Moreover, pFN level significantly negatively correlated with PF integrative grade (Spearmen's rho = -0.21, p=0.007). Regarding IL-10, IL36, MMP-1, MMP-9 and HA levels, there were no significant differences either in patients with different PF integrative grade, or in groups divided by perilobular and intralobular PF (p>0.05). We revealed no significant correlations between specified biomarkers levels and PF grade (p>0.05).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The FN serum level significantly decreased in patients with severe PF in contrast to patients with mild PF who had comparatively higher serum FN level. Oppositely, IL-10, IL36, MMP-1, MMP-9 and HA had shown no effect in PF grade assessment. It could be useful for noninvasive pancreatic fibrosis diagnosis and even for patients' selection for advanced diagnostics.

Contact E-Mail Address: christian.reinhard@gmail.com

Introduction: Pancreatic exocrine insufficiency (PEI) is characterized by a significant reduction in pancreatic exocrine activity within the intestine, impairing normal digestive processes [(1)]. This condition results in malnutrition-related complications and a diminished quality of life. Faecal pancreatic elastase serves as an optimal biomarker for evaluating pancreatic function in individuals with PEI. Its high stability ensures that faecal pancreatic elastase is concentrated during intestinal transit, thereby accurately reflecting total pancreatic secretion. The BÜHLMANN fPELA® turbo is a particle-enhanced turbidimetric immunoassay (PETIA) that is commercially available for the automated quantification of pancreatic elastase in faecal extracts using clinical chemistry analyzers.

Additionally, BÜHLMANN has developed the Quantum Blue® fPELA, a lateral flow immunoassay (LFIA) designed for environments requiring lower sample volumes. This study aimed to evaluate the clinical performance of both assays and compare them to a commercially available ELISA reference method.

Aims & Methods: A total of 189 symptomatic patients, comprising 82 non-PEI controls and 107 PEI-diagnosed patients, were utilized to compare the clinical performance of PETIA and LFIA against the ELISA reference assay. Sensitivity and specificity for both assays were determined using cutoffs of 100 µg/g and 200 µg/g.

Results: The area under the curve (AUC) was 0.809 for the BÜHLMANN fPELA® turbo (optimal cut-off: 166 µg/g), 0.792 for the Quantum Blue® fPELA (optimal cut-off: 109 µg/g), and 0.814 for the reference ELISA (optimal cut-off: 154 µg/g). At clinically relevant cut-offs of 100 µg/g and 200 µg/g, the BÜHLMANN fPELA® turbo demonstrated sensitivity of 0.57 and 0.74, and specificity of 0.9 and 0.76, respectively. The Quantum Blue® fPELA showed sensitivity of 0.62 and 0.71, and specificity of 0.93 and 0.74, respectively. The reference ELISA exhibited sensitivity of 0.64 and 0.73, and specificity of 0.87 and 0.70, respectively. A direct method comparison using at least 60 samples within the linear measuring range of all assays revealed a relative median difference in Bland-Altman analysis of 9.3% between the BÜHLMANN fPELA® turbo and the reference ELISA, 10.8% between the ELISA and the Quantum Blue® fPELA, and 11.0% between the PETIA and the LFIA.

Conclusion: The study demonstrated that both the BÜHLMANN fPELA® turbo and the Quantum Blue® fPELA exhibit strong diagnostic performance to detect PEI in symptomatic patient population and high concordance with the reference ELISA assay. The BÜHLMANN fPELA® turbo, a particle-enhanced turbidimetric immunoassay, is an accurate, non-invasive, automated test ideal for large-scale determination of pancreatic elastase levels in faecal extracts.

Meanwhile, the Quantum Blue® fPELA rapid test is well-suited for smaller laboratories, offering a faster time to result compared to traditional ELISA methods, while offering a coequal clinical performance.

Introduction: Malnutrition is a typical complication of pancreatic diseases. Vitamin D (VD) insufficiency or deficiency is present in chronic pancreatitis (CP), leading to increased cardiovascular risk, bone complications, impaired quality of life and increased mortality.

Aims & Methods: The study aimed to determine the prevalence of VD deficiency or insufficiency in patients with CP, and to assess its relationship to CP progression and associated cardiovascular and bone complications. 70 patients (45 males) were enrolled, with a mean age of 54.01±13.46 years. Alcohol abuse was the most common aetiology. Imaging morphological data were assessed by Cambridge classification for CT/MRCP; pancreatic exocrine insufficiency (PEI) - by fecal elastase-1, CP severity - by M-ANNHEIM classification; bone densitometry - by Dual-energy X-ray absorptiometry; and cardiovascular risk - by 10-year risk of mortality scores (SCORE and Framingham Risk Score - FRS) and by the arterial stiffness using pulse wave velocity (PWV) at a.carotis and a.femoralis.

Determination of 25-hydroxyvitamin D was performed by a LC-MS/MS method. Vitamin D status was assessed as deficiency (<25 nmol/L), severe insufficiency (25–50 nmol/L), mild insufficiency (50–80nmol/L), and sufficiency (>80 nmol/L). Resting energy expenditure was calculated using the Harris-Benedict formula. Statistical analysis was performed by SPSS.

Results: Mean VD levels were 37.86±24.36 nmol/L (range 3.854–99.874 nmol/L); 26 patients had deficiency; profound insufficiency was found in 25 patients; another 14 were with mild insufficiency, and only 5 patients were in a sufficiency status. We found no significant relation between VD levels and gender. VD levels correlated significantly with BMI but not with symptoms (weight loss, pain and steatorrhea). 12 patients reported

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

no symptoms, however, 10 of them had levels of VD less than 50 nmol/L. Resting energy expenditure correlated significantly with VD levels (r=0.53, p=0.000). In patients with severe structural changes, we observed significantly lower VD levels regardless of etiology (p<0,01). VD levels were lower in patients with PEI, p<0.05. Patients with mild CP by M-ANNHEIM had lower VD levels compared to patients with moderate and advanced CP, p<0.05.

We found an association of VD with pancreatolithiasis. At a cut-off of VD 11.95 nmol/L, we verified pancreatic lithiasis with 89.4% sensitivity and 83.3% specificity and AUC of 0.826±0.113 (95% CI, 0.61-1). VD status worsened with increasing the 10-year risk of mortality by both SCORE and FRS, p<0,05.

We observed lower vitamin D levels with increasing PWV. Lower VD levels were associated with diabetes mellitus. 35.6% of the investigated patients had osteopenia or osteoporosis. Bone density was affected and significantly decreased in patients with VD deficiency or severe insufficiency.

By increasing and optimising the dose of pancreatic enzymes in patients with pancreatic insufficiency, we demonstrated clinical improvement with a significant increase in BMI (p<0.0001) and VD levels, p<0.01.

Conclusion: Most of our patients with CP were VD insufficient. Monitoring of nutritional status in patients with CP is mandatory to prevent the development of malnutrition complications and associated morbidity and mortality.

An effort should be the point of a multidisciplinary approach for an up-to-date strategy for patients with pancreatic disorders, ensuring optimal therapeutic results and better quality of life.

SPLENIC VEIN THROMBOSIS PREVALENCE IN CHRONIC PANCREATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

R.Z. Borbély[1,2], J. Hoferica[1,3], B. Teutsch[1,4,5], E.Á. Szalai[1], P.J. Hegyi[1,6], B. Eross[1,6,5], N. Faluhelyi[1,7], P. Hegyi[1,5,8]

Introduction: Chronic pancreatitis (CP) is a progressive inflammatory disorder that predisposes patients to various complications, including vascular events. Among these, splenic vein thrombosis (SVT) represents a siginficant, but often underdiagnosed complication, with reported prevalence rates varying widely. SVT may lead to sinistral portal hypertension, resulting in gastric varices and, in severe cases, life-threatening gastrointestinal hemorrhage.

This systematic review and meta-analysis aims to determine the true pooled prevalence of SVT in CP patients and to evaluate the bleeding rate among those with splenic thrombosis by synthesizing data from studies in which all participants underwent appropriate imaging for SVT detection.

Aims & Methods: An exploratory search was conducted to identify key articles reporting on the prevalence of SVT among CP patients. Four studies were selected based on their provision of relevant, poolable data on prevalence with the use of proper imaging techniques for detecting SVT, encompassing a total of 1,973 patients. A random effects meta-analysis was performed using SPSS, and a forest plot was genrated to visually represent both individual and overall prevalence estimates. An ongoing PRISMA compliant systematic literature search continues to capture all pertinent studies on this topic.

Results: Analysis of data from the four selected studies (n = 1,973) revealed a pooled SVT prevalence of 12.7% in CP patients. Although individual study estimates varied, likely reflecting differences in study design, CP etiology, and follow-up duration, the overall result indicates that approximately one in eight patients with CP develops SVT.

Conclusion: Our preliminary findings demonstrate that, when appropriate imaging is employed, SVT occurs in approximately 12.7% of chronic pancreatitis cases. These results underscore the clinical importance of SVT, particularly given its association with an increased risk of gastrointestinal hemorrhage. Routine evaluation for SVT in CP patients should be considered, and further research is warranted to elucidate underlying risk factors and to refine management strategies for this potentially life-threatening vascular complication.

Introduction: Pain is the hallmark and most disabling symptom of chronic calcific pancreatitis (CCP), often severe and significantly impairing patients' quality of life. Its pathophysiology involves increased intraductal pressure, chronic inflammation, and neuropathic changes.

Aims & Methods: This study aimed to assess the prevalence of pain in CCP and to identify factors associated with its occurrence and severity.

This was a retrospective analytical study including patients followed for CCP. We collected data on disease duration, etiology, clinical manifestations, complications, analgesic treatments (AT), and symptom evolution under treatment. Pain intensity and impact on quality of life were assessed using the Izbicki Score (IS), which categorizes pain as mild (0–20), moderate (21–40), severe (41–60), or very severe (>60). Incomplete records that prevented IS calculation were excluded. Data were entered and analyzed using SPSS software, with statistical significance set at p < 0.05.

Results: We included 22 patients (14 men and 8 women), with a mean age of 55.6 years [27–80 years]. The most common symptoms were epigastric pain (n=18), weight loss (n=13), and chronic diarrhea (n=6). The mean delay between symptom onset and diagnosis was 25 months [1–120 months]. Etiologies included hyperparathyroidism (n=6), alcohol use (n=2), pancreas divisum (n=2), autoimmune causes (n=2), and were undetermined in 10 cases. The IS ranged from 0 to 93.75, with a mean of 40.22. Eight patients had an IS >40. Morphine was required in four cases; paracetamol was prescribed for 12 patients, and tramadol for two. Endoscopic treatment was indicated in three cases, while one patient underwent a Wirsungojejunostomy.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In univariate analysis, alcohol consumption was significantly associated with the occurrence of epigastric pain (p=0.01). Smoking and alcohol use were both linked to a higher IS (>50) (p=0.04). Smoking cessation was associated with a better analgesic response (p=0.04). Morphine use was significantly more frequent among alcoholic patients (p=0.01), and their treatment response was often unfavorable (p=0.02).

Conclusion: In our cohort, 80% of patients with CCP experienced pain, which was severe to very severe in nearly half the cases. Pain intensity was significantly associated with tobacco and alcohol consumption, while cessation improved treatment response. These findings underscore the importance of therapeutic education focused on smoking and alcohol cessation, in addition to analgesic management, to slow disease progression and improve pain control.

FREQUENCY ANALYSIS OF THE RS7057398 MUTATION AT THE CLDN2-MORC4 LOCUS IN CHRONIC PANCREATITIS

B. Kazi[1,2], B. Bako[1,2], P. Hegyi[3,4,5], B. Nemeth[1,2], Hungarian Pancreatic Study Group

[1]University of Szeged, Department of Medicine, Center for Gastroenterology, Szeged, Hungary, [2]Hungarian Centre of Excellence for Molecular Medicine – University of Szeged, Translational Pancreatology Research Group, Szeged, Hungary, [3]Interdisciplinary Centre of Excellence for Research Development and Innovation, University of Szeged, Translational Pancreatology Research Group, Szeged, Hungary, [4]University of Pecs Medical School, Institute for Translational Medicine, Pecs, Hungary, [5]Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary

Contact E-Mail Address: nemeth.balazs@med.u-szeged.hu

Introduction: The rs7057398 mutation in the *CLDN2-MORC4* locus on the X chromosome has been linked to chronic pancreatitis according to several recent publications and a meta-analysis. However, the mutation itself is located very far from both genes (CLDN2 and MORC4), and according to our current knowledge, the protein products of CLDNS and MORC4 genes are not functionally related to the development of chronic pancreatitis.

Aims & Methods: Our aim was to investigate the frequency of the rs7057398 mutation in Hungarian patients with alcoholic and non-alcoholic pancreatitis and controls. Our study included 139 non-alcoholic (NACP) and 161 alcoholic chronic pancreatitis (ACP) patients and 509 controls recruited by the Hungarian Pancreatic Study Group (HPSG). The rs7057398 mutation (*CLDN2* c.-26930T>C) status in DNA samples was examined by conventional PCR amplification and Sanger sequencing.

Results: The "C" allele of the rs7057398 mutation showed significant accumulation in patients with chronic pancreatitis (p<0.0001, OR 1.96, 95% CI 1.6-2.4), especially in the alcoholic group (p<0.0001, OR 2.56, 95% CI 1.98-3.3). When women are grouped separately, it is seen that the significant accumulation of the "C" allele is only significant in alcoholic chronic pancreatitis (p<0.005, OR: 2.5, CI: 1.3-4.8), which is also confirmed by the genotype distribution in the same group containing only women (dominant model: p 0.017, OR 3.55, 95% CI 1.3-10, recessive model: p 0.049, OR 3.01, 95% CI: 1.01-9.01).

Conclusion: The rs7057398 mutation located in the CLDN2-MORC4 locus on the X chromosome predisposes to the development of chronic pancreatitis in the Hungarian population, which association is particularly true in chronic pancreatitis of alcoholic etiology.

Introduction: Autoimmune pancreatitis (AiP) is a rare form of chronic pancreatitis. Studies from Japan and Germany suggest that AiP patients may have a higher incidence of malignancies compared to the general population. However, reliable data in this regard are still lacking.

Aims & Methods: We initiated a retrospective, multicenter observational study within the Pancreas 2000 framework to investigate the incidence of malignancy in AiP Patients.In our global multicenter retrospective observational trial, we are currently collecting data from patients with AiP diagnosed after 2005, including type 1, type 2, and not-otherwise-specified (NOS) AIP, regardless of the diagnostic criteria used. Patients with less than 12 months of follow-up after AIP diagnosis and those with immune checkpoint inhibitor-induced pancreatitis are excluded.

Our primary outcome is to determine the occurrence of the first invasive cancer in AiP patients. The secondary outcome is to evaluate the characteristics of AiP patients with distinct pancreatic and/or extrapancreatic cancers and the prevalence of all cancer diagnoses within 12 months prior to AiP diagnosis. The standardized incidence ratio of any first invasive cancer after AiP diagnosis will be compared to age-grouped and gender-matched controls in the general population. The expected number of cancers in the general population will be determined using the Cancer Incidence in Five Continents Volume XI (CI5XI) registry.

Results: We will present the current status of recruitment and preliminary data. To date, 16 centers from Europe and America have entered 321 cases. Ethics submissions have already been applied for in an additional 45 centers across four continents (Europe, Asia, America, and Oceania).

Conclusion: To the best of our knowledge, this is the first global observational trial analyzing the risk of developing cancer in patients with AiP.

Disclosure: Nothing to disclose.

AUTOIMMUNE PANCREATITIS SUBTYPES BEHAVE DIFFERENTLY: A 20-PATIENT EXPERIENCE FROM TURKEY

Y. Özden[1]
[1]University of Health Sciences, Kayseri Faculty of Medicine, Gastroenterology, Kayseri, Türkiye

Contact E-Mail Address: yavuzozden@gmail.com

Introduction: Autoimmune pancreatitis (AIP) is a rare, immune-mediated form of chronic pancreatitis, classified into three subtypes. Type 1 AIP, the pancreatic manifestation of IgG4-related disease, often presents with multisystem involvement and frequent relapse (1,2). Type 2 AIP is pancreas-limited, tends to affect younger individuals, and is commonly associated with inflammatory bowel disease (IBD) (2,3). A third form—checkpoint inhibitor-related pancreatitis (CIP or Type 3 AIP)—has been recently described in patients receiving immune checkpoint inhibitors, typically asymptomatic but may result in pancreatic atrophy (4).

Precise subtyping is critical due to differences in clinical behavior, relapse risk, and treatment response (1,2,3). We present a single-center series comparing clinical, radiologic, and histopathologic characteristics of Type 1 and Type 2 AIP.

Aims & Methods: We retrospectively reviewed 20 patients diagnosed with AIP between 2020–2024 at a tertiary center. Classification followed International Consensus Diagnostic Criteria (1). Diagnostic evaluation included endoscopic ultrasound (EUS), serum IgG4 levels, and contrast-enhanced CT/MRI/MRCP (1,2). EUS-guided fine-needle biopsy (FNB) was performed where malignancy could not be excluded. Histopathology differentiated lymphoplasmacytic sclerosing pancreatitis (LPSP, Type 1) from idiopathic duct-centric pancreatitis (IDCP, Type 2) (2). Data on extra-pancreatic involvement, steroid response, and relapse were collected.

Results: Fifteen patients were diagnosed with Type 1 AIP and five with Type 2. Type 1 patients had a mean age of 63 years and were predominantly male (80%). Obstructive jaundice was the most common presentation. All had elevated serum IgG4. EUS revealed diffusely hyperechoic parenchyma and long-segment ductal narrowing. Histology confirmed LPSP. Extra-pancreatic involvement was observed in 60%, most commonly IgG4 cholangitis. All responded to corticosteroids; 40% relapsed within one year and received rituximab (5).

Type 2 patients had a mean age of 38, with equal gender distribution. Presenting symptoms included abdominal pain and acute pancreatitis. Serum IgG4 was normal in all cases. EUS revealed focal hypoechoic lesions with short-segment narrowing. Histology confirmed IDCP. Two patients (40%) had ulcerative colitis. All achieved remission with steroids, and no relapses were observed (2,3).

Conclusion: This series emphasizes the distinct clinical courses of AIP subtypes. Type 1 AIP represents a systemic IgG4-related disease with high relapse risk, often requiring long-term immunosuppression (5). Type 2 AIP affects younger patients, remains confined to the pancreas, and shows sustained remission after steroid therapy (2,3). Accurate classification using EUS, MRCP, IgG4, and histology is crucial for appropriate management and long-term outcomes (1,2).

UTILITY OF PANCREATIC DUCT WALL THICKENING ON ENDOSCOPIC ULTRASOUND IN THE DIAGNOSIS OF AUTOIMMUNE PANCREATITIS

S. Nishiyama[1], T. Hisa[1], N. Kodaira[1], A. Ego[1], N. Miyasaka[1], S. Sakata[1], Y. Ito[1], A. Kudo[1], T. Yamada[1], S. Osera[1], H. Fukushima[1]
[1]Saku Central Hospital Advanced Care Center, Department of Gastroenterology, Saku, Japan

Contact E-Mail Address: shigeru.050516@gmail.com

Introduction: In autoimmune pancreatitis (AIP), if the disease is serum IgG4-negative, focal-type, and without other organ involvement, it is difficult to distinguish it from pancreatic cancer. The histopathological diagnosis of AIP using endoscopic ultrasound (EUS)-guided fine needle biopsy needles has been useful; however, the accuracy rate remains suboptimal, ranging from 54.7% to 87.2%[1,2,3].

We focused on a novel EUS finding of pancreatic duct wall thickening, which reflects the periductal lymphoplasmacytic infiltration characteristic of AIP[4].

Aims & Methods: This study aimed to evaluate the utility of pancreatic duct wall thickening on EUS in diagnosing AIP that is serum IgG4-negative, focal-type, and without other organ involvement. We retrospectively analyzed 35 patients diagnosed with AIP at our institution between March 2017 and January 2024, based on the Japanese Clinical Diagnostic Criteria for Autoimmune Pancreatitis 2018 (JPS2018). EUS was performed in all patients and the presence of pancreatic duct wall thickening was assessed. We defined pancreatic duct wall thickening as symmetric hypoechoic wall thickening of the pancreatic duct with a superficial hyperechoic layer. The presence of pancreatic duct wall thickening was evaluated along with localization, serum IgG4 level, and other organ involvement.

Results: Of 35 patients with AIP, 28 were male and 7 were female, with a median age of 72 years (range: 42–82). Fourteen patients (40%) had diffuse-type disease and 21 (60%) had focal-type disease. The median serum IgG4 level at diagnosis was 402 mg/dL (range: 14–2560). 29 patients (82.9%) were IgG4-positive (≥135 mg/dL) and 6 patients (17.1%) were IgG4-negative (<135 mg/dL). Other organ involvement was found in 12 patients (34.3%). Pancreatic duct wall thickening was observed on EUS in 30 patients (85.7%). Among 23 patients with focal-type and no other organ involvement, pancreatic duct wall thickening was observed in 15 of 17 (88.2%) serum IgG4-positive patients and in 5 of 6 (83.3%) serum IgG4-negative patients.

Conclusion: In AIP, EUS shows a high rate of pancreatic duct wall thickening, which is particularly useful in IgG4-negative, focal-type cases without other organ involvement.

A NETWORK META-ANALYSIS OF B-CELL DEPLETION FOR IGG4-RELATED DISEASE

R. Motta[1], I. Castro Vitor[2], M. Tomé[3], W. Fernandes Oliveira Amador[3], E. Culver[1]
[1]University of Oxford, Translational Gastroenterology and Liver Unit, Oxford, United Kingdom, [2]Federal University of the State of Rio de Janeiro, Department of Medicine, Rio de Janeiro, Brazil, [3]Federal University of Campina Grande, Department of Medicine, Cajazeiras, Brazil

Contact E-Mail Address: rodrigo.vieiramotta@ndm.ox.ac.uk
Introduction: IgG4-related disease (IgG4-RD) is a chronic fibro-inflammatory multi-systemic disease. Pancreato-biliary involvement is reported in up to 60%, which can lead to exocrine and endocrine pancreatic insufficiency. Glucocorticoids can be used to control active inflammation but are associated with substantial toxicity. B-cell depletion with anti-CD20 chimeric Rituximab (RTX) and anti-CD19 humanised Inebilizumab (INEB) are steroid-sparing and used to control disease flares. INEB is the only FDA-approved medication for the treatment of IgG4-RD.
Aims & Methods: Our aim was to compare B-cell depleting agents for the treatment of IgG4-RD. We searched PubMed, Cochrane Central Register of Clinical Trials and Embase databases for studies of maintenance therapy in IgG4-RD with a pre-defined strategy and performed a network meta-analysis to assess relapse at 12 months, occurrence of infections and infusion-related reactions.
Results: 96 out of 2545 manuscripts underwent full text review after exclusions. Three studies met eligibility for the meta-analysis, two reporting the use of RTX and one of INEB (Table 1).
For the primary outcome of disease relapse at 12 months, INEB had a risk ratio (RR) of 5.8 (95% CI 0.29 - 115.02) and RTX had an RR of 2.29 (95% CI 0.19 - 28.21), with INEB being superior in preventing relapses. The RR for infections with INEB was 0.81 (95% CI 0.19 - 3.41) whilst with RTX was 0.62 (95% CI 0.13 - 3.04). The RR for infusion-related reactions with INEB was 1.27 (95% CI 0.09 - 18.76) and for RTX was 0.93 (95% CI 0.11 - 8.19). These must be interpreted in the context of study design; INEB in a phase 3 randomised trial following a stringent safety protocol for reporting of adverse events, and RTX in retrospective observational studies.

Author	Year published	Design	Country	Sample size	Comparison	Follow up (months)	Male
Campochiaro	2020	Retrospective cohort	Italy	14	RTX vs placebo	-	7 (50%)
Majumder	2018	Retrospective cohort	US	43	RTX vs placebo	34 / 27	34 (79%)
Stone	2024	Randomised, placebo-controlled blinded	Global	135	Inebilizumab vs placebo	12	88 (65%)

Conclusion: This Network Meta-analysis demonstrates that INEB is superior to RTX at preventing disease relapses in patients with IgG4-RD at 12 months. Adverse events, such as infection and infusion-related reactions, were comparable in lieu of the methodological differences between studies.

ASSOCIATION BETWEEN DURATION OF DOUBLE-PIGTAIL PLASTIC STENT PLACEMENT AND PANCREATIC PSEUDOCYST RECURRENCE: A RETROSPECTIVE STUDY

Z. Yan[1], Z. Xie[1], Y. Zhang[1], Y. Feng[2], A. Yang[2]
[1]Peking Union Medical College Hospital, Beijing, China, [2]Peking Union Medical College Hospital, Gastroenterology, Beijing, China

Contact E-Mail Address: xiezx2001@outlook.com
Introduction: Pancreatic pseudocysts (PPs), common complications of acute or chronic pancreatitis, are often managed with endoscopic ultrasound-guided double pigtail stent (EUS-DPS) drainage. However, the relationship between stent indwelling duration and PPs recurrence remains poorly defined.
Aims & Methods: We aimed to investigate whether shorter stent dwelling duration is associated with a higher risk of PPs recurrence. Patients diagnosed with PPs who underwent EUS-DPS drainage at Peking Union Medical College Hospital between June 2006 and December 2024 were retrospectively reviewed. Clinical outcomes including technical success, clinical success, postoperative complications, and recurrence were analyzed. Furtherly, the stent indwelling duration-recurrence relationship and risk factors were evaluated.
Results: A total of 116 patients were included (84 males, 72.4%), with a mean age of 48.29±13.56 years. The most common etiologies were biliary pancreatitis (28.4%) and alcoholic pancreatitis (25.9%). PPs were primarily located in the pancreatic body and tail (78.4%), with a mean diameter of 10.23±4.17 cm. Regarding drainage success, technical success was achieved in 106 cases (91.4%), and clinical success in 81 cases (69.8%). Postoperative adverse events occurred in 33.6% of patients, including infections (n=31), bleeding (n=3), perforation (n=2), and cardiopulmonary events (n=3).
Patients with clinical success were stratified by stent indwelling duration (0-2 months, 2-6 months, >6 months), while PPs recurrence was significantly higher in the short-duration group compared to the intermediate- and long-duration groups (p-value < 0.05).
No postoperative adverse events occurred beyond 30 days in any group, suggesting that prolonged stent indwelling duration does not increase the risk of long-term complications.
Meanwhile, multivariate regression analysis identified longer stent dwelling duration and elevated high-sensitivity C-reactive protein as independent protective factors for clinical success.
Conclusion: EUS-DPS placement represents a safe and effective modality for internal drainage and therapeutic approach for PPs. Our findings support that maintaining stent placement for more than six months to significantly reduce recurrence risk and improve long-term clinical outcomes, with manageable adverse events.
Disclosure: Nothing to disclose.

DIAGNOSTIC PERFORMANCE OF EUS-FNB IN PANCREATIC CYSTIC AND MIXED LESIONS

N. El-Domiaty[1,2], R. Ayoubbou-Farah[1], V. Laurent[1], C. Bellanger[1], A. Amiot[1], F. Carbonnel[1], I. Boytchev[1], A. Martin[1]

Contact E-Mail Address: nadadomty@hotmail.com

Introduction: Pancreatic cystic lesions (PCLs) are common and could vary from a simple benign cyst to a highly malignant cyst.[1] Mixed lesions with a solid part and a cystic part are very uncommon. They could be a sign of malignant transformation of a cyst.[2]

Recently the awareness of these lesions has increased, especially with the increased incidence of asymptomatic pancreatic cysts worldwide primarily due to improved detection by different advanced imaging modalities.[3]

Therefore, the proper diagnosis, differentiation and staging of these lesions are crucial for proper management and avoiding unnecessary treatment of benign ones and missing early treatment of the pre-malignant lesions.[4]

EUS-guided fine needle biopsy (EUS-FNB) may overcome these limitations of EUS-FNA through acquisition of core tissue samples that provide the ability to assess cyst wall architecture via histology. At this point, ESGE does not recommand use of EUS-FNB for diagnosis of cystic lesions.[5]

Aims & Methods: Aim: Based to the literature, there are few reports regarding the role of EUS-FNB replacing EUS-FNA in the diagnosis of PCL. This work aims to study the feasibility and safety of EUS-FNB 22G in diagnosis of PCLs.

Methods: Of 640 consecutive EUS-FNB 22G for different lesions between January,2019 and December,2023 at our center. 60 EUS-FNB 22G were done for the patients who underwent EUS-guided sampling of pancreatic cystic or mixed lesions diagnosed by abdominal MRI and/or CT scan. The patients were retrospectively and prospectively followed. All the solid lesions, pancreatic pseudocysts (round, non-septated lesions, presence of internal debris, recent acute pancreatitis or radiologic imaging of chronic pancreatitis) and lesions interposed vessels or main pancreatic duct are excluded from this study.

Patients with history of severe hemorrhagic risk (platelet count <50,000 / Lor prothrombin activity <50%) are excluded. We statistically analyse the clinical and technical success rates, in addition to evaluate the diagnostic accuracy of EUS-FNB in differentiating benign and malignant pancreatic cystic lesions.

Evaluation of the cyst location, primary diagnosis, adverse events, and comparison between the cytologic fluid analyses and histopathology was performed. Technical success was defined as visible tissue present after biopsy. Clinical success was defined as the presence of a specimen adequate to make a histologic or cytologic diagnosis.

Results: A total of 60 patients (mean age 65.0 ± 12.1, 36.6% females) with 60 PCLs consecutively were referred for EUS-FNB 22G and enrolled in a prospective study. 41/60 (68.3%) lesions were mixed (cystic and tissue) and 19/60 (31.7%) lesions are cystic lesions. The mean lesion size was 32.4 ± 16.6mm. The EUS-FNB 22G procedure was technically and clinically successful in all patients (100%). The mean number of needle passes, as defined as unique transluminal needle insertions into the cystic compartment, was 1.9 ± 0.6. No immediate adverse events were developed after the procedure.-In 57/60 (95.0%) pancreatic cystic lesions, the specimens were adequate for cyto-histologic assessment. Among the 10 patients who had surgical teatment, the concordance of FNB compared to surgical pathology was noticed.

Conclusion: The diagnosis of pancreatic cystic and mixed lesions with a solid and liquid component can be achieved with fine needle biopsy using a 22-gauge needle in a safe and practicable manner. This method has a great diagnostic yield and does not increase the rate of complications.

ADVANCED ENDOSCOPIC RISK STRATIFICATION IN SUSPECTED MAIN-DUCT IPMN: A REAL-WORLD CASE SERIES

N. Shumka[1], P. Karagyozov[1]
[1]Acibadem City Clinic University Hospital Tokuda, Clinic of Gastroenterology, Sofia, Bulgaria

Contact E-Mail Address: shumkanadica97@gmail.com

Introduction: Patients with suspected main-duct intraductal papillary mucinous neoplasms (MD-IPMN) are frequently referred for surgery due to the high risk of malignancy (as high as 40% to 60% in the literature). However, many present with significant comorbidities or concurrent malignancies, complicating the surgical risk-benefit assessment. In such cases, advanced endoscopic procedures may assist in guiding clinical decision-making.

Aims & Methods: This study aimed to evaluate the role of EUS-guided fine-needle biopsy (EUS-FNB) and pancreatoscopy in individualized risk stratification and management decisions for patients with suspected MD-IPMN. We retrospectively analyzed eight patients treated at our center between March 2020 and March 2025. All patients presented with significant comorbidities or active oncologic disease. Data collected included endoscopic findings, biopsy results, complications, and final management decisions.

Results: Eight patients with suspected main-duct IPMN were included (mean age: 67.6 years; 3 females, 37.5%). The mean main pancreatic duct (MPD) diameter was 9.1 mm. All patients were evaluated in a multidisciplinary setting due to clinical complexity, including comorbidities or concurrent malignancies. EUS-guided fine-needle biopsy (EUS-FNB) was performed in 3 patients, and pancreatoscopy in 5. All procedures were technically successful.

Biopsy samples were diagnostic in 2 of 3 EUS-FNB cases and 5 of 5 pancreatoscopy cases and contributed directly to management decisions. In 1 EUS-FNB case, the sample was non-diagnostic. Pancreatoscopy revealed mucin extrusion in 4/5 patients, papillary or villous projections in 3/5, and a ‚fish egg' appearance in 2/5. These features supported risk assessment and, in several cases, justified a conservative approach in high-risk

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients. Three patients underwent surgery following multidisciplinary review. One had concordant findings (high-grade dysplasia), while two had discordant outcomes: one with low-risk pancreatoscopy findings had invasive adenocarcinoma, and one with EUS-FNB showing low-grade atypia had high-grade dysplasia on final pathology. Five patients were managed with active surveillance. One case of mild post-ERCP pancreatitis occurred; no other complications were reported. Endoscopic findings influenced management in 5 of 8 patients (62.5%).

Conclusion: In this real-world case series, EUS-FNB and pancreatoscopy contributed meaningfully to individualized decision-making in patients with suspected MD-IPMN. However, discordance between endoscopic impressions and final pathology in two cases highlights the limitations of visual and cytologic assessment. These findings reinforce the need for integrating endoscopic data with imaging, clinical context, and multidisciplinary input when evaluating main-duct IPMN.

IPMN OF BRANCH DUCTS: IS IT POSSIBLE TO DEFINE CRITERIA FOR AVOIDING AND/OR SUSPENDING SURVEILLANCE?

P. Gomes[1], A. Ruge[1], D. Simas[2], I. Caetano[1], A.G. Antunes[1], A. Fernandes[1], H. Vasconcelos[1]

Introduction: Branch-duct intraductal papillary mucinous neoplasms (IPMN-BD) account for 80% of cystic lesions pancreatic. The prevalence of these lesions is increasing and, theoretically, these patients should be monitored, given the increased risk of pancreatic carcinoma. However, the morbidity and mortality associated with pancreatic surgery and the costs of surveillance programmes are significant.

The aim is to assess: whether it is possible to select patients who will not benefit from surveillance, using the risk scores determined by comorbidities; and whether the application of the Kyoto 2024 follow-up criteria for suspension of follow-up is appropriate.

Aims & Methods: Retrospective analysis of IPMN-BD cases with at least 1 year of follow-up in a single centre. We analysed the ROC curves of the Charlson Comorbidity Index (CCI) and the Adult Comorbidity Evaluation 27 score (ACE-27) at diagnosis to predict mortality at 1, 3 and 5 years. In a secondary analysis, the evolution of IPMN≤20mm, without High-risk stigmata(HRS) or Worrisome Features(WF), was monitored after 5 years of stability.

Results: 109 patients were included (males-32.1%; mean age-68.9±12 years; mean follow-up-53±35 months; presence of HRS-1.8%; presence of WF-23.9%; progression to adenocarcinoma-1 patient). Five-year mortality was 13.6% (no deaths attributable to IPMN progression). Both the ICC (AUC=0.969; p<0.001) and ACE-27 (AUC=0.961; p<0.001) scores showed good discriminative capacity, with no statistically significant differences, the cut-off point with the best accuracy in predicting 5-year mortality being an ICC≥6 and severe ACE-27 (sensitivity-83.3% and specificity-94.7% versus sensitivity-100% and specificity-92.1%). 20 patients met the Kyoto 2024 criteria for suspending surveillance and none of themMshowed subsequent progression.

Conclusion: Patients with IPMN-BD and CHF≥6 or severe ACE-27 do not seem to benefit from follow-up due to the high probability of death unrelated to pancreatic cancer. In selected cases, in the absence of progression after 5 years of follow-up, discontinuation of surveillance may be considered.

Introduction: Pancreatic cystic neoplasms are common in the general population, with intraductal papillary neoplasm of the pancreas (IPMN) being the most prevalent, carrying a risk of malignant transformation. IPMNs can be classified into three morphological types (Main-duct, Branch-duct, and Mixed-type) and exhibit a range of neoplastic transformations from low-grade dysplasia (LGD) to invasive carcinoma (IC). Identifying high-grade dysplasia (HGD)/IC has a strong clinical value.

Aims & Methods: The aim of this study is to evaluate the role of endoscopic ultrasound (EUS) in detecting predictive factors of malignancy. This is a monocentric retrospective study using a prospectively maintained database of consecutive patients who underwent surgical resection for

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

IPMN between 2015 and 2023 and had available preoperative EUS data performed at our tertiary referral center. The following EUS features were considered:

- Presence of worrisome feature (WF), high-risk stigmata (HRS) or macroscopic solid component (MSC) at diagnosis
- Pancreatic duct (PD): PD dilation, hypoechoic thickened walls of PD (HTW-PD), contrast-enhancement of PD walls (CE-PDW) presence and dimension of PD nodules (PDN), contrast-enhancement (CE)/ real time elastography (RTE) of PDN.
- Cysts: dimension >30 mm, thickened walls, CE on walls, presence, and size of mural nodules (MN), CE/RTE on MN.

Patients were eligible for inclusion if they met the following criteria: age > 18 years; a final histological diagnosis of IPMN after surgery; and availability of a preoperative EUS evaluation conducted at our center. All EUS videos and images were reviewed by two experienced pancreatic endosonographers.

Univariate and multivariate analyses were performed using Pearson correlation coefficient, with statistical significance set at $P < 0.05$.

Results: We enrolled 198 patients (median age: 70 years, male sex: 57.6%). The presence of WF, HRS, and MSC at diagnosis was 40.9%, 44.9%, and 19.1%, respectively. The final histological diagnoses were LGD in 36.4%, HGD in 29.8%, and IC in 33.8%.

EUS predictors of HGD and IC at univariate logistic regression included MSC dimension (p=.02), PDN presence and size (p=.021; p=.016).

EUS predictive factors for IC included: MSC presence and size (p<.001), HTW-PD (p=.037), and presence, size, enhancement, and rigid pattern at RTE of PDN (p=.003; p=.002; p=.003; p=.004).

In multivariate analysis, predictors of HGD-IC included HTW-PD (p=.04), CE-PDW (p=.03), PDN size (p=.02), CE of PDN (p=.09), rigid pattern at RTE of PDN (p=.02), cyst dimension >30 mm (p=.07), and CE of MN (p=.04). All these variables predicted IC too.

Conclusion: In conclusion, while the current guidelines primarily emphasize the use of radiological imaging for the assessment of IPMNs, this study supports the growing role of EUS in identifying features that may predict malignant progression.

Moreover, some of the predictive factors associated with aggressive behavior, such as, the characteristics of the pancreatic duct and the use of real time elastography, are not mentioned in current international guidelines.

Introduction: Differentiating mucinous (MPCLs) from non-mucinous pancreatic cystic lesions (NMPCLs) remains critical for appropriate therapeutic decisions. While carcinoembryonic antigen (CEA) levels >192 ng/mL have been the conventional benchmark, their limited sensitivity underscores the need for more accurate alternatives. Recent data suggest intracystic glucose levels may be a promising biomarker.

This study prospectively evaluated the diagnostic performance of intracystic glucose compared to CEA in pancreatic cyst fluid obtained via EUS-guided fine needle aspiration (EUS-FNA).

Aims & Methods: From July 2018 to October 2024, 24 patients with pancreatic cystic lesions undergoing EUS-FNA using a 22G needle were included. Glucose and CEA concentrations were measured using standard biochemical protocols. Final diagnosis was based on surgical pathology (n=5), cytopathology (n=9), or consensus radiologic/endoscopic evaluation by two blinded expert pancreatologists (n=10). All procedures and analyses were performed in a tertiary academic gastroenterology center in Morocco.

Results: Mean patient age was 59.8 years. Diagnoses comprised 13 mucinous cysts (54.2%; including 9 IPMNs and 4 MCNs), 7 serous cystadenomas (29.2%), 2 cystic neuroendocrine tumors (8.3%), 1 pseudocyst, and 1 simple cyst.

The mean intracystic glucose level in MPCLs was 14.1 mg/dL (95% CI: 5.6–22.6), versus 90.3 mg/dL (95% CI: 82.1–98.6) in NMPCLs ($p < 0.0001$). A glucose threshold of ≤30 mg/dL yielded an AUC of 0.94 (95% CI: 0.84–0.99), with 92.3% sensitivity and 100% specificity.

For CEA ≥192 ng/mL, AUC was 0.71 (95% CI: 0.54–0.86), with 46.1% sensitivity and 100% specificity. No significant correlation was found between glucose levels and either CEA or cyst size.

Conclusion: Intracystic glucose represents a simple, cost-effective, and highly accurate marker for distinguishing mucinous from non-mucinous pancreatic cystic lesions. It demonstrates superior sensitivity compared to CEA and can be a valuable adjunct in the diagnostic algorithm of pancreatic cysts, particularly in resource-conscious settings.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer that poses significant therapeutic challenges. In this regard, the identification of prognostic biomarkers is crucial to improve the prediction of clinical outcomes and guide therapeutic decisions. Tumour-associated autoantibodies (TAAbs) have been identified as prognostic biomarkers in several types of cancer, as they can be generated before the first clinically detectable signs of disease.

Aims & Methods: The aim of this study was to identify TAAbs that can be used as prognostic biomarkers in PDAC. 80 sera from patients with PDAC, divided into four groups according to disease stage, were included in the study: patients with premalignant lesions (n = 20), patients undergoing curative resection after diagnosis (CR) (n = 20), patients with unresectable advanced locoregional disease (LA) (n = 20) and patients with metastatic disease (MT) (n = 20). Sera from each group were analysed divided into 4 pools of 5 samples each using the HuProt Human Protreome microarray v4.0 (CDI Laboratories, Baltimore, MD). Candidate TAAbs with high specific reactivity in MT and/or LA samples were selected according to the following criteria: z-score ≥ 3 in at least 2/4 pools and fold-change > 1.2. The RNAseq data collected in the Human Protein Atlas were used to determine protein expression levels and prognostic value. The GSE15471, GSE28735 and GSE16515 databases were used to compare expression levels with those of healthy subjects without the disease.

Results: 43 TAAbs demonstrated high levels of specific reactivity in samples from MT and/or LA patients. Of these highly recognised proteins, 15 were selected for showing notable levels of expression in tumour tissue from PDAC patients and prognostic capacity in some types of cancer. Of these 15, 2 proteins involved in tumour development were identified. Survival analyses showed that six of the 15 selected proteins were significantly associated with a worse prognosis in PDAC patients ($p < 0.05$). Finally, in the comparison with control tumour tissue, 5 proteins were identified with significantly higher expression in patients diagnosed with the disease ($p < 0.05$ in at least 2 of the cohorts used).

Conclusion: 15 TAAbs have been identified as promising candidates for prognostic biomarkers in PDAC. Further validation studies are required to confirm their prognostic value and to develop a robust biomarker signature with potential for clinical application and market translation.

Disclosure: Nothing to disclose.

Contact E-Mail Address: horvath.zsofia@med.u-szeged.hu

Introduction: Pancreatic ductal adenocarcinoma (PDAC) ranks among the most aggressive malignancies, with a five-year survival rate below 10%. Its poor prognosis stems from late diagnosis, rapid disease progression, and marked resistance to conventional therapies, largely driven by frequent KRAS and TP53 mutations.

These genetic alterations disrupt multiple cellular processes, including intracellular calcium (Ca^{2+}) signaling, which plays a critical role in tumor progression. Plasma membrane calcium ATPase isoform 4 (PMCA4) is a major regulator of cytosolic Ca^{2+} levels, essential for maintaining cellular homeostasis.

Elevated expression of PMCA4 in PDAC has been associated with enhanced cell migration, apoptosis resistance, and poor clinical outcomes. PMCA4 localizes at focal adhesions, supporting motility and metastatic potential. Paradoxically, PMCA4 dysfunction can lead to Ca^{2+} overload, activating oncogenic pathways that drive cell proliferation and survival.

The cystic fibrosis transmembrane conductance regulator (CFTR), an epithelial chloride channel, also modulates calcium homeostasis. CFTR deficiency or dysfunction impairs PMCA4 activity, while paradoxically inducing its overexpression, likely as a compensatory mechanism in response to altered Ca^{2+} signaling.

This functional interaction between CFTR and PMCA4 is particularly relevant in pancreatic ductal epithelial cells, where both proteins co-localize at the apical membrane. Their coordinated function is crucial for regulating calcium and chloride transport, and its disruption may contribute to PDAC progression.

Aims & Methods: This study aim to investigate whether CFTR deficiency contributes to PMCA4 overexpression in PDAC cells and whether pharmacological restoration of CFTR function using Trikafta can normalize calcium signaling and modulate tumor cell behavior. Therefore we utilized both human pancreatic ductal organoids (hPOs) and the Capan-1 PDAC cell line to assess calcium and chloride transport.

Intracellular calcium levels were measured using FURA-2-AM, and chloride efflux was monitored with MQAE dye. Immunofluorescence staining was employed to analyze the expression and localization of CFTR, PMCA4, SOX9, Vimentin, and α-SMA.

Results: We successfully cultured human pancreatic organoids from adult pancreas-derived stem cells using standard 3D culture conditions. Following the establishment of primary organoids, we performed the first passage to expand the culture. The organoids were then dissociated into single cells and plated onto 24 mm cover glasses for further analysis.

Our experiments confirmed the expression of ductal markers in 2D human pancreatic organoids (hPOs) with the lack of mesenchymal markers Vimentin, and α-SMA. Immunofluorescent staining was visualized using a Zeiss LSM880 confocal microscope.

Functional assays revealed that Capan-1 cells exhibited significantly reduced Ca^{2+} and Cl^- efflux compared to hPOs, indicating impaired CFTR and PMCA acitivty.

Notably, treatment with Trikafta, a clinically approved CFTR modulator, successfully restored CFTR and PMCA4 activity in Capan-1 cells.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Our findings indicate that CFTR dysfunction contributes to the increased PMCA expression in PDAC cells, which can be ameliorated by Trikafta treatment. This study highlights the critical interplay between CFTR dysfunction and calcium homeostasis in pancreatic ductal adenocarcinoma (PDAC). These results underscore the relevance of epithelial ion transport pathways in PDAC pathophysiology and support further investigation of adjunctive approach in PDAC treatment.

Introduction: Over 90% of pancreatic cancers are KRAS mutation-positive; however, it is known that KRAS-negative pancreatic cancers often harbor draggable genes. Recently, the efficacy of KRAS G12C inhibitors has also been demonstrated. In this study, we performed KRAS mutation analysis (KRAS G12/13 and KRAS G12C) using droplet digital PCR (ddPCR) on ROSE samples obtained during EUS-FNA for pancreatic cancer.

Aims & Methods: Retrospective Study: Fifty-five cases of pancreatic cancer that underwent EUS-FNA at our institution between November 2019 and August 2021 were included. Samples included 55 ROSE samples (107 slides), 30 plasma cell-free DNA samples derived from peripheral blood, 30 germline DNA samples from whole blood, and 20 formalin-fixed paraffin-embedded (FFPE) samples from surgical specimens. DNA was extracted from each sample, and KRAS mutation-positive rates and concordance rates with surgical specimens were compared.

Prospective Study: Fifty-six cases of pancreatic cancer that underwent EUS-FNA between October 2022 and August 2024 were included. KRAS mutation analysis was performed on ROSE samples.

Results: Retrospective Study: The average amount of DNA extracted from ROSE samples was 66.7 ng per slide, and the DNA yield increased significantly with an increase in the number of cells on the ROSE slide. The positive rates for KRAS G12/13 mutations were 94.5% (52/55) for ROSE samples, 20.0% (6/30) for plasma cell-free DNA, 90.0% (18/20) for FFPE samples, and 0% (0/30) for germline DNA.

The concordance rate with surgical specimens for KRAS G12/13 mutations was 85.0% (17/20) for ROSE samples and 27.3% (3/11) for plasma cell-free DNA. ROSE samples demonstrated a significantly higher concordance rate with surgical specimens compared to plasma cfDNA.Prospective Study: In two cases, DNA was below the detection sensitivity. KRAS G12/13 positivity was 82% (46/56), and KRAS G12C positivity was 2% (1/56).

Comprehensive genomic profiling (CGP) was performed in 14% (8/56) of the cases, and all cases showed concordance in KRAS mutation status or wild-type status between ROSE samples and CGP results. One case identified a draggable gene (BRCA) via CGP, which was KRAS G12/13-negative in ROSE samples.

Conclusion: KRAS mutation analysis using ddPCR with ROSE samples successfully identified KRAS-negative pancreatic cancers and KRAS G12C-positive pancreatic cancers.

Introduction: Cadmium (Cd), a group 1 carcinogen, is linked to the development of pancreatic cancer, though its dose-response relationship, especially at low exposure levels, is not well-defined.

Aims & Methods: To investigate the relationship between Cd exposure and the risk of pancreatic cancer through a meta-analysis focusing on pooled relative risk, biomarker comparisons, and dose-response relationships.

Methods: This meta-analysis adhered to PRISMA guidelines and applied the PECO framework. A systematic search of key databases including PubMed, Cochrane Library, Web of Science, EMBASE, ScienceDirect, and ProQuest was carried out without language restrictions. Studies that met the predefined PECO criteria were chosen, extracting data on effect estimates such as hazard ratios, odds ratios, and relative risks (RR), along with Cd biomarker concentrations.

Analyses involved pooled relative risks, standardized mean differences for biomarker comparisons, and dose-response relationships, utilizing random-effects meta-analysis and meta-regression. Statistical procedures were performed on R version 4.3.0.

Results: Cd exposure was significantly associated with an increased risk of pancreatic cancer, with a pooled RR of 1.42 (95% CI = 1.16–1.73). Subgroup analyses indicated sex-specific variations: men demonstrated a significant increase in pancreatic cancer risk), while the risk for women was not statistically significant. Dose-response analyses revealed that higher Cd biomarker levels correlated with greater pancreatic cancer risk (β = 0.610, p = 0.035).

Conclusion: Cd exposure is associated with an increased risk of pancreatic cancer, as confirmed by a dose-response relationship and elevated biomarker levels in cases. Cd exposure is a modifiable risk factor for pancreatic cancer, meriting further investigation.

COMPARATIVE STUDY OF HISTOPATHOLOGICAL AND IMAGING FINDINGS IN HIGH-GRADE PANCREATIC INTRAEPITHELIAL NEOPLASIA (PANCREATIC CARCINOMA IN SITU)

K. Hanada[1], A. Shimizu[1], S. Yazumi[1], A. Kurita[1], T. Kin[1], Y. Takayama[1], K. Yoshida[1], M. Kitano[1], M. Takenaka[1], M. Serikawa[1], T. Sasaki[1], R. Ashida[1], S. Yasukawa[1], A. Yanagisawa[1], T. Furukawa[1], A. Kanno[1], T. Otsuka[1], H. Maguchi[1], M. Tanaka[1]
[1]Japan Study Group on the Early Detection of Pancreatic Cancer, Hiroshima, Japan

Contact E-Mail Address: kh-ajpbd@nifty.com
Introduction: Early diagnosis of pancreatic cancer is crucial for improving patient outcomes. High-grade pancreatic intraepithelial neoplasia (HG-PanIN), considered a carcinoma in situ of the pancreas, can lead to long-term survival when surgically resected—even in the absence of detectable lesions on conventional imaging such as CT or MRI.
In this study, we analyzed resected cases of HG-PanIN collected through the Japanese Early-stage Diagnosis Project of Pancreatic Cancer (JEDPAC), focusing on correlations between histopathological findings and preoperative imaging to identify potential diagnostic indicators.
Aims & Methods: Fifty cases (32 males, 18 females; age range 52–89 years, mean age 69.8 years) of surgically resected HG-PanIN, confirmed via central pathological review by two expert pathologists, were selected from JEDPAC-affiliated centers between 2011 and 2018. Preoperative imaging findings—including CT, MRI (MRCP), EUS, and ERCP—were retrospectively compared with pathological data.
Results: Lesions were located in the pancreatic head in 11 cases and in the body/tail in 39 cases. Sixteen cases involved only the main pancreatic duct (MPD, Group A), 27 involved both MPD and branch ducts (Group B), and 7 were confined to branch ducts (Group C). In Groups A and B, 40 cases showed longitudinal intraductal spread of ≥10 mm, and 14 exhibited skip lesions with discontinuous HG-PanIN components.
MPD stenosis was frequently observed in cases with ≥10 mm ductal spread, particularly in Groups A and B, and was often accompanied by focal parenchymal atrophy corresponding to the lesion. In skip lesions, however, HG-PanIN foci did not consistently correspond to areas of ductal stenosis, making precise preoperative localization by imaging difficult. In Group C, round or oval-shaped cystic lesions near branch ducts were frequently identified, and associated parenchymal atrophy was minimal.
Conclusion: HG-PanIN often involves both main and branch pancreatic ducts, with MPD stenosis and localized parenchymal atrophy serving as important imaging clues for diagnosis. However, skip lesions challenge accurate localization with current imaging modalities. In cases confined to branch ducts, subtle atrophy and the presence of small, round cystic lesions may aid early detection.
Disclosure: Nothing to disclose.

Contact E-Mail Address: marko.damm@uk-halle.de
Introduction: With a rising incidence and unchanged poor prognosis, pancreatic cancer is increasingly becoming a focus of gastroenterological oncology, but there is a lack of real-world data.
Aims & Methods: The aim of the current study was to investigate trends in survival and treatment patterns by analyzing German health claims data. Pancreatic cancer patients diagnosed between 2010 and 2017 were identified from the German Pharmacoepidemiological Research Database (GePaRD, approximately 20% of the German population). Data on demographics, tumor treatment within one year after diagnosis and survival were extracted.
Results: The study population comprised 23,339 patients with a median age of 74 years (IQR 66-80) and 44% with localized and 56% with metastatic disease. Overall, 52.4% received any chemotherapy and curative intended resection was performed in 28.3%. Neoadjuvant and adjuvant therapy were performed in 4.4% and 58.7% of the cases, respectively. The median overall survival of the whole study population was 7.84 months. Patients diagnosed in the most recent period (2014-2017) had a significantly better prognosis (8.20 months (95%CI 7.97-8.43)) than patients who were diagnosed in the earlier period (2010-2013) (7.54 months (95%CI 7.31-7.70)), with an age-, sex- and stage-adjusted hazard ratio of 0.87 (95% CI 0.85-0.9).
Over time, the most pronounced treatment trends have affected patients with localized disease, with increasing frequency of resection and neoadjuvant therapy and decreasing frequency of best supportive care.
Conclusion: This comprehensive insight into survival and treatment of pancreatic cancer in Germany shows presumably medically beneficial therapy trends with, however, only marginal improvements in prognosis to date.
Disclosure: Nothing to disclose.

Introduction: Despite advancements in diagnostics and treatment, pancreatic cancer (PC) remains one of the deadliest forms of cancer. Due to its asymptomatic nature, it is often diagnosed at an advanced stage, resulting in poor survival outcomes with a five-year survival rate of 10%.[1]

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Surgical resection is the only treatment with curative potential; however, only 15-20% are typically eligible for resection, stressing the need to identify high-risk populations for early detection and improved prognosis.[1-5]
Acute pancreatitis (AP), an inflammatory disorder of the pancreas, is a common gastrointestinal condition, affecting 34 per 100,000 people annually worldwide.[6]
While most AP cases resolve without complication, accumulating evidence suggests a potential bidirectional relationship between AP and PC.[7] Although the link between AP and PC has been established, the magnitude of the risk remains unclear.
Aims & Methods: This systematic review and meta-analysis aimed to quantify the occurrence of PC in AP, the risk of PC following AP, and the impact of specific risk factors. The systematic search was conducted in PubMed, EMBASE, and CENTRAL from inception until October 11th, 2023 (PROSPERO: CRD42023470350). Eligible studies included adult populations reporting on the association between AP and PC.
Primary outcomes included prevalence, incidence, and risk of PC in individuals in AP, including subset analyses of specific factors. Meta-analyses were performed using random-effects models to calculate pooled outcome measures and corresponding 95% confidence intervals (CI).
Results: A total of 49 studies were included with 34 providing sufficient data for quantitative synthesis. The prevalence of PC among AP patients was 2% (CI: 2-4%). Although this may seem low, it is clinically relevant given the poor prognosis of PC and the potential for it being missed when AP occurs. The time dependent analysis revealed that the risk of PC was highest near the episode of AP, with the risk gradually decreasing over time; however, the risk remained significantly high in the long term: <24 months (HR: 53.27, CI: 11.60-244.58), 24-60 months (HR: 3.19, CI: 2.21-4.60), and >60 months (HR: 1.94, CI: 1.63-2.32).
Additionally, our subset analyses found that AP patients with subsequently diagnosed chronic pancreatitis (CP) showed significantly increased odds of developing PC (OR: 3.54, CI: 1.05–11.92). We found no evidence for increased odds for PC in AP with diabetes, smoking, and alcoholic and gallstone etiologies.
Conclusion: Given the notable prevalence and significantly elevated short-term risk of PC among AP patients, clinicians should maintain a high index of suspicion during the first few years following an episode of AP. Although the risk decreases with time, the long-term risk of PC in AP should not be neglected. CP may further elevate this risk, highlighting the need for targeted surveillance strategies in high-risk populations.

Introduction: Incidence of sporadic ductal pancreatic adenocarcinoma (PDAC) in the Czech Republic is the third highest in Europe (23.1/100,000 population). New-onset diabetes mellitus with weight loss (> 5% within < 6 months) in patients over sixty can be an early sign of PDAC. New-onset diabetes mellitus was recorded in 12.2% subjects three years prior to the diagnosis of PDAC (in the 60-74+ age group:13.8%) in the Czech Republic in the period 2017-2021 [ref. 1].
Aims & Methods: The aim of this study was to evaluate the standardized incidence ratio (SIR) of PDAC in patients with diabetes mellitus with and without previous history of any other malignancy within a 12-year period.
Methods: The analysis was based on individual population data from the Czech National Registry of Reimbursed Health Services, the National Cancer Registry, and the Death Certificate Information System in the period 2010 - 2021.
Patients were divided into two groups: the first one included subjects with diabetes mellitus who had a history of any malignancy prior to the diagnosis of diabetes (follow-up 865,956 person-years); the second cohort consisted of people with diabetes mellitus who had no history of malignancy prior to the diagnosis of diabetes (7,971,090 person-years). The calculated person-years at risk were stratified by sex, age and time periods (2010-2013; 2014-2017; 2018-2021).
Subgroup analyses were performed considering follow-up and age at diagnosis of diabetes. The first report of any antidiabetic drug (ATC group A10) was the determinant for the diagnosis of diabetes mellitus in a particular individual. SIR was calculated as the ratio of observed to expected (estimated from incidence in the general population) cases of PDAC.
Results: Selected SIRs stratified according to age and follow-up are displayed in Table 1.
A significantly higher risk of PDAC in diabetes mellitus with a history of previous malignant diseases (compared to the general population) was found for the following: head and neck cancer (SIR 2.54), gastric cancer (2.12), colorectal cancer (1.38), laryngeal cancer (2,51), malignant melanoma (1.65), breast cancer (1.61), cervical cancer (2.22), uterine cancer (1.72), prostate cancer (1.59), testicular cancer (3.1), kidney cancer (1.75), urinary bladder cancer (1.74), thyroid cancer (2.13), Hodgkin lymphoma (2.74), non-Hodgkin lymphoma (2.15) and leukaemias (1.93).

Diabetes mellitus with history of previous malignant disease n = 144,946 individuals		Diabetes mellitus with no history of malignant disease n = 1,123,065 individuals	
Age at diagnosis of diabetes mellitus	SIR (95% C.I.)	Age at diagnosis of diabetes mellitus	SIR (95% C.I.)
60 - 69 years	3.13 (2.84 - 3.45)	60 - 69 years	2.12 (2.04 - 2.19)
70 - 79 years	1.58 (1.45 - 1.73)	70 - 79 years	1.05 (1.01 - 1.10)
≥ 80 years	0.79 (0.68 - 0.91)	≥ 80 years	0.63 (0.58 - 0.68)
Follow-up	SIR (95% C.I.)	Follow-up	SIR (95% C.I.)
up to 3 months	5.49 (4.62 - 6.49)	up to 3 months	4.82 (4.46 - 5.20)
3 months to 1 year	2.79 (2.41 - 3.20)	3 months to 1 year	2.49 (2.34 - 2.65)
from 1 to 2 years	1.74 (1.48 - 2.04)	from 1 to 2 years	1.62 (1.52 - 1.74)

Table 1. Risk of PDAC in diabetes mellitus.
C.I.: Confidence Intervals.

Conclusion: Risk of PDAC in patients with diabetes mellitus was higher in subjects with a history of various malignant diseases compared to those with no previous history of any malignancy. Particular attention should be paid to new-onset diabetes (diagnosis made within one last year). History of a malignancy, as an important risk factor for PDAC, should be taken into account when surveilling patients with diabetes mellitus.

BETA-BLOCKERS ARE ASSOCIATED WITH LOWER RISK OF PANCREATIC CANCER IN PATIENTS WITH TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY

J.T. Tan[1], X. Mao[1,2], D.T.-W. Lui[1], H.M. Cheng[1], W.-K. Seto[1,2], K.S. Cheung[1]

Introduction: Diabetes is associated with increased pancreatic cancer (PC) risk. Beta-blockers may mitigate PC risk and progression by inhibiting β-adrenergic receptor-mediated signaling pathways involved in tumor cell proliferation, invasion, and angiogenesis. However, the potential oncopreventive effect of beta-blockers on PC risk in patients with type 2 diabetes (T2D) remains unclear.

Aims & Methods: We aimed to assess the association between beta-blocker use and PC risk in newly diagnosed T2D patients after adjusting for risk factors. This territory-wide retrospective cohort study included adults (≥18 years) newly diagnosed with T2D between 2001 and 2020. Patients with type 1 diabetes, prior PC, immunoglobulin G4-related disease, pancreatectomy, or fewer than two HbA1c results were excluded.

To minimize reverse causality between PC and T2D, those diagnosed with PC within 1 year of T2D diagnosis or with <1 year of follow-up were excluded. Primary exposure was beta-blocker use (e.g., acebutotlol, atenolol, bisoprolol, carvedilol, celiprolol, esmolol, labetalol, metoprolol, nadolol, nebivolol, pindolol, propranolol, and sotalol).

In the primary (time-fixed) analysis, exposure was defined as ≥90 days of use after T2D diagnosis (i.e. index date). The outcome was incident PC. Patients were followed until PC, pancreatectomy, death, or study end (December 31, 2020).

Adjusted hazard ratios (aHRs) were derived from multivariable Cox models adjusting for 31 covariates: age, sex, smoking status, alcohol use disorder, body index mass, glycemic control (in terms of time-weighted mean HbA1c), pancreatitis, cholangitis, colectomy, Charlson's comorbidity index, metabolic and cardiovascular comorbidities, and concomitant medications (aspirin, non-steroidal anti-inflammatory drugs, statins, and other antidiabetics).

Sensitivity analyses included time-dependent analysis (drug use was defined as ≥180 days/year; to address immortal time bias), and multiple propensity score (PS)-based approaches (matching, regression adjustment, weighting, and matching weights). Dose- and duration-response relationships were evaluated.

Results: Among 431,261 T2D patients (mean age: 59.1±11.4 years; male: 52.5%; 61,917 beta-blocker users and 369,344 beta-blocker non-users), 1,303 (0.3%) developed PC during a mean follow-up of 9.4±5.0 years. The 18-year cumulative incidence was 0.68% (95% CI: 0.57%-0.80%) in beta-blocker users and 0.76% (95% CI: 0.70%-0.82%) in non-users (P = 0.02; Figure 1).

Beta-blocker use was associated with lowered PC risk in time-fixed analysis (aHR: 0.81; 95% CI: 0.70-0.95), time-dependent analysis (aHR: 0.75; 95% CI: 0.62-0.91), and all PS-based methods (aHR range: 0.83-0.86). A dose- and duration-dependent inverse relationship was observed (P_{trend} <0.001).

Higher cumulative defined daily dose (cDDD) reduced the risk (aHR: 0.84, 95% CI: 0.72-0.98, for <4,000 cDDD; aHR: 0.31, 95% CI: 0.12-0.82, for ≥4,000 cDDD). Longer use also lowered the risk (aHR: 1.12, 95% CI: 0.92-1.37, for <5 years; aHR: 0.70, 95% CI: 0.57-0.87, for 5 to <15 years; aHR: 0.11, 95% CI: 0.04-0.35, for ≥15 years).

Each additional 1,000 cDDD and 1-year increase in use was associated with a 21% (aHR: 0.79, 95% CI: 0.72-0.88) and 6% (aHR: 0.94, 95% CI: 0.92-0.96) risk reduction, respectively.

Conclusion: Beta-blocker use was associated with a lowered risk of PC among patients with newly diagnosed T2D, in a dose- and duration-dependent manner.

Introduction: Malnutrition and pancreatic exocrine insufficiency (PEI) are common among patients with pancreatic cancer. Despite the potential of pancreatic enzyme replacement therapy (PERT) to correct PEI, its usage and association with survival in pancreatic cancer remain uncertain. Our study aimed to evaluate the trend in PERT prescription over recent years and to explore potential association with mortality among patients with pancreatic cancer.

Aims & Methods: This single-center, matched case-control study analyzed data from patients diagnosed with pancreatic ductal adenocarcinoma (PDAC) who were discussed at multidisciplinary tumor board meetings at a tertiary hospital during 2008–2012 and 2015–2018. Cases, defined as patients who died within one year of diagnosis, were matched 1:1 with controls alive at one year. Patients were classified as PERT users or non-users based on prescriptions following the PDAC diagnosis.

Conditional logistic regression was performed to estimate the association between PERT usage and all-cause mortality at one-year post-diagnosis.

Results: Overall, 1247 patients with pancreatic cancer were included: 756 (61%) who died within one year (cases), and 491 (39%) who survived (controls). Cases exhibited, advanced disease stage (80% *vs.* 52%) with more comorbidities, whereas controls had more cases with pancreatic head localization (75% *vs.* 60%) and more frequently underwent surgery (55% *vs.* 12%). The prescription of PERT showed an increasing trend when comparing the periods 2008–2012 and 2015–2018, particularly in the palliative setting (p=0.001).

Matching yielded 487 pairs, with no significant differences in baseline characteristics. During a follow up of 12 months, 264 (39%) PERT-users and 223 (74%) PERT non-users died. In multivariable logistic regression models, PERT use was associated with lower odds of one-year mortality (adjusted OR [aOR], 0.49; 95% CI: 0.34–0.71). Similar associations were observed in subgroups undergoing surgery (aOR, 0.34; 95% CI: 0.16–0.74) and best supportive care (aOR, 0.12; 95% CI: 0.03–0.33). No clear association was observed in patients receiving chemotherapy alone (aOR, 0.75; 95% CI: 0.44–1.24), although the direction of effect suggested a potential benefit.

Conclusion: In this matched case-control study, PERT use was associated with lower one-year mortality among patients with PDAC. The results may be overly optimistic due to potential confounding factors related to patient selection, and randomized controlled studies are needed to confirm these effects.

Introduction: The prognosis for patients with advanced pancreatic cancer (PC) remains exceptionally bleak, with a 5-year survival rate estimated at just 4%. This condition is frequently accompanied by pancreatic exocrine insufficiency, which contributes to malnutrition and a significant decline in nutritional status. While conventional laboratory markers such as serum albumin and lymphocyte counts are commonly employed to assess nutritional health, integrative nutritional indices have emerged as meaningful prognostic indicators across various malignancies. Specifically, the hemoglobin, albumin, lymphocytes, and platelets index (HALP) has shown promise in predicting overall survival in cancer cohorts. However, other indices, such as the prognostic immune nutritional index (PINI), have yet to be examined in the context of pancreatic cancer.

Aims & Methods: Aim: This study aims to assess the prognostic value of the HALP and PINI in patients with advanced pancreatic cancer.

A retrospective analysis was conducted utilizing electronic medical records from 158 patients diagnosed with advanced pancreatic cancer who had begun treatment. Conventional parameters were employed to calculate HALP and PINI levels, which were then compared between patients with proximal and distal tumor locations prior to the initiation of chemotherapy.

Within a subgroup of 125 patients receiving FOLFIRINOX, baseline HALP and PINI values were analyzed in relation to outcomes categorized into three groups at the 12-week follow-up: mortality (n=21), disease progression (n=51), and disease stabilization (n=53). The log-rank test was utilized to evaluate statistical differences between high and low nutritional index groups.

Univariate and multivariable analyses were performed to identify risk factors for mortality within three months of chemotherapy initiation.

Results: Among the 158 patients included in the analysis, those with tumors located in the pancreatic head exhibited significantly lower HALP (32.34 vs. 43.05, p=0.021) and PINI (3.23 vs. 3.48, p=0.003) compared to patients with distal tumors. In the FOLFIRINOX subgroup, HALP levels were significantly lower in individuals who deceased by the first follow-up (25.76 vs. 36.115 and 41.8, p=0.041), while PINI did not demonstrate a similar relationship.

Univariate analysis revealed that a HALP value below 26.85 (HR 2.548; 95% CI: 1.021-6.357, p=0.045) and a PINI below 3.26 (HR 3.49; 95% CI: 1.31-9.299, p=0.012) were independent predictors of mortality.

In multivariate analysis, the presence of two or more metastatic sites beyond the primary tumor was the sole factor associated with a heightened risk of death at the first follow-up (HR 7.21; 95% CI: 2.02-25.738, p=0.002).

Conclusion: Our findings support the notion that HALP and PINI are closely related to nutritional status and serve as independent risk factors for mortality within three months of initiating chemotherapy in patients with advanced pancreatic cancer.

Introduction: Radioactive phosphorus (^{32}P) is an innovative therapy for locally advanced pancreatic cancer that is implanted through endoscopic ultrasound (EUS). Pancreatic cancer is the fourth cause of death and is responsible for 7% of all deaths caused by cancer. Nowadays the improvement of chemotherapy and the usage of combination therapies led to a better prognosis and studies showed an improvement of the survival parameters (OS, Free Progression Survival). One of the most innovative therapies is the implantation of radioactive phosphorus-32 which is a

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

type of brachytherapy. It is indicated for the treatment of patients with Locally Advanced Pancreatic Cancer (LAPC) in combination with gemcitabine-based chemotherapy.

Aims & Methods: The primary goal of this study is to determine the safety of the intra-tumoral implantation of radioactive phosphorus (^{32}P) through EUS and the complications of the procedure of implantation. The secondary goals are to determine the Local Disease Control Rate (LDCR) at 16 weeks and the effectiveness of the implantation of radioactive phosphorus by measuring Overall Survival (OS), Progression Free Survival (PFS) and Local Progression Free Survival (LPFS). We currently have made the implantation in eight patients with similar clinical and demographic features who suffer from locally advanced pancreatic cancer. They receive gemcitabine-based chemotherapy in combination with an intra-tumoral therapy with radioactive phosphorus (^{32}P) through a 22-gauge FNA needle guided by EUS. The adverse events of the implantation are evaluated by the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0. The LDCR is evaluated at 16 weeks and the alteration of Tumor Volume every two months for the first year after implantation and every three months the second year after implantation according to RECIST 1.1.

Results: The eight procedures (median age of patients: 68,5 years) were unremarkable and no complication during the procedure was noted. The patients did not have any major adverse events during the day of the procedure. Five out of eight patients (62,5%) revealed mild abdominal pain on the second day which recovered with typical pain killers. The LDCR, for all patients, at 16 weeks, was 100%. Two of the patients had a major reduction in the tumor so it was resectable. The operations were without any complications and the pathology test showed R0 resection. Two patients died after 12 months of follow up (one patient showed progression disease after 10 months from implantation and one patient had stable disease until death) and one patient revealed progression of disease after 12 months and is still alive after 15 months of follow up. Three patients have stable disease after 6 months of follow up, even though a slight reduction of the tumor has been noted. The six patients (including the two that died and not including the two that underwent surgery) have been followed up for 6 to 15 months, depending on time of implantation. The median Progression Free Survival for these six patients is 7 months (max 12 months – min 6 months) and the median Local Progression Free Survival is 6 months (max 12 months – min 6 months).

Conclusion: We must include more patients to conduct more useful results, but the initial results look promising.

Introduction: Neurofilaments are cytoskeletal proteins specific to neuronal tissue. As their blood levels rise following neuronal damage, they are increasingly being studied as the biomarkers for neuroaxonal injury in various conditions, such as Alzheimer's disease, multiple sclerosis, amyotrophic lateral sclerosis, or type 2 diabetes mellitus (T2DM) related neuropathy. Pancreatic ductal adenocarcinoma (PDAC) is a malignant disease known for its poor prognosis, rapid spread, silent progression, and lack of effective diagnostic tools in its early stages. Perineural and/or endoneural invasion and neuronal damage are hallmarks of PDAC.

Aims & Methods: The aim of our study was to measure the levels of neurofilament light chain (NfL) in patients with PDAC, T2DM, chronic pancreatitis (ChP), and healthy controls. We used a Single Molecule Array (Simoa; Quanterix) to measure NfL levels in patients with PDAC (n=50, mean age 63.16 ± 8.8 years), T2DM (n=42, mean age 61.6 ± 8.4 years), ChP (n=30, mean age 56 ± 13.6 years), and healthy controls (n=46, mean age 54 ± 9.06 years).

Results: The following concentrations of NfL were obtained from the samples: PDAC: 30.31 ± 39.79 pg/ml, T2DM: 12.59 ± 10.19 pg/ml, ChP: 16.64 ± 13.78 pg/ml, Healthy controls:
7.93 ± 4.18 pg/ml. NfL levels were significantly different between PDAC and healthy controls ($p < 0.001$) and between T2DM and healthy controls ($p < 0.001$). Differences between other groups were not significant. Further analysis confirmed age as a significant predictor of NfL levels ($p < 0.001$), indicating that NfL levels increase with age by 0.48 per year. We did not find a significant impact of glycemic control (represented by glycated haemoglobin levels) or body mass index on NfL concentrations. Because of the correlation between age and NfL levels, we examined the relationship between age, diagnosis, and NfL levels using a statistical model comparison approach. After controlling for age, we found that PDAC and ChP showed significantly higher NfL levels compared to T2DM and healthy controls ($p < 0.01$). No significant differences were found between T2DM and healthy controls

Conclusion: This is the first study to date that evaluates serum levels of NfL in PDAC and chronic pancreatitis. The results support the possible role of NfL as a biomarker in certain non-neurological conditions. Elevated serum levels of NfL in PDAC and ChP suggest that this biomarker reflects neuronal damage, which is present in ChP and is a key feature of PDAC, even in the early stages of the disease.

EARLY-ONSET PANCREATIC CANCER IS ASSOCIATED WITH ACTIVE SMOKING HABIT AND WITH BETTER OVERALL SURVIVAL

R. Ponz de Leon Pisani[1], L. Archibugi[1], C. Fortunato[1], L. Apadula[1], I. Marengon[1], G. Lauri[1], N. Liscia[2], F. Aleotti[3], M. Reni[2], M. Falconi[3], P.G. Arcidiacono[1], G. Capurso[1]

Contact E-Mail Address: ponz.ruggero@hsr.it

Introduction: Early onset pancreatic cancer (EOPC) arises in patients aged ≤50 years or, and accounts between 5%-10% of all the cases of pancreatic ductal adenocarcinoma (PDAC). Compared to late-onset pancreatic cancer (>50 years, LOPC), EOPC has been described as holding not only peculiar biology, but also poorer outcomes. However, data on the topic is scarce and controversial.

Aims & Methods: Our aim is to investigate risk factors and outcomes of EOPC compared to LOPC. This is a single-center prospective study on a cohort of consecutive histologically diagnosed PDAC patients enrolled between April 2016 and September 2024, in the context of a biobank/exposome observational registry study (NCT06552078), at Pancreas Translational and Clinical Research Centre of San Raffaele Hospital in Milan (Italy). Data on environmental and genetic risk factors, clinical and pathological information were recorded in a dedicated clinical report form (CRF) at time of diagnosis, and treatment and survival outcomes were prospectively collected during follow-up. Variables were compared using Mann-Whitney U test or Chi-square test as appropriate. Multivariable logistic regression analysis was employed to investigate factors associated with risk of EOPC. Overall survival (OS) probability was calculated with the Kaplan-Meier curve and Cox regression, adjusted for confounders.

Results: A total of 840 PDAC patients were included, of which 798 (95%) LOPC and 42 (5%) EOPC. Overall, 406 patients (48.3%) deceased after a median follow-up of 14 months (95% CI: 13-15 months). Staging at diagnosis did not significantly differ between the two groups, and 540 patients (64.2%) underwent intensive polychemotherapy, with no significant difference among the two groups. Median age was 46.5 years (95% CI: 46-48 years) for EOPC patients and 69 years (95% CI: 69-70 years) for LOPC patients.

Current smoking (p<0.0001), ever smoking habit (p=0.008), smoking intensity (pack/years) (p=0.03), alcohol consumption (p=0.007) and history of chronic pancreatitis (p=0.02) were significantly more frequent in EOPC vs LOPC patients. No significant differences were observed among the two groups regarding gender, body mass index (BMI), CA19.9, 1st degree family history of any cancer, familial pancreatic cancer (FPC), previous cholecystectomy, genetic syndromes or history of diabetes.

The only significant risk factor for the diagnosis of EOPC at the multivariable analysis resulted to be current smoking, with an OR of 6.3 (95% CI: 2-19, p=0.001).

Median OS was significantly higher in the EOPC patients compared to LOPC (35 vs 17 months, p=0.02), and EOPC resulted as a significant prognostic factor for better OS at Cox proportional hazard regression adjusted for gender, stage and polychemotherapy (HR 0.61; 95% CI: 0.37-1.01; p=0.05).

Conclusion: EOPC seems related to active smoking, but not to familial syndromes. Younger patients display better outcomes compared to older ones. Whether this is due to different molecular behavior requires further investigation.

Disclosure: Nothing to disclose.

TOO YOUNG TO SUSPECT IT? DIAGNOSTIC INERTIA AND LATE-STAGE PRESENTATION OF PANCREATIC CANCER IN ADULTS UNDER 50

Y. Dendane[1], M. Aymane[1], F. Amri[1], O. Elmqaddem[1], H. Koulali[1], Z. Abdelkrim[1], Z. Ismaili[1], G. Kharrasse[1]
[1]Faculty of Medicine and Pharmacy of Oujda/ University Hospital Center Mohammed VI, Department of Hepatology and Gastroenterology, Oujda, Morocco

Contact E-Mail Address: dendane.youness@gmail.com

Introduction: While pancreatic cancer is traditionally associated with older age, its incidence is rising in adults under 50. This younger population often falls outside standard screening and triage pathways, contributing to delayed diagnosis. In the absence of risk factors, early symptoms may be overlooked or misattributed, delaying imaging and leading to advanced-stage discovery. Although a minority of patients carry hereditary risk, the majority of young cases present without identifiable predispositions.

Aims & Methods: This study aimed to describe the clinical, biological, and diagnostic profile of pancreatic cancer in adults under 50, with a focus on diagnostic delays, tumor marker levels, disease stage, and the presence of traditional risk factors.

A retrospective monocentric analysis was conducted on all patients diagnosed with pancreatic cancer between January 2020 and December 2024 at a regional reference center. Patients were divided into two age groups: <50 and ≥50 years. Variables included age, sex, BMI, smoking status, diabetes, CA 19-9 levels, time from symptom onset to diagnosis, and tumor stage (resectable, borderline, locally advanced, metastatic). Statistical analyses used chi-square and non-parametric tests.

Results: Among 293 patients, 24 (8.2%) were under 50 years (range: 31–49; median age: 46.5 years).

- This younger group had a male predominance (62%) and lower median BMI (22.3 kg/m^2).
- Diagnostic delays >30 days were more frequent in younger patients (71%) vs. older adults (56%) (p = 0.04), with a longer median delay (45 vs. 35 days).
- Median CA 19-9 was higher in the younger group (970 vs. 503 U/mL), and values >1000 U/mL were observed in 41% vs. 24% of older adults.
- Stage at diagnosis in younger patients:
  - Resectable: 8.3%
  - Borderline: 20.8%
  - Locally advanced: 33.3%
  - Metastatic: 37.5% (no significant difference vs. older group; p = 0.61).
- Only 4.2% of younger patients had traditional risk factors (smoking, obesity, diabetes).
- Among those without any risk factor, 78% presented with advanced-stage disease.

Conclusion: Pancreatic cancer in adults under 50 is an emerging and underrecognized challenge. In our cohort, younger patients experienced longer diagnostic delays and more frequent advanced-stage presentations—despite lacking classical risk factors. These findings expose a diagnostic blind spot, likely shaped by age-related bias.

Clinicians should not dismiss elevated CA 19-9 values in younger adults, even in the setting of cholestasis, and should maintain a high index of suspicion in those presenting with persistent abdominal symptoms or unexplained weight loss. Earlier imaging and broader clinical vigilance could help reduce missed opportunities for curative intervention in this vulnerable group.

TOO WEAK FOR THE FIGHT? UNDERNUTRITION AND EARLY MORTALITY IN PANCREATIC CANCER: REVISITING BMI AND ALBUMIN THROUGH THE NRI LENS

M. Aymane[1], Y. Dendane[1], F. Amri[1], O. Elmqaddem[1], H. Koulali[1], Z. Abdelkrim[1], Z. Ismaili[2], G. Kharrasse[1]
[1]Faculty of Medicine and Pharmacy of Oujda/University Hospital Center Mohammed VI, Hepatology and Gastroenterology, Oujda, Morocco, [2]Medical School, Hepato Gastroentetology, Oujda, Morocco

Introduction: Malnutrition is an early yet frequently overlooked dimension of pancreatic cancer, often present at diagnosis due to systemic inflammation, cachexia, or silent pancreatic exocrine insufficiency (PEI). Low body mass index (BMI) and hypoalbuminemia are individually recognized as risk factors for poor outcomes, but their combined evaluation may offer a more robust tool for risk stratification. The Nutritional Risk Index (NRI), which integrates both parameters, is a simple, validated score that remains underused in pancreatic oncology.

Aims & Methods: This study aimed to evaluate whether undernutrition at diagnosis, assessed by BMI, albumin, and NRI, predicts non-resectability and early mortality in patients with pancreatic cancer.

We retrospectively analyzed all pancreatic cancer cases diagnosed at a tertiary center between January 2020 and December 2024. BMI was categorized as <20 vs. ≥20 kg/m^2. Serum albumin levels were collected, and NRI was calculated using the simplified formula: 1.519 × albumin (g/L), due to unavailable weight loss data. Patients were stratified according to NRI into no risk (≥97.5), moderate risk (83.5–97.4), and severe risk (<83.5). Tumor stage and resectability were assessed through imaging (resectable) or histology (non-resectable). A subgroup analysis was performed on patients with available 3-month survival data. Statistical comparisons used chi-square and non-parametric tests.

Results: Among 293 patients (mean age 64±11 years; 55% male), BMI data were available for 248 cases. Of these, 101 (38.4%) had a BMI <20 kg/m^2. This group showed lower rates of curative surgery (8.8% vs. 16.9%; p=0.04), more frequent metastatic disease (52.7% vs. 34.2%; p=0.01), and higher rates of hypoalbuminemia (44% vs. 21%; p<0.01).

Serum albumin was available for 289 patients. According to NRI, 39% had severe nutritional risk (NRI <83.5) and 42% had moderate risk. Severe NRI was strongly associated with metastatic disease (61% vs. 28%; p=0.002) and early mortality.

Among 112 patients with 3-month survival data, 83 (74%) had died. Mortality was significantly higher in patients with BMI <20 (82.6% vs. 66.1%; p=0.03) and was even more pronounced in those with NRI <83.5 (87.1% vs. 58.2%; p<0.01).

Conclusion: Undernutrition at diagnosis—whether assessed by BMI, albumin, or NRI—is a strong and early indicator of poor prognosis in pancreatic cancer. The NRI, by combining two simple and routinely available markers, could serve as a practical triage tool to support early nutritional interventions and treatment decisions. Its integration into initial staging workflows may improve outcomes, especially if pancreatic exocrine insufficiency is also considered.

Further multivariate analyses are needed to validate NRI as an independent predictor and to facilitate its routine use in multidisciplinary care planning.

Disclosure: Nothing to disclose.

PP1134

OPERATIVE RISK FACTORS FOR CLINICALLY RELEVANT POSTOPERATIVE PANCREATIC FISTULA AFTER PANCREATICODUODENECTOMY: A PROSPECTIVE MULTICENTER COHORT STUDY

M. Omar[1]
[1]South Valley University / Qena Faculty of Medicine, General Surgery Department, Qena, Egypt

Contact E-Mail Address: elqefty@yahoo.com

Introduction: Pancreatic fistula remains the most dangerous complication after pancreatoduodenectomy (PD).

Aims & Methods: This study aimed to identify the operative risk factors for clinically relevant postoperative pancreatic fistula (CR-POPF) after PD. Methods: This prospective multicenter cohort study investigated the association between CR-POPF and operative risk factors in 107 patients who underwent PD at three tertiary centers from August 2017 to July 2022.

Results: The incidence of CR-POPF was 26.2%. With univariate analysis, soft pancreatic texture, pancreatic duct diameter (≤ 3 mm), right-sided pancreatic transection, absorbable suture, pancreatico-enteric anastomosis invagination technique, non-stented pancreatic drainage, internal pancreatic drainage, long anastomotic time (> 40 min), and R1 resection margin were risk factors for CR-POPF.

Multivariate analysis identified four independents risk factors for CR-POPF:

1. Soft pancreatic texture (OR 0.219; 95% CI 0.061-0.792; P < 0.021),
2. Small main pancreatic duct diameter (OR 0.280; 95% CI 0.086-0.910; P < 0.034),
3. Right-sided pancreatic transection (OR 0.168; 95% CI 0.032-0.881; P < 0.035), and;
4. Non-stented pancreatic drainage (OR 3.771; 95% CI 1.147-12.401; P < 0.029).

Conclusion: The incidence of CR-POPF after PD is reduced significantly by left-sided pancreatic transection and pancreatic drainage. Soft pancreatic texture and small main pancreatic duct diameter are independent risk factors for CR-POPF, and clinically postoperative prophylactic measures should be implemented as soon as possible.

IMPACT OF THE INCLUSION OF USTEKINUMAB BIOSIMILAR IN THE TREATMENT ALGORITHM OF INFLAMMATORY BOWEL: A COST-EFFECTIVENESS ANALYSIS

I. Rodríguez-Lago[1], M. Barreiro-De Acosta[2], J.I. Peinado Fabregat[3], M. Guigini[3], F. Ibáñez[4], C. Crespo[4]
[1]Hospital Universitario de Galdakao, Inflammatory Bowel Disease Unit, Gastroenterology Department, Bilbao, Spain, [2]Complejo Hospitalario Universitario de Santiago de Compostela, Inflammatory Bowel Disease Unit, Gastroenterology Department, Santiago de Compostela, Spain, [3]Fresenius Kabi SAU, Barcelona, Spain, [4]Axentiva Solutions SL, Barcelona, Spain

Contact E-Mail Address: manuel.barreiro.de.acosta@sergas.es

Introduction: This study aimed to evaluate the impact in the cost-effectiveness of the introduction of biosimilar ustekinumab (bsUST) in different treatment sequences for moderate-severe Crohn's disease from the Spanish National Healthcare System (NHS) perspective.

Aims & Methods: Six treatment sequences were defined per current clinical practice in Spain and incorporated into the model. A scenario using bsUST as the first line of treatment was considered the base case for all comparisons. Surgery was the last and only therapeutic alternative after four lines of previous pharmacological treatment. A Markov model with a lifetime horizon was developed including active disease, response, remission, surgery, and death as funnel health states to simulate treatment-induction times with 2-week cycles, and a change of treatment after loss of response; considering time-to-progression between consecutive treatment lines.

Efficacy of the comparators [adalimumab (ADA), infliximab (IFX), risankizumab (RISAN), upadacitinib (UPA), vedolizumab (VDZ), and surgery (Q)] was obtained combining data from prior network meta-analysis and clinical trials. Unitary costs were sourced from the literature and databases such as "*Registro de Actividad Sanitaria Especializada*" (RAE-CMBD) and Botplus. Pharmacological costs were ex-factory prices, applying the deduction from "*Real Decreto-Ley*" (RDL) 8/2010. For comparators with available biosimilars, the mean cost of the marketed presentations for the indication was used.

Results: Depending on the sequence, Quality Adjusted Life Years gained ranged from -0.09 (for the sequence ADA-bsUST-UPA-RISAN-Q) to 0.25 (for the sequence IFX-RISAN-bsUST-UPA-Q) and incremental costs per patient in all the comparisons (Table 1). The Incremental Cost-Effectiveness Ratio (ICER) showed that the sequence including bsUST as first-line treatment was dominant or cost-effective vs the remaining alternatives.

Moreover, when compared to the sequence with ADA as first line and bsUST as second-line, none of the four remaining sequences resulted cost-effective.

Conclusion: First-line bsUST is cost-effective and an efficient alternative for the Spanish NHS, even positioned before anti-TNFs. Additionally, none of the alternative sequences proved to be cost-effective compared to the sequence with ADA as first-line and bsUST in second line. Hence, bsUST could change the current paradigm of Crohn's disease treatment in Spain, allowing broader access for patients while being a cost-saving alternative.

	Lifetime cost/ patient	Δ Cost	QALYs/ patient	Δ QALYs	ICER
Sequence 1 (bsUST, ADA, UPA, RISAN, Q)	157,595.7 €		11.87		Reference
Sequence 2 (ADA, bsUST, UPA, RISAN, Q)	158,476.5 €	880.9 €	11.78	-0.09	Sequence 2 dominated
Sequence 4 (ADA, UPA, bsUST, RISAN, Q)	159,447.3 €	1,851.7 €	11.79	-0.07	Sequence 4 dominated
Sequence 3 (IFX, bsUST, UPA, RISAN, Q)	172,229.2 €	14,633.6 €	12.05	0.19	Sequence 3 not cost-effective (78,983.8 €/QALY)
Sequence 6 (IFX, UPA, bsUST, RISAN, Q)	173,196.1 €	15,600.5 €	12.07	0.20	Sequence 6 not cost-effective (77,043.1 €/QALY)
Sequence 5 (IFX, RISAN, bsUST, UPA, Q)	173,258.4 €	15,662.8 €	12.12	0.25	Sequence 5 not cost-effective (62,347.7 €/QALY)

A DIETITIAN-LED DISORDERS OF THE GUT BRAIN INTERACTION CLINIC INCORPORATING INTESTINAL ULTRASOUND DELIVERS COST EFFECTIVE CARE AND IMPROVED PATIENT OUTCOMES

S. Plush[1,2,3], R.M Mathias[1,2,3], S. Kumar[4], R.V Bryant[1,2,3], A. Day[1,2,3]
[1]The University of Adelaide, School of Medicine, Adelaide, Australia, [2]The Queen Elizabeth Hospital, Department of Gastroenterology and Hepatology, Woodville South, Australia, [3]The Basil Hetzel Institute, Inflammatory Bowel Disease Research Group, Adelaide, Australia, [4]The University of South Australia, Allied Health and Human Performance, Adelaide, Australia

Contact E-Mail Address: Samantha.plush@sa.gov.au

Introduction: Disorders of the gut brain interaction (DGBI) describe a range of chronic, debilitating gastrointestinal symptoms, including irritable bowel syndrome (IBS). Whilst DGBI can be responsive to first-line dietary therapy, in South Australia, tertiary care service models are typically gastroenterologist-led with on-referral to a dietitian. To address the increasing demand of DGBI care on a tertiary outpatient gastroenterology service, a new dietitian-led DGBI service model utilising intestinal ultrasound performed by a gastroenterologist was developed.

Aims & Methods: The aim of the study was to investigate the clinical outcomes, cost of service delivery, and activity-based funding (ABF) generated by a dietitian-led DGBI model of care. This prospective study between Sep-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tember 2022 and October 2024 included patients with DGBI and no high-risk clinical features. Patient reported outcome measures were assessed with validated IBS-symptom severity score (IBS-SSS). The per patient episode of care costs were calculated including staffing, both medical and allied health, investigations ordered, emergency department presentations and hospital admissions. ABF is an Australian commonwealth government funding model that allocates government funding to healthcare providers based on the volume and complexity of health care services delivered. ABF was calculated using 2023 National Weighted Activity Units (NWAU) ($5797.00) multiplied by the allied health specialist interventions price weight (0.567). Descriptive and inferential statistics were used to analyse demographics, clinical outcomes and costing presented ($AUD).

Results: Fifty-six of one-hundred and sixty-eight patients participated in this study. The median age was 30 years (interquartile range (IQR 25-37)) and 42/56 (75%) were female. There were 3 (IQR 1-4) occasions of service per episode of care. There was a 98.8-point (95% CI 68-6-128.1) reduction the IBS-SSS scores (p<0.001). The cost per patient episode of care cost was $286.25 (IQR 221.25-351.87). The ABF funding generated was $1064.66 (IQR 656.00-1640.00). Each $1 invested into the clinic returned $2.58 in ABF funding to the health service.

Conclusion: A dietitian-led DGBI clinic utilising intestinal ultrasound delivers improvement in patient reported outcome measures and positive financial return on investment.

Disclosure: Nothing to disclose.

NATIONWIDE LONGITUDINAL TRENDS IN THE EPIDEMIOLOGIC AND ECONOMIC BURDEN OF DIGESTIVE DISEASES IN KOREA, 2010 – 2020

S. Yu[1], E.S. Jeong[1], H.-K. Jung[1], M.J. Yoon[1], H.S. Lim[1], Y. Kim[2]
[1]Ewha Womans University/College of Medicine, Department of Internal Medicine, Seoul, South Korea, [2]Inha University/College of Medicine, Department of Social and Preventive Medicine, Incheon, South Korea

Contact E-Mail Address: coral159753@hanmail.net

Introduction: Digestive diseases constitute a major component of healthcare utilization in Korea. However, up-to-date data on long-term trends in their epidemiologic and economic burden are scarce. This study aimed to assess nationwide changes in prevalence, healthcare utilization, and direct medical costs related to digestive diseases over the past decade.

Aims & Methods: Aims: Digestive diseases constitute a major and rising component of Korea's healthcare demand. We therefore quantified longitudinal changes in their epidemiologic and economic burden by comparing nationwide data from 2010 to 2020.

Methods: We analysed the National Patient Sample from the Health Insurance Review and Assessment Service (HIRA), which is representative of the entire Korean population. Medical utilization was analyzed based on principled estimates defined as primary diagnosis and extensive estimates defined as primary diagnosis and 1st listed secondary diagnosis. Patient numbers, hospitalizations, emergency-department (ED) visits, outpatient encounters and inflation-adjusted direct expenditures and derived compound annual growth rates (CAGR) were calculated.

Results: On the principal estimate, the number of patients with digestive diseases rose from 17.3 million in 2010 to 18.5 million in 2020, while total expenditures escalated from US $4.2 billion to US $8.5 billion, effectively doubling per-patient costs. Intestinal infectious diseases remained the leading cause of hospitalization and emergency-department visits in both years. In the outpatient setting, the most frequent diagnosis shifted from gastritis/duodenitis in 2010 to gastro-esophageal reflux disease in 2020. The fastest-growing categories were gallbladder disorders (CAGR 19.5 %), pancreatic disorders (CAGR 12.0 %) and benign colonic neoplasms (CAGR 9.1 %), all exceeding the overall mean growth of 7.0%.

Conclusion: From 2010 to 2020, digestive diseases rose by 7 %, but related healthcare costs doubled, sharply raising per-patient spending. Rapid surges in gallbladder and pancreatic disorders and benign colonic neoplasms call for intensified prevention, early screening, and stronger primary-care management.

THE USE OF MILLIPORE STRIP BIOPSY TECHNIQUE REDUCES FINANCIAL AND CARBON COSTS. EXPERIENCE FROM A NEW ZEALAND TERTIARY CENTRE

L. Hollingsworth[1], J. Kubovy[1], M. Arnold[1]
[1]Christchurch Hospital, Gastroenterology, Christchurch, New Zealand

Contact E-Mail Address: LauraH3@adhb.govt.nz

Introduction: The demand for gastrointestinal (GI) endoscopy has significantly increased worldwide over the last decade along with associated waste[1-3]. Millipore strips (MPS) enable biopsy specimens from different areas of the GI tract to be placed in one pottle and aligned on a strip according to specific sites. This reduces the number of pottles and saves on lab time showing great promise in terms of cost savings and carbon foot print[4-6].

The use of MPS has been successfully used in a number of countries[4]. The technique was first introduced and validated at our centre in 2009.

Aims & Methods: We aimed to review the utilisation of MPS over a two-year period and to determine the impact on cost and estimated carbon emission reduction. This was compared to the initial cost saving analysis proposed in 2009.

A retrospective cohort study of all endoscopic biopsies performed at our centre between July 2021 to June 2023 was conducted. Data was obtained from Delphic Sysmex pathology processing system.

Cost analysis was based on pathology lab processing costs per specimen pottle which included lab time and materials but excluded Goods and Service Tax (GST). The carbon footprint per pottle was based on previously published data with an estimate per pottle of 0.29kg carbon dioxide equivalent (CO_2e) [3,4].

Results: MPS utilisation across our department ranged from 0 to 97 per endoscopist per annum with a mean usage of 12 MPS per endoscopist per annum.

A total of 12288 endoscopies that included biopsies were performed in our endoscopy unit over the two-year period generating 24659 specimen pottles. Of these biopsy yielding endoscopies, 10% (1205) utilised MPS, with a mean of one MPS pottle per procedure. In comparison 90.2% (11083) used standard biopsy collection alone with an average of 6.7 pottles per procedure.

The following figures were used to calculate the cost of histologically processing samples (inclusive of lab processing and materials but excluding GST): Millipore strip $NZ 102.36 (average 4-6 biopsies per strip). Standard biopsy $69.74 (average 1 biopsy per pottle).

Despite the imperfect uptake, the calculated annual cost saving was $NZ 109,404 per annum. The cost saving estimate in 2009 was $NZ 135,200 per annum.

An estimated three pottles per procedure were saved translating to a total of 1808 pottles per annum. This equates to an estimated 1kg CO_2e saved per procedure and a total of 603kg CO_2e saved per annum with the current MPS use within our department.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: MPS use results in significant cost savings and carbon footprint reduction. Improved intra-departmental MPS utilisation could potentially multiply these gains in sustainable endoscopy.

APPROPRIATENESS OF GASTROINTESTINAL ENDOSCOPY FOR HOSPITALIZED PATIENTS: THE IMPORTANCE OF CONSULTANT LED TRIAGE

C. Soares[1], A.C. Carvalho[1], R.A. Cardoso[1], R. Araújo[1], A.J. Taveira da Silva[1]
[1]Viseu Dão-Lafões Health Unit, Gastroenterology, Viseu, Portugal

Contact E-Mail Address: carol.soares555@gmail.com

Introduction: A range of criteria have been created to evaluate the appropriateness of gastrointestinal (GI) endoscopy. The most widely recognized were set by the American Society for Gastrointestinal Endoscopy and the European Panel of Appropriateness of Gastrointestinal Endoscopy (EPAGE), updated EPAGE-II criteria. Nevertheless, the application of general rules is not sufficient, especially in hospitalized patients. The complexity, singularity, and dynamic clinical evolution demands the proactive involvement of an experienced endoscopist to make the decision whether or not to perform the exam.

Aims & Methods: Our aim was to analyze the appropriateness of endoscopic exam requests in hospitalized patients over the course of one year. A prospective observational study was conducted in an endoscopic unit of a tertiary hospital center. The requested exams were triaged by a gastroenterologist after reviewing the patient's medical record, assessing clinical status and complementary diagnostic tests. In cases of unclear indication, and no absolute contraindication, the decision to proceed was discussed with the referring physician.

Results: A total of 184 requests for inpatient endoscopy and/or colonoscopy were received during 1 year (table 1). 154 (84%) of the requests were thought to be appropriate. 12 (6%) were cancelled during triage: 2 were patients on best supportive care, 1 died, 3 had other diagnosis which plausibly justified the clinical situation, 2 had recent endoscopic exams, and 4 presented no clinical/analytical evidence of GI bleeding). 18 (10%) requests were initially postponed (8 were awaiting imaging results; 5 had poor clinical status and 5 respiratory distress) and ended up being cancelled (8 had another diagnosis in imaging tests, 8 maintained clinical deterioration contraindicating exam and 3 died). In total 30 (16%) of the requests were cancelled.

The most frequent exam requested was endoscopy, and the most common indication was suspected GI neoplasia. From a total of 58 suspected GI neoplasms, 11 were confirmed as gastric neoplasia, which was the most common finding.

None of the patients with a cancelled exam was diagnosed with a GI disease during follow up.

Mortality rate was considerably higher in the group with cancelled exams (33% vs 11% during hospitalization, 50% vs 32% during follow up, 15% vs 1.8% within 30 days after discharge). Mean age was similar between groups. This findings reveal a frail group of patients, with little likelihood of benefiting from an invasive exam.

Total, n=184	GI endoscopy performed	GI endoscopy deferred and/or cancelled
N, %	154 (84)	30 (16)
Sex, male (%)	89 (58)	16 (53)
Age (years), mean (±SD)	72 (12.8)	71 (14)
Type of exam		
Endoscopy, n (%)	68 (44)	13 (42)
Colonoscopy, n (%)	28 (18)	6 (19)
Endoscopy + Colonoscopy, n (%)	55 (36)	10 (33)
Flexible sigmoidoscopy, n (%)	3 (19)	1 (33)
Indication, n		
Anemia	42	5
Diarrhea	5	-
Dysphagia	8	-
Epigastric pain	3	1
Chronic liver disease	7	-
Suspected GI neoplasia¥	44	20
Suspected upper GI neoplasia	14	-
Suspected colorectal neoplasia	15	-
Suspected GI bleeding	4	4
Relevant endoscopy findings, n		
Hypopharyngeal neoplasm	2	
Grade C, D esophagitis	2	
Esophageal neoplasia	2	
Esophagogastric varices	6	
Gastric angiodysplasia	3	-
Gastric neoplasia	11	
Neoplastic infiltration of duodenum	2	
Colorectal neoplasia	7	
Inconclusive (poor bowel preparation)	3	
Motive to defer and/or cancel, n		
Awaiting imaging results		8
Clinical deterioration		5
Respiratory distress		5
End-of-life care		2
Evidence of myeloma	-	1
Evidence of ovarian cancer		2
Recent endoscopic evaluation		2
Without analytical or clinical evidence of bleeding		4
Death		1
Death during hospitalization, n (%)	17 (11)	10 (33)
Death within 30 days after discharge, n (%)	2 (1.8)	3 (15)

Table 1. Patient's characteristics and exam indications and findings.
¥ Suspected GI neoplasia includes constitutional syndrome, evidence of metastases without a known primary source, ascites and/or pleural effusion.

Conclusion: 16% of the requests were considered inappropriate, which allowed to avoid 30 unnecessary exams.

Developing standardized indications for endoscopic exams in inpatient care is difficult, and an individualized approach is critical in order to reach an equilibrium between overusage and overlooking, while considering the principle of *primum non nocere.*

Contact E-Mail Address: emma.culver@ndm.ox.ac.uk

Introduction: IgG4-related disease (IgG4-RD) is a chronic inflammatory condition that culminates in fibrosis and organ damage. The real-world diagnosis, treatment and outcomes of IgG4-RD patients remain poorly understood.

Aims & Methods: To characterise diagnosis, clinical characteristics, treatment and disease burden, healthcare use and patient-reported outcomes (PRO) in IgG4-RD patients. Data were drawn from a real-world, cross-sectional survey of physicians and patients with IgG4-RD in Europe (France, Spain, Italy, Germany and the United Kingdom), Brazil and the Kingdom of Saudi Arabia (KSA) from September 2023 – September 2024. Physicians reported patient demographics, clinical characteristics, patient journey, treatment patterns and healthcare resource use. Patients self-reported on burden of fatigue using the FACIT-Fatigue Scale, and work and activity impairment using the WPAI questionnaire (Table 1). Analyses were descriptive.

Results: Data were reported by 208 physicians on 982 patients (France: n=181, Spain: n=96, Italy: n=160, Germany: n=162, UK: n=143, Brazil: n=89, KSA: n=151), of whom 254 provided self-reported data. Mean (standard deviation; SD) patient age was 53.8 (13.4) years (59.6% Male; 73.7% White). Overall, mean (SD) age at symptom onset was 49.6 (13.0) years. Time from symptom onset to diagnosis was 8.9 (19.5) months, ranging from 3.3 (8.1) in KSA and 21.0 (30.0) in Brazil. Fatigue (57.0%), weight loss (32.3%), and joint pain (24.1%) were the most common symptoms at first consultation; the most common organ manifestations being pancreas (41.9%), bile ducts (25.2%) and abdominal/pelvic lymph nodes (23.9%). Primary care physicians (46.3%) and gastroenterologists (17.4%) were most often consulted first about symptoms, with gastroenterologists (37%) and rheumatologists (31%) most often confirming IgG4-RD diagnosis. Most patients were treated by gastroenterologists (53.9%), rheumatologists (46.8%) and primary care physicians (20.4%). Patients required a mean (SD) of 5.1 (4.0) consultations and 17.4 (8.9) tests prior to diagnosis; physical examination (85.7%), serum IgG4 levels (84.5%), and tissue biopsy (81.0%) were most frequently used to aid diagnosis. 86.0% of patients had another condition suspected prior; most commonly pancreatitis (28.3%), cholangiocarcinoma (14.1%) and Sjögren's syndrome (12.5%). Post-diagnosis, mean (SD) time to treatment initiation was 16.5 (28.0) months, ranging from 12.0 (22.5) in Europe to 34.6 (38.2) in KSA. Prednisone was the most common first line therapy (78.6%), followed by rituximab (12.7%) and azathioprine (9.7%). In the 12 months prior to survey, 26.7% of patients were hospitalised (21.4% in Europe; 15.4% in Brazil and 56.0% in KSA). Of those hospitalised, the mean (SD) number of hospitalisations was 1.4 (0.8), ranging from 1.2 (0.5) in KSA to 1.5 (0.9) in Brazil. 41.6% of patients were admitted via the emergency room (ER) and spent 5.9 (5.0) nights in hospital.

	Overall n=982	France n=181	Spain n=96	Italy n=160	Germany n=162	UK n=143	Brazil n=89	KSA n=151
FACIT Fatigue score (normal range ~40-45); n (Mean ± SD)	254 (34.8 ± 10.5)	30 (36.4 ± 10.9)	27 (34.9 ± 11.4)	10 (46.1 ± 4.1)	104 (37.7 ± 9.2)	10 (20.1 ± 4.7)	2 (42 ± 7.1)	71 (30 ± 8.8)
Overall work impairment (WPAI); n (Mean ± SD)	84 (26.5 ± 24.1)	15 (23.1 ± 28.2)	9 (9.6 ± 14.8)	4 (0.0 ± 0.0)	30 (20.7 ± 19.5)	2 (62 ± 0.7)	0 (0.0 ± 0.0)	24 (43.6 ± 19.0)
Activity impairment (WPAI); n (Mean ± SD)	252 (34.7 ± 26.0)	29 (39.3 ± 30.7)	27 (26.7 ± 26.2)	10 (3.0 ± 9.5)	104 (29.5 ± 24.9)	10 (55.0 ± 9.7)	2 (35.0 ± 49.5)	70 (45.1 ± 20.9)
Impairment whilst working (WPAI); n (Mean ± SD)	117 (24.9 ± 20.4)	16 (22.5 ± 26.2)	12 (10 ± 12.8)	4 (0.0 ± 0.0)	58 (23.1 ± 16.7)	2 (50.0 ± 0.0)	0 (0.0 ± 0.0)	25 (39.6 ± 18.4)
Work time missed (WPAI); n (Mean ± SD)	84 (4.0 ± 7.9)	15 (2.2 ± 8.6)	9 (1.2 ± 3.7)	4 (0.0 ± 0.0)	30 (2.0 ± 5.8)	2 (24 ± 1.4)	0 (0.0 ± 0.0)	24 (7.7 ± 8.3)

Table 1: Distribution of patient-reported outcomes in the overall study sample and by country.

Conclusion: The diagnostic journey for IgG4-RD patients is often delayed, involving multiple consultations, tests and misdiagnoses. Despite the heterogeneous nature of the disease, most patients reported substantial burden of illness and impact to daily lives. Optimizing diagnosis and treatment pathways may improve disease burden and quality of life among patients with IgG4-RD.

FINANCIAL TOXICITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE AT THE NATIONAL HOSPITAL SRI LANKA: A CROSS-SECTIONAL STUDY

P. Perera[1], D. Wickramasinghe[1], N. Wickramasinghe[2], D. Wickramasinghe[1], R. Wannakuwatte[1], N. Fernandopulle[1]
[1]University of Colombo, Department of Surgery, Colombo, Sri Lanka, [2]University of Colombo, Department of Physiology, Colombo, Sri Lanka

Contact E-Mail Address: piyumiperera3350@gmail.com

Introduction: Inflammatory bowel disease (IBD) imposes severe financial burdens in low-middle income countries (LMICs). Sri Lanka's healthcare system faces unique challenges in managing chronic diseases like IBD. This study evaluates financial toxicity (FT) using the validated FACIT-COST instrument.

Aims & Methods: This cross-sectional study aimed to quantify financial toxicity (FT) and identify risk factors among IBD patients at Sri Lanka's National Hospital. 132 IBD patients (68 Crohn's disease [CD], 64 ulcerative colitis [UC]) were recruited. Demographics, education levels, and disease characteristics were collected via structured interviews and medical records. FT was assessed using the 12-item ‚FACIT-COST - Version 2' validated questionnaire (range: 0-44, lower = worse). Data was analyzed using Spearman's correlation and t-tests.

Results: The cohort's mean age was 40.55 ± 15.7 years, with a balanced gender distribution (males: 65 years, females: 67 years). The majority (62.8%) had completed secondary education or higher. The mean FT score was 19.44 ± 7.28, indicating a mild-to-moderate financial burden. FT was significantly higher in CD patients (mean = 20.65) compared to UC (mean = 18.16, p=0.049). Medication costs were the main financial concern for 75% of patients. FT scores correlated weakly but significantly with education level (rho=+0.229, p=0.008), suggesting higher education modestly reduces financial toxicity. No correlation was found with age of onset or diagnostic delay (mean = 851 days).

A notable proportion reported significant financial hardship (FT-12: 47%), and 35.6% felt IBD reduced satisfaction with their financial situation. The mean age of onset differed markedly by disease type: CD patients presented earlier (males: 23.1 years; females: 23.9 years) than UC patients (males: 32.4 years; females: 37.1 years).

Conclusion: IBD imposes a significant financial burden, particularly in patients with Crohn's disease, who face both earlier onset and higher toxicity. Targeted interventions should include:

1. Subsidies for high-cost drugs,
2. Patient education programs,
3. Improved accessibility of hospital medications,
4. Quality enhancement of available treatments,
5. Local guidelines for resource-limited settings, and
6. Establishment of IBD support groups.

These systemic solutions are essential to mitigate financial distress and improve the quality of life for Sri Lankan IBD patients.

APPROPRIATENESS AND DIAGNOSTIC YIELD OF UPPER GASTROINTESTINAL ENDOSCOPY: NEED TO IMPROVE PATIENT SELECTION FOR GREATER SUSTAINABILITY

M. Capasso[1], C. Londoni[1], R. Bertè[1], L. Ranieri[2,1], A. Cerrone[1], S. Romeo[1], S. Alicante[1], F. Metelli[1], S. Bertolazzi[1], G. Manfredi[1]
[1]ASST Crema Maggiore Hospital, Gastroenterology and Digestive Endoscopy, Crema, Italy, [2]University of Naples "Federico II", Department of Clinical Medicine and Surgery, Diseases of the Liver and Biliary System Unit, Naples, Italy

Contact E-Mail Address: claudiolondoni@libero.it

Introduction: The diagnosis of most upper gastrointestinal (GI) tract disorders is mainly clinical, with specific indications for endoscopy. Adherence to guidelines about indications for upper-GI endoscopy is cost-effective in an open-access system [1-2]. However, in the era of sustainable medicine, literature lacks observational studies aimed at evaluating the endoscopic appropriateness in an open-access systems.

Aims & Methods: The aim of the study is to investigate the appropriateness of prescriptions for upper-GI endoscopy, including the associated diagnostic yield.

This monocentric observational study was conducted by enrolling all consecutive patients undergoing upper-GI endoscopy. A detailed interview was performed before endoscopy to investigate symptoms, dietary habits, gastrointestinal history and other significative clinical information before the endoscopic examination. The appropriateness of the endoscopy was defined according to the ASGE guidelines [3]. After the endoscopic examination, the diagnostic yield, defined as a relevant diagnosis that could change the clinical history of patients (neoplasms, coeliac disease, conditions require treatment or follow-up [4]), was evaluated.

Results: A total of 437 patients were enrolled. Most of them were female (234, 53.5%), mean age 59.8 yrs (IQR 48.8-71). The main prescriber was the general practitioner (GP) (273, 62.4%), followed by gastroenterologists (107, 24.4%) and other specialists (57, 13%). The most frequent endoscopic findings were gastritis and/or duodenitis (141, 32.2%), followed by normal findings (95, 21.7%), low-risk premalignant conditions (51, 11.6%) and high-risk premalignant conditions (38, 8.6%), while malignant neoplastic lesions were 10 (2.2%).

The overall appropriate prescriptions rate was 44.3% (194 exams). Gastroenterologists had a higher rate of appropriate prescriptions (89/107, 83.1%), followed by other specialists (27/57, 47.3%) and GPs (78/273, 28.5%) (p<0.0001). Seventy-six out of 243 (31.2%) of the patients with an inappropriate indication had undergone an upper-GI endoscopy within the previous 5 years, with findings did not require follow-up [5]. The overall diagnostic yield rate was 25.6% (112/437 exams), with significant differences between appropriate and inappropriate exams: 94/194, (48.4%) vs 18/243, (7.4%) (p<0.0001), including 61 (31.4%) new relevant diagnosis vs 14 (5.7%) (p<0.0001).

Conclusion: Adherence to guidelines for the appropriateness of upper GI endoscopy is confirmed to be more effective, including the added benefit from the diagnostic yield of appropriate upper GI endoscopies. These results suggest that if proper education of practitioners were implemented, a better endoscopy-utilization would be expected.

ACUTE ABDOMINAL PAIN IN ELDERLY PATIENTS CONSULTING IN GASTROENTEROLOGY EMERGENCIES

M. Safdi[1], Z. Boukhal[1], F.Z. Elrhaoussi[1], M. Tahiri Joutei Hassani[1], F. Haddad[1], W. Hliwa[1], A. Bellabah[1], W. Badre[1]
[1]Ibn Rochd University Hospital, Hepato-Gastro-Enterology, Casablanca, Morocco

Contact E-Mail Address: mahasafdi@gmail.com
Introduction: Acute abdominal pain is a common reason for consultation in gastroenterology emergency departments among elderly patients. Diagnosis can be challenging due to atypical symptoms, which may delay treatment and increase the risk of complications or even threaten short-term survival.
Aims & Methods: This study aims to analyze the frequency, causes, and specific characteristics of acute abdominal pain in elderly patients to improve their management.
Materials and Methods: This is a retrospective descriptive study conducted over one year (December 2023 to December 2024), including all patients over 65 years old who consulted the gastroenterology emergency department for acute abdominal pain. Data were collected from medical records and entered into Excel.
Results: A total of 300 patients presented to the gastroenterology emergency department for acute abdominal pain, of whom 60 were over 65 years old, representing 20% of cases. There was a slight male predominance, with a male-to-female sex ratio of 1.3.
Among the elderly patients, 25% were managed on an outpatient basis, while 75% were hospitalized.
Regarding medical history, 25.2% of patients had hypertension, 17.6% had diabetes, 9.2% had a history of heart disease, 21.8% had cirrhosis, 17.3% had undergone previous surgery, and 19.4% had no significant medical history.
Abdominal pain was associated with vomiting in 10.6% of cases, diarrhea in 8.5%, bowel obstruction in 9.4%, and gastrointestinal bleeding in 6%. A general deterioration was observed in 42.7% of patients.
The pain was diffuse in 34.2% of cases, epigastric in 28.5%, and localized to the right hypochondrium in 17.2% of patients.
All patients underwent additional diagnostic tests. C-reactive protein was measured in all cases, with elevated levels in 72% of patients (mean: 68.3 mg/L). An abdominopelvic CT scan was performed in 76.4% of patients, while 39.7% had an abdominal ultrasound. Standard abdominal X-rays showed air-fluid levels in four patients, pneumoperitoneum in three cases, and signs suggestive of a sigmoid volvulus in one patient.
Digestive causes were the most frequent, with acute pancreatitis being the leading diagnosis (16.5%), followed by intestinal obstruction (9.3%), cholecystitis (7.3%), portal vein thrombosis (6.7%), diverticulitis (5.8%), cholangitis (3.9%), liver abscess (3.3%), and sigmoid volvulus (1.6%). A tumor-related cause was identified in 6.4% of patients.
Extra-digestive causes accounted for 13.3% of cases, including cardiac conditions (5%), urinary tract disorders (5%), and gynecological conditions (3.3%).
All patients received appropriate medical and/or surgical treatment along with symptomatic management.
Conclusion: Multiple diagnoses can be responsible for acute abdominal pain in elderly patients, some of which are life-threatening in the short term. More than one-third of cases require surgical intervention. It is crucial to establish clear guidelines to improve patient management and reduce morbidity and mortality in this vulnerable population.
Disclosure: Nothing to disclose.

MEDICAL DESERTIFICATION: KEY FACTORS IN ATTRACTING GASTROENTEROLOGISTS TO RURAL AND DISTRICT HOSPITALS

R. Fernández Bezanilla[1], R. Velamazan Sandalinas[2], L. Hernández Villalba[3]
[1]Hospital Universitario de Cruces, Vizcaya, Spain, [2]Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain, [3]Santos Reyes, Gastroenterology, Aranda de Duero, Spain

Contact E-Mail Address: fernandezbezanillarut@gmail.com
Introduction: Physician shortages in rural and underserved areas, so-called medical deserts, pose a significant barrier to specialized care across Spain and Europe.
Aims & Methods: We conducted a national, anonymous survey among members of the Spanish Association of Gastroenterology (AEG), focusing on early-career professionals. Thirty-eight factors potentially influencing job acceptance in district hospitals were rated on a 10-point scale (1 = least important, 10 = most important), and grouped into seven thematic domains. Data were analyzed for the overall cohort, and stratified by age (<35 vs. ≥35 years) and prior experience in district hospitals.
Results: A total of 110 gastroenterologists from all Spanish regions participated, with advanced endoscopy identified as the main clinical interest (54%). Alignment with personal clinical interests was considered essential by 74% of respondents.
The seven domains evaluated were: training, work environment, clinical activity, quality of life (QoL), research and teaching, on-call duties, and job stability and finances. Of these, quality of life (mean [M]: 8.62), on-call duties (M: 8.66), and job stability and financial conditions (M: 9) were rated highest.
The possibility of regularly performing endoscopy, flexible scheduling, competitive salary, and exemption from internal medicine and emergency on-call duties (all with a median score of 10) were the most valued individual factors.
Analysis of responses (see Table 1) revealed significant differences according to prior district hospital experience.
Those without such experience prioritized formal educational opportunities such as attending courses, master's programs, conferences; doctoral research; longer-term contracts; and reported greater need for support in complex clinical and endoscopic scenarios, especially in hepatology, gastrointestinal bleeding, and endoscopic management of colonic perforations. In contrast, gastroenterologists with prior district hospital exposure valued greater autonomy, fewer on-call duties, and felt less apprehension about leaving their comfort zone. Teaching opportunities were rated more highly by those aged ≥35 years (p = 0.046).
Table 1. Results (median and interquartile range) for the 10 most relevant survey items. Shown for the overall group (N=110), as well as for subgroups by age (< and ≥ 35 years) and prior experience working in a district hospital (yes/no); subgroup analysis. IQR: interquartile range. P value by Mann–Whitney U test.

DOMAIN (OVERALL MEANS OF MEDIANS)	ITEM	OVERALL (N=110) Median (IQR)	<35 YEARS (N=54) Median (IQR)	≥35 YEARS (N=55) Median (IQR)	P VALUE (AGE)	NO PRIOR DISTRICT HOSPITAL EXPERIENCE (N=56) Median (IQR)	PRIOR DISTRICT HOSPITAL EXPERIENCE (N=54) Median (IQR)	P VALUE (EXPERIENCE)
TRAINING	More opportunities to attend courses/master's programs/conferences	6 (4-8)	6 (4-8)	6 (3-8)	0.638	7 (4-8)	5 (1-7)	<0.001
WORK ENVIRONMENT	Greater autonomy in daily practice	8 (6-9)	8 (6-9)	8 (7-8)	0.579	7,5 (6-8)	8 (7-9)	0.016
	Fear of being alone in complex medical situations	7 (5-9)	8 (5-9)	7 (5-8)	0.414	8 (6-9)	7 (4-8)	0.004
	Fear of being alone in complex endoscopic situations	7 (6-9)	7 (6-9)	7 (5-8)	0.199	8 (6-9)	6 (4-8)	<0.001
QUALITY OF LIFE	Fear of leaving comfort zone	5 (2,5-7,5)	5 (4-8)	5,5 (1,75-7,25)	0.439	6 (4-8)	5 (1,25-7)	0.005
RESEARCH & TEACHING	Greater ability to complete a doctoral thesis	5 (2-7)	5 (3-7)	5 (1-7,25)	0.329	5 (3-8)	4 (1-7)	0.034
	Facilities to undertake university teaching	7 (5-9)	7 (4-8,5)	7 (5-9)	0.307	7 (4-8)	7,5 (5-9,25)	0.036
ON-CALL DUTIES	Possibility to perform fewer on-calls	8 (5,5-10)	7,5 (6-10)	9 (5-10)	0.333	7 (4,75-10)	9 (6-10)	0.036
JOB STABILITY & FINANCES	Long-term contracts	9 (7-10)	9 (7-10)	9 (6-10)	0.388	10 (8-10)	8 (5-10)	0.011

Table 1.

Conclusion: Incentives related to quality of life, on-call burden, and job stability are critical for attracting gastroenterologists to rural and underserved settings. Prior exposure to district hospitals substantially shifts professional priorities, emphasizing the importance of tailored, flexible strategies. These findings offer actionable guidance for national and European health policymakers aiming to reduce workforce disparities and improve access to specialist care in medical deserts.

PP1116

PHYSICIAN TRIAGE TIME FOR INTERVENTIONAL GI PROCEDURE REFERRALS - BALANCING PRACTICE EFFICIENCY AND PHYSICIAN WELL-BEING

T. Savides[1]

[1]University of California San Diego, Gastroenterology, Del Mar, United States of America

Contact E-Mail Address: tsavides@health.ucsd.edu

Introduction: Triaging interventional gastroenterology (GI) referrals improves care efficiency but is associated with large amount of uncompensated work done outside of normal work hours. It is unknown how much time physicians spend on this essential yet undocumented work. The purpose of this study was to assess the physician workload for triaging interventional GI referrals.

Aims & Methods: This is a prospective observational study from March to November 2024 involving an academic medical center with seven interventional endoscopists who share triage referral responsibilities each week they are on call and also triage referrals when not on call if the referral is specifically requesting them.

To systematically capture triage work performed by interventional endoscopists, an electronic medical record (EMR) "smart phrase" was created to track the following variables: Diagnosis/Reason for Triage, Triaging Physician, Triage Disposition, Procedure Ordered, Type of Anesthesia, Time Frame, Requested Provider, Triage Comments. With this triage form, time spent on performing triaging work could be approximated from the EMR's user access log.

Results: 2092 triages were captured, with a mean of 53±16 triages per week. Physicians spent an average of 3.8 ±1.0 minutes in each triage note. The physicians varied in time spent per triage from 2 minutes to 6 minutes per triage. The on-call attending of the week performed 47% of the weekly triages. 67% of referrals were triaged directly to procedures, 23% to clinic, and 10% to other (e.g. oncology or surgery or get more information). 38% of patients were triaged to have urgent (<4 weeks) procedures/visits (5% within 1 week, 12% within 2 weeks, 21% within 4 weeks). The mean amount of time per week spent by the on-call physician doing triage was 92.0 ± 61.2 minutes. The mean amount of time per week spent by the non on-call physicians doing triage was 22.3 ± 32.2 minutes. 50% of triages were done after hours (5 pm to 7 am) or on weekends.

Conclusion: Physician triage of interventional GI referrals requires an average of 4 minutes per triage and the on-call physician spends more than 90 minutes per week doing triages. Physicians not on call also spend additional time (>20 minutes per week) triaging direct referrals to them. 50% of these triages were done after hours during nights and/or weekends.

Although triaging improves clinical operations efficiency, scheduling, and patient care, it may decrease physician wellness and compensation. Future efforts should look at providing adequate time, resources, and compensation for triage of interventional GI referrals.

Disclosure: Nothing to disclose.

EARLIER USE OF GUSELKUMAB IS PROJECTED TO YIELD LONG-TERM SUSTAINED REMISSION IN PATIENTS WITH MODERATE-TO-SEVERE ULCERATIVE COLITIS

M. Dimova[1], M.J. Keng[2], D. Naessens[2], S. Kachroo[3], S. Adsul[3], M.A. Gomez Camacho[4], E. Wu[3]
[1]Janssen-Cilag, Issy-les-Moulineaux, France, [2]Janssen Pharmaceutica, Beerse, Belgium, [3]Johnson & Johnson Innovative Medicine, Horsham, PA, United States of America, [4]Johnson & Johnson, Spring House, PA, United States of America

Contact E-Mail Address: cwu60@its.jnj.com

Introduction: Ulcerative colitis (UC) is a progressive disease and associated with reduced quality of life.[1] Treatment goals for patients with UC are to induce and maintain clinical remission, and avoid or delay the need for surgery.[2,3] Increasing number of advanced treatment options have been approved in recent years for patients with UC.

However, the optimal treatment pathway is not well understood. Guselkumab, a dual-acting IL-23 inhibitor, has demonstrated clinical remission as high as 50.0% at maintenance Week 44 in the Phase 3 QUASAR study, suggesting the potential of guselkumab to provide durable clinical remission.[4]

A disease model was developed to identify the optimal treatment sequence with guselkumab for patients with moderate-to-severe UC.

Aims & Methods: A hybrid decision tree/Markov disease model was developed to project rates of clinical remission, response and active disease for patients with UC over five years. Patients were first distributed into health states representing remission, response without remission, and active UC (no response) based on the rates of clinical remission and response reported in the induction phases of Phase 2 and Phase 3 trials.

Over time, loss of response and transition to the next line of therapy is derived based on loss of response rates in the trial data. Up to three treatment lines were modelled, and patients who lose response after third-line treatment are categorized as in active disease state where they can receive surgery.

Age- and sex-adjusted mortality rates obtained from the US population life table were applied in the model. Three treatment sequences were assessed, where guselkumab was placed in first-line, second-line, and third-line, respectively. A treatment basket was used for the other lines of therapy, informed by 2024 market share data from MarketScan.

We report the predicted average proportion of time spent in each health state for each of the three treatment sequences over five years.

Results: Over a 5-year period, the predicted average proportion of time patients spent in active disease is consistently lower for patients treated with guselkumab as a first-line therapy compared to those receiving it in later lines. In the first year, patients receiving first-line guselkumab spent 28% of time in active disease, while those treated with guselkumab in the second or third line spent 33%.

This difference becomes more pronounced over the 5-year period, with proportion of time in active disease at 36% for first-line guselkumab use versus 48% and 51% for second- and third-line use, respectively. The reduction in time in active disease with earlier use of guselkumab infers that patients are asymptomatic, as patients are also projected to experience longer time in remission.

The model predicts that, over 5 years, patients treated with first-line guselkumab spend an average of 52% of their time in remission, in contrast to 40% and 38% for those treated with guselkumab in the second- or third-line, respectively.

Table 1: Projected average proportion of time spent in each health state over a 5-year period

	Remission	Response without remission	Active UC	Surgery
First-line guselkumab	52.1%	10.8%	36.4%	0.7%
Second-line guselkumab	39.5%	11.9%	47.7%	0.9%
Third-line guselkumab	38.1%	9.9%	51.0%	1.0%

Conclusion: Model projections suggest that using guselkumab in first line is associated with long-term sustained remission for patients with UC, compared to using guselkumab in later lines of treatment.

COMPARATIVE ANALYSIS OF LARGE LANGUAGE MODELS TO RESPONSE OPEN-ENDED QUESTIONS REGARDING GASTROENTEROLOGY

Q. Luo[1], N. Zhou[1], L. Ye[1], B. Hu[1]
[1]West China Hospital, Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

Contact E-Mail Address: nuoyazhou9@163.com

Introduction: The performance of large language model (LLM) across specific medical domains is uncertain. We evaluated the performance of ChatGPT-4 and two Chinese LLMs in answering open-ended questions regarding gastroenterology.

Aims & Methods: We selected ChatGPT (4-Turbo, OpenAI) and two Chinese LLMs (model A and B), and embedded our own digestive disease-related knowledge database in the LLMs via retrieval-augmented generation (RAG). We presented 200 questions, with 3 different expressions for each question and 5 repeated queries for each expression.

Questions were selected from those commonly encounter in a clinical setting from patients. The accuracy and readability were assessed using a three-classification criterion (good, borderline, poor).

Responses with "good" rating in accuracy were further assessed using a 3-point scale. For responses with "poor" rating in accuracy, the LLMs were further prompted to self-correct. The stability was assessed through the consistency in changing-expression and repeating-query groups.

Results: For accuracy evaluation, model B demonstrated superior accuracy, with 94.9% of "good" rating, compared to 92.3% in model A and 90.3% in ChatGPT-4 (all P <0.001). Three LLMs showed comparable average scores in "good" rating responses (2.590 vs 2.573 vs 2.536, P=0.754).

For readability evaluation, ChatGPT-4 and model A demonstrated superior readability, with 94.4% and 93.1% of "good" rating, compared to 76.3% in model B (all P< 0.001).

The average response length of ChatGPT-4 was comparable to model A and significantly shorter than model B (207.45 vs 271.33 vs 336.87, P<0.001). For stability evaluation, model A demonstrated superior sta-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

bility in repeating queries than ChatGPT-4 and model B. The stability in changing different expressions was not satisfactory for all the three LLMs and needs to be further improved.

Conclusion: Our study preliminarily demonstrated three LLMs' potential in accurately answering questions regarding gastroenterology, and their application to clinical practice still needs further exploration.

Introduction: In recent years, the incidence of pancreatic solid tumors—especially pancreatic neuroendocrine neoplasms (pNENs) and pancreatic ductal adenocarcinomas (PDACs)—has increased due to improved imaging and aging populations. Differentiating these tumors is crucial given their distinct prognoses. Endoscopic ultrasound is considered the gold standard for their diagnosis.

However, EUS-tissue acquisition could have low diagnostic accuracy, especially in pNENs. Unlike PDACs, pNENs exhibit a significantly higher microvascular density (MVD), and this is showed by different contrast uptake EUS with contrast enhancement (CE-EUS). Recent studies, indeed, have shown a very low interobserver agreement in CE-EUS evaluation, even among expert endosonographers.

Aims & Methods: This proof-of-concept study aimed to prospectively evaluate the role of objective quantification of contrast uptake during CE-EUS in differentiating pNENs from PDACs, potentially improving diagnostic accuracy and reducing operator dependency. This prospective monocentric observational study, compliant with STROBE guidelines, included patients who underwent EUS for pancreatic diseases at San Raffaele Hospital (Milan) between January and June 2024. Eligible patients had a solid pancreatic lesion with a final cytological diagnosis of PDAC or pNEN and a complete DICOM-format CE-EUS video including both arterial and venous phases.

Exclusion criteria were lack of consent or poor-quality/unstable videos. EUS was performed under deep sedation by experienced operators using a linear echoendoscope. Lesions were evaluated with B-mode, Doppler, elastography, and CE-EUS following the injection of 4.8 ml of SonoVue®, recording at least 120 seconds of video (arterial: 10–30 s; venous: 30–120 s). Videos were archived in DICOM format.

Post-procedural analysis was conducted with VueBox® software, which provides quantitative contrast uptake parameters. ROIs were manually selected in the lesion and adjacent normal parenchyma. Assessed metrics included peak enhancement, wash-in/wash-out rates, time-to-peak, perfusion indices, and area-under-curve measurements.

Results: After applying inclusion criteria, 73 patients with solid pancreatic lesions were enrolled (51 PDACs, 22 pNENs). No significant differences in general features were found between groups. Median tumor size was 31 mm overall (32.6 mm PDACs, 27.3 mm pNENs). Operator-based CE-EUS evaluation showed hypo-enhancement in 88.2% of PDACs and only 4.6% of pNENs ($p<0.001$). VueBox® analysis revealed significant differences in contrast uptake parameters between the two groups: pNENs consistently showed higher values for MeanLin, PE, WiAUC, WiR, WiPI, WoAUC, and WiWoAUC (all $p<0.001$). ROC analysis identified WiPI (AUC 0.838) and WiR (AUC 0.804) as the best discriminators; combining them via logistic regression increased the AUC to 0.961.

Univariate analysis showed that in pNENs, contrast parameters were influenced by lesion size, echogenicity, and lymphadenopathies. However, multivariate analysis confirmed only lesion diameter as significantly correlated with local transit time ($p<0.0001$), while no patient- or tumor-level variables showed significant associations with contrast uptake in the full cohort.

Conclusion: CE-EUS improves pancreatic tumor assessment but is limited by subjectivity and low interobserver agreement. This study shows that qCE-EUS effectively distinguishes pNENs from PDACs, with key parameters like WiPI and WiR achieving 96.1% accuracy. qCE-EUS may reflect tumor angiogenesis and offers a reproducible, non-invasive tool for diagnosis, staging, and treatment planning.

APPLICATION OF ABDOMINAL POINT-OF-CARE ULTRASOUND IN WAR CONDITIONS AFTER 2-DAY TRAINING COURSES: A CROSS-SECTIONAL STUDY

S. Kravchuk[1], A. Neverovskyi[2]

[1]Danylo Halytsky Lviv National Medical University, Gastroenterology, Lviv, Ukraine, [2]Bogomolets National Medical University, Kyiv, Internal Medicine No.1 with a Course in Gastroenterology, Kyiv, Ukraine

Contact E-Mail Address: kravchuck.stanislav@gmail.com

Introduction: Point-of-care ultrasound (POCUS) plays a crucial role in emergency medicine, including in wartime settings. Different POCUS studies are designed to answer specific clinical questions, quickly guiding the management of potentially fatal emergencies. Unfortunately, the experience of Ukrainian combat medics in using POCUS in war conditions is relatively limited. However, short POCUS training programs can help improve their proficiency.

Aims & Methods: The aim of this study was to evaluate the application of POCUS and identify potential barriers to its use in various settings during the war in Ukraine by combat medics without prior ultrasound experience after completing a two-day training course. This was a cross-sectional survey of former participants (n=140) of two-day POCUS training courses organized by the charitable organizations *Razom for Ukraine* and the *Christian Medical Association of Ukraine* between January 2023 and September 2024.

The 2-day training included 4 hours of theoretical lectures and 10 hours of practical sessions. An online survey consisting of 41 questions assessed the challenges and characteristics of ultrasound use at different stages of evacuation after completion of the training. Among the participants, 87% were doctors, 56% worked at stabilization points, 31% in military hospitals, and 14% in medical transport.

Results: 89% of participants used POCUS at least once a day. The most commonly used applications of abdominal POCUS were FAST (Focused Assessment with Sonography in Trauma) – 89% of respondents; followed by ultrasound of the kidneys (40% of respondents) and ultrasound of the liver and gallbladder (36% of respondents). Other frequent applications were pneumothorax (72%), vascular access (62%), soft tissue (54%), and nerve blocks (44%). The most common barriers to use were image inter-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pretation (47%) and image acquisition (31%). The most common technological problems were damage to the probe or cord (36%), a short battery lifespan (32%), and not having access to a machine (26%).

Conclusion: After a brief two-day training, novice ultrasound users among combat medics regularly utilized abdominal POCUS in the care of wounded Ukrainian soldiers, primarily through the FAST exam.

Future efforts to overcome barriers to the routine use of POCUS should focus on additional education in image acquisition and interpretation, as well as the procurement of higher-quality ultrasound machines.

Disclosure: Nothing to disclose.

BEYOND THE SCOPE: A MIXED-METHODS ANALYSIS OF CONTRIBUTORY FACTORS TO PATIENT SAFETY INCIDENTS IN GASTROINTESTINAL ENDOSCOPY USING THE SEIPS 2.0 FRAMEWORK - A UK NATIONAL DATABASE STUDY

S. Little[1,2], J. Tawn[1], D. El-Sawy[1], A. Saghir[3], D. Das[3,2], M. O'Reilly[1], A. Chilton[2], M.F. Peerally[2,1]
[1]University of Leicester, Department of Population Health Sciences, Leicester, United Kingdom, [2]Kettering General Hospital, Department of Gastroenterology, Northamptonshire, United Kingdom, [3]University of Leicester, Leicester Medical School, Leicester, United Kingdom

Contact E-Mail Address: sl798@leicester.ac.uk

Introduction: Patient Safety Incidents (PSIs) are not uncommon in gastrointestinal endoscopy, arising from complex interactions between factors at all levels of healthcare. Understanding the contributory factors (CF) to PSIs is crucial to improve safety, yet are poorly characterised in endoscopy care.

This study presents an analysis of CFs associated with PSIs across the UK over 5 years, using a validated Human Factors Framework.

Aims & Methods: This was a retrospective mixed-methods study of anonymised PSI reports associated with at least moderate harm in GI endoscopy, submitted to the National Reporting and Learning System between 2017-2022. A descriptive analysis of cases was undertaken to identify incident type, phase of care and urgency. The Systems Engineering for Patient Safety (SEIPS 2.0) framework was used to identify CFs from reports, based on principles of content analysis.

Results: Of 1,575 reports analysed, 133 were excluded as unrelated to GI endoscopy. Of those remaining, 100 (6.9%) resulted in death, 268 (18.6%) in severe harm and 1,074 (74.5%) in moderate harm.

The most frequently occurring incident type was 'known complication' (n=587, 40.7%), with 'perforation' (n=341, 58.1%), 'bleeding' (n=94, 16.0%) and 'missed cancer' (n= 59, 10.1%) being most common. The second most common incident was 'follow-up related' (n=268, 18.6%), largely characterized by 'delayed follow-up or diagnosis' (n=152, 53.1%) and 'lost to follow-up' (n=84, 29.4%). Issues with endoscopy 'timing or decision' was the third most coded incident (n=124, 8.6%). Most PSIs occurred peri-endoscopically (n=642, 44.5%), followed by pre-endoscopy (n=409,28.3%) and post-endoscopy phases (n=392, 27.2%). Elective procedures (n=647,44.8%) had more incidents than emergency (n=245,17%).

Of included reports, 1,057 (73.3%) contained enough information to yield 1,441 CF references captured within SEIPS.

Table 1 provides an overview of the three most frequently referenced SEIPS domains, with a non-exhaustive presentation of leading themes. 'Person' CFs, influenced largely by communication issues, was the most significant driver. 'Organisation' constituted over a third of references, driven largely by resource availability and recruitment. Most CF references within ‚Task' related to complex tasks, dominated by challenging anatomy or physiology. Of the remaining domains, 'Tools and technology' (n=106, 7.4%) was mostly driven by equipment malfunction (48.1%). The 'External environment' (n=55, 3.8%) was almost exclusively COVID-19 policy changes (96.4%), while 'Internal environment' formed a minority of CFs (n=9, 0.6%).

SEIPS domain	Theme and sub-theme	Number of references
Person n=750, 52.0%	Communication	382 (59%)
	Between specialist teams	161
	Poor documentation	96
	Between patient and healthcare team	63
	Knowledge, competence and skills	247 (32.9%)
	Team cohesiveness	51 (6.8%)
Organisation n=269, 18.7%	Resource availability and recruitment	160 (59.5%)
	Endoscopy list capacity	68
	Multiple hospital sites	26
	Equipment availability	18
	Workload assignment	43 (16.0%)
	Communication infrastructure	35 (13.0%)
Task n=252, 17.5%	Complexity	132 (49.1%)
	Challenging anatomy or physiology	128
	Complication management	24
	Differently abled patient	24
	Difficulty	43 (17.1%)
	Ambiguity	10 (4.0%)

Table 1. Three most referenced SEIPS domains implicated in PSIs of at least moderate harm.

Conclusion: This novel systems-based analysis of CFs in endoscopy-related PSIs provides critical insight for improving safety. The predominance of issues relating to People and Teams, Organisation and Task highlights key areas for intervention.

The next phase of this research includes a content analysis of PSIs associated with mild harm and development of simulations based on findings, aiming to improve safety in endoscopy.

Disclosure: Nothing to disclose.

Introduction: Informed consent (IC) serves as the ethical foundation for all medical interventions, empowering patients to make informed, autonomous decisions while safeguarding clinicians. Barriers such as limited health literacy and document complexity may hinder comprehension[1,2].

This study evaluated the comprehensibility, readability, and effectiveness of the documents provided for IC and instructions for endoscopic procedures.

Aims & Methods: Outpatients undergoing endoscopic procedures completed a questionnaire assessing their understanding of IC, preparation instructions, and adherence to guidelines. Patient confidence and doc-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ument comprehensibility were assessed through self-reported scales. Readability was assessed using Flesch Reading Ease score adapted for portuguese (FRE-PT)[3].

Results: Among 186 participants (mean age: 58.1 ± 16.1 years), 76.9% reported full-extent reading of the provided instructions and IC document. Patients with primary education (≤4th grade) were less likely to read the documents fully (59.2% vs. 83.2%, p < 0.001) and were independently associated with the need for additional assistance (OR 5.65, 95% CI: 1.92 - 16.68, p = 0.002).

Full-extent reading was independently associated with greater risk awareness (OR 5.52, 95% CI: 2.37 - 11.55, p < 0.001), reduced need for additional assistance (OR 0.22, 95% CI: 0.09 - 0.51, p < 0.001), and higher compliance with medication guidelines (75.7% vs. 45.8%, OR 3.42, 95% CI: 1.28 - 9.20, p = 0.015). Patients with primary education rated document's comprehensibility lower (median:8, IQR 7-10) compared to those with higher education (median: 10, IQR 8 - 10, p < 0.001) and reported lower levels of confidence and preparation for the procedure (median: 8, IQR 7 - 10 vs. median: 9, IQR 8 - 10; p = 0.018).

Outcomes did not differ significantly between patients aged 65 years or older compared to younger patients. FRE-PT scores classified readability as ''very difficult'' for both upper endoscopy (20.87) and colonoscopy (26.00).

Conclusion: Full-extent reading IC and instruction documents reduces the need for assistance, improves compliance with pre-procedural measures, risk awareness and patient confidence. However, the document's complexity and difficult readability disproportionately challenge and discourage patients with limited education. Future research should explore strategies to foster more equitable informed decision-making.

ADVANCING INFLAMMATORY BOWEL DISEASE CARE IN AFRICA: OUTCOMES FROM A MULTIDISCIPLINARY EDUCATIONAL SYMPOSIUM

A. Autiak Ayii Chol[1,2], O. Komolafe[3], M. Ahmad[4], G. Oyeleke[5], A. Asombang[2,6]

[1]Suez University Faculty of Medicine, Suez, Egypt, [2]Pan-African Organization for Health Education and Research (POHER), St. Louis, United States of America, [3]University Hospitals Wishaw, Wishaw, United Kingdom, [4]University Hospitals Dorset, Dorset, United Kingdom, [5]Lagos University Teaching Hospital, Lagos, Nigeria, [6]Massachusetts General Hospital, Boston, United States of America

Contact E-Mail Address: autiakangelo2018@gmail.com

Introduction: Inflammatory Bowel Disease (IBD) is emerging as a significant but under-recognized health challenge in Africa. Diagnostic delays, limited awareness, and a lack of educational opportunities for healthcare professionals persist. The Inaugural Inflammatory Bowel Disease in Africa Symposium was held on April 10th in Abuja, Nigeria, to foster collaboration in IBD diagnosis and management, promote awareness of medical and surgical care options, and support patient advocacy.

Aims & Methods: A hybrid (in-person and virtual) full-day symposium was designed and developed, bringing together specialists in gastroenterology, surgery, nursing, pathology, radiology, and oncology from across the continent. The program featured expert-led lectures and multidisciplinary team case-based discussions.

A post-symposium electronic survey was deployed to assess participants' satisfaction, knowledge gains, practice impacts, and IBD management challenges and provide recommendations for enhancing future symposia. Quantitative responses were analyzed descriptively; qualitative feedback was thematically categorized.

Results: A total of eighty-four individuals registered, with speakers and faculty representing Nigeria, South Africa, Ghana, Zambia, Zimbabwe, the United States, the United Kingdom, Egypt, and Kenya. Fifty-eight (69%) of 84 completed the survey. These comprise nurses (34.5%), surgeons (27.6%), gastroenterologists (17.2%), radiologists (8.6%), pathologists (6.9%), and oncologists (5.2%).

Overall, 93% rated the program as Satisfied, with 88% reporting significant knowledge gains in African-context IBD management. Diagnostic and treatment confidence improved in 83% and 76% of participants, respectively, with 69% gaining skills in biopsy techniques and 67% differentiating IBD mimickers. Major challenges reported included limited access to endoscopy and histopathology, low disease awareness among patients, high diagnostic costs, misdiagnosis as infectious diarrhea or tuberculosis, and lack of referral networks.

The absence of multidisciplinary care teams was also noted. A strong majority (95%) supported establishing an African IBD registry, emphasizing the need for sustainable funding, technical infrastructure, and training. Hybrid learning and case-based approaches were preferred for future symposia, with interest in pediatric IBD and resource-adapted care.

Conclusion: The symposium significantly enhanced knowledge and confidence in IBD care among participants while exposing critical gaps in diagnostics, treatment access, and care coordination. These findings highlight the need for sustained collaborative efforts to strengthen IBD education and care. Supporting regional training and cross-disciplinary engagement will be essential to building capacity, improving outcomes, and advancing equitable IBD management across the continent.

KNOWLEDGE AND ATTITUDES TOWARD GASTRIC CANCER SCREENING IN A LOW-LITERACY ROMA COMMUNITY

R.-A. Farcas[1], D. Olteanu[2], T. Surdea-Blaga[3], L.-E. David[3], D.L. Dumitrascu[4]

[1]Iuliu Hatieganu University of Medicine and Pharmacy, 2nd Medical Department, Cluj-Napoca, Romania, [2]Public Health Department of Cluj County, Cluj-Napoca, Romania, [3]University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj-Napoca, 2nd Medical Department, Cluj-Napoca, Romania, [4]Iuliu Hatieganu University of Medicine and Pharmacy Cluj-Napoca, 2nd Medical Dept., Cluj-Napoca, Romania

Contact E-Mail Address: radufr@gmail.com

Introduction: Gastric cancer is a major cause of cancer-related mortality, and early detection improves outcomes. However, organized gastric cancer screening programs are largely absent in Europe, and vulnerable groups often have low awareness of preventive services. Roma communities face pronounced health disparities and barriers to healthcare, including social exclusion and low literacy, which may limit their use of preventive services [1].

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: We aimed to explore the knowledge, attitudes, and preferences regarding gastric cancer screening among Roma adults with low health literacy in Cluj-Napoca, Romania, to inform culturally tailored outreach strategies, as part of the TOGAS project. Approximately 40 Roma adults (18–72 years) were recruited via community centers for three focus groups (two urban, one rural) in Cluj-Napoca. All participants first attended a brief educational session on digestive health and gastric cancer to ensure baseline understanding. Guided by trained moderators, groups discussed their awareness of gastric cancer and perceptions of screening methods (endoscopy, blood tests, stool tests). All discussions were audio-recorded, transcribed, and thematically analyzed.

Results: Baseline awareness of gastric cancer screening was minimal. Most participants had never heard of any screening test or program for gastric cancer, indicating a major knowledge gap.

Nevertheless, after receiving information, many expressed interest in screening for early detection. A prominent theme was communication preferences: nearly all participants preferred to receive health information via mobile phone or social media (e.g., messaging) and also through traditional channels like primary care providers. Overall, participants were open to screening if it was offered conveniently and respectfully.

Conclusion: Outreach is needed to improve engagement in cancer prevention among underserved populations. The lack of awareness in this Roma community echoes reports of poor knowledge of cancer prevention in other Roma groups and signals the need for targeted health promotion to reduce inequalities. As European health authorities consider implementing gastric cancer screening, input from vulnerable communities will be vital for equitable uptake.

GAMIFIED ENDOSCOPY TRAINING WITH AI-BASED IMAGE AND SPEECH RECOGNITION

M. Pauletti[1], J. Troya[1,2], V. Wettstein[1], A. Meining[2,1], A. Hann[3]
[1]University Hospital Würzburg, Department of Internal Medicine II, Interventional and Experimental Endoscopy (InExEn), Würzburg, Germany, [2]Bavarian Cancer Research Center (BZKF), Würzburg, Germany, [3]University Hospital Würzburg, Department of Internal Medicine II, Würzburg, Germany

Contact E-Mail Address: Hann_A@ukw.de

Introduction: Proper training in upper gastrointestinal endoscopy (GI) is critical prior to first patient contact[1,2]. While multiple training simulation models are available, they often lack interactive elements and thus motivating experiences, which may limit engagement and skill acquisition[1]. Gamification, the application of game-like elements to non-game contexts, has shown promise in enhancing learning and motivation in medical education[2].

Aims & Methods: This study aimed to enhance engagement in endoscopic training through the gamification of a commercially available silicone upper GI tract model (SimStar Gastro Advanced, Dr. Henke GmbH), which features four pathological findings: Barrett's esophagus, a gastric polyp, gastric varices, and a gastric ulcer. We developed an AI-based system that integrates real-time image recognition using a ResNet18 deep learning model to detect pathologies in the video feed, and speech recognition using Whisper AI (OpenAI, San Francisco, USA) to automatically log the findings. Endoscopists were instructed to perform a complete diagnostic examination as quickly and accurately as possible while verbally reporting each pathology. The AI-based system gave real-time feedback regarding the verbally reported diagnosis. No prior training with the system was provided. After completing the task, participants filled out a 10-item System Usability Scale (SUS) questionnaire.

Results: Five out of six endoscopists successfully identified and dictated all four pathologies. The median examination time was 64.4 seconds. The image recognition system achieved a frame-by-frame accuracy of 74.4%, while the speech recognition system demonstrated 90% transcription accuracy. The overall usability was rated positively, with a median SUS score of 74.5 for the participants who successfully completed the test, indicating good acceptance and ease of use.

Conclusion: The integration of computer vision and voice recognition into a gamified endoscopic simulation model offers a promising, engaging, and autonomous method for training novice endoscopists. Our pilot study demonstrates the feasibility and usability of this approach, supporting the development of more engaging training tools in GI endoscopy.

GAME-BASED LEARNING TO PROVIDE EXPOSURE TO ENDOSCOPY

M. Solinski[1]
[1]McGaw Medicine of Northwestern University, Medicine, Chicago, United States of America

Contact E-Mail Address: Mark.solinski@northwestern.edu

Introduction: There is tremendous potential in using serious games as an avenue for future medical education tools. An advantage to using serious games over other forms of simulation is the low cost and high level of accessibility for students. We presented students with a phone-based game that presented students challenging and rare endoscopy-based patient case scenarios, which we believe can be applied to other interventional fields, such as gastroenterology.

Aims & Methods: Second year undergraduate medical students were invited to participate in the study via email at the beginning of the academic year. Participants were randomly assigned into either the control group or the intervention group and asked to complete a pre and post-survey. Students completed a pre-study survey asking them about their interest in interventional medicine, and their level of familiarity with each topic as well as their confidence treating a patient with pathology that they will learn about in the app and recognizing several different structures endoscopically.

Results: Compared to control, the intervention group reported a significant increase in knowledge and skill acquisition ($p < 0.01$, $p < 0.003$) as well as interest in pursuing a career in interventional medicine ($p = 0.04$). Students reported that the virtual cases helped them understand the course material (60%) and enjoyed their experience with the app (80%). 100% of participants reported that they would recommend the app to a colleague interested in gastroenterology.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Recent research has shown that there is a need for development and validation of medical education research in the field of gastroenterology. Game-based learning offers students an opportunity to engage in the content that they are learning about in class in a novel way that has the potential to enhance their pre-clinical knowledge, increase their confidence to manage future patients, and may influence their career interests. Given the notorious difficulty of pre-clinical curriculums, it is important to find ways for students to be able to solidify course content while also maintaining their wellbeing. Game-based learning offers students an opportunity to engage in the content that they are learning about in class in a novel way that has the potential to not only enhance their pre-clinical knowledge but also increase their confidence managing patients when they enter the clinical years.

Introduction: Endoscopic submucosal dissection (ESD) demands a high level of endoscopic skill and extensive training, even for experienced endoscopists, with a particularly steep learning curve for colonic ESD. Over the last three years, the French Society of Digestive Endoscopy (SFED) has implemented a structured ESD training program.

This study aimed to evaluate the effectiveness of the SFED ESD training program to achieve competency in ESD and to identify factors associated with it.

Aims & Methods: Participants who attended the SFED ESD training curriculum over the past three years were invited to join the study. After completing a standardized initial simulation training week, each participant was asked to document each ESD procedures performed in their training center, along with technical details for each (lesion size and location, en bloc resection, R0 resection status, and procedural complications).

Additionally, participants completed an online survey to gather information about their practice environment, ongoing ESD activity, and demographic data (e.g., gender, age, prior endoscopy experience). Successful dissection was defined as en-bloc resection with free lateral and deep margins (R0) and no need for surgical intervention due to complications. The performance threshold for achieving proficiency in ESD was defined, in line with ESGE guidelines, as achieving an en-bloc resection rate of >90% and a complication-related surgery rate of <1%. The learning curve to reach these competence standards was assessed using the LC-CUSUM method.

Results: A total of 45 students participated in the study. The majority were men (70%), with a median age of 36 years. They practice endoscopy for 6 years (IQR 4-10) and 82% performed interventional endoscopy (ERCP and EUS).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

A total of 2,068 ESD procedures were performed by the trainees. The median number of ESDs conducted post-training was 34 (IQR 22-66), with the majority being colorectal (42.9% rectal and 42.7% colonic). Lesions had a median size of 45 mm (IQR 34-60), with a resection speed of 17.4 mm^2/min (IQR 10.5-26.5). En bloc resection and R0 resection were achieved in 93.6% and 85.8% of cases, respectively, with a surgical complication rate of 0.94%.

The overall success rate of ESD procedures was 92.7%. Success was more likely in rectal (97%) than colonic (90.4%) procedures. 75% of the students were competent. Among those who reached competence, the median number of ESDs required was 45. Factors associated with competency were: ESD localization (rectum > colon), the age (HR 0.92 [0.86-0.99]; p = 0.03) and experience (HR 0.91 [0.84-0.99]; p = 0.03) were inversely correlated to the competency. Practiced in a high volume ESD center (>100 ESD/year) lead to reach competency faster (p =0.008).

Conclusion: This study provides the first assessment of the SFED ESD training program in France. Competence in ESD is reachable after appropriate training. A big experience is not needed to attempt ESD. Supervised training is essential, and seems easier in a high-volume center to achieve competence more quickly. These findings may help inform the selection of future candidates for ESD training to ensure effective skill acquisition and safe practice.

ADEQUACY OF DISCLOSURES OF CONFLICTS OF INTEREST IN ORAL PRESENTATIONS AT THE 2025 CONGRESS OF EUROPEAN CROHN'S AND COLITIS ORGANISATION

E. Tan[1], Z.C. Xu[1], M. Garg[1,2], R. Little[1,3]
[1]Northern Health, Gastroenterology, Melbourne, Australia, [2]University of Melbourne, Medicine, Melbourne, Australia, [3]Monash University, Medicine, Nursing and Health Sciences, Melbourne, Australia

Contact E-Mail Address: mayur.garg@nh.org.au

Introduction: Conflicts of interest (COIs) introduce potential bias into study design, scientific interpretation, clinical decision making and guideline development (1). COIs within gastroenterology research are common yet their presentation at international gastroenterology conferences has not been previously evaluated.

Aims & Methods: Our aim was to characterise the adequacy of COI disclosures at the 20th Congress of the European Crohn's and Colitis Organisation (ECCO) 2025. Two investigators independently conducted assessments of COIs for all scientific presentations on the ECCO 2025 virtual portal. Outcomes included presence of a disclosure slide, disclosure slide duration, number of COIs, adequacy of disclosures (defined as highlighting how COIs may relate to the presentation), presence of a potential drug/industry product in the presentation and consistency with written abstract COIs.

Results: COI statements were missing in 18% of presentations, and 22% had inconsistencies in COI data between written abstracts and oral presentations. The median disclosure slide duration and was 2.3 seconds (IQR 1.5-3.4) and median number of COIs 10 (IQR 5-29). There was no correlation between slide duration and number of COIs (r = 0.059, p = 0.53). Whilst 59% of presentations contained at least one COI with relevance to the presentation topic, only 6% of COIs were assessed as adequately discussed. The median slide display time for adequately discussed COIs was higher at 6.5 seconds (IQR 3.5-9.3) versus 2.3 seconds (IQR 1.4-3.0) for inadequately discussed COIs (p = 0.006).

Conclusion: COI disclosure practice was suboptimal in oral presentations at the 20th Congress of ECCO. When presented, disclosure slide duration was too brief for meaningful interpretation. Discussion of COIs relevant to the presentation topic was inadequate in 94%, even though the time difference required for adequate disclosure was only 4.2 seconds. Formal guidance and standardised criteria for COI disclosures are warranted to facilitate transparency and allow informed interpretation of presented data.

Introduction: Quality assessment is a priority in the field of gastroenterology. However, limited data are available from Greece regarding adherence to quality standards in gastrointestinal endoscopy.

Aims & Methods: This study aims at assessing the knowledge and compliance of Greek gastroenterologists with established quality standards for upper and lower digestive endoscopy, while exploring factors that may influence compliance.

This prospective study recorded data on the quality of upper and lower digestive endoscopy performed in Greece from October 2024 to January 2025. All members of the Hellenic Society of Gastroenterology (n=668) were invited to participate via an electronic survey. The survey included a questionnaire designed specifically for this study, covering demographic and professional characteristics, as well as quality indicators for gastroscopy and colonoscopy.

Results: A total of 164 gastroenterologists participated (response rate 24.55%), of whom 107(65.24%) were male, and 102(62.2%) working in public or academic hospitals. The duration of gastroscopy was not recorded by 116(70.73%) participants, while 102(62.2%) systematically used photodocumentation. Most participants utilized the Prague and Los Angeles classifications 156(95.12%) and 159(96.95%) respectively. Additional-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ly, 140(85.37%) followed the Seattle protocol, and 158(96.34%) conducted biopsies according to ESGE guidelines for precancerous gastric lesions. However, 83(50.61%) don't use a registry for patients with Barrett's esophagus. Complications were systematically recorded after gastroscopy by 103(62.8%) and after colonoscopy by 90(54.88%).

In colonoscopy, 149(90.85%) use the BBPS scale, and 158(96.34%) reported successful cecal intubation. Withdrawal times exceeded six minutes for 151(92.07%) participants. An adenoma detection rate of over 25% was achieved by 117(71.78%), while 103(62.8%) consistently used the Paris classification. Proper polypectomy techniques were employed by 111(67.68%), but 100(60.98%) recommended follow-up intervals shorter than guidelines suggest.

Patient experience following gastroscopy and colonoscopy was not recorded by 126(76.83%) and 116(70.73%) participants, respectively. Overall, compliance with quality indicators for upper and lower digestive endoscopy was observed in 87(53.05%) and 75(45.73%) participants, respectively.

Multivariate analysis revealed that 5-15 years of experience (p=0.05), the use of video recording (p=0.01) and use of high-resolution endoscopes (p<0.01) were associated with improved compliance with quality indicators of upper endoscopy. Whereas age above 55 (p<0.01), use of high-resolution endoscopes(p<0.01), use of video recording (p=0.02) and attendance of educational seminars relevant with quality in endoscopy (p=0.05) were associated with improved compliance with quality indicators of colonoscopy.

Conclusion: In this study, discrepancies were observed in the compliance of Greek endoscopists with endoscopic quality indicators, highlighting the need for further improvement. The systematic recording of these quality indicators is essential, underlining the important role of scientific societies in this process.

PHYSICIANS' AWARENESS OF THE HARMFUL EFFECTS OF ALCOHOL USE

I. Pantic[1], N. Rajovic[2], S. Lugonja[3], M. Vojnovic[1], T. Milovanovic[4]
[1]Clinic of Gastroenterology and Hepatology, University Clinical Center of Serbia, Belgrade, Serbia, [2]University of Belgrade, Faculty of Medicine, Institute of Medical Statistics and Informatics, Belgrade, Serbia, [3]General Hospital Zrenjanin, Zrenjanin, Serbia, [4]University Clinical Center of Serbia, School of Medicine University of Belgrade, Clinic for Gastroenterology and Hepatology, Belgrade, Serbia

Contact E-Mail Address: tamara.alempijevic@med.bg.ac.rs

Introduction: According to the World Health Organization statements, there is no "safe" level of alcohol consumption that can be deemed free from potential health harm. While the detrimental role of alcohol in the pathogenesis of liver disease is well known, its contribution to extrahepatic disorders remains underrecognized.

Due to inadequate public health strategies and the global normalization of alcohol use, its harmful effects are often underestimated, not only by the general public but also among healthcare providers. Therefore, we aimed to assess physicians' knowledge, attitudes, and personal behaviors related to harmful alcohol use.

Aims & Methods: This prospective, cohort study utilized a structured questionnaire distributed among physicians specializing in gastroenterology. The questionnaire comprised three sections: demographic data, the AUDIT-C tool, and questions assessing knowledge of alcohol-related harm. Alcohol misuse was defined by an AUDIT-C score ≥4 for men and ≥3 for women. Distribution was achieved through direct communication, social media (Twitter), and the United European Gastroenterology "MyConnect" network, using an electronic survey format (Google Forms). All responses were anonymized, compiled into a central database, and analyzed using descriptive and inferential statistical methods.

Results: The study included 204 physicians, predominantly female (60.8%, mean age: 44.05±12.63 years). Participants were mainly from Serbia (35.8%), Russia (20.1%), Montenegro (18.1%), and Slovakia (11.8%). Most respondents were married or in a relationship (80.9%) and worked in academic centers (57.8%). Regarding specialization, 83.8% specialized in gastroenterology, 44.6% in hepatology, 31.9% in inflammatory bowel disease, and 29.9% in advanced endoscopy. A smaller proportion reported expertise in internal medicine (2.9%), oncology (2.0%), and transplant hepatology (3.9%). The median professional experience was 15 years. In terms of knowledge and attitudes, 99.6% of respondents agreed that alcohol negatively impacts all organ systems, and 82.4% believed women are at increased risk for alcohol-related harm. A majority (60.8%) stated there is no safe level of alcohol consumption, while 46.6% acknowledged alcohol as a carcinogen linked to 5–10 types of cancer.

Additionally, 44.6% believed that moderate alcohol consumption may have certain protective effects. Most agreed that alcohol-related health consequences typically arise in individuals with alcohol use disorder (60.8%) and that alcohol use worsens disease prognosis (97.5%).

The most commonly identified preventable risk factors were tobacco and alcohol use, and obesity (76.8%). Notably, 69.5% of respondents believed the five-year incidence of cardiovascular disease is twice as high in affected populations compared to the general population. AUDIT-C indicated that 28.9% of respondents met criteria for alcohol misuse.

Significant predictors of misuse included younger age (OR=0.972, p=0.031), specialization in transplant hepatology (OR=4.383, p=0.048), disagreement with the systemic effects of alcohol (OR=0.467, p=0.025), and belief in the potential protective effects of moderate consumption (OR=1.461, p=0.003).

Conclusion: Although physicians demonstrated a high level of awareness regarding the harmful effects of alcohol, a substantial proportion agreed on possible protective effects of alcohol use, while one third of participants engaged in risky drinking behavior. Improving awareness of alcohol's systemic impact may contribute to more effective prevention strategies within both clinical and public health settings.

EPIDEMIOLOGY AND RISK FACTORS FOR POST-INFECTIOUS IBS IN PATIENTS INFECTED WITH COVID-19

Y. Sohn[1], J. Huh[1], B. Kim[1], K.W. Kim[1], J. Yang[1], S.H. Kim[1], J.W. Kim[1], H.W. Kang[1]
[1]Seoul National University College of Medicine/Seoul National University Boramae Medical Center, Internal Medicine, Seoul, South Korea

Contact E-Mail Address: mdskw1094@nate.com

Introduction: Given the impact of COVID-19 on the gastrointestinal system and the characteristics of irritable bowel syndrome (IBS), the incidence and specific risk factors associated with COVID-19-related PI-IBS remain poorly understood.

Aims & Methods: The study included patients who were hospitalized with a confirmed diagnosis of COVID-19 between November 2021 and November 2023. Patients diagnosed with IBS based on the ROME IV criteria were compared with a control group without IBS.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Baseline demographic and clinical characteristics.

Among the 300 patients included in this study, the mean age was 61.2 years, with 158 females (52.7%) and 142 males (47.3%). 46 participants (15.3%) were current alcohol consumers.

In the univariable analysis, the blood test results at the time of admission, including WBC, ANC levels, and the history of probiotic intake, were found to be significant factors influencing the development of IBS. In the multivariable analysis, with a cutoff *p-value* of 0.05, WBC and Probiotics in the last 1 month were identified as significant factors. (adjusted OR: 2.152, 95% CI: 1.247–3.714, *p = 0.006*; adjusted OR: 4.750, 95% CI: 0.630–35.820, *p = 0.023*, respectively) (Table.)

Subgroup analysis of risk factors was performed by dividing participants into five subgroups based on questionnaire responses. (Q2; whether abdominal pain onset occurred before or after six months, Q3; presence or absence of a relationship between abdominal pain and bowel movements, Q4; changes in bowel movement frequency, Q5; normal versus abnormal average bowel movement frequency, Q6; stool form change) The third and fifth subgroup, only the WBC showed statistically significant results in the univariable analysis (adjusted OR:1.132, 95% CI: 1.001 –1.281, *p* = 0.049, adjusted OR: 1.115, 95% CI: 1.001–1.243, *p* = 0.049 respectively), though this significance did not carry over to the multivariable analysis.

Table. Risk factors contributing to the development of IBS following COVID-19 infection

Factors	Univariable analysis		Multivariable analysis	
	OR (95% CI)	P value	OR (95% CI)	P value
Sex	1.827(0.584-5.719)	0.301		
Age(years)	1.017 (0.980-1.056)	0.364		
BMI(㎏/kg)	0.169(0.966-1.218)	0.169		
Laboratory result				
WBC (/ul)	1.221(1.058-1.410)	0.006	2.152(1.247-3.712)	0.007
Hb (g/dL)	1.128(0.843-1.510)	0.419		
Platelet (x10³/ul)	1.001(0.993-1.008)	0.862	1.000(0.999-1.000)	0.052
ANC (/mm³)	1.000(1.000-1.000)	0.040		
Cholesterol (mg/dL)	1.005(0.994-1.017)	0.371		
Protein (g/dL)	0.932(0.403-2.154)	0.869		
Albumin (g/dL)	0.855(0.281-2.600)	0.782		
Total bilirubin (mg/dL)	1.360(0.229-8.078)	0.736		
GFR (/min/1.73)	1.001(0.986-1.015)	0.931		
CRP (mg/dL)	0.964(0.860-1.082)	0.538		
Hypertension	1.720(0.564-5.248)	0.341		
History of underlying disease, clinical course, and medication				
Diabetes mellitus	2.135(0.675-6.748)	0.197		
Antibiotics in the last 1 month	1.229(0.262-5.763)	0.794	4.750(0.630-35.820)	0.023
Probiotics in the last 1 month	5.616(1.082-29.138)	0.040		
Alcohol history	1.702(0.450-6.439)	0.433		
Vaccination	2.143(0.645-7.117)	0.213		
Previous covid-19 infection Hx	3.333(0.379-29.296)	0.278		
Hospital day	0.965(0.855-1.089)	0.564		

Table.

OR, odds ratio; CI, confidence interval; SD, standard deviation; BMI, body mass index; WBC, white blood cell; ANC, absolute neutrophil Count; GFR, Glomerular Filtration Rate; CRP, C-reactive protein

Conclusion: In conclusion, we found that probiotic intake and higher WBC count could be associated with the incidence of IBS following COVID-19 infection. While there is growing evidence of a link between COVID-19 and PI-IBS, further research is necessary to elucidate the underlying mechanisms and evaluate the preventive potential of probiotics.
