Introduction: Gastric cancer remains a prevalent malignancy, with molecular drivers critical for its progression and therapeutic targeting. Recently, some malignancies have been linked to the lncRNA ZFAS1, but its mechanism of action and the reasons for its dysregulation in gastric cancer are unknown.

Aims & Methods: We evaluated ZFAS1 expression in gastric cancer cells (SGC7901) by RT-qPCR and compared it with GES-1 cells. The LnCAR database provided insight into ZFAS1 levels in STAD compared to normal tissue. The effect of ZFAS1 knockdown on cell invasion, migration and proliferation was evaluated using transwell invasion, wound healing assays, CCK8 and flow cytometry. In addition, ZFAS1 promoter regions were examined using the JASPAR database and subsequent ChIP assays to understand SP1 transcription factor binding. The effect of ZFAS1 on the AKT/mTOR pathway was clarified using Western blotting.

Results: SGC7901 cells were shown to have increased ZFAS1 expression, which was linked to a poor prognosis for gastric cancer. Knockdown of ZFAS1 in SGC7901 cells inhibited cell invasion, migration and proliferation and induced apoptosis. In addition, SP1 was found to upregulate ZFAS1 transcription by binding to its promoter region. ZFAS1 knockdown resulted in a significant reduction of key proteins (p-AKT, AKT, p-mTOR, and mTOR) of the AKT/mTOR pathway. When the AKT activator SC79 was introduced, the repressive effects of ZFAS1 knockdown on cell invasion, migration, proliferation, and AKT/mTOR signaling were partially reversed.

Conclusion: Our results highlight the pivotal role of ZFAS1 in gastric cancer cell malignancy, which is modulated by the AKT/mTOR pathway. The regulatory involvement of SP1 in ZFAS1 transcription provides a novel understanding of the molecular mechanisms driving cancer progression and offers potential therapeutic avenues.

IMPACT OF CHOLECYSTECTOMY ON GASTRIC MUCOSAL C-MYC AND HTERT EXPRESSION: A POTENTIAL LINK TO GASTRIC CANCER DEVELOPMENT

E. Kasap[1], S. Sabah Özcan[2], L. Elmas[3], F.S. Özalp Ateş[4], M. Korkmaz[2]

Introduction: Gastric cancer is a multifactorial malignancy influenced by genetic and environmental factors. Cholecystectomy, the surgical removal of the gallbladder, may lead to bile reflux—backflow of duodenal contents into the stomach—potentially damaging gastric mucosa. hTERT and c-MYC play vital roles in cellular proliferation and cancer development. Although epidemiological data generally show no strong link between cholecystectomy and gastric cancer, existing studies are limited and may be influenced by other risk factors.

Aims & Methods: This study aimed to evaluate whether bile acid exposure post-cholecystectomy contributes to gastric cancer and to assess the expressions of hTERT and c-MYC in this context. We included 100 participants at Manisa Celal Bayar University Hospital between September 2021 and May 2023, divided into three groups: gastric cancer (n=32), cholecystectomy history (n=34), and control (n=34). Data on demographics, H. pylori, intestinal metaplasia, and gene expression levels were collected. Ethics approval and informed consent were obtained. Gene expression analysis was performed from endoscopic biopsy samples.

Results: Mean ages were 65.2 (cancer), 60.5 (cholecystectomy), and 59.9 (control), with no significant difference except for higher age in cancer patients. Females were predominant in the cholecystectomy group ($p=0.021$). Fourteen cancer patients had distant metastasis, but no significant differences in c-MYC or hTERT expression were observed based on metastasis status. No significant differences were found in H. pylori or intestinal metaplasia prevalence.

However, c-MYC and hTERT levels were significantly lower in the cholecystectomy group compared to controls and cancer patients ($p<0.001$). Gender also affected gene expression: females had lower c-MYC and hTERT levels than males ($p<0.05$), though this effect was consistent across all groups. The presence of H. pylori or intestinal metaplasia did not significantly alter c-MYC or hTERT expression in any group.

Conclusion: Although cholecystectomy was not directly associated with increased gastric cancer risk, in individuals with a genetic predisposition, it may act as a contributing factor. Lower expressions of c-MYC and hTERT post-cholecystectomy suggest potential for these markers in cancer risk evaluation. Further research is necessary to clarify their roles in post-cholecystectomy follow-up.

Introduction: Volatile organic compounds (VOC) in stool samples may reflect functional activity of gut microbiome. Previous studies showed that gut flora may influence transient relaxations of lower esophageal sphincter through short-chain fatty acids production and thus - participate in pathogenesis of gastroesophageal reflux disease (GERD). However, the role of VOC in pathogenesis of GERD is poorly studied yet.

Aims & Methods: The aim of this study (FGMF-2025-0003) was to perform correlation analysis between concentrations of VOC in stool samples and GERD-Q score.

We enrolled willing to participate patients referred to perform multichannel 24-h pH-impedance recording (Ohmega, Laborie). According to the Lyon 2.0 criteria patients were allocated to the GERD or the control group. GERD-Q questionnaire was filled in by the participants on the same day as stool samples were collected. Thermo TSQ 8000 triple quadrupole mass-spectrometer (GC/MS) was used for the measurement of VOCs in stool samples were analyzed with. Correlation analysis (Spearman rank R) was performed between values of 80 VOCs in stool samples and the results of GERD-Q questionnaire.

Results: Data of 76 patients were eligible: 42 with GERD and 34 - of the control group. Participants in the GERD group were older (54.7±12.2 y.o. vs 46±14.9 y.o., $P<0.05$) and their BMI was greater (30.9±5.2 vs 27.2±6.5 kg/m^2, $P<0.05$). GERD-Q score was logically greater in GERD group (11.0±2.5 vs 5.2±1.2, $p<0.01$). Correlation analysis revealed significant correlations between GERD-Q score and concentrations of 2-methylbutyric acid (Spearman R =-0.31), caproic acid (0.34) and enantiic acid (0.396) in stool samples.

Conclusion: GERD-Q score positively correlates with concentrations of Caproic acid (0.34) and Enantiic acid (0.396) in stool samples and negatively – with 2-Methylbutyric acid.

The data of this pilot study may serve as a basis for further research on the role of functional activity of gut microbiome in pathogenesis of GERD.

UNRAVELING GI SYMPTOMS IN HYPERMOBILITY EHLERS–DANLOS SYNDROME: A FUNCTIONAL AND STRUCTURAL DIAGNOSTIC PERSPECTIVE

R. Levin[1], Y. Gazit[2], D. Carter[3]
[1]Chaim Sheba Medical Center, Internal department 'B', Ramat Gan, Israel, [2]Chaim Sheba Medical Center, EDS clinic, Ramat Gan, Israel, [3]Sheba Medical Center Dept. of Gastroenterology, Gastroenterology, Ramat Gan, Israel

Introduction: Ehlers–Danlos syndrome (EDS) is a connective tissue disorder characterized by a non-inflammatory nature. Hypermobility EDS (hEDS) accounts for 80–90% of all EDS cases[1].

Over the past two decades, studies have reported a high prevalence of gastrointestinal (GI) symptoms among hEDS patients, including abdominal pain, bloating, constipation, diarrhea, nausea, vomiting, and reflux disease.

Aims & Methods: To characterize the GI symptoms in patients with hEDS and to explore the potential contribution of functional and anatomical abnormalities to the GI manifestations observed in this population.

We conducted a retrospective cohort study of patients diagnosed with hEDS who were evaluated at both the EDS and Gastroenterology clinics. Eligible patients had a clinical diagnosis of hEDS based on the Brighton criteria.

Patients with a documented diagnosis of inflammatory bowel disease (IBD) were excluded. Demographic data, GI symptoms, and results from diagnostic evaluations—including anorectal manometry, balloon expulsion test, defecography, gastric emptying scans, transit studies, and endoscopic procedures—were collected and analyzed.

Results: A total of 76 patients with hEDS were included with a median age of 33.7 years. Common comorbidities included endometriosis (43.5%), fibromyalgia (36.8%). Macrophage activation syndrome was diagnosed in 2.6%.

Upper GI symptoms were frequently reported, with heartburn (31.6%), postprandial pain (30.3%), early satiety (25%), epigastric pain unrelated to meals (22.4%), and dysphagia (13.2%) being the most prevalent.

Lower GI complaints were even more common: constipation affected 64.5% of patients, bloating 57.9% and chronic diarrhea 40.8%. Notably, 19.7% experienced both constipation and diarrhea.

Among 32 patients who underwent colonoscopy, 30 had normal findings. Anorectal manometry revealed hyposensitivity in 54% of constipated patients and hypersensitivity in 54% of diarrhea patients. Squeeze pressure was low in 38% of diarrhea patients. Balloon expulsion failure occurred in ~50% of patients across groups.

Defecography demonstrated a high prevalence of anatomical abnormalities: rectocele (67–78%), enterocele (47–78%), and rectal prolapse (53–78%). Gastroparesis was identified in 45–60% of patients undergoing gastric emptying scans due to lower GI complaints. Prolonged colonic transit was found in 25–50% of those evaluated.

Conclusion: Patients with hEDS commonly experience a broad range of upper and lower GI symptoms, often presenting with multiple overlapping complaints. Functional and structural abnormalities—such as rectal hyposensitivity, pelvic floor dysfunction, rectocele, and enterocele—were frequently identified and may underlie these symptoms. Notably, gastroparesis was prevalent, highlighting the widespread impact of EDS on GI motility.

These findings underscore the importance of comprehensive GI assessment in EDS patients, integrating both functional testing and imaging to guide appropriate management.

Introduction: Thyroidectomy is one of the most common surgical procedures worldwide, yet its potential effects on esophageal function remain inadequately characterized. While post-thyroidectomy issues such as voice changes have been well-documented, alterations in esophageal motility following this procedure have received limited attention in scientific literature.

Aims & Methods: This study aims to evaluate the impact of thyroidectomy on esophageal motility parameters using High-resolution manometry (HRM), with particular attention to upper esophageal sphincter (UES) function. Seventeen patients (11 females), who were to undergo total thyroidectomy or hemithyroidectomy, were prospectively recruited between the months of February and May 2023. Ten of them had goiters, while seven had thyroid nodules. Exclusion criteria were having an age under 30 or over 70 years old, having to also undergo a parathyroid surgery and taking medications that could alter the esophageal sphincter. All of them underwent a pre-operative HRM and a second one thirty days after surgery. HRM were performed according to the Chicago Classification 4.0 and the data were analyzed using the online analysis platform "Swallow Gateway". Gastrointestinal (GI) symptoms were assessed using a standardized questionnaire, before the first and the second HRM. No after procedural complication was reported.

Results: UES function significatively changed after thyroidectomy, as it is shown by HRM metrics such as Pharyngeal Contractile Integral (CI), Velopharyngeal CI, Hypopharyngeal CI, UES-CI, UES Integrated Relaxation Pressure (UES-IRP), Post-Deglutitive UES CI, Proximal Contractile Integral (PCI), which all significatively decreased ($p < 0.05$) at the HRM performed after surgery. Compared to Swallow Gateway normal values, there was an important increase of pathological HRM metrics after thyroidectomy. No significant HRM difference was found between the two categories of patients (goiter and thyroid nodules) and no significant correlation was registered between GI symptoms pre- and post-surgery and between GI symptoms and HRM metrics.

Conclusion: Thyroidectomy may significantly affect esophageal motility, especially the function of the upper esophageal sphincter. This finding could be useful in the diagnostic and therapeutic pathway of these patients, although further and larger studies are required to confirm this result.

Introduction: Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by multisystemic fibrosis. Gastrointestinal involvement, primarily affecting the esophagus, is common and represents the third most frequent clinical manifestation after Raynaud's phenomenon and cutaneous alterations. While several studies have investigated esophageal involvement using manometry, few have focused on asymptomatic SSc patients.

This study aimed to analyze esophageal motility disorders in these patients using high-resolution manometry and identify potential associations with other SSc characteristics.

Aims & Methods: This retrospective, descriptive, bicentric study included patients diagnosed with systemic sclerosis but without clinical signs of esophageal involvement (i.e., absence of gastroesophageal reflux, epigastric pain, or dysphagia). These patients underwent esophageal manometry in the gastroenterology department over a 20-year period (2004-2024). Clinical manifestations were assessed according to standardized protocols: skin involvement was evaluated using the modified Rodnan score, while pulmonary involvement was evaluated through clinical examination, imaging (high-resolution computed tomography), and pulmonary function tests.

Statistical analysis was conducted in two phases: a descriptive phase followed by an analytical phase, using SPSS software (version 26). The Chi-square test was employed, with a significance threshold set at $p < 0.05$.

Results: The study included 47 patients, predominantly female (46 women, 1 man), with a median age of 32 years (range: 27-74 years). All patients underwent esophageal manometry, which revealed normal motility in 7 cases.

However, the majority exhibited abnormalities, including lower esophageal sphincter (LES) hypotonia in 21 patients, ineffective esophageal motility in 10, and aperistalsis in 9 ($p = 0.03$).

These esophageal motility disorders appeared to be linked to the type of SSc. Specifically, 87.2% of patients had the localized form of the disease, whereas 12.8% had diffuse SSc, which was more frequently associated with LES hypotonia ($p < 0.05$).

Additionally, pulmonary involvement was observed in 53.2% of patients, suggesting a connection between esophageal motility disorders and respiratory impairment. More specifically, LES hypotonia was particularly associated with interstitial lung disease (21.9%) and restrictive syndrome on pulmonary function tests ($p < 0.05$).

Immunological profile analysis revealed a higher prevalence of manometric abnormalities in patients negative for anti-topoisomerase I (Scl-70) (57.6%), anti-centromere (64.7%), anti-RNA polymerase III (79.4%), and anti-PM-Scl (76.5%) antibodies. These associations were statistically significant ($p < 0.05$).

Conclusion: This study revealed a notably high prevalence of esophageal motility disorders, particularly lower esophageal sphincter hypotonia, among asymptomatic systemic sclerosis patients. The disorder was correlated strongly with diffuse cutaneous involvement, pulmonary complications, and the absence of specific autoantibodies (e.g., anti-centromere

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. CORRELATION BETWEEN CUTANEOUS, PULMONARY, AND UPPER DIGESTIVE INVOLVEMENT IN SYSTEMIC SCLEROSIS

S. Laabidi[1], F. Ghrab[1], T. Ben Achour[2], D. Gouiaa[1], S. Chtioui[1], L. Zouiten[1], B.M.E.B.Z. Nadia[1], M. Serghini Ep Ghachem[1], A. Labidi[1], M. Fekih[1]

Contact E-Mail Address: ghrab.faten2112@gmail.com

Introduction: Systemic sclerosis (SSc) is a rare autoimmune disease marked by multisystemic fibrotic and vascular involvement, mainly affecting the skin, lungs, and upper digestive tract. Skin involvement may serve as a marker for visceral severity, particularly regarding pulmonary and upper digestive manifestations. This study examined its correlation with these systemic complications in SSc patients.

Aims & Methods: A retrospective, descriptive, bicentric study was conducted on SSc patients followed in the internal medicine department between 2004 and 2024. Clinical evaluation included cutaneous involvement via modified Rodnan score, pulmonary assessment by clinical examination, imaging, and pulmonary function tests. Upper digestive involvement was explored through symptoms, esophagogastroduodenoscopy, and esophageal manometry performed in the gastroenterology department to assess motility and mucosal integrity. Statistical analysis (descriptive and analytical) was performed using SPSS (version 26) with the Chi-square test and a significance threshold of $p < 0.05$.

Results: A total of 160 patients were included, mostly female (91.2%), with a median age of 50 years (range:13–81). Localized scleroderma was diagnosed in 76.2%. Skin involvement was assessed in 121 patients using the Rodnan score (mean:15.31; range:0–51), categorized as mild (0–10) in 35%, moderate (11–20) in 15%, severe (21–30) in 16.3%, and very severe (>30) in 9.4%.

Upper digestive involvement was observed in 31.4%, 14.9%, 18.2%, and 9.1% of patients with mild to very severe skin involvement, respectively. Among associated symptoms: epigastric pain was present in 8.4%, 5%, 5%, and 3.4%; gastroesophageal reflux disease (GERD) in 21.2%, 9.3%, 16.9%, and 8.5%; and dysphagia in 15.3%, 7.6%, 13.6%, and 6.8%, respectively.

Esophageal manometry was performed in 36.2%, showing lower esophageal sphincter (LES) hypotonia in 5%, 2.5%, 5%, and 3.3% of mild to very severe cases, respectively. Aperistalsis was noted in 3.3%, 1.7%, 0.8%, and 0.8%, with rare ineffective motility and hypocontractility. No significant association was found between skin severity and upper digestive involvement, either clinically ($p=0.458$) or manometrically ($p=0.98$).

Similarly, no correlation was found between skin and pulmonary involvement. Lung disease was observed in 56.3% of localized and 19.4% of diffuse forms. Among these, interstitial lung disease was present in 26.3%, 12.7%, 16.1%, and 9.3%; pulmonary fibrosis in 15.6%, 6.4%, 8.3%, and 1.8%; and restrictive syndrome in 15%, 9.3%, 13.1%, and 5.6%, across increasing skin severity (all $p > 0.3$).

However, pulmonary involvement was noted in 60% of patients with upper digestive symptoms. Dyspnea was reported in 66.9%, crackles in 29.4%, cough in 27.5%, and chest pain in 6.3%. Radiology showed interstitial lung disease in 58.8% and pulmonary fibrosis in 28.8%. Among these, GERD was present in 46.5%, dysphagia in 36.1%, epigastric pain in 19.2%, and isolated abdominal pain in one case. Manometry revealed LES hypotonia in 13.1%, aperistalsis in 5%, and ineffective motility in 0.6%. In contrast to skin involvement, a significant association was found between pulmonary and upper digestive manifestations ($p<0.01$).

Conclusion: No correlation was found between the severity of cutaneous involvement and digestive disorders. However, a significant link was observed between pulmonary involvement and upper digestive symptoms, suggesting that uncontrolled acid reflux may contribute to pulmonary fibrosis in SSc patients. This highlights the need for early management and multidisciplinary monitoring.

Disclosure: Nothing to disclose.

PP0008

IMPACT OF UPPER ESOPHAGEAL SPHINCTER (UES) ABNORMALITIES ON CLINICAL MANIFESTATIONS OF PATIENTS AFFECTED BY ESOPHAGOGASTRIC JUNCTION OUTFLOW OBSTRUCTION (EGJOO): A HIGH-RESOLUTION ESOPHAGEAL MANOMETRY STUDY

A. Ioannou[1], S. Michailidou[2], X. Tsamakidis[2], A. Gkagkanteros[2], F. Torresan[3], D. Dimitroulopoulos[2]

Introduction: Upper esophageal sphincter (UES) is a muscular structure located at the transition from the pharynx to the esophagus, with the cricopharyngeal muscle as the most important component. One of its main functions is to prevent esophago-pharyngeal reflux; however, it also plays a key role during swallowing, belching, and vomiting. Data on UES involvement on pathogenesis and clinical manifestations of esophagogastric junction outflow obstruction (EGJOO) are lacking.

Aims & Methods: Aim of this study the UES manometric parameters analysis and study of their impact on pathogenesis and clinical presentation of patients affected by Esophagogastric Junction Outflow Obstruction (EGJOO) according to the Chicago Classification v4.0 criteria. Manometric tracings, epidemiological and clinical data of patients with a diagnosis of EGJOO in our departments between 07/2021- 03/2025 were analyzed. Clinical presentation was evaluated by performing Dysphagia Symptom Questionnaire (DSQ) and Eckardt score. Manometric parameters of UES function (mean basal pressure, mean residual pressure, resting time and recovery time) as well as the other manometric parameters were analyzed and correlated through multifactor statistical analysis (MFA) with clinical and epidemiological data.

Results: Data from 94 patients (73F/21M, mean age 66 years) were analyzed. 40.4% presented dysphagia, 46,8% GERD related symptoms and 12.8% Non-Cardiac Chest Pain (NCCP) as main clinical presentation at the time of HRM examination. Mean basal pressure of the lower esophageal sphincter (LES) was 50.85 mmHg (R19.5-78.8), mean integrated relaxation pressure (IRP) was 19.15 mmHg (R 15.2-40.4), mean Distal Contractile Integral (DCI) 5.031 (mmHg -cm-s) (R 3.487-7.345), mean Distal Latency 6.4 (R 4-10.2), mean UES basal pressure 53.3 mmHg (R27.8-220), mean UES residual pressure 8.75 mmHg (R 0.2 -70.9), mean UES resting time 181 ms (R48-476), mean recovery time 465 (R46-880). 34 patients (36.2%) had abnormal UES manometric parameters. Multifactorial statistical analysis revealed a statistically significant correlation of the pathological UES re-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sidual pressure with abnormal LES basal pressure (p = 0.040), dysphagia as main clinical symptom (p=0.030), LES length (p=0.013) and dysphagia symptom severity evaluated by DSQ: p=0.017 and Eckardt: p=0.041.

Conclusion: UES motility has not been extensively studied on HRM in patients affected by EGJOO. Our study revealed that a significant number of EGJOO patients presented abnormal UES function. UES motility abnormalities in these patients are correlated with abnormal LES function, symptoms severity and particularly characterize patients with predominant dysphagia.

Introduction: The causes of most esophageal motility disorders (EMDs) remain unknown. Recent reports have suggested a potential association between achalasia and varicella zoster virus (VZV) reactivation. Salivary detection of VZV DNA is recognized as a potential diagnostic marker for herpes zoster and enteric zoster. If a correlation between salivary VZV DNA and VZV antibodies and EMDs is demonstrated, it could provide new insights into the pathogenesis of EMDs.

Aims & Methods: This study aimed to investigate the relationship between various EMDs and VZV infection.

This was cross-sectional study. The participants in this study underwent high-resolution manometry (HRM) at our hospital between 2022 and 2024. Saliva and blood samples were collected from all patients.

The presence of VZV DNA in the saliva was determined using nested polymerase chain reaction (PCR) and electrophoresis.

VZV-immunoglobulin M and immunoglobulin G antibody titers were measured in the blood samples. Based on the HRM results, the patients were divided into an EMD group and a normal group. The results were compared between these groups.

Results: A total of 72 patients were included. Of these, 32 (44.4%) were in the normal group and 40 (55.6%) were in the EMD group, including 22 with esophagogastric junction (EGJ) outflow disorders (achalasia and EGJ outflow obstruction) and 18 with peristalsis disorders (absent contractility, distal esophageal spasm, hypercontractile esophagus, and ineffective esophageal motility). One patient with absent contractility had a concurrent herpes zoster infection, and VZV DNA was detected in this patient's saliva. However, all other patients tested negative for VZV DNA. No significant difference in VZV antibody titers was observed between the two groups.

Conclusion: This study found no significant differences in the rates of salivary VZV DNA or VZV antibody titers between EMD patients and controls. Given the complex, multifactorial nature of EMDs, further research is warranted to explore alternative mechanisms that may underlie this group of disorders.

Disclosure: Nothing to disclose.

DYSPHAGIA IN INEFFECTIVE ESOPHAGEAL MOTILITY IS NOT EXPLAINED BY EVIDENCE OF OBSTRUCTION OR POORER PERISTALSIS AT HIGH-RESOLUTION ESOPHAGEAL MANOMETRY: RESULTS FROM A PROSPECTIVE STUDY

G. Adamo[1], P. Visaggi[1], I. Solinas[1], F. Ovidi[1], M. Bellini[2], E.V. Savarino[3], N. de Bortoli[4]

Contact E-Mail Address: giuliadamo@live.it

Introduction: Ineffective esophageal motility (IEM) is a rare motility disorder characterized by weak or failed peristalsis at high-resolution manometry (HRM). There is an established association between IEM and gastroesophageal reflux-disease (GERD) symptoms. However, it is unclear why some patients present with dysphagia. In this study we aimed to investigated whether dysphagia in IEM is associated with specific HRM or pH-impedance monitoring (MII-pH) findings.

Aims & Methods: Adults (≥18 y) who underwent HRM for upper gastrointestinal symptoms who were diagnosed with IEM according to Chicago v4.0 between January 2021 and November 2024 were included. Patients' gender, age, symptoms (dysphagia, chest pain, heartburn, regurgitation, belching), response to proton pump inhibitor (PPI) treatment and HRM data were recorded.

All patients underwent MII-pH. Wilcoxon rank sum test, Pearson's chi-squared test and Fisher's exact test were used for comparisons. Significance was set at $p<0.05$.

Results: In the study period, 54 patients were diagnosed with IEM. Of them, 33 (61%) did not report dysphagia (IEM-GERD), while 21 (39%) had dysphagia (IEM-DYSPHAGIA). Of note, patients with or without dysphagia had a comparable prevalence of heartburn, chest pain, regurgitation, and erosive esophagitis.

In addition, IEM-GERD and IEM-DYSPHAGIA were comparable in age and response to PPI treatment. IEM-GERD and IEM-DYSPHAGIA did not show significant differences in EGJ type, EGJ contractile integral (EGJ-CI), integrated relaxation pressure (IRP), percentage of ineffective or failed swallows, or the rapid drinking challenge (RDC) findings ($p>0.05$ for all), demonstrating an overall similar pathophysiology of peristalsis and EGJ opening. In terms of MII-pH, there was no statistical difference in GERD-related parameters between IEM-GERD and IEM-DYSPHAGIA, who showed comparable values of acid exposure time (AET), mean nocturnal baseline impedance (MNBI), symptoms association indexes (SI), and post-reflux swallow-induced peristatlic wave index (PSPW-I) ($p>0.05$ for all).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: We showed that dysphagia in IEM is not explained by impaired EGJ outflow or worse peristalsis. IEM with and without dysphagia have a similar proportion of GERD symptoms, comparable MII-pH findings, and respond similarly to PPI treatment. Our findings suggest that dysphagia in IEM could be a symptomatic manifestation of GERD.
Disclosure: Nothing to disclose.

THE PREVALENCE OF POST-INFECTION AND POST-SEPSIS DYSPHAGIA IN HOSPITALISED PATIENTS, AN OVERLOOKED PATHOLOGICAL ENTITY

A. Sasegbon[1], K. Bastawisy[2], I. Cheng[3], S. Hamdy[1]

Introduction: Studies have generally highlighted three groups of patients at particular risk of dysphagia: the elderly, those with neurological pathology and the critically ill. Over the last decade, there has been increasing interest in the role of critical illness related dysphagia, however, less is known about the impact of infection and sepsis on unwell patients in hospital. In this study, we aimed to assess the prevalence and factors predicting dysphagia in patients with no prior history of dysphagia, admitted to hospital with infections or sepsis.
Aims & Methods: Participants ≥ 18 years of age admitted to hospital with infections or sepsis caused by pneumonia, urine tract infections or cholecystitis were recruited from an NHS Trust. Researchers, electronic patient record administrators and clinical coding staff screened patient data over 12 months from 01/02/2022 to 01/02/2023. All patients with potentially confounding conditions or pathology, such as previous or ongoing dysphagia, acute head injuries or stroke, were excluded. Those that remained had data extracted from their notes, including age, gender, length of stay (LOS), intensive care unit (ICU) admission status, co-morbidities, type of infection/sepsis, obesity, frailty and mortality. Patient data was then subjected to statistical analysis, including Chi-squared, T-Tests, Logistic regression and Cox regression.
Results: Over the study period, 4475 patients (M: 2031, F: 2444) were admitted with infections (Pneumonia 2465, UTI 1888 and Cholecystitis 401). Of these, 189 (4.2%) developed dysphagia (Pneumonia 6.0%, UTI 3.5%, Cholecystitis 0.8%).
Additionally, 865 patients (M: 434, F: 431) were admitted with sepsis (Pneumonia 535, UTI 413 and Cholecystitis 55). Of these, 54 (6.2%) had dysphagia (Pneumonia 9.3%, UTI 3.4%, Cholecystitis 3.6%).
Logistic regression revealed that increasing age, the presence of sepsis, delirium, dementia and Parkinson's disease (PD) were significantly associated with an increased risk of dysphagia (OR 1.02, 1.74, 1.60, 2.43, 3.88; P 0.002, 0.013, 0.008, <0.001, <0.001). Obesity and female gender were associated with a reduced risk of dysphagia (OR 0.53, 0.65; P 0.006, 0.001). Other comorbidities such as diabetes, chronic obstructive pulmonary disease (COPD), cirrhosis and heart failure were not significantly associated with dysphagia.
Additionally, Cox regression revealed that increasing age, sepsis, dysphagia, delirium and frailty all significantly increased LOS (HR 0.99, 0.63, 0.59, 0.67, 0.79; P <0.001, <0.001, <0.001, <0.001, <0.001).
Conclusion: Our study has identified that infection and sepsis-associated dysphagia is a major syndrome, with age being a significant determinant. Additionally, patients with PD, delirium or dementia without previous or existing dysphagia are at high risk of developing dysphagia should they be admitted with infections or sepsis. Our novel findings should increase clinical awareness of infection and sepsis-associated dysphagia in hospitalised patients and prompt greater study of this phenomenon.

A RETROSPECTIVE SERVICE EVALUATION TO INVESTIGATE THE DISCORDANCE BETWEEN IDENTIFIED OESOPHAGEAL MOTILITY DISORDERS FOR LIQUID AND SOLID SWALLOWS UTILISING THE CHICAGO CLASSIFICATION 4.0

G. Fairlamb[1,2], J. Devenney[1,2], C. Sykes[1,2], A. Davidson[1,2], N. Page[1,2], J. Blake[1,2], H. Parker[1,2]

Contact E-Mail Address: grace.fairlamb@nhs.net
Introduction: The Chicago Classification version 4.0©(CC4) provided an updated classification of oesophageal motility disorders based on high-resolution oesophageal manometry (HRM) findings[1-2]. A key modification included using solid swallows which have been shown to increase the diagnostic yield of oesophageal motility disorders[3]. CC4 fails to offer guidance on the weighting of relevant findings when wet and solid swallows are discordant[3]. Clinical judgement, such as incorporating patient reported symptoms, is therefore required when interpreting HRM findings[2-3].
Aims & Methods: This retrospective service evaluation aimed to determine the frequency of CC4 diagnostic discordance between wet and solid swallows and how this was managed clinically. Data was collected from consecutive patients at a single National Health Service Trust (UK) site over a 6-month period. HRM was performed using a 36-channel HRM solid state catheter with impedance (Medtronic ManoScan™ ESO HRM) following the upright study CC4 protocol[2]. All patients had 5 mL saline swallows and those with dysphagia or abnormal primary swallows underwent solid swallows (rice test meal)[3].
Results: 69 patients underwent HRM during the 6-month period. 51 studies included solid swallows, 61% (n=31) showed agreement between wet and solid CC4 findings and 39% (n=20) showed disagreement. Of those with discordance, it was concluded that 9 were inconclusive due to mixed appearances. In 7 studies the solid swallows were deemed more clinically relevant and in 4 studies the liquids swallows best reflected the clinical context.
10 patients had abnormalities detected on wet swallows but normal solids, 50% of which showed ineffective oesophageal motility (IOM) and 50% showed oesophago-gastric junction outflow obstruction (OGJOO). Of the patients with OGJOO on wet swallows and normal solids, 3 were concluded to be normal due to a lack of symptoms, good bolus clearance on HRM and normal endoscopy and barium swallow results. One was deemed inconclusive as the patient was symptomatic to bolus hold-up measured on HRM. One was concluded as OGJOO due to abnormal rapid drink challenge, upright swallows and supine swallows.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Of the 5 studies showing IOM on liquid swallows but normal solids, 2 were overall concluded to be normal due to a lack of symptoms. 2 were concluded as IOM, although only one was symptomatic to ineffective swallows. Both reports did, however, mention evidence of peristaltic reserve. One study was concluded inconclusive as possible IOM.

3 patients who had normal liquid swallows had abnormalities on solids. One showed IOM on solids which was concluded as insignificant due to a lack of symptoms. One had hypercontractile oesophagus which was concluded as significant due to the presence of symptoms[3].

The other showed symptomatic OGJOO with solids. This was classed as inconclusive as the patient had normal bolus clearance on barium swallow.

Conclusion: More patients had abnormalities on liquid swallows which normalised on solids, despite studies indicating increased motility disorder diagnosis with solid swallows[4].

Test analysers placed greater significance on solid swallow findings compared to liquids. However, many tests were reported as inconclusive. Tests with abnormal liquid swallows but normal solids frequently had differing conclusions, in part due to adjunctive test findings and reported symptoms. This emphasizes the importance of symptoms and overall clinical judgement when reporting. Future CC iterations should consider discordant findings and offer guidance on what is clinically relevant during HRM studies.

Introduction: Tradipitant is a novel NK1R antagonist studied in diabetic and idiopathic gastroparesis. This report presents a nausea responder analysis from the open-label arm of a multicenter, randomized, double-blind, placebo-controlled study (VP-VLY-686-3301) assessing the efficacy of tradipitant in relieving symptoms of gastroparesis.

Aims & Methods: N=531 idiopathic and diabetic gastroparesis patients with delayed gastric emptying received open label 85mg tradipitant BID for 12 Weeks. Symptoms were assessed using the 5-point Gastroparesis Core Symptom Daily Diary (GCSDD). A nausea responder (N=267) was defined as having ≤1 average nausea severity at week 12 using the GCSDD. Gastroparesis symptoms were assessed every 2 weeks in clinic using the Gastroparesis Cardinal Symptom Index (GCSI).

Results: Nausea responders improved average nausea score significantly from baseline after 12 weeks tradipitant (improvement of -1.40 vs 1.67 at baseline, p<0.0001). A significant improvement was also seen in the percent of nausea free days (an addition of 49.32% of days for tradipitant vs 28.57% at baseline, p<0.0001). Significant improvement was also seen in other cardinal gastroparesis symptoms including average times vomited in the past 24 hours (improvement of -0.32 vs 0.40 at baseline, p<0.0001), stomach fullness (improvement of -1.48 vs 2.86 at baseline, p<0.0001), not being able to finish a normal-sized meal (improvement of -1.45 vs 2.47 at baseline, p<0.0001), bloating (improvement of -1.36 vs 2.70 at baseline, p<0.0001), and upper abdominal pain (improvement of -1.25 vs 1.99 at baseline, p<0.0001).

Conclusion: Tradipitant demonstrated statistically significant improvement from baseline in average nausea severity in this 12 week open label study in both idiopathic and diabetic gastroparesis subjects. Notably, nausea responders on tradipitant also significantly improved in all cardinal gastroparesis symptoms including those unrelated directly to nausea such as abdominal pain. These results suggest tradipitant has the potential for comprehensive gastroparesis symptom relief in tradipitant responders.

Introduction: Idiopathic gastroparesis (IG) remains a challenging condition, with few effective therapeutic options available. Despite recent European and international consensuses, some management modalities are still different in the French practice (1).

Aims & Methods: We aimed to develop French recommendations on the diagnosis and management of IG in adults and paediatric patients, highlighting the similarities and differences with recent consensuses. A Delphi

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

process was conducted among a panel of 16 French neurogastroenterology experts, including gastroenterologists and paediatricians. A first list of statements was drafted with a literature summary. After revisions and clarifications, 3 voting rounds were conducted and consensus statements were identified (defined as ≥ 80% agreement).

Results: Consensus was reached for 39 out of 46 statements. Definition and diagnostic modalities were similar to recent guidelines. IG was defined as symptoms associated with delayed gastric emptying (GE), in the absence of a mechanical obstruction. The panel agreed that nausea and vomiting are cardinal symptoms, with postprandial distress symptoms frequently overlapping. Variable presentations according to age were highlighted in paediatric patients.

Delayed GE can be confirmed by either scintigraphy or a GE breath test, using a solid meal, and a 4-hour measurement. Food retention at endoscopy was not considered a diagnostic criterion. Pyloric EndoFlip was not considered a diagnostic or pretherapeutic tool. A blood test and screening for *Helicobacter pylori* were supported before diagnosing IG.

Regarding the management, like in recent guidelines, the panel supported a first-line therapy using dietary advice and dopamine antagonists (metoclopramide or domperidone). The panel supported the efficacy of intravenous erythromycin, but not oral erythromycin. Agreement on the efficacy of other drugs, including prucalopride, antiemetics, or neuromodulators, was not reached. The use of nutritional support was recommended if deemed necessary for refractory vomiting and malnutrition, with enteral post-pyloric nutrition recommended as the first option.

The consensus supported different strategies for the management of refractory gastroparesis. Stopping opioids, or drugs inducing delayed GE, and the treatment of associated constipation were recommended before considering more invasive procedures. The efficacy of pyloric toxin injection was not agreed upon. Gastric endoscopic pyloromyotomy and gastric electrical stimulation were considered effective therapies for refractory IG. Finally, surgical procedures were not supported.

Conclusion: This consensus shows that the diagnostic modalities for IG are similar in France as compared to international guidelines, but highlights differences in the management of refractory gastroparesis, supporting endoscopic pyloromyotomy or the implantation of gastric electrical stimulation.

Introduction: Gastrointestinal (GI) transit abnormalities due to dysmotility often affect multiple regions of the GI tract rather than occur in isolation. Identifying regional GI transit delays may influence clinical management. Use of wireless motility capsules (WMC) enable regional and whole GI transit times to be objectively measured; the relationship between symptom profiles and regional transit times are explored here with a new capsule device, the Atmo Capsule.

Aims & Methods: The Atmo Capsule was administered to subjects with suspected upper and/or lower gastrointestinal dysmotility. This analysis utilized data from subjects where valid transit measurements via the Atmo Capsule were available for all regions of the GI tract, and no protocol deviations pertaining to the use of contraindicated medication or inclusion criteria violations were incurred. Regional transit times were considered delayed as follows: gastric emptying ≥ 5 h; small bowel transit, ≥ 6 h; colonic transit, ≥ 59 h.

Delays affecting a single region (i.e., gastric, small bowel, or colon) were considered 'isolated', delays affecting multiple (> 1) regions were considered 'generalized'. Symptom profiles were assessed using the Patient Assessment of Gastrointestinal Disorders - Symptoms (PAGI-SYM) and Patient Assessment of Constipation – Symptoms (PAC-SYM) questionnaires: all patients completed the PAGI-SYM while those with symptoms suggestive of lower GI dysmotility completed the PAC-SYM. Data were analyzed via Kruskal-Wallis test.

Results: The WMC was administered to 209 subjects (median age 41; 188 female), of whom 170 had data suitable for this analysis. Delayed GI transit was identified in 100 (59%) subjects: 65 were isolated and 35 were generalized. There were no differences in overall symptom scores in subjects with no delays (PAGI-SYM, median 1.5 [IQR: 1.1, 2.1]; PAC-SYM, 2.0 [1.5, 2.6]), isolated delays (1.5 [1.0, 2.1]; 1.9 [1.2, 2.6]) and generalized transit delays (1.8 [1.4, 2.3]; 2.1 [1.4, 2.8]) ($p>0.05$ for both) or symptom sub-scores (Table 1).

Gastric transit was delayed in 46 subjects: 19 (41%) were isolated and 27 (59%) were generalized. Colonic transit was delayed in 60 subjects: 31 (52%) were isolated and 29 (48%) were generalized. GI symptom profiles were not different in subjects with isolated and generalized transit delays for either the stomach or colon ($p>0.05$ for all relevant subscales).

Questionnaire	Subscale	None	Isolated	Generalized	P value
Patient Assessment of Gastrointestinal Disorders – Symptoms	Heartburn/regurgitation	1.6 (1.1, 1.9)	1.6 (0.9, 2.0)	1.9 (1.4, 2.3)	0.11
	Nausea/vomiting	0.7 (0.0, 1.3)	0.7 (0.0, 1.3)	1.0 (0.3, 1.7)	0.39
	Postprandial fullness	2.0 (1.0, 2.5)	2.0 (1.5, 3.0)	2.5 (1.5, 3.0)	0.47
	Upper abdominal pain	1.5 (1.0, 2.1)	1.5 (1.0, 2.0)	2.0 (1.3, 2.5)	0.18
	Bloating	2.0 (1.5, 2.6)	2.0 (1.0, 2.5)	2.0 (1.5, 2.5)	0.86
	Lower abdominal pain	1.5 (1.0, 2.5)	1.5 (1.0, 2.5)	2.0 (1.5, 2.5)	0.50
Patient Assessment of Constipation – Symptoms	Abdominal	2.3 (1.5, 2.8)	2.0 (1.3, 2.8)	2.3 (1.8, 2.9)	0.59
	Rectal	1.5 (1.0, 2.3)	1.5 (0.8, 2.3)	1.5 (0.8, 2.4)	0.67
	Stool	2.3 (1.8, 3.0)	2.0 (1.0, 2.8)	2.8 (1.3, 3.4)	0.15

Table 1. Symptom profiles amongst patients with no transit delay, isolated transit delay (affecting a single region) and generalized transit delay (affecting multiple regions). Data presented as median (interquartile range) and analyzed via Kruskal-Wallis test.

Conclusion: WMC measurements of regional and whole GI transit using the Atmo Capsule revealed that delayed transit impacting multiple regions were common. However, symptom profiles were unable to distinguish between isolated vs. generalized transit delays, suggesting that symptoms are an unreliable predictor of abnormalities in GI transit as previously found via other transit modalities.

HYPERCONTRACTILE ESOPHAGUS: ENHANCED DIAGNOSTIC YIELD FROM PROVOCATIVE TESTS WITH HIGH RESOLUTION MANOMETRY. CLINICAL PRESENTATION AND LONG TERM OUTCOMES FROM AN ASIAN COHORT

Y.L. Ong[1], A. Tan[1], F.M. Manejero[1], C.K. Tan[1], T.L. Ang[1], S.W.D. Ang[1]
[1]Changi General Hospital Dept. of Gastroenterology, Dr., Singapore, Singapore

Contact E-Mail Address: yanling.ong@mohh.com.sg

Introduction: Hypercontractile esophagus (HE) is rare. Esophageal high-resolution manometry (HRM) with solid test meal (STM) in Chicago Classification (CCv4.0) may improve diagnostic yield but outcome data are lacking.

Aims & Methods: Aim: Evaluate the clinical features and long-term outcome of HE, and determine the clinical significance of hypercontractility detected only using STM.

Methods: Single-center analysis of all patients with >/=2 hypercontractile swallows (HS) (distal contractile integral [DCI]>8000mmHg.s.cm) on HRM studies with single water swallows(SWS) and/or STM between June 2014-December 2021. A telephone survey was conducted between January-June 2023 using Impaction Dysphagia Questionnaire [IDQ], Eckardt scores and the Gastro-Esophageal Reflux Disease Questionnaire (GERD-Q) to determine long-term outcomes.

Results: 48 patients (29[60.4%]Female, 63.0[13.4] years) with HE who presented with dysphagia (60%), reflux (37.5%) and chest pain (29.2%) and 58 controls (28[48.3%]Female,49[13.4] years) with dysphagia(n=43.1%), reflux (n=41.4%) and chest pain(15.5%) with normal HRM findings with both SWS and STM were identified from 454 studies performed. More patients had HS with STM vs SWS (n=41[85.4%] vs. n=7[14.6%], p<0.001). Dysphagia was significantly associated with mean DCI(B=0.000,p=0.035) and maximal DCI (B=0.000, p=0.036) during STM. 43% (n=3/7) and 22% (n=9/41) of patients with >/=2 HS using SWS and STM respectively were on medical therapy at mean(SD) clinic follow-up of 28.7(29.2) months. At mean(SD) follow-up telephone survey of 61.3(27.1) months from HRM, symptom scores (mean,SD) amongst 36/48 (75%) patients and 58 controls showed significantly higher dysphagia scores: IDQ (3.8[7.2] vs 1.0[1.9],p=0.03).

Whilst overall Eckardt scores were not significantly different between patients and controls (1.2 [1.9] vs 1.2[1.4, p=0.4), patients recorded significantly higher Eckardt dysphagia score compared to controls (0.46[0.7] vs 0.14[0.3], p=0.007) respectively. Conversely, patients had lower Eckardt chest pain scores compared to controls (0.14[0.36] vs 0.45[0.68], p=0.02) and similar GERDq scores (6.4[1.9] vs 7.0[1.9], pNS) respectively.

Conclusion: STM enhanced diagnostic yield of hypercontractile esophagus and identified more patients who benefitted from medical therapy. Dysphagia was significantly associated with HRM parameters during the STM, with higher symptoms scores for dysphagia compared to controls at long term follow up. However, most patients did not require aggressive intervention.

Disclosure: Nothing to disclose.

THE RISE OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS (GLP-1RA) – A CAUSE FOR CONCERN? A RETROSPECTIVE STUDY ON THE GASTROINTESTINAL EFFECTS OF GLP-1RA IN ASIAN PATIENTS

Z.G. Ng[1], A. Sim[1], H.Y. Ling[1], J. Kuang[1]
[1]Tan Tock Seng Hospital, Gastroenterology & Hepatology, Singapore, Singapore

Contact E-Mail Address: zhiguang_ng@ttsh.com.sg

Introduction: Obesity and type 2 diabetes mellitus (T2DM) represent growing global health challenges, affecting millions of individuals worldwide. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have emerged as a cornerstone in the management of both conditions due to their metabolic benefits, including weight loss and glycemic control. European cohort studies have reported a high prevalence of gastrointestinal symptoms – including nausea, vomiting and early satiety among patients using GLP-1RAs. In parallel, increased rates of residual gastric content (RGC) during upper endoscopy have raised safety concerns, prompting reevaluation of pre-procedural fasting guidelines. However, data on the effects of GLP1-RA on the gastrointestinal (GI) tract in Asian patients is limited.

Aims & Methods: Our primary aim was to characterize a cohort of patients who received treatment with GLP1-RA in terms of their gastrointestinal side effects and presence of RGC during upper endoscopy. The secondary objective was to compare the afore-mentioned variables be-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. tween 2 groups: oral versus subcutaneous mode of administration. We conducted a retrospective cross-sectional cohort study of 139 Asian adult patients with T2DM and/or obesity who were prescribed GLP-1RAs at a tertiary hospital between 01 January 2022 to 01 January 2023. Data collected included demographics, anthropometric measurements, co-morbidities, GI symptoms and upper endoscopy findings. Upper endoscopy images were analysed and adequacy of mucosal visibility was graded using the POLPREP scale. Patients were further stratified into two subgroups based on route of GLP-1RA administration: oral versus subcutaneous. Statistical analysis compared symptom prevalence and POLPREP scores across subgroups using chi square test, with p <0.05 considered statistically significant.

Results: A total of 139 patients were analysed. 19.4% of patients had GLP-1RA prescribed for T2DM, 21.6% for Obesity, and 58.8% for both. The most commonly prescribed GLP-1RA was Liraglutide (33.8%) followed by oral Semaglutide (28.1%). Majority of patients (66.9%) did not have any GI side effects. The most commonly reported GI symptoms were abdominal bloating (15.8%), nausea (7.9%) and early satiety (4.3%). 13.7% of patients underwent upper endoscopy with 89.5% having a POLPREP score of 3 with no significant complications reported. None of the patients withheld GLP-1RA prior to endoscopy. Upon stratifying patients based on route of administration, analysis revealed that patients on oral GLP-1RAs were more likely to report nausea compared to those on subcutaneous formulations (15.8% vs 5.0%, p=0.03). There were no significant differences in the other GI symptoms or POLPREP scores.

Conclusion: Based on our Asian cohort, these findings suggest that GLP-1RAs have an acceptable GI symptom profile with a potential route-dependent difference in symptomatology. In addition, discontinuing these drugs prior to upper endoscopy may be unnecessary.

Contact E-Mail Address: ariadna.agca@gmail.com

Introduction: High-resolution manometry (HRM) is an invasive and technically demanding procedure. Despite the existence of a well-established standard protocol, technically imperfect studies are common and may reduce diagnostic certainty.

Aims & Methods: The aim of this study was to develop a practical and feasible quality score for HRM that correlates the technical quality of the study with the reliability of the diagnosis.

A 10-point quality score was developed based on seven quality indicators: catheter passage across the esophagogastric junction (EGJ), evaluable resting pressures, valid wet swallows, completion of multiple rapid swallows (MRS) and rapid drink challenge (RDC), upright swallows, and absence of artifacts.

The obtained score was used to classify manometric studies into five diagnostic reliability categories: 1) 0–2 points: Uninterpretable manometry, 2) 3–4 points: Deficient manometry with low diagnostic reliability, 3) 5–6 points: Deficient manometry with moderate diagnostic reliability, 4) 7–8 points: Deficient manometry with high diagnostic reliability, 5) 9–10 points: Excellent manometry allowing a certain diagnosis

An initial exploratory evaluation was conducted by two observers (one high-experience, one low-experience observer) who prospectively reviewed 90 HRM studies. A revised version of the score was subsequently implemented and applied in a second evaluation round. In addition to assigning a final quality score, each observer provided the manometric diagnosis of each revised HRM according to Chicago IV classification (CC4.0) and rated the diagnostic confidence level (high, medium, low reliability). In case of disagreement, a third expert adjudicated.

Results: Initial agreement on quality score classification was reached in 30 cases (Cohen's kappa=0.274) using the original score, improving to 67 out of 90 studies when the revised version was used (Cohen's kappa=0.718). The main sources of disagreement in the remaining 23 studies were the number of valid swallows (12 studies) and the presence of intragastric pressurization (8 studies).

Further evaluation by the expert supported the high-experience observer in 13 cases and the low-experience observer in 5; no consensus was reached in five studies. Overall, 85% of the studies were scored as high-quality studies (score≥7). Diagnostic confidence was rated as high in 86 % of the cases, medium in 14 %, and no cases were rated as low confidence.

There was a good association between quality score and diagnostic confidence among the observers. Hence, 90 % of the studies rated as high-quality studies had a high confidence rate in the diagnostic accuracy, and 62 % of the low-quality studies had a medium level of confidence (p<0.001).

Despite some uncertainty, the two observers agreed on diagnosis in 82 studies (disagreement occurred in two low-quality studies and six high-quality studies).

Following expert adjudication, full consensus in diagnosis was reached in all 90 studies. Notably, most of the diagnoses were normal motility or ineffective esophageal motility (86 %), while only 10 % were classified as major motility disorders. Four patients had inconclusive diagnoses according to CC4.0 (two low-quality and two high-quality studies).

Conclusion: A new developed quality score appears to be a valuable tool

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ENDOLUMINAL FUNCTIONAL LUMEN IMAGING PROBE IN THE FUNCTIONAL ASSESSMENT OF PYLORIC SPHINCTER IN GASTROPARESIS: A SYSTEMATIC REVIEW WITH META-ANALYSIS OF NORMATIVE VALUES

A. Barchi[1], M. Gupta[2], N. Warringa[3], F.V. Mandarino[1], E. Vespa[1], S. Passaretti[1], S. Danese[1], A.J. Bredenoord[3], G.M. Masclee[3]

Contact E-Mail Address: barchi.alberto@hsr.it

Introduction: Gastroparesis (GP) is a chronic motility disorder characterized by recurrent upper gastrointestinal (GI) symptoms, namely early satiety, nausea and vomiting, in the absence of a mechanical obstruction. Functional Lumen Imaging Probe (FLIP) is a potential game-changer in anatomical sphincter assessment. Recently, wide prospective trials[1] and a randomized sham-controlled study[2] implemented FLIP to predict response of pyloric-targeted treatments. This has prompted the need for a comprehensive analysis of available FLIP data in GP.

Aims & Methods: The aim of this systematic review was to investigate FLIP role in GP. Meta analysis of normative values and treatment comparative outcomes was also performed. A systematic search was performed until May 2024 on 4 major databases (Pubmed-MEDLINE, Embase, Web of Science, Cochrane). Studies on post-oncological/bariatric surgery gastroparesis were excluded. Pooled baseline mean of FLIP metrics and mean differences (MDs) pre vs post-treatment were calculated. In addition to estimate clinically meaningful normative values for GP, upper-limit reference ranges were estimated by pooled standard deviations (SDs) implementing the formula *pooled mean ± 1.96 × pooled SD*. Random effects meta-analysis with Knapp-Hartung correction for 95% confidence intervals (CIs) adjustment and I^2 statistics with subgroup analysis to address heterogeneity were performed.

Results: Twenty studies (N= 805 patients) were included. The majority focused on treatment response, particularly pyloromyotomy. The most assessed FLIP metrics were distensibility index (DI) and cross-sectional area (CSA). Three studies (on 7 total) reported a positive correlation between DI and CSA with specific symptoms (dyspepsia spectrum and nausea/vomiting) and their severity at baseline. Ten studies (on 15 total) studies showed an association between FLIP parameters with clinical response. Pooled mean DI ranged from 7.5 to 8.9 mm^2/mmHg and CSA from 85.5 to 195.6 mm^2 at baseline. Minimum diameter (Dmin) ranged between 10.6 and 16.5 mm while Pressure (P) between 14.8 and 34.5 mmHg (table 1.). Upper-limit normative values for GP ranged from 173-317 mm^2 for CSA, 17-27 mm for Dmin, 32-64 mmHg for P (between 30-50 mL of fill volumes), while for DI at 50mL the reference limit attested at 21.5 mm^2/mmHg. Comparing pre-and post-treatment response, MD of 2.5 mm^2/mmHg (I^2 24%) for DI at 50 mL, 46.7 mm^2 (I^2 47%) and 68.8 mm^2 (I^2 0%) for CSA at 40 and 50 mL respectively, were statistically significant.

Table 1. FLIP metrics pooled mean values at different fill volumes at baseline in gastroparesis patients

Pooled mean values#	30 mL	I^2(%)	40 mL	I^2(%)	50 mL	I^2(%)
DI (mm^2/mmHg)	7.5 (6.1-8.9)	38	8.9 (7.5-10.4)	83.4	7.1 (6.1-8.1)	88.1
CSA (mm^2)	85.5 (75.4-95.6)	0	125.3 (108.3-142.3)	78	195.7 (175.5-215.9)	70
Dmin (mm)	10.7 (9.1-12.3)	85	13.4 (12.1-14.7)	92	16.5 (15.7-17.3)	80
P (mmHg)	15.0 (11.3-18.7)	77	18.8 (16.5-21.1)	74	34.0 (29.2-38.8)	91

#Values are expressed as pooled means and 95% CIs
CIs Confidence Intervals CSA Cross-Sectional Area DI Distensibility Index Dmin Minimum Diameter FLIP Functional Lumen Imaging Probe P Pressure

Conclusion: This is the first systematic effort in gathering evidence on FLIP in gastroparesis. CSA and DI significantly changed after pylorus-targeted treatments. Normative values displayed substantial heterogeneity and wide CIs. The cut-off of 10 mm^2/mmHg for DI seems feasible to categorize patients to be addressed to pylorus-targeted treatments. Further studies to calculate prediction ability of this cut-off are warranted.

CLINICAL EFFECTIVENESS AND SAFETY OF SHORT LENGTH PERORAL ENDOSCOPIC MYOTOMY (POEM) COMPARED TO LONG LENGTH MYOTOMY FOR THE TREATMENT OF ACHALASIA IN A UNIVERSITY HOSPITAL IN COLOMBIA

V. Dávila Ruales[1], H. Vergara[2], A. Castañeda[1], R. Vargas-Rubio[3], O.M. Muñoz-Velandia[1], J. Rodriguez[4]
[1]Pontificia Universidad Javeriana/Hospital Universitario San Ignacio, Bogota, Colombia, [2]Universidad Javeriana - Hospital san ignacio, Gastroenterologia, Bogota, Colombia, [3]Javeriana University-Hospital San Ignacio, Gastroenterology, Bogota, Colombia, [4]Abbott, Bogota, Colombia

Contact E-Mail Address: hvergara21@hotmail.com

Introduction: Endoscopic peroral myotomy is a less invasive treatment for achalasia with efficacy rates equal to or superior to traditional methods. As it has evolved and developed, the traditional long-length myotomy and the current short-length myotomy have been described. Studies have shown no difference in efficacy or safety between the two, with a difference in procedure time. Therefore, the aim of our study is to evaluate the efficacy and whether there are differences in periprocedural complications, assessed according to the iPOEM classification of adverse events, taking into account that a longer procedure time may be associated with more complications.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: Patients were retrospectively collected from the records of the databases of the gastroenterology unit who underwent POEM for achalasia at the Hospital Universitario San Ignacio, Colombia, between 2017-2024. Sociodemographic, clinical and manometric characteristics were described and compared between patients with short and long myotomy. Effectiveness was assessed according to the Eckardt scale and safety for perioperative adverse events according to the iPOEM classification, and the difference between the two groups was evaluated using the $\chi 2$ test for categorical variables and the Mann-Whitney U test to compare continuous variables.

Results: Clinical efficacy and safety of short peroral endoscopic myotomy (POEM) compared with long myotomy for the treatment of achalasia in a university hospital in Colombia57 patients were included, 25 (44%) underwent short myotomy and 32 (56%) underwent long myotomy with a mean esophageal length of 5 cm and 11 cm respectively. The mean age was 4.6.6 years, with a female predominance of 56.1%, 20 patients (35%) had undergone a previous procedure for achalasia, which was Heller myotomy in 50%. The most common type of achalasia in both groups was type II. The mean preoperative Eckardt score was 7.6 points, with no difference between groups. Patients who underwent long myotomy had more minor complications such as capnoperitoneum and abdominal puncture compared to the short myotomy group (65.6% and 56.2% versus 16% and 12% respectively) P<0.001. There was no difference in hospital stay but there was a shorter operative time in the short myotomy group median 80 minutes IQR 70-95 minutes compared to 127.5 minutes IQR 102-155 minutes in the long myotomy group with statistical significance, P<0.001. In terms of efficacy at one year, 84.3% of patients in the short myotomy group and 88% in the long myotomy group achieved an Eckardt ≤3, which was not statistically significant.There was also no difference in reflux symptoms between groups P 0.277 and the majority (65%) responded to PPI management.

Conclusion: Short myotomy in POEM for achalasia appears to be noninferior to long myotomy in terms of clinical success and long-term reflux disease. In addition, it offers the advantages of shorter procedure times and potentially lower rates of minor complications, which makes it a preferable option in many cases and could also be considered the first choice in previously operated patients.

Disclosure: Nothing to disclose.

PP0021

THE PREVALENCE AND CHARACTERISTICS OF GASTROPARESIS IN PARKINSON'S DISEASE USING CLINICAL SCORE AND ITS RELEVANCE WITH GASTRIC EMPTYING SCINTIGRAPHY

S. Jandee[1], K. Jandee[2], N. Pawakkaranon[3]
[1]Prince of Songkla University, Gastroenterology and Hepatology Unit, Division of Internal medicine, Hatyai, Thailand, [2]Prince of Songkla University, Department of Epidemiology, Faculty of Medicine, Hatyai, Thailand, [3]Bangkok Hospital Siriroj, Phuket, Thailand

Contact E-Mail Address: tekikung@gmail.com

Introduction: Gastrointestinal dysfunction, especially gastroparesis is a common non-motor disorder among Parkinson's disease resulting to serious complications and poor quality of life. There are still some limitations on an evaluation and diagnostic test to detect the patients with gastroparesis for early intervention improving outcome.

Aims & Methods: All Parkinson's disease patients were inquired to complete GCSI, GERD-Q, and PAC-SYM questionnaires. The correlation between the scores and disease severity was evaluated. Factors associated with significant gastroparesis symptoms (GCSI ≥9) were analyzed. Patients who have had gastrointestinal symptoms compatible with gastroparesis were further test for gastric emptying scintigraphy.

Results: 76 patients completed GI questionnaires. The majority of patients (60.6%) were classified in PD stage 2 and 3. A large number of patients (82.9%) reported gastroparesis symptoms using GCSI score. The median (IQR) of total GCSI score was 4 (2, 10) with postprandial fullness predominant in subscale. PD duration ≥6 years was associated with high gastroparesis symptoms (GCSI ≥9), adjust OR = 2.96 (1.01, 8.71), p=0.043. Eight consecutive participants could undergo physiologic testing. Only one of eight was definitely confirmed for delayed gastric emptying. No correlation between GCSI score and physiologic testing was observed.

Table 1.Logistic regression analysis on potential factors associated with significant GCSI score.

	Crude OR (95%CI)	Crude P-value	Adjust OR (95%CI)	P-value (LR-test)
PD stage ≥3	0.45 (0.14,1.44)	0.179	0.4 (0.12,1.34)	0.123
PD duration ≥6 years	2.66 (0.95,7.41)	0.062	2.96 (1.01,8.71)	0.043
Coexisting DM	0.89 (0.2,3.9)	0.873	1.01 (0.2,5.21)	0.987
eGFR <60 mL/min/1.73m^2	0.88 (0.24,3.28)	0.850	1.19 (0.29,4.93)	0.812
Anticholinergic	0.96 (0.32,2.83)	0.937	0.87 (0.28,2.72)	0.812

Conclusion: Gastroparesis symptoms with postprandial fullness predominant were common among Parkinson's disease. The strong correlation between gastrointestinal scores may illustrate an extensive gastrointestinal involvement, especially in the patients with long term disease duration. However, clinical scores might have a limitation for real-life implementation in Parkinson's disease because poor correlation between GCSI score and physiologic testing was observed. Score validation and long-term outcome, especially nutritional status and pulmonary complication as sequelae of gastrointestinal dysfunction would be considered in future research.

PP0022

EXPLORING THE CONNECTION BETWEEN FUNCTIONAL DYSPEPSIA AND SLEEP DISORDERS: UNRAVELING THE LINK

W. Khomate[1], W. Wongpipathpong[1], T. Phongnarudech[1], N. Tungtrongchitr[1]
[1]Chakri Naruebodindra Medical Institute, Faculty of medicine Ramathibodi hospital, Mahidol University, Samut prakan, Thailand

Contact E-Mail Address: winrada.kho@student.mahidol.edu

Introduction: Functional dyspepsia is a common gastrointestinal disorder with unknown causes. Though a potential link between sleep disorders and digestive issues exists, evidence is inconclusive. This study aims to explore this relationship.

Aims & Methods: This prospective study was conducted at a medical school hospital from January 2023 to November 2023. Patients diagnosed with functional dyspepsia, according to the Rome IV criteria, were classified into two subtypes. Investigations were undertaken to exclude other potential diagnoses, which included a blood test, abdominal ultrasound, and upper endoscopy with *H. pylori* testing. We measured patients' sleep quality and daytime alertness with the Pittsburgh Sleep Quality Index (PSQI) and the Epworth Sleepiness Scale (ESS).

Results: A total of 134 patients were diagnosed with functional dyspepsia after careful evaluation. Among them, functional dyspepsia with postprandial distress syndrome predominate group (FD-PDS) was found at 60.4%. FD-PDS was linked to a higher PSQI score, with an average of 8.47 ($p < 0.05$). Additionally, there was a positive association between FD-PDS and the sleep quality ($p < 0.05$). The FD-PDS group was significantly associated with excessive daytime sleepiness ($p < 0.05$). Interestingly, the PSQI and ESS scores correlated with FD-PDS, with correlation coefficients yielding a *p-value* of less than 0.05.

	FD-EPS (N = 53)	FD-PDS (N = 81)	p-value
PSQI score, Mean (+/- SD)	6.4 (2.68)	8.47 (3.21)	0.002*
Nonsignificant, N (%)	37 (69.81)	37 (44.68)	0.012**
Significant sleep disturbance, N (%)	16 (30.19)	44 (55.32)	
ESS score, Mean (+/- SD)	6.34 (3.5)	8.85 (4.41)	0.004*
Normal, N (%)	46 (86.79)	42 (51.85)	<0.001***
Excessive daytime sleepness, N (%)	7 (13.21)	39 (48.15)	

**Two-sample T test*
***Fisher exact test*
****Chi-square test*

Conclusion: The findings indicate that FD-PDS is associated with elevated PSQI severity and abnormal ESS scores. Sleep disorder assessment should be conducted alongside evaluation in patients with functional dyspepsia, especially those with postprandial distress syndrome.

Disclosure: Nothing to disclose.

PP0023

SYMPTOM BURDEN IN PATIENTS WITH DGBI REFERRED FOR SPECIALIZED INTEGRATED CARE TREATMENT BEFORE, DURING AND AFTER THE COVID-19 PANDEMIC

D. Kulin[1,2], T. Fairlie[2], A. Shah[2], G.J. Holtmann[2]
[1]University of Queensland, Faculty of Medicine, Brisbane, Australia, [2]Princess Alexandra Hospital, Gastroenterology & Hepatology, Brisbane, Australia

Contact E-Mail Address: g.holtmann@uq.edu.au

Introduction: Disorders of Gut-Brain Interaction (DGBI), previously also referred to as functional gastrointestinal disorders, are characterised by chronic or relapsing gastrointestinal symptoms not explained by structural or biochemical abnormalities identified in the routine clinical setting. Psychological factors, including depression and anxiety, appear to play a role in these patients. A previous systematic review and meta-analysis[1] suggests that the COVID-19 pandemic had adverse effects on symptom severity of DGBI patients. Against this background we aimed to compare symptom burden and clinical outcomes of patients with severe DGBI (defined as experiencing symptoms impacting daily life) and their response to a highly structured 3 month clinical treatment program (the Integrated Care Clinic, ICC) delivered by a multiprofessional team (gastroenterologists, a primary care physician, psychologists, dietitians and exercise physiologists).

Aims & Methods: We hypothesise that in the emotionally challenging environment of the COVID-19 pandemic the DGBI symptom burden increased, while the response to a multimodal therapy that aimed to address biological and psychological disease mechanisms remained unchanged.

All patients with severe DGBI symptoms not sufficiently managed in the routine primary care or specialist setting who were referred and subsequently treated in the ICC between 2017 and November 2024 were included. Symptom burden was assessed with the validated Structured Assessment of Gastrointestinal Symptoms Scale (SAGIS) at baseline and after 3 months of treatment. We compared baseline and post-treatment SAGIS data for patients treated before, during and after the COVID-19 pandemic. The periods were defined by introducing and discontinuing travel restrictions for the respective community. Means were compared using the Wilcoxon and Kruskal-Wallis tests (GraphPad Prism 10).

Results: Overall, 287 patients with DGBI (mean age of 44.2±15.3 years, 75% female) completed the ICC program. The pre-pandemic cohort comprised 117 patients, the active pandemic cohort included 130 patients, and the post-pandemic cohort comprised 40 patients. On a global scale, the overall COVID-19-related mortality in the respective community was low (963/1,000,000 in Australia vs. 2812/1,000,000 in the EU). Overall, the ICC intervention resulted in a 25.8% (±41.4%) reduction of the SAGIS score ($p<0.0001$), and 170 (59%) patients experienced a >20% improvement of the SAGIS score during treatment. 47% of patients with severe or very severe symptoms at baseline did not have severe or very severe symptoms after treatment.

Symptom improvement assessed by SAGIS scores before, during and after COVID-19 pandemic was not statistically different (before: 9.475±11.99, during: 9.369±13.68, after: 6.875±13.11, $p>0.5$). However, comparing the global symptom burden at baseline (as assessed by SAGIS) there was a statistically significant increase in symptom burden during and after the active phase of the COVID-19 pandemic compared to the pre-pandemic symptom burden (before: 49.98±27.51, during 58.97±25.61 and after: 60.68±26.1, $p<0.05$).

Conclusion: The data from this cohort study suggest that the improvement of symptoms in patients with severe DGBI symptoms who participated in a 3-month intensive multiprofessional treatment course is not

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

influenced by the COVID-19 pandemic. In contrast, the overall symptom burden of patients treated during and after the pandemic is higher than before the COVID-19 pandemic. Further studies are required to determine if this is an effect due to COVID-19 infection or other pandemic-related factors.

FUNCTIONAL DYSPEPSIA REDEFINED: EVIDENCE SUPPORTING INFLAMMATORY DYSPEPSIA – A SYSTEMATIC REVIEW

L. Phang[1], K. Rostami[2], A.H.M. Kim[3]
[1]University of Otago, Wellington School of Medicine, Wellington, New Zealand, [2]Palmerston North DHB, Gastroenterology, Palmerston North, New Zealand, [3]University of Otago, Dean's Department, Wellington, New Zealand

Contact E-Mail Address: laurenwwphang@gmail.com

Introduction: Functional dyspepsia (FD) is a common yet complex gastrointestinal disorder, characterised by postprandial fullness, early satiety, epigastric pain, and burning. With growing evidence linking diet to inflammation and symptoms, our objective was to review the evidence for the impact of dietary factors on FD symptomatology.

Aims & Methods: A systematic review was conducted to identify dietary components influencing FD symptoms in adults. Databases searched included MEDLINE, EMBASE, PsycINFO, Scopus, and Cochrane, covering January 2000 to December 2024. A total of 14 studies met eligibility criteria, with findings synthesised through narrative analysis.

Results: The search strategy yielded 18,424 articles, of which 14 met the inclusion criteria. Analysis identified seven key dietary components associated with FD: (1) a low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet significantly improved symptoms ($p = 0.04$), while gluten intake was linked to early satiety ($p = 0.03$); (2) probiotics or prebiotics provided symptom relief (RR 1.15, $p = 0.52$), with probiotics alone showing a trend toward improved FD scores (RR 1.35, $p = 0.061$); (3) capsaicin significantly exacerbated symptoms ($p < 0.001$), and spicy foods were associated with increased gastric fullness ($p = 0.001$); (4) both peppermint-caraway oil ($p < 0.00001$) and cinnamon oil ($p < 0.001$) demonstrated significant symptom relief; (5) ginseng-based herbal porridge led to a higher rate of epigastric symptom remission by day 90 compared to placebo (45.71% vs. 20.69%, $p = 0.036$), while the STW 5-II formulation (a nine-herb extract) also yielded significant improvement ($p = 0.008$); (6) prokinetic agents reduced symptom severity (RR 0.81, $p < 0.0001$), while amitriptyline outperformed both placebo (40%) and escitalopram (38%), relieving symptoms in 53% of patients—particularly those with ulcer-like FD; and (7) ginger/artichoke capsules improved symptoms within 14 days ($p = 0.017$), while ginger/perilla tablets offered progressive relief over one to two weeks ($p < 0.05$ and $p < 0.01$, respectively).

Study quality was assessed using ROBIS, RoB 2.0, and ROBINS-I tools. Of the included studies, three were rated as low risk of bias, eight as moderate, and three as serious. Despite adherence to a standardised PRISMA-based search strategy, variability in outcome reporting limited direct comparability across studies.

Author	Study type	Outcomes	Author	Study type	Outcomes
Goyal (2022)	RCT	Both low-FODMAP diet and traditional dietary advice significantly improve FD symptoms.	Zobeiri (2021)	RCT	Both cinnamon oil and placebo showed improvements in gastrointestinal symptoms.
Du (2018)	Case-control	Gluten-rich diets may trigger FD symptoms, notably early satiety.	Wang (2024)	RCT	Herbal porridge is an effective and safe option for improving symptoms in FD patients.
Zhang (2020)	Systematic Review and Meta-Analysis	Probiotics and prebiotics showed positive effects on FD symptom scores, but data was limited.	Vinson (2024)	RCT	STW 5-II herbal extract is effective and safe for up to 8 weeks in patients with FD meeting Rome II or IV criteria.
Agah (2020)	Systematic Review and Meta-Analysis	Probiotics may improve GI symptoms in FD patients but high-quality RCTs are required to confirm this.	Pittayanon (2019)	Systematic Review and Meta-Analysis	Prokinetics may help alleviate FD symptoms, but the evidence quality was low.
Fuhrer (2011)	RCT	There is evidence that FD patients show chemical hypersensitivity in response to capsaicin.	Talley (2015)	RCT	Amitriptyline was more effective than both placebo and escitalopram in providing symptom relief, showing a greater benefit in patients with ulcer-like FD.
Lee (2016)	Prospective study	Capsaicin-rich foods likely contribute to feelings of stomach fullness.	Giacosa (2015)	RCT	Ginger and artichoke leaf extracts are safe and effective in treating FD.
Li (2019)	Systematic Review and Meta-Analysis	Peppermint oil and caraway oil is an effective and safe short-term treatment for FD, but evidence quality was low.	Di Pierro (2020)	Retrospective cohort study	The perilla/ginger supplement may serve as an effective natural option for FD.

Table 1.

Conclusion: This review highlights dietary interventions as a promising strategy for managing FD. Our findings show that specific dietary components can be implicated in inducing inflammation and symptoms in FD. Since the symptoms are related to inflammation, we propose using "inflammatory dyspepsia" to represent the true presentation of this form of dyspepsia. Large-scale randomised trials are needed to confirm findings and refine dietary guidelines.

Disclosure: Nothing to disclose.

DISORDERS OF GUT-BRAIN INTERACTION AND PSYCHOLOGICAL DISTRESS AFFECT DIETARY BEHAVIOR. ITALIAN DATA FROM THE WORLDWIDE ROME FOUNDATION GLOBAL EPIDEMIOLOGY STUDY

E.S. Corazziari[1], E. Ribichini[2], O.S. Palsson[3], A.D. Sperber[4], S.I. Bangdiwala[5]
[1]IRCCS Humanitas Research Hospital, Rozzano, Italy, [2]Sapienza University, Internal Medicine and Medical Specialties Gastroenterology Unit, Rome, Italy, [3]University of North Carolina, Chapel Hill, Medicine, Chapel Hill, United States of America, [4]Ben-Gurion University of the Negev, Faculty of Health Sciences, Farod, Israel, [5]McMaster University, Hamilton, Canada

Contact E-Mail Address: enrico.corazziari@uniroma1.it

Introduction: Disorders of Gut-Brain Interaction (DGBI) often arise or worsen after food intake, leading patients to modify their diets. These disorders are also strongly associated with psychological distress (PD).

Aims & Methods: To evaluate how DGBI and/or PD influence dietary habits.:

A total of 2,063 adults from the general Italian population completed the Italian Rome IV Diagnostic Questionnaire, which includes 86 diagnostic, 3 red-flag symptoms, and 10 food consumption questions. After excluding individuals with organic conditions (n=133) or GI symptoms not meeting DGBI criteria (n=390), the remaining 1,540 participants were categorized into two groups:

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

• Comparison Group (CG): No GI symptoms (n=650).
• DGBI Group: Diagnosed with one or more DGBI (n=890).
Psychological distress was assessed using the Patient Health Questionnaire-4 (score ≥6 indicating high PD). Associations between DGBI, PD, and weekly rate of assumption of HF and LF foods were assessed with multivariable Poisson regression models adjusted for sex, age, smoking, and alcohol consumption. Adjusted risk ratios (aRR) and 95% CI were used to quantify associations.

Results:

- PD and Dietary Habits in CG: Compared to CG with low PD, CG individuals with high PD consumed less high-FODMAP (HF) vegetables (aRR=0.79; 95% CI: 0.65–0.95) and low-FODMAP (LF) vegetables (aRR=0.80; 95% CI: 0.67-0.97), as well as less HF fruits (aRR = 0.84; 95% CI: 0.71–0.99), and LF fruits (aRR = 0.77; 95% CI: 0.64–0.92). Moreover, they were observed to consume less aged hard cheese (aRR=0.80; 95% CI: 0.64-0.99).
- DGBI and PD: DGBI was associated with a higher prevalence of PD (aRR = 3.90; 95% CI: 2.83–5.38).
  - DGBI subjects with high PD consumed less HF fruits (aRR = 0.85; 95% CI: 0.78–0.92), LF fruits (aRR = 0.83; 95% CI: 0.76–0.91) compared to CG with low PD.
  - DGBI subjects with low PD had slightly reduced LF vegetable consumption (aRR = 0.91; 95% CI: 0.86–0.97).

HF Cereals and Dairy: Intake of HF foods like pasta, bread, and dairy did not differ significantly between CG with low PD and the other groups.

Conclusion:

1. Psychological distress influences diet: High PD is associated with reduced consumption of HF and LF fruits and LF vegetables in both CG and DGBI individuals.
2. Dietary modifications in DGBI: While DGBI individuals tend to modify their diets by avoiding some HF and LF foods, they continue to consume HF cereals and dairy, suggesting unselective dietary changes.
3. PD amplifies dietary restrictions: The presence of PD exacerbates dietary modifications in both DGBI individuals and CG.

These findings highlight that food choices are significantly influenced by psychological distress and are also probably related to the traditional presence of HF cereals and dairy products in the Italian cuisine, often leading to unselective dietary restrictions that may not alleviate GI symptoms effectively.

Disclosure: NO COI.

EXPLORING THE LINK BETWEEN ESOPHAGEAL MOTILITY DISORDERS AND REFLUX DISEASE IN PATIENTS WITH SUPRAGASTRIC BELCHING DISORDER

L. Miguel García[1], V. G. Pintor[1], P. Fernández Rodríguez[1], S. Casabona-Francés[2], M.T. Pérez Fernández[2], E. Resina Sierra[2], C. Santander[2]

Contact E-Mail Address: elenaresina93@gmail.com

Introduction:

Supragastric belching disorder (SBD) is characterized by unconscious air swallowing and its immediate expulsion from the esophagus. Diagnosis is usually made by history and physical examination though supplementary evaluations can be considered. High-resolution esophageal manometry combined with stationary impedance (HRIM) allows confirmation of SBD diagnosis in patients with esophageal symptoms. Better understanding of this condition is needed to increase recognition and guide treatment. With the aim of characterizing the population diagnosed with SBD using HRIM and its association with other esophageal motility disorders (EMDs) or gastroesophageal reflux disease (GERD), we conducted a descriptive study.

Aims & Methods: We identified patients with SBD diagnosis who underwent HRIM using MMS-Unisensor® solid-state probe with 36 channels coupled with 16 channels of impedance in a tertiary hospital from January 2020 to December 2024. HRIM studies were interpreted according to Chicago classification v3.0 and v4.0. Demographic and clinical characteristics were collected. Data from pH-metry and/or pH-Impedance (pH-IMM) tests were also gathered to assess presence of pathological acid gastroesophageal reflux (GER).

Results: 39 patients were included (64% women) with a mean age of 52.7 years. Demographic and clinical characteristics are summarized in Table 1. Some patients developed SBD after esophagogastric surgery (10.4%). One-third of patients had some EMD: ineffective esophageal motility (27%) and esophageal absent contractility (5.4%). 12.9% of patients associated rumination disorder (RD). 25% patients had pathological acid GER in pH-metry and/or pH-IMM. A significant association was observed between the presence of pathological acid GER and symptoms of regurgitation (p=0.02) and vomiting (p=0.05), and between pathological acid GER and EMD finding in HRIM (p=0.05). 94.1% patients had consumed proton pump inhibitors (PPIs) in the previous 6 months, but only 50% showed symptomatic improvement with PPIs therapy. Symptoms improved in 91% of follow-up patients with diaphragmatic breathing exercises and patient education about the pathophysiology of the disorder to motivate active patient participation in their treatment. On average, patients experienced a diagnostic delay of 38.2 months (IQR: 24–54).

Sex (women)	**25 (64.1%)**
Age (years)	52.7 (IQR: 39.1 - 65.9) (minimum 13, maximum 81)
Patients diagnosed with pathological acid GERD	7 (25.9%)
Acid exposure time	12.8% (IQR: 6% - 16.7%)
DeMeester Index	44.9 (IQR: 21.7 - 53.2)
Number of refluxes	49,1 (IQR: 27 - 72)
Number of acid refluxes in patients with GERD	38 (IQR: 27 - 66)
Number of belching events in patients with GERD	130 (IQR: 23 - 111) (minimum 2; maximum 996)

Table 1. Demographic and clinical variables from the SGB patients sample

Conclusion: SBD is more common in middle-aged women as other functional gastrointestinal disorders. Association of SBD with RD is notable. Both SBD and RD could be misdiagnosed as PPI-refractory GERD. It is important to study the presence of GERD in order to optimize PPI treatment: in our study, only one quarter of the patients exhibited esophageal acid burden. Most patients improved with non-pharmacological treatment. SBD may be effectively treated with diaphragmatic breathing exercises and training patients for awareness of belching episodes. Diagnostic delay may be due to lack of awareness and limited access to diagnostic tests. Promoting knowledge about pathophysiology, symptoms and complementary tests would reduce diagnostic time and would improve the management of this rare disorder.

RESILIENCE IN PATIENTS WITH FUNCTIONAL DYSPEPSIA: A PROSPECTIVE QUESTIONNAIRE STUDY

R. Chase[1], D. Cangemi[2], L. Keefer[3], K. Chase[2], B. Lacy[4]
[1]Mayo Clinic Florida, Internal Medicine, Jacksonville, United States of America, [2]Mayo Clinic Florida, Gastroenterology and Hepatology, Jacksonville, United States of America, [3]Icahn School of Medicine at Mount Sinai, Gastroenterology, New York, United States of America, [4]Mayo Clinic Hospital, Gastroenterology, Ponte Vedra Beach, United States of America

Contact E-Mail Address: lacy.brian@mayo.edu

Introduction: Functional Dyspepsia (FD), a common disorder of gut-brain interaction [1], is associated with alterations in gastric accommodation, gastric emptying, gastric sensitivity, gastroduodenal permeability, and the gut microbiome. Resilience, the ability to maintain function under personal or physical stress, may play a role in the development of FD, although no studies have evaluated this theory.

We hypothesize that FD patients have lower resilience than the general population, which may lead to a new therapeutic target.

Aims & Methods: This prospective questionnaire study compared patients with FD (Rome IV criteria) with internal medicine clinic patients without dyspepsia at a tertiary referral center. Participants completed the FD symptom severity score [2], Brief Resilience Scale (BRS) [3], Connor-Davidson Resilience Scale (CDRS) [4], hospital anxiety and depression scale (HADS) [5], early childhood adverse life event questionnaire [6], and perceived stress score [7]. Questionnaires were distributed to clinic patients meeting inclusion/exclusion criteria.

Results: 38 FD (mean age 43 years old, 87% female) and 31 control (mean age 57 years old, 39% female) patients completed the survey. FD patients exhibited lower resilience on the CDRS (96.83 vs. 90.26, P<0.04, CI -12.93 to -0.21) but not on the BRS (3.018 vs. 3.022, P<0.96, CI -0.15 to 0.13). FD patients and controls scored no different on the HADS anxiety index (17.05 vs. 18.38, P<0.064, CI -2.74 to 0.08) and depression scores (P<0.14, CI -0.21 to 1.5). The FD group reported "high" perceived psychological stress while the control group reported a "moderate" level (P<0.004, CI 2.002 to 9.827). In childhood, FD patients had significantly more adverse childhood events (29.3% vs. 15%, P<0.004, CI 0.05 to 0.25).

FD patients were more likely to have been exposed to a household member suffering from a psychiatric illness compared to control patients (47% vs. 20%, P<0.049, CI 0.001 to 0.5). FD patients were also more likely to report psychological abuse in childhood (53% vs. 17%, P<0.03, CI 0.034 to 0.67).

No other significant differences were found in types of early childhood trauma including physical abuse, familial substance abuse, witnessed maternal violence, or criminal behavior by a household member.

Conclusion: This novel, prospective questionnaire pilot study shows that FD patients have lower resilience compared to the general outpatient population on the CDRS. The long-term symptoms of FD may further decrease resilience.

While anxiety and psychological stress are not strongly associated with FD, the significant exposure to childhood household members with a psychiatric diagnosis and significantly higher prevalence of self reported psychological abuse may explain the higher prevalence of antidepressant use in this population, especially considering the significantly higher level of self perceived psychological stress [8].

Otherwise, early childhood trauma appears similar between FD patients and patients without FD and is thus not likely to influence resilience markers. Understanding the contribution of resilience to development of FD may lead to therapies enhancing resilience, improving symptoms, and patient well-being.

Introduction: Patients with functional dyspepsia (FD) experience symptoms such as postprandial fullness, epigastric pain/burning and upper abdominal bloating. The relationship between symptoms and alleviating factors may influence how patients describe their symptoms in questionnaires. Understanding the specific location of these symptoms and their connection to bowel movements can enhance diagnosis and management.

Aims & Methods: To identify the location of uncomfortable fullness, pain/burning, and bloating in patients with FD, and determine differences between Europe and Asia. Furthermore, to assess differences in these abdominal regions between patients with FD and whether these symptoms are alleviated by bowel movements or flatus.

In total 481 FD patients from 8 European (N=281, 58.4%) and 7 Asian (N=200, 41.6%) specialist care centers completed questionnaires, including symptom localization on an abdominal pictogram dived into nine regions. Symptom relief by bowel movement and flatus was examined by dividing patients into three groups based on relief magnitude (never relieved, relieved in ≤ 50% and relieved in > 50%). The anatomical location of symptoms was compared between these subgroups.

Results: Asian FD patients reported significantly fewer symptoms in the hypogastric region compared to European patients (Table 1). Patients with FD whose postprandial fullness was relieved by bowel movement

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(>50%) reported significantly less fullness in the epigastric region and more in the six lower regions (right lumbar, umbilical, left lumbar, right iliac, hypogastric and left iliac regions) (p<0.001). A similar result was found for postprandial fullness relieved by flatus, except for the right lumbar and right iliac region. Patients with FD, whose postprandial fullness was relieved by bowel movement (>50%) reported significantly less pain/burning in the epigastric region and more in the umbilical, left lumbar and hypogastric regions (p<0.001).

A similar result was found for pain/burning relieved by flatus with significant differences in the epigastric and umbilical region. For bloating, the only significant difference was less bloating in the right iliac region for FD patients relieved by flatus. There was no significant difference in regions for bloating relieved by bowel movements.

	Postprandial fullness		Pain/burning		Bloating	
	Europe	Asia	Europe	Asia	Europe	Asia
Right hypochondriac region	10.3%	5.3%	12.8%*	4.9%*	13.5%*	4.0%*
Epigastric region	79.8%	76.7%	78.9%*	69.9%*	47.2%	49.2%
Left hypochondriac region	11.9%	14.0%	15.7%	13.3%	14.2%	12.1%
Right lumbar region	12.3%	10.0%	14.5%*	6.3%*	28.5%*	18.5%*
Umbilical region	55.1%*	42.7%*	45.5%	44.8%	77.5%	69.4%
Left lumbar region	14.8%	16.7%	16.5%	14.7%	33.3%	25.0%
Right iliac region	9.5%	7.3%	5.4%	2.8%	22.5%*	11.3%*
Hypogastric region	28.0%*	15.3%*	16.9%*	8.4%*	56.9%*	29.0%*
Left iliac region	9.9%	6.7%	7.4%	4.2%	25.1%*	12.1%*

*Table 1. Location of uncomfortable fullness, pain/burning and bloating in the European versus Asian FD population. Bold percentages followed by an *are indicating significant differences between Europe and Asia, corrected for multiple testing with Bonferroni. The overall p-value of the Chi²-test for postprandial fullness is 0.015 and for pain/burning 0.003. The overall p-value of the Chi²-test for bloating is < 0.001.*

Conclusion: Asian FD patients report less frequently symptoms in the hypogastric region compared to European patients. Symptoms relieved by bowel movements or flatus are less perceived in the upper abdominal and more in the six lower abdominal regions. These symptom characteristics, including regional distribution and change with passage of gas or stool, may help to inform therapy choices in FD.

Disclosure: Nothing to disclose.

PP0029

UPPER GI BIOFEEDBACK THERAPY: EMPOWERING PATIENTS TO ADDRESS AIR SWALLOWING AND OPTIMISE CARE PATHWAYS

S. Scott[1]
[1]University Hospitals Bristol and Weston NHS Foundation Trust (UHBW), GI Physiology, Bristol Royal Infirmary, Bristol, United Kingdom

Contact E-Mail Address: samantha.scott2@uhbw.nhs.uk

Introduction: Behaviours such as supra-gastric belching, gastric belching, and aerophagia, often identified during oesophageal physiology studies (e.g., 24-hour pH and impedance study), are known to exacerbate symptoms like reflux, bloating, and regurgitation. These behaviours are frequently misunderstood and may lead to unnecessary referrals to specialists or invasive interventions. Upper GI biofeedback (UGI BFB) therapy offers a tailored, non-invasive approach to help patients manage these behaviours. By teaching specific techniques such as diaphragmatic breathing, open-mouth posture, and the multiple rapid swallow technique, patients are empowered to take control of their symptoms, improve their quality of life, and reduce reliance on surgical or gastroenterology pathways.

Aims & Methods: • Participants: Between December 2022 and December 2024, 35 patients were referred for UGI BFB therapy. Most referrals (n=31) came after oesophageal physiology studies, with additional referrals from gastroenterologists for belching and bloating (n=2) and from clinical endoscopists for persistent hiccups and audible wheezing (n=2).

• Intervention: Patients attended a one-hour education session in the Gastrointestinal (GI) Physiology unit. This included a review of diagnostic findings and practical training in diaphragmatic breathing, open-mouth posture, and the multiple rapid swallow technique. A follow-up telephone consultation at 6–8 weeks allowed for monitoring progress. For cases of poor oesophageal clearance, referring clinicians were advised to consider prokinetics. For frequent gastric belching, small intestinal bacterial overgrowth (SIBO) breath testing was recommended to assess any additional contributing factors.

Results: • Supra-gastric belching episodes were reduced by 50% (mean: 24 episodes pre-therapy to 12 post-therapy; p<0.001).

- GERD-HRQL scores improved by 45%, indicating significant quality-of-life improvements (mean: 22 pre-therapy to 12 post-therapy; p<0.001).
- 75% of patients reported substantial reductions in belching, bloating, and reflux-like symptoms.
- Half of the patients (50%) no longer required specialist referrals, as symptoms were successfully managed with therapy or GP-led interventions, including prokinetics or medications for hypersensitivity.
- Stress emerged as a critical factor for most patients. Relaxation techniques, mindfulness, and stress management strategies played an important role in symptom control. One patient, who became a mental health first aider at work, reported long-term symptom relief due to stress reduction efforts.

Conclusion: Upper GI biofeedback therapy is a valuable approach for addressing behavioural contributors to symptoms like air swallowing, belching, and bloating. A multidisciplinary approach, involving cognitive behavioural therapy or hypnotherapy alongside UGI BFB, can be highly beneficial. The GI Physiology team also recognises its limitations and has found that referrals to Speech and Language Therapy can be instrumental when patients are unable to engage fully with the therapy. This collaborative, patient-centred approach ensures that UGI BFB therapy not only reduces the need for invasive procedures and specialist consultations but also empowers patients to adopt long-lasting lifestyle and behavioural changes.

THE IMPACT OF CANNABIS USE ON GASTROINTESTINAL SYMPTOMS AND GASTRIC EMPTYING BREATH TESTING

M. Berliner[1], G. Berman[2], M. Ben Yehoyada[2], R. Dekel[2], Y. Ron[2], Y. Mazor[2]
[1]Azrieli Faculty of Medicine, Bar-Ilan University, Zefat, Israel, [2]Tel Aviv Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel

Introduction: Gastroparesis is a disorder characterized by delayed gastric emptying without mechanical obstruction, leading to symptoms such as nausea, vomiting, abdominal pain, and bloating. Cannabis and its active compounds are thought to interact with the gastrointestinal system through cannabinoid receptors, influencing motility, sensation, and inflammation. Nevertheless, data pertaining to the interactions between cannabis use, gastric motility and gastrointestinal (GI) symptoms is still scant[1].

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: The aim of the current study was to compare GI symptoms and gastric motility in a cohort of patients referred for gastric emptying breath test (GEBT). In this prospective study, all consecutive patients referred for motility testing in a tertiary hospital were recruited. Following obtaining written informed consent, questionnaires, including ROME, SCL-90-R and SF36 were filled out by the patients. Carbon-13 spirulina GEBT was done performed according to protocol, following consumption of a standardized meal. Patients with ongoing (regular or occasional) cannabis use were compared with non-cannabis users for all symptoms, quality of life and GEBT testing results. An additional healthy cohort of volunteers was recruited for validation of GEBT cut-off values and comparison to the symptomatic cohort.

Results: A total of 88 patients and 14 healthy volunteers were included in the current study. Among patients, 15 (17%) were identified as cannabis users, and these were compared with 73 non-users. Mean age and gender did not differ between users and non-users (52.4 vs 43.0, and 21% vs 33% males, respectively, p=NS). Gastric emptying breath test results did not significantly differ between groups, both in terms of mean values ($t^{1/2}$ 127.2 vs 129.2 minutes, users versus non-users, respectively; p=NS) and in the proportion of delayed gastric emptying (26.7% versus 32.9%, users versus non-users, respectively; p=NS).

None of the healthy volunteers displayed delayed gastric emptying results. Cannabis users demonstrated a higher gastrointestinal symptom burden and a greater number of diagnosed disorders of gut-brain interaction (DGBI) compared to non-users.

Conclusion: In our cohort of patients referred for gastric emptying breath tests, gastric emptying was similar between cannabis users and non-users. This is in line with previous studies suggesting that cannabis does not improve delayed gastric emptying. Nevertheless, previous studies suggested that cannabis may alleviate gastroparesis-associated symptoms[2]. In this context, our results show that cannabis use was rather associated a more severe and systemic symptomatic manifestation of gut-brain disorders, in contrast to a more localized upper gastrointestinal involvement seen in non-users.

Although causality cannot be established, we do note that despite ongoing cannabis use, treatment response was sub-optimal in the user patient group. Factors contributing to these differences, such as physiological or psychological constructs, should be further explored.

A FEASIBILITY STUDY OF VIRTUAL REALITY FOR THE TREATMENT OF NONCARDIAC CHEST PAIN

A. Koop[1], B. Lacy[2]

[1]Mayo Clinic, Gastoenterology, Jacksonville, United States of America, [2]Mayo Clinic Hospital, Gastroenterology, Ponte Vedra Beach, United States of America

Contact E-Mail Address: lacy.brian@mayo.edu

Introduction: Noncardiac chest pain (NCCP) is a challenging condition associated with decreased quality of life, diagnostic uncertainty, and a high healthcare burden. The most common gastrointestinal causes are gastroesophageal reflux disease (GERD), functional chest pain, and spastic esophageal motor disorders. Effective treatments are lacking particularly for patients who do not respond to proton pump inhibitors. Virtual reality (VR), an innovative non-invasive tool providing multi-sensory stimulation through a head mounted display, has demonstrated usefulness in treating acute and chronic pain, anxiety, and other gastrointestinal disorders. The objective of this study was to assess the feasibility of virtual reality for the treatment of NCCP.

Aims & Methods: This was a feasibility study of 11 adult patients with NCCP, defined as persistent angina-like chest pain despite the exclusion of a cardiac source. All patients underwent esophagogastroduodenoscopy (EGD) to exclude treatable, secondary gastrointestinal causes. Participants were provided a VR headset preloaded with three-dimensional immersive environments including relaxation simulations and guided diaphragmatic breathing. Participants were asked to use the headset at least 15 consecutive minutes daily for 14 days.

The primary objective was to assess the overall feasibility of VR for the treatment of NCCP and challenges that may impact the performance of a future clinical trial.

As a secondary objective, we assessed the effectiveness of VR to improve pain severity, gastrointestinal symptoms, hypervigilance, quality of life, depression, anxiety, and resilience through validated questionnaires. Continuous variables were compared with the paired-samples t-test and categorical variables with McNemar's test.

Results: Eleven patients completed the study with a median age 59 (range 44-72) years, 10 (91%) female, and median body mass index 24.9 kg/m^2 (19.6-28.7). Ten patients had a normal endoscopic appearance of the esophagus, and one patient had Los Angeles grade A esophagitis. All patients had incomplete treatment response to a proton pump inhibitor. There were improved depression scores by the Hospital Anxiety and Depression Scale compared to baseline after one (median 4 vs. 1, p=0.008) and two weeks (4 vs. 1, p=0.02) and improvement in the composite depression and anxiety score after 2 weeks (10 vs. 6, p=0.009) of the study. There was a trend in improvement of the Esophageal Hypersensitivity and Anxiety Scale although this did not meet statistical significance (43.5 vs. 39.0, 0.097). The virtual reality headset was well-tolerated by all patients without adverse events or safety concerns.

Conclusion: In this two week, prospective feasibility study of patients with NCCP, virtual reality was well tolerated and led to improvement in depression and anxiety scores. These findings provide a foundation for the use of VR for the treatment of NCCP in a larger, prospective randomized controlled trial.

Disclosure: Nothing to disclose.

Introduction: Exposure to Helicobacter pylori (H. pylori) has been associated with a decreased risk of eosinophilic oesophagitis (EoE).

Aims & Methods: As the epidemiology of EoE is rapidly increasing, we conducted an updated systematic review and meta-analysis to determine the association between H. pylori infection and EoE. We searched MEDLINE, Scopus, and ISI Web of Science, through to November 2024.We included studies reporting the status of H. pylori infection in patients with and without EoE or oesophageal eosinophilia (EE). A random-effects model was used to pool estimates.

Results: Nineteen studies including 1.704.821 subjects were analysed. H. pylori infection was associated with a 46% lower risk of EoE/EE (OR: 0.54, 95% CI 0.43 to 0.67). Comparable findings were observed when subgrouping studies by location or design.

A nonsignificantly decreased risk for EoE was observed in pediatric patients exposed to H. pylori (OR 0.57, 95% CI 0.26 to 1.24) and in studies using serology to diagnose H. pylori (OR: 0.41, 95% CI 0.16 to 1.04).

We found a lower risk of EoE compared with the overall findings in studies that diagnosed H. pylori only by gastric biopsy (OR 0.43, 95% CI 0.25 to 0.74) and in those published after 2019 (OR 0.44, 95% CI 0.28 to 0.68).

Conclusion: In a large systematic review and meta-analysis, exposure to H. pylori was significantly associated with decreased risk of EoE. As a stronger protective effect was found in more recent studies, the epidemiology of this association may evolve and deserves to be further monitored.

THE RELATIONSHIP BETWEEN BACTERIAL FLORA IN SALIVA AND ESOPHAGEAL MUCUS AND ENDOSCOPIC SEVERITY IN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

M. Sasahira[1], H. Matsumoto[1], A. Shiotani[1]
[1]Kawasaki Medical School, Okayama, Kurashiki, Japan

Contact E-Mail Address: momomo0318@gmail.com

Introduction: Eosinophilic esophagitis (EoE) is a chronic inflammatory disease characterized by esophageal dysfunction and eosinophilic inflammation of the esophageal mucosa.

In this study, we investigated the bacterial flora in saliva and esophageal mucus in patients with EoE and examined the relationship between EoE disease activity and mucosal cytokine expression.

Aims & Methods: Cases consisted of patients with active and inactive EoE (A-EoE and I-EoE, respectively). A-EoE was defined as a peak eosinophil count > 15/high-power field, according to the 2025 consensus guidelines. Saliva samples were collected from the patients before the endoscopic examination. Brushing samples were collected from the distal esophagus of patients with EoE during endoscopic procedures. The degree of EoE inflammation was assessed using the EoE endoscopic reference score (EREFS). The samples were profiled using the Illumina MiSeq platform. The V3–V4 regions of the 16S rRNA gene (460 bp) were amplified by using tailed PCR.

Results: Fifty-nine patients were enrolled, including 8 with I-EoE, 17 with A-EoE, and 28 non-EoE controls. Major bacterial genera, such as *Streptococcus*, *Prevotella*, *Veillonella*, and *Alloprevotera*, were detected in both the oral cavity and esophagus. Compared with the control group, the active EoE group had significantly more *Prevotella* spp. in the saliva and esophageal mucosa.

Conversely, significantly fewer *Neisseria* spp. were found in the saliva and *Streptococcus* spp. in the esophageal mucosa of patients with active EoE. The EREFS of EoE and *Streptococcus* were inversely correlated.

Conclusion:

In this study, we clarified the characteristics of the bacterial flora in the saliva and esophageal mucosa of patients with eosinophilic esophagitis.

Disclosure: Nothing to disclose.

Contact E-Mail Address: paulinazybul@gmail.com

Introduction: Eosynophilic oesophagitis (EoE) is a chronic disease which clinically presents with symptoms related to oesophageal dysfunction while pathologically it is characterized by eosinophilic infiltration of oesophageal epithelium. Most patients with EoE present food and/or inhalant allergies symptoms. The results of animal models studies and genetic studies, as well as efficacy of elimination diets in managing the symptoms, suggest an atopic background of the disease.

Aims & Methods: The aim of this study was to evaluate the prevalence of EoE in a group of patients with upper gastrointestinal symptoms and food and/or inhalant allergies and to assess the influence of drugs used in type I allergies on the results of endoscopic, histopathological and immunohistochemical tests.

Methods. This was a prospective observational study. Patients with inhalant/food allergies and upper esophageal symptoms formed study group while control group formed patients without allergy diagnosed with dyspepsia or irritbale bowel syndrome.

All study participants were tested for allergies including prick testing, blood tests, all participants were evaluated with a gastroscopy with specimen collection. Oesophageal specimens were stained for eotaxin-1 and desmoglein-1.

Results: Based on histopathology results eosinophilic oesophagitis was found in 9 of the 73 patients from the study group. All patients with EoE presented with multimorbidity and were diagnosed with at least one allergic disease in addition to EoE. Positive staining for CCL-11 was found in 56 (78%) patients in the study group, including all patients with EoE while ony in 3 (17%) individuals from control group.

The presence of DSG-1 in oesophageal specimens was detected in 6 (7%) subjects from the study group in contrary to 14 (78%) subjects from the control group. DSG-1 was not found in any of the specimens of patients diagnosed with EoE.

Conclusion: EoE is rare disease usually accompanied by allergic multimorbidity. Positive staining for eotaxin-1 and negative staining for desmoglein-1 in patients with esophageal symptoms and allergy but who did not met EoE diagnostic criteria, could be indicative of subclinical course of the disease or masking effect of corticosteroids. It is now critically important for both researchers and practicing clinicians to recognize that eosinophilic esophagitis (EoE) is not a homogeneous disease but rather consists of multiple subtypes (phenotypes). The so-called “classic” form of EoE—defined by current diagnostic criteria as having more than 15 eosinophils per high-power field on histopathological examination—appears to represent only the tip of the iceberg.

There is an urgent need for further research to refine endoscopic techniques, expand the scope of histopathological assessments, and identify novel biomarkers to better define the distinct phenotypes of eosinophilic esophagitis.

PREVALENCE OF EOSINOPHILIC ESOPHAGITIS AMONG PATIENTS PRESENTING WITH ESOPHAGEAL DYSFUNCTION SYMPTOMS AT THE ENDOSCOPY UNIT OF A TERTIARY CARE CENTER IN WESTERN MEXICO

P.A. Mendoza Rosales[1], M.E. Marín Contreras[1], F.A. Caderón García[2]
[1]Mexican Institute of Social Security, Gastroenterology and endoscopy, Guadalajara, Mexico, [2]Mexican Institute of Social Security, Pathology, Guadalajara, Mexico

Contact E-Mail Address: pedroalberto.mr@hotmail.com

Introduction: Eosinophilic Esophagitis (EoE) is a chronic, immune-mediated esophageal disease characterized by esophageal dysfunction symptoms and histological eosinophilic infiltration. Diagnosis requires ≥15 eosinophils per high-power field and exclusion of other causes. Though its pathophysiology is not fully understood, food antigens—such as milk and wheat—are considered primary triggers, leading to chronic inflammation, mucosal damage, and fibrosis. EoE predominantly affects white males and is managed through dietary therapy, PPIs, and topical corticosteroids. Since its identification in the 1990s, prevalence has increased, especially in Western populations, with notable regional and ethnic variability. In Latin America, prevalence also varies between countries. Esophageal biopsies are essential in patients with esophageal dysfunction, even in the absence of visible endoscopic changes. However, the frequency of esophageal eosinophilia in this population remains unknown in our region and institution.

Aims & Methods: A cross-sectional, descriptive, and retrospective study was conducted on patients over 18 years of age with symptoms of esophageal dysfunction who underwent upper endoscopy with esophageal biopsies between January 2020 and October 2023. A convenience sample of 164 patients was determined based on a 4% expected prevalence of EoE. Clinical records, endoscopy reports, and pathology files were reviewed to identify cases meeting diagnostic criteria. Data were analyzed using descriptive and inferential statistics, with a significance level set at $p < 0.05$.

Results: Demographics and Medical Background:The study included 152 patients (72.36% women; mean age 55.28 ± 14.07). Chronic conditions were present in 60.52% of the participants, the most frequent being hypertension (16.44%), asthma (11.18%), and diabetes mellitus (9.21%).

Clinical Presentation: Gastroesophageal reflux symptoms (GERD) were reported in 51.31% of patients, with 28.28% presenting alarm symptoms (mainly dysphagia). Dysphagia alone was the second most common symptom (34.86%). Food impaction occurred in 6.57%, and esophageal strictures in 4.60%. Symptoms of Esophageal Dysfunction:Dysphagia was the most common symptom (67.76%), followed by heartburn (47.36%) and regurgitation (44.73%). Less common symptoms included food impaction, globus sensation, and non-cardiac chest pain. Endoscopic Find-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ings:Findings suggestive of eosinophilic esophagitis (EoE) were relatively uncommon: esophageal rings (26.97%), strictures (11.18%), exudates (13.81%), longitudinal furrows (9.21%), and edema (0.65%). Hiatal hernia was observed in 28.94% of patients, and a wide hiatus in 41.44%.
Prevalence of EoE:EoE (≥15 eosinophils/HPF) was diagnosed in 11 patients (7.2%). The average age was 48.63 ± 16.5 years, with dysphagia (72.7%), heartburn (63.6%), and regurgitation (54.5%) as the most frequent symptoms. Endoscopic signs suggestive of EoE were present in only 36.36% of these patients.

Conclusion: This study investigates the clinical and diagnostic characteristics of Eosinophilic Esophagitis (EoE) in a specific population. A high prevalence of chronic comorbidities (60.52%) and a predominance of female patients (72.36%) were found. GERD symptoms were common (51.31%) and overlapped with EoE, especially in dysphagia and heartburn. EoE prevalence was 7.2%, with hiatal hernia linked to symptoms and food impaction. Diagnostic indicators showed good specificity but limited sensitivity. These findings emphasize the need for a comprehensive approach, combining clinical and endoscopic data, for accurate diagnosis and effective management of EoE.

Introduction: Budesonide orodispersible tablets (BOT) have been shown to be a safe and effective treatment for both induction and maintenance therapy of eosinophilic esophagitis (EoE). However, real-life data identifying baseline factors associated with a lack of response to BOT induction therapy are still lacking.

Aims & Methods: We aimed to compare baseline clinical, endoscopic, and histological characteristics between responders and non-responders after 3 months of induction therapy with BOT, and to identify possible predictors of therapeutic response in adult EoE patients.
A retrospective study was conducted, including consecutive adult EoE patients (May 2023 – February 2025). EoE was defined by a peak eosinophil count (PEC) ≥15 eos/HPF. All patients received induction therapy with BOT 1 mg twice daily and underwent follow-up gastroscopy with at least six esophageal biopsies after 3 months of treatment. Response to therapy was defined as the simultaneous achievement of histological (<15 eos/HPF) and endoscopic remission (EREFS score <2). Baseline data—including demographic and anthropometric characteristics, allergic comorbidities, occurrence of symptoms before EoE diagnosis, prior proton pump inhibitor (PPI) use, diagnostic delay, EREFS score, PEC, and index of severity for EoE (I-SEE) —were compared between responders and non-responders at univariate and multivariate logistic regression analyses to assess for eventual predictors of response to BOT induction therapy.

Results: A total of 32 EoE patients were included (87.5% male; mean age 40.2 ± 14.6 years). Among them, 18 (56.3%) were classified as responders (88.9% male; mean age 40.9 ± 15.0 years), and 14 (43.7%) as non-responders (85.7% male; mean age 39.3 ± 14.5 years).
No significant differences were observed between the two groups in terms of gender, age, body mass index, allergic comorbidities, diagnostic delay, occurrence of symptoms before EoE diagnosis, PEC, EREFS score, and I-SEE score. Food impaction at diagnosis requiring emergency gastroscopy was significantly more frequent among non-responders compared to responders (57.1% vs. 22.2%, p = 0.043). Prior PPI use was also more common in non-responders (57.1% vs. 27.8%, p = 0.093).
At multivariate logistic regression analysis, food impaction at diagnosis requiring emergency gastroscopy (OR 7.95, 95% CI 1.25–50.61, p = 0.028) and prior PPI use (OR 0.13, 95% CI 0.017–0.93, p = 0.043) were identified as independent predictors of non-response to BOT induction therapy.

Conclusion: Patients presenting with food impaction requiring emergency gastroscopy may be less likely to respond to induction therapy with BOT, potentially due to a more advanced stage of EoE. Moreover, patients with prior PPI use also seem to have a reduced likelihood of therapeutic response, possibly due to symptom masking and consequent diagnostic delay, ultimately reducing treatment effectiveness.

Introduction: Eosinophilic esophagitis (EoE) is a chronic inflammatory disorder from the atopic disease spectre. Despite being studied for years, the EoE-specific therapy has been approved only recently and includes budesonide orodispersible tablet (1) and IL-4R antagonist, dupilumab (2). Therefore, data on the management of the patients who do not respond to this treatment is scarce. Especially those who were diagnosed long in the past and have undergone different therapeutical approaches remain an understudied group. The aim of this project was to provide information on the treatment courses in a real-world setting over past 10 years.

Aims & Methods: This was a retrospective nation-wide project collecting data on patients with EoE in 7 Austrian centres since January 2014. The last follow-up was marked as of February 2025. Information on patients' demographics, previous medical history, number of esophageal food impactions and different treatment lines were recorded. Due to the descriptive character of the work, no power analysis was carried out.

Results: In total, 336 patients (30.1% female) were included. Approximately one third of them (119/336) experienced an esophageal food impaction before the diagnosis was made. The most common 1st line therapy was budesonide orodispersible tablet (193/336, 57.4%), followed by proton pump inhibitors (87/336, 25.9%) and food elimination diet (20/336, 6.0%). Two hundred twenty (220/336, 65.5%) patients did not remain on the 1st line treatment. Forty-four (44/336, 13.1%) subjects required more than 2 therapies and one person received even 7th line medication. Biologic treatment – dupilumab – was given to forty-one (12.2%) patients. It was the first line treatment in 1 person, the others received it in the further course. These drugs were well-tolerated and 97.6% (40/41) patients remained on it until the last follow-up and reached symptomatic remission. Three patients were diagnosed more than 10 years before they received biologic treatment and 2 of them responded to it. One person discontinued due to side effects. The most common reasons for switch for dupilumab were clinical and/or histological activity (24/41, 58.5%), side effects (10/41, 24.4%) and patients' preference (2/41, 4.9%).

Conclusion: This is the first study on different therapy courses in patients with EoE in Europe. Due to its retrospective character, no direct conclusions on the superiority of one approach upon another in case of refractoriness are possible.

Introduction: The eosinophilic esophagitis (EoE) endoscopic reference score (EREFS) is the validated scoring system for endoscopic findings of EoE. EREFS findings are currently scored cumulatively and correlate modestly with histological disease activity (HDA), symptoms, and adaptive behaviors. However, inflammatory and fibrotic findings may reflect different aspects of EoE, but this has never been evaluated.

Aims & Methods: We investigated the correlation of EREFS inflammatory and fibrotic subscores with HDA, symptoms and adaptive behaviors. In three tertiary referral centres for EoE, consecutive adults (>18 years) undergoing upper endoscopy for suspected or follow up EoE were prospectively enrolled. EREFS was scored as follows: edema 0-1; rings 0-3; exudates 0-2; furrows 0-2; stricture 0-1. The EREFS inflammatory subscore (EREFS-i) combined the scores of edema, exudates and furrows. The EREFS fibrotic sub-score (EREFS-f) combined the scores of moderate-severe rings (score ≥2) and stricture.

Subsequently, at least six esophageal biopsies were collected to assess HDA based on peak eosinophil count/high-power field (PEC/HPF) (active EoE PEC ≥15/HPF; EoE in remission: PEC<15/HPF). Symptoms were assessed using the dysphagia symptoms questionnaire (DSQ). Adaptive behaviors were assessed using the Pisa EoE Adaptation Questionnaire v1.0 (PiEAQ) [reference 1].

Clinical characteristics were recorded. Kruskal-Wallis Rank Sum Test and Pearson's Chi-squared were used for comparisons. ROC curve analysis was used to calculate the diagnostic accuracy (AUC). Spearman's test and linear regression models were used to assess relationships between variables. Significance threshold was p<0.05.

Results: 121 patients were included. 58% had active EoE, 42% were in histological remission. Baseline clinical data are reported in Table 1. The EREFS total score had modest AUC for predicting HDA (0.68) and did not show significant correlation with DSQ and PiEAQ.

In contrast, EREFS-i had AUC of 0.73, with 88.2% sensitivity and 51.4% specificity for predicting HDA, being significantly more accurate compared to the EREFS-f (p<0.001; Figure 1).

There was a significant correlation between EREFS-i and PEC/HPF with Spearman's Rho=0.5 (p<0.001), with linear regression showing that an increase of 1 point of any inflammatory feature corresponded to an increase of 12 eosinophils/HPF (p<0.0001).

In contrast, EREFS-f correlated significantly with the use of adaptive behaviors assessed with PiEAQ [Spearman's Rho of 0.6 (p<0.001); Figure 2], with linear regression showing that an increase of 1 point of any fibrotic feature corresponded to an increase of one adaptive behavior (p=0.001). EREFS, EREFS-i, and EREFS-f had nonsignificant negative correlation with DSQ (p>0.05 for all).

Conclusion: We confirmed that, while total EREFS provides a global assessment of endoscopic disease severity, it lacks correlation with histological and clinical disease activity. However, we demonstrated that EREFS-i correlates significantly with PEC and predicts PEC/HPF and that EREFS-f correlates significantly with the use of adaptive behaviors assessed with PiEAQ, which represent known clinical markers of disease activity. Neither EREFS-i nor EREFS-f correlated significantly with DSQ.

In conclusion, we showed that, compared to the total EREFS, EREFS subscores improve the correlation between endoscopy findings with histology and clinical disease activity markers. Applied to clinical practice, our results represent another step towards precision medicine in the setting of EoE.

Characteristic	N = 121
Sex (M/F)	82/39
Age	40 (31, 50)
EREFS_Score_Total	2.00 (0.00, 3.00)
EREFS_Inflammatory	1.00 (0.00, 2.00)
EREFS_Fibrotic	1.00 (0.00, 2.00)
Dysphagia	73 / 116 (63%)
DSQ	14 (0 – 42)
PiEAQ score	0 (0 – 2)
EREFS total score	2 (0-3)

Introduction: One of the cornerstones of pharmacological treatment for patients with eosinophilic esophagitis (EoE) is the use of swallowed topical steroids (STCs). An esophageal formulation of orodispersible budesonide tablets (BOT) is currently available in Europe and has shown high response rates in clinical trials. However, real-world data on its long-term efficacy and safety are still lacking.

Aims & Methods: The aims of our single-centre study are to describe the efficacy and incidence of adverse events (AEs) of BOT during induction and maintenance therapy and to identify factors associated with lack of response and the occurrence of AEs.

We retrospectively enrolled EoE patients who started induction therapy with BOT (2 mg) and completed at least 1 year of follow-up with maintenance therapy (1 mg). Histological response was defined as <15 eosinophils per high-power field (HPF). The rate of clinical, endoscopic and histological remission was assessed at the end of induction treatment (T1) and after 1 year of maintenance treatment (T2). BOT-related AEs were also assessed at T1 and T2.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 104 patients were enrolled in the study. The median age at diagnosis was 30 years, 79.8% were male, with a median diagnostic delay of 58.5 months. At diagnosis, 41.4% of patients had a fibrostenotic disease phenotype, 21.8% presented with esophageal stenosis and 44.3% had a history of gastroesophageal reflux disease (GERD). Patients started BOT as first-line therapy (15.3%), after switching from off-label STCs (20.1%) and after failure of proton pump inhibitors (PPIs) treatment. Prior to starting BOT therapy, 2.17% of patients had evidence of erosive esophagitis (EE) on upper GI endoscopy. Of the 104 patients, 102 (98%) completed the induction phase of treatment (T1) and 55 (53.9%) completed at least one year of follow-up in the maintenance phase (T2).

In terms of histological response to treatment, 89.2% of patients had remission at T1. At T2, 23.8% of patients lost histological response to BOT therapy. At T2, loss of histological remission was associated with a Dysphagia Symptom Score (DSS) ≥ 3 (p<0.001) and tended to be associated with the presence of esophageal stenosis at diagnosis (p=0.085). The DSS was found to have high specificity, meaning that a score ≥ 3 as highly predictive of histological recurrence during maintenance therapy.

The prevalence of EE was 13% at T1 and 14.5% at T2, significantly increased compared to T0. Risk factors for the development of EE were younger age at diagnosis (p=0.033), delayed diagnosis (p=0.053) and BOT monotherapy without concomitant PPIs (p=0.004) at T1 and a history of GERD (p=0.03) at T2.

In terms of AEs, 33.7% and 20.4% of patients experienced BOT-related side effects at T1 and T2, respectively. Esophageal and oral candidiasis were the most common and were in most cases successfully treated with local or systemic antifungal therapy. However, the recurrence of AEs during the maintenance phase led to discontinuation of BOT in 2/55 cases (3.64%). The history of GERD was found to be a risk factor for the development of candidiasis at T1 (p=0.032) and T2 (p=0.039).

Conclusion: On the basis of our results, BOT therapy is effective in the induction and maintenance of histological remission in EoE. BOT monotherapy and a history of GERD are risk factors for the development of erosive esophagitis after BOT induction and maintenance, respectively. These findings suggest the need for a more personalized treatment approach and highlight the potential role of BOT-PPI combination therapy in selected cases.

Introduction: The I-SEE score, Index of Severity for Eosinophilic Esophagitis (EoE), is a recently developed clinical tool designed to assess the severity of EoE, a chronic, immune-mediated disease characterized by esophageal eosinophilic infiltration. Unlike traditional approaches, the I-SEE score integrates multiple domains, such as symptoms burden, endoscopic features and histo-pathologic activity, to provide a comprehensive evaluation of disease impact. Recent studies have begun to validate the I-SEE score in real-world settings, examining its correlation with treatment outcomes, patient-reported measures, and long-term disease management. Current research are focused on refining the scoring system, exploring its utility across patients' populations, and determining its reliability for identifying disease activity, thus helping its management.

Aims & Methods: This is a multicentre, prospective, observational study aiming to evaluate the reliability of the I-SEE score in identifying disease activity in patients with EoE, by comparing scores obtained before and after therapeutic interventions with budesonide orodispersible tablet (BOT). Patients diagnosed with EoE, aged > 18 years old, treated with BOT 2 mg, as induction treatment for 12 weeks (T1) and with 0,5/1 mg qd as maintenance for 52 weeks (T2) were enrolled. Clinical and demographic characteristics were collected. I-SEE score was calculated before and after the treatment.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 306 patients (241 males, 79%; mean age 38±14) treated with BOT were enrolled, in 8 Italian Centres and 1 Israelian Centre. The most frequent symptoms at diagnosis were dysphagia (82%) and food bolus impaction (70%). Allergic comorbidities were present in 65% of patients.

At baseline, all patients had an I-SEE score higher than 2, median value 6 (5-8); 14/306 presented a severe disease (I-SEE score≥15) and 136/306 a moderate active disease (I-SEE score 7-14). At T1, the I-SEE score passed from 6 (5-8) to 2 (1-3) (p<0.0001). Moreover, only 1/276 patients had a persisting severe disease, 5/270 moderate disease, while 40/276 achieved complete remission (I-SEE score<1).

After 1 year of treatment (T2), 135 patients were evaluated; the I-SEE score significantly decreased from T0 (6 (5-8) to 1 (0-3), p<0.0001) and from T1 (2 (1-3) to 1 (0-3), p<0.0001). Moreover, 4/135 patients presented moderate-severe disease, while in 40/135 EoE was inactive.

Considering only histologic assessment, all patients defined primary non-responder to BOT at T1 (20/270, 8 with moderate-active disease at T0) and secondary non-responder after tapering down the treatment at T2 (12/135, 5 with moderate-active disease at T0), met the criteria of mild disease according to the I-SEE score. All data are resumed in Table 1.

	n, T0	n, T1	n, T2	T0 vs T1	p	T0 vs T2	p	T1 vs T2	p

Histologic fibrostenotic features, median value (25-75 perc.) (0-2 points)	306	270	135	2 (0-2) vs 0 (0-2)	<0.0001	2 (0-2) vs 0 (0-2)	<0.0001	0 (0-2) vs 0 (0-2)	0.5

Table 1: I-SEE score and features assessment at T0, T1 and T2.

Conclusion: In this prospective observational study, the application of the recently developed I-SEE score for EoE assessment confirms the high efficacy of the treatment of BOT. However, baseline I-SEE score calculation was not useful in predicting nor stratifing patients' response to drug therapy. Further studies are necessary to outline the weighted scoring of each feature involved into score calculation.

POPULATION-BASED STUDY OF EOSINOPHILIC OESOPHAGITIS IN THE CANTERBURY REGION, NEW ZEALAND: INCIDENCE, AND PREVALENCE OF STRICTURING DISEASE AND PERIPHERAL EOSINOPHILIA

H.N. Lee[1], A. Ravikulan[2], J.H. Ngu[2]
[1]Auckland City Hospital, Hepatology, Auckland, New Zealand, [2]Christchurch Hospital, Gastroenterology, Christchurch, New Zealand

Contact E-Mail Address: Honamhk@gmail.com

Introduction: Eosinophilic oesophagitis [EoE] is a chronic, antigen-driven, immune-mediated oesophageal disease characterised by eosinophil-predominant inflammation. It typically presents with dysphagia, food bolus impaction, and, in children, feeding difficulties and failure to thrive [1].

Histologically, it is defined by ≥15 eosinophils per high-power field on oesophageal biopsy in the absence of other causes of eosinophilia [2].

The incidence and prevalence of EoE have increased markedly over recent decades, particularly in Western countries, likely due to increased recognition, changing environmental exposures, and altered microbiota [3,4].

Though EoE is increasingly reported worldwide, data specific to Aotearoa New Zealand, and especially regional patterns by ethnicity, remain limited.

Aims & Methods: This study aimed to describe the incidence, demographic distribution, and clinical characteristics of EoE in the Canterbury region over an 11-year period.

We conducted a retrospective analysis of electronic medical records from 2013 to 2023, identifying EoE cases using diagnostic codes and histological confirmation. Demographic data, clinical presentations, and laboratory findings were collected. Crude incidence rates were calculated using average population data for the Canterbury region, stratified by ethnicity (European vs. non-European). Clinical features including food bolus obstruction, oesophageal strictures, and peripheral eosinophilia were assessed. Incidence rates are reported per 100,000 population with 95% confidence intervals (CI).

Results: A total of 219 cases of EoE were identified between 2013 and 2023. The average annual incidence was 3.23 per 100,000 population (95% CI: 1.82–4.65), based on a regional population of 618,409. The mean number of cases per year was 20 (IQR 16–22). Among European individuals (average population 395,690), the mean annual incidence was 4.42 per 100,000 (95% CI: 2.35–6.49), with 17.5 average cases per year (IQR 14–21). Among non-European individuals (average population 222,627), the mean incidence was 1.08 per 100,000 (95% CI: -0.29–2.44), with 2.4 average cases per year (IQR 1–4).

Of the 219 cases, 70 patients (31.9%) presented with oesophageal food bolus impaction. The annual number of such presentations ranged from 3

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

to 12 per year (median 6, IQR 4–9). Twenty patients (9.1%) had documented stricturing disease on endoscopy, and 60 patients (27.4%) exhibited peripheral eosinophilia at diagnosis.

Conclusion: In our cohort, eosinophilic oesophagitis presents commonly with oesophageal food bolus impaction. There was a higher incidence of EoE observed in individuals of European descent. Just under one-third of patients in our cohort presented with oesophageal food bolus impaction and about 9% had stricturing disease. The frequent presentation with food bolus obstruction and the presence of complications such as strictures highlight the importance of timely recognition and management. Peripheral eosinophilia was found commonly in our cohort but the prevalence of this finding is not adequate to be used as a diagnostic test in EoE, although more studies are needed.

PREVALENCE OF DYSPHAGIA AND EOSINOPHILIC ESOPHAGITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE OR TYPE 2 INFLAMMATION – INTERIM ANALYSIS OF A PROSPECTIVE, MULTICENTER SCREENING STUDY

M. Bäuerle[1], J. Maurer[1], G. Novacek[1], C. Primas[1], L. Kazemi-Shirazi[1], S. Dabsch[1], A. Frick[1], J. Pokryszka[1], W. Reinisch[1], C. Dejaco[1], M. Trauner[1], S. Stoshikj[2], C. Bangert[3], S. Schneider[4], S. Wöhrl[5], P. Schreiner[1]

Introduction: Eosinophilic esophagitis (EoE) is a chronic, type-2 inflammation-driven esophageal disease causing dysphagia and esophageal dysfunction. Patients with inflammatory bowel disease (IBD) or other type-2 inflammatory disorders may have an increased risk of EoE, but prevalence data are limited.

This study examines the prevalence of dysphagia and EoE in patients with type-2 inflammatory diseases or IBD.

Aims & Methods: In this prospective, multicentric, questionnaire-based screening study, patients from the departments of gastroenterology, pulmonology, dermatology, and otolaryngology at the Medical University of Vienna, as well as from the Allergy Center Floridsdorf, were screened for dysphagia using the validated brief esophageal dysphagia questionnaire (BEDQ). The primary endpoint was the prevalence of clinically relevant dysphagia, defined as a BEDQ score ≥10 or a history of bolus impaction in the past year. Endoscopy was offered to symptomatic patients without recent biopsies. Patient characteristics and differences in absolute eosinophil count, eosinophilic cationic protein (ECP), and IgE levels were analyzed using independent-samples T-tests.

Results: A total of 690 patients (45.7% female, mean age 54.5 years) were screened; 54.4% had IBD, 20.2% allergic rhinitis, 16.4% asthma, 8.7% atopic dermatitis, 6.4% chronic rhinosinusitis with nasal polyps (CRSwNP), and 5.2% IgE-mediated food allergy with multiple diagnoses possible. Overall, 5.1% (n=35) exhibited clinically relevant dysphagia. EoE was previously diagnosed in 2.0% (n=14), including four patients with clinically relevant dysphagia. Among the remaining 31 patients, eight had prior endoscopies ruling out EoE, seven underwent endoscopy revealing two new EoE cases, and 16 are still awaiting gastroscopy. No significant differences in IgE, eosinophilic count, or ECP were found between patients with EoE, those with dysphagia, and asymptomatic individuals.

Conclusion: Patients with IBD and type-2 inflammatory diseases exhibit a high prevalence of dysphagia. While EoE is more common than in the general population, most dysphagia remains unexplained. Systematic dysphagia screening in this high-risk population may reduce diagnostic delay.

PREDICTORS OF TREATMENT RESPONSE OF PPI THERAPY IN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

H. Antwerpen[1], S. Nennstiel[1,2], S. Weidlich[3], C. Schlag[1,2]

[1]Klinikum rechts der Isar TU München, Klinik und Poliklinik für Innere Medizin II, München, Germany, [2]University Hospital Zurich, Zürich, Switzerland, [3]Klinikum rechts der Isar TU München, Gastroenterology, München, Germany

Introduction: One possible treatment option for Eosinophilic Esophagitis (EoE) is Protone Pump Inhibitor (PPI) therapy. The possible mechanisms of action discussed include acid suppression and a direct anti-inflammatory effect. However, only up to 50% of EoE patients respond to PPI therapy.

Predicting the therapeutic response is challenging, so the aim of this study was to identify potential predictors for a response to such therapy.

Aims & Methods: Patients with active EoE (defined as the presence of esophageal symptoms and simultaneous detection of >15 eosinophilic granulocytes per high-power field [HPF] in at least one biopsy from the esophagus) were retrospectively identified from the hospital database of a tertiary university referral center over 5 years. These patients had received sufficient PPI therapy (defined as double standard dose for at least four weeks). The analysis focused on their therapeutic response and potential predictors including clinical, histological and functional parameters of treatment success.

Results: 151 EoE patients were screened and of them 57 patients (mean age: 41 years; 81% male; mean maximum eosinophil count: 55/HPF) who had received PPI therapy at double standard dose for at least 4 weeks (mean duration: 62 days) were finally included. Histopathological complete remission (defined as <5 eosinophils/HPF) was achieved in 18 of 57 patients (31.6%) following PPI treatment, while partial remission (defined as <15 eosinophils/HPF) was observed in 25 of 57 patients (43.9%). No response to PPI therapy was noted in 14 of 57 patients (24.6%). There were no significant differences of the assessed predictors in EoE patients with

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. and without PPI response, although patients with PPI response showed a distally emphasized esophageal eosinophilia and a higher acid exposure time in pH-metry (both non-significant).

Conclusion: No definitive predictors for the response to PPI therapy in EoE patients could be identified. However, a distally predominant esophageal eosinophilia and higher acid exposure time in patients responding to PPI therapy may suggest a contributory role of gastroesophageal reflux in this cohort.

THE ROLE OF MAST CELLS IN EOSINOPHILIC ESOPHAGITIS: A PRELIMINARY STUDY

D. Novielli[1,2], A. Quaranta[3], A. Marzullo[3], M.R.D. Principi[2]
[1]National Institute of Gastroenterology "S. de Bellis", Gastroenterology, Castellana Grotte, Italy, [2]University of Bari, Italy, Section of Gastroenterology, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy, [3]University of Bari, Italy, Pathology Unit, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy

Contact E-Mail Address: noviellidomenico@libero.it

Introduction: Eosinophilic esophagitis (EoE) is a chronic inflammatory disease characterized by esophageal dysfunction and a peak eosinophil count of >15 cells per high power field (HPF). Recent studies suggest that mast cells play a key role in its pathophysiology. This study investigates the presence of mast cells in different groups of patients with EoE.

Aims & Methods: Biopsy samples from patients newly diagnosed with EoE were analyzed, and the Eosinophilic Esophagitis Histology Scoring System (EOEHSS) grade and stage scores were calculated. Biopsy samples were divided in two groups: t0 (before the starting of EoE therapy) and t1 (after EoE therapy). Mast cells were detected using tryptase immunohistochemistry, and the maximum number of mast cells counted in a high-power field (PMC), was recorded. Univariate correlation analysis were performed between PMC and peak eosinophil count (PEC), PMC and EOEHSS grade, PMC and EOEHSS stage, PMC and EREFS.

Results: 12 patients affected by EoE were divided in group 1, treated with PPIs [Esomeprazole 40 mg, bis in die (bid)] and group 2, treated with BOT (budesonide oral tablets 1 mg, bid). Univariate correlation analysis were performed at t0 and t1.

Results from Pearson's R for analysis at t0 are showed a positive linear correlation in PEC-PMC (0,567, p=0,043) and EOEHSS grade-PMC (0,559, p=0,047). At t1, EREFS-PMC had a positive correlation (0,726, p 0,005), like also EOEHSS grade-PMC (0,74, p=0,002) and EOEHSS stage-PMC (0,818, p<0,001).

	R	p
EREFS-PMC (t0)	0.244	0.423
PEC-PMC (t0)	0.567	0.043
EOEHSS grade-PMC (t0)	0.559	0.047
EOEHSS stage-PMC (t0)	0.390	0.187
EREFS-PMC (t1)	0.726	0.005
PEC-PMC (t1)	0.340	0.256
EOEHSS grade-PMC (t1)	0.74	0.002
EOEHSS stage-PMC (t1)	0.818	<0.001

Conclusion: PCM positively correlates with PEC, EOEHSS grade, EOEHSS stage and EREFS in untreated samples, supporting their role in EoE and type-2 inflammation. In treated cases, PMC correlate with PEC, EOEHSS grade, EREFS.

A highly statistically significant strong positive linear correlation was found between PMC and EOEHSS stage, as the latter is more likely to reflect the whole esophageal histologic changes.

Our study suggests that mast cell count, alongside eosinophil counts, could be an important factor in evaluating anti-inflammatory therapeutic interventions and it may be a useful adjunct to existing endoscopic and histologic markers in assessing EoE severity, supporting their role in EoE and type-2 inflammation. To confirm these findings, further longitudinal prospective studies are required.

Contact E-Mail Address: christoph.schlag@gmx.de

Introduction: Eosinophilic esophagitis (EoE) is a chronic, progressive, type 2 inflammatory disease of the esophagus characterized by multiple histopathologic abnormalities. In children and adults, EoE is diagnosed with a peak eosinophil count (PEC) ≥15 eosinophils/high-power field (eos/hpf) in endoscopically-obtained esophageal biopsies, yet PEC may not be a reliable marker of disease severity or treatment response. The EoE Histologic Scoring System (EoEHSS) provides an objective method for evaluating a range of histologic changes associated with EoE, beyond eosinophilia. Dupilumab, a fully human monoclonal antibody that blocks interleukin (IL)-4 and IL-13, key drivers of type 2 inflammation, is approved in the US and EU for the treatment of EoE in patients aged ≥1 year, weighing ≥15 kg.

Aims & Methods: This post hoc analysis assesses the impact of dupilumab vs placebo on histopathologic endpoints, PEC and EoEHSS grade/stage scores, in children, adolescents, and adults from a pooled analysis of the

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. EoE KIDS (NCT04394351) and LIBERTY EoE TREET (NCT03633617) studies. Patients from Part A of EoE KIDS randomized to weight-tiered, higher-exposure (HE) dupilumab or placebo for 16 weeks, and patients from Parts A/B of LIBERTY EoE TREET randomized to weekly dupilumab 300 mg or placebo for 24 weeks, were included. Patients continued dupilumab or switched from placebo to dupilumab to Week (W) 52. Biopsies were collected from proximal, mid, and distal esophagus. PEC and EoEHSS grade/stage scores were assessed at W16/24 and W52. All *P*-values are nominal.

Results: The pooled cohort included 159 patients who received dupilumab and 152 who received placebo. Baseline characteristics were generally comparable between the dupilumab and placebo groups (mean [standard deviation] EoE-HSS grade score: 1.3 [0.4] and 1.3 [0.4], EoEHSS stage score: 1.3 [0.3] and 1.3 [0.4], respectively). At W16/24, higher proportions of patients achieved ≤1, ≤6, and <15 eos/hpf with dupilumab vs placebo (26% vs 1%, 61% vs 5%, and 79% vs 7%, respectively). At W52, effects were maintained with continued dupilumab and increased from W16/24 in patients switching to dupilumab HE from placebo (Table). Dupilumab also improved percent change from baseline EoEHSS total grade and stage scores vs placebo at W16/24 (Table). At W52, improvements were maintained in the dupilumab group.

Conclusion: In this pooled analysis of two phase 3 studies, dupilumab improved histopathologic abnormalities of EoE compared with placebo during treatment initiation (W16/24) and maintenance (no evidence of relapse at W52), in children, adolescents, and adults with EoE. These improvements may be clinically meaningful as individual components of EoEHSS, as determined by EoEHSS grade/stage score, are implicated in altered esophageal motility, and persistent symptoms of EoE following diminution/ablation of eosinophil infiltrates. The safety profile of dupilumab was consistent with the overall known safety profile.

Contact E-Mail Address: joanacamoesneves@gmail.com

Introduction: Eosinophilic Esophagitis (EoE) is a clinicopathological disease that requires an integrated assessment combining clinical, endoscopic, and histological findings. Despite this, treatment decisions often remain symptom based. A treat-to-target strategy has recently been proposed to guide EoE management.

Aims & Methods: Retrospective single-center study of EoE patients followed between March 2012 and January 2024, with ≥12 months of follow-up. Clinical, endoscopic, histological data, and complications were assessed using the I-SEE score.

Results: A total of 82 patients with EoE were evaluated [75.6% (n=62) male, mean age 29 ± 13 years], with 37.8% (n=31) diagnosed during childhood. The most frequent symptom was food impaction (74.4%), and atypical symptoms were more common in pediatric patients (p=0.014). At baseline, 55.1% (n=43) presented with a fibrostenotic phenotype, more frequently in adults (p=0.012), and 32.9% (n=27) had moderate-to-severe disease based on the I-SEE score.

During follow-up, 56.1% (n=46) developed complications, most commonly food impaction requiring endoscopy. The presence of a fibrostenotic phenotype on initial endoscopy was a predictor of complications (OR 3.122; 95% CI 1.210–8.055; p=0.019). Both fibrostenotic phenotype (p=0.018) and moderate-to-severe I-SEE scores (p=0.004) were associated with increased need for therapeutic switching.

At 12 months, 50.0% (n=41) were asymptomatic; however, only 12.2% (n=10) had endoscopic healing and 9.8% (n=8) histologic remission. Throughout the study period, the rates of endoscopic and histologic healing remained below 25%.

Conclusion: The authors highlight the clinical dissociation of inflammatory activity and emphasize the importance of endoscopic and histologic healing to prevent disease progression.

LONG-TERM DUPILUMAB TREATMENT IMPROVES ENDOSCOPIC FEATURES IN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

M. Pesce[1], M. Ricchiuti[1], M. Falco[1], G. Cioffi[1], A. Chini[1], F. Maione[1], G. Sarnelli[1]
[1]Università Degli Studi Federico II Di Napoli, Department of Clinical Medicine and Surgery, Naples, Italy

Contact E-Mail Address: mapesc@hotmail.com
Introduction: Eosinophilic esophagitis (EoE) is a chronic, immune-mediated disease characterized by eosinophilic inflammation of the esophagus. EoE may result in esophageal remodeling and fibrotic changes which may lead to esophageal strictures and impair esophageal function. It has been widely demonstrated that all EoE therapies can revert esophageal fibrosis in short-term treatment, but to date no evidence has been produced on the long-term effects of specific EoE treatment on esophageal fibrosis and EoE endoscopic features.
Aims & Methods: We prospectively enrolled consecutive EoE patients referred to our center since 2022. Baseline EGDs with esophageal biopsies were performed in all patients before starting treatment and after at least 12 weeks of each therapy modification to evaluate histological and endoscopic response. The standardized EREFS score was used to evaluate EoE endoscopic signs, by differentiating the stenotic (Rings, Strictures) and inflammatory (Edema; Exudates, Furrows) subitems. In all patients who achieved clinical/histological remission and whose treatment remained unchanged (type and dose of therapy) for at least one year, a further EGDs with esophageal biopsies was performed at 52 weeks from the same experienced endoscopist. Results are expressed as mean±SD
Results: During the study period, 62 patients were prospectively enrolled (48M; 33±13y), of whom 41 achieved histological remission: 18 while on PPI, 14 on budesonide and 9 on Dupilumab. At 52 weeks, 15 patients on stable therapy underwent EGDs, 8 while on PPI therapy and 7 on Dupilumab. The two populations did not differ for sex, age at diagnosis and age of onset (7vs8M; 28.6±11.2vs 31.1±14.5y; 16.4±16.5vs 25.4±16.9y; p=NS) though a significantly increased diagnostic delay was observed in Dupilumab-treated patients (12.1±8.3vs5.6±3y; p=<0.05). At baseline, total EREFS scores were comparable between the two groups (4±2vs 3.6±1.2; p=NS). However, when analyzing the single EREFS subitems, Dupilumab patients scored significantly higher in the stricture subitem as compared to PPI group (0.3±0.49vs0±0; p<0.05).
At 12 weeks of therapy, both Dupilumab and PPI treated patients showed a significantly reduced total EREFS score compared to baseline (4±2vs2.6±1.4 and 3.6±1.2vs3±1; both p<0.05) with similar results both in terms of fibrotic and inflammatory subscores (1.3±0.95vs1.4±0.52 and 1.3±0.76vs1.55±0.73 in Dupilumab and PPI group, respectively; p=NS). The total EREFS score in both Dupilumab (2.6±1.4 vs 0.9±0.9) and PPI (3±1vs 2.4±0.7) groups consistently continued improving at 52 weeks of treatment (both p<0.05).
However, at 52 weeks, in dupilumab patients, both the total EREFS score and the fibrostenotic and inflammatory subitems were significantly lower compared to PPI group (0.9±0.9vs2.4±0.7; 0.4±0.53vs1.3±0.5 and 0.4±0.53vs 1.1±0.6; respectively, all p<0.001) with an almost complete resolution of the endoscopic signs of the disease in the Dupilumab group.
Conclusion: Our study showed a consistent improvement in endoscopic disease activity in both PPI and Dupilumab treated EoE patients after one year of treatment.
Notably, despite their lengthier diagnostic delay and higher fibrostenotic burden at baseline, Dupilumab patients showed a significant improvement in all EoE endoscopic features at 52 weeks compared to PPI responders, highlighting its potential impact on halting esophageal remodeling.
Disclosure: Marcella Pesce and Giovanni Sarnelli served as speakers for Sanofi.

Introduction: Eosinophilic esophagitis (EoE) is a chronic, immune-mediated disease characterized by symptoms of esophageal dysfunction and eosinophilic inflammation. Dietary therapy is an effective treatment for EoE patients of any age. However, data on the clinical effectiveness of dairy free diet (DFD) in adults remain limited.
Aims & Methods: Our study aims to explore the clinical, endoscopic and histological responses to a 12-week course of a dairy-free diet in adult patients diagnosed with EoE. We conducted a real-life multicenter prospective study on adult patients with histologically active EoE. After nutritional counseling, DFD was prescribed to adult EoE patients with one of the following indications: as a first-line therapy for newly diagnosed EoE; as an add-on therapy for EoE patients who were clinical responders but histological non-responders to proton pump inhibitors (PPIs); and as a second-line therapy. Clinical assessments and quality of life were evaluated using EEsAI, I-SEE, and the EOE-QOL-A scores at baseline and after 12 weeks of DFD. Adherence to DFD was assessed using VAS scale. Esofagogastroduodenoscopy with biopsies was repeated after 12 weeks for endoscopic and histological assessments.
Results: Twenty-one adult EoE patients undergoing DFD at 5 Italian Centers were enrolled from October 2022 to June 2024. Baseline characteristics of patients are described in Table 1. After 12 weeks of DFD, 50% of patients were histological responders and, among them, 90% were also clinical responders to DFD. Histological responders to DFD showed a significant reduction in both EEsAI and ISEE scores (p=0.01) compared to non-responders. Median EoE-QoL-A score significantly improved independently from response to therapy. Patients with both clinical and histological response showed higher adherence score measured by VAS

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. scale compared to the other patients (p=0.02). No factors were predictive of adherence to DFD therapy.

Age, years, median (IQR)	37 (28.5;54.5)
Males, n (%)	15 (71.4)
Dilations anytime, n (%)	5 (23.8)
Eosinophils/HPF at baseline, median (IQR)	41 (29;62)
DFD indications, n (%):	
I line therapy in naive patients	6 (28.6)
add-ON therapy to PPI in Clinical-PPI-Responders and Histological-PPI- Non Responders	4 (19.0)
II-line therapy	11 (52.4)
VAS adherence score, median (IQR)	8 (7; 9)

Table 1.Baseline characteristics

Conclusion: DFD can be offered as an effective therapy for adult EoE patients and significantly improves quality of life.

CURRENT STATUS OF DIAGNOSIS AND TREATMENT OF EOSINOPHILIC ESOPHAGITIS IN CHILE: RESULTS OF A NATIONWIDE SURVEY

J. Chahuán Abde[1], M. Barrera Oñate[1], O. Corsi[1], A. Espino[1], D. Reyes-Placencia[1], M. Pizarro Véliz[1], I. Gran[1], P. Rey Gnecco[1], A.J. Lucendo[2], H. Monrroy[1]

Contact E-Mail Address: jnchahuan@gmail.com
Introduction: Eosinophilic esophagitis (EoE) is an emerging disease in Latin America; however, little is known about medical practices related to its diagnosis, treatment, and follow-up. In Chile, the lack of a consensus-based practice guideline may lead to heterogeneous management among physicians. In contrast, standardized approaches and clinical recommendations have been established internationally.
Aims & Methods: To characterize current practices in the diagnosis, management, and follow-up of EoE in Chile.
A 55-item survey was developed to assess various aspects of eosinophilic esophagitis diagnosis, treatment, and monitoring. Five gastroenterologists reviewed a pilot version to evaluate its clarity and relevance. The survey invitation was emailed to all physician members of the Chilean Society of Gastroenterology. Additional open invitations were extended during the 50th Chilean Congress of Gastroenterology and through peer-to-peer contacts. Participants provided informed consent digitally, after which they received a link to complete the survey. The local ethics committee approved the study.
Results: The response rate was 11.9%, with 69 responses analyzed. The mean age of the participants was 50.4 years (SD ±12.77). Most respondents (66.7%) practiced in Santiago, and 91.3% were adult gastroenterologists. A total of 47.8% had more than 20 years of clinical experience, and 49.3% reported treating fewer than five EoE patients per year.
Among respondents, 82.6% generally or always performed esophageal biopsies in cases of dysphagia, and 69.6% for refractory reflux symptoms. The EREFS endoscopic classification was generally or always used by 52.2%. In emergency endoscopies for food impaction, 66.7% reported obtaining biopsies. Furthermore, 81.8% of endoscopists collected six or more biopsies when EoE was suspected.
Proton pump inhibitors (PPIs) were used as first-line therapy by 75.4% of respondents in over 75% of their patients, with esomeprazole being the most commonly prescribed PPI. 24.6% used topical corticosteroid as first-line treatment in over 75% of their patients. The most commonly used was liquid budesonide.
Regarding dietary therapy, whether as monotherapy or in combination with pharmacological treatment, the most frequent strategy was a two-food elimination diet with a step-up approach if needed. A total of 88.4% aimed for histologic remission as a therapeutic goal. In patients in clinical and histological remission without treatment changes, 55% reported follow-up intervals between three and six months.
Conclusion: There is variability among Chilean physicians in the diagnostic and therapeutic approaches to EoE. Most adhere to international biopsy standards and perform appropriately biopsies in patients with dysphagia. Many also align treatment with recommended therapeutic goals. However, biopsy collection during the index emergency endoscopy for food impaction should be reinforced to ensure timely diagnosis and early initiation of treatment. Overall, improved physician education and the development of national guidelines are needed to optimize and standardize the management of EoE in Chile.
Disclosure: Nothing to disclose.

EPIDEMIOLOGICAL AND CLINICAL CHARACTERISTICS OF PATIENTS DEVELOPING GASTRO-OESOPHAGEAL REFLUX DISEASE FOLLOWING BARIATRIC SURGERY: A SINGLE-CENTRE RETROSPECTIVE STUDY

R. Aghajani[1], S. Nario[1], C. Park[1,2], M. Wong[1,2]
[1]Royal North Shore Hospital, Gastroenterology, Sydney, Australia, [2]University of Sydney, Northern Clinical School, Sydney, Australia

Contact E-Mail Address: steffnario@gmail.com
Introduction: Gastroesophageal reflux disease (GORD) is a recognised complication of bariatric surgery; however, the clinical phenotype of patients who develop postoperative GORD remains poorly characterised. Improved understanding of this cohort may aid in risk stratification and management.
Aims & Methods: This study aimed to identify the epidemiological and clinical features of patients with upper gastrointestinal symptoms following bariatric surgery and to evaluate whether these vary by surgery type. This retrospective study examined 31 post-bariatric surgery patients with upper gastrointestinal symptoms referred to a quaternary gastroenterology service between 2004 and 2023. Data collected included age, sex, comorbidities, type and number of bariatric procedures, time from surgery to symptom onset, and symptom profile.
Results: Patients were predominantly female (80.6%) with high prevalence of comorbid depression (45.2%) and anxiety (53.3%). Sleeve gastrectomy was the most common procedure (70.9%), followed by adjustable gastric banding (35.5%); 16.1% patients underwent more than one bariatric surgery. On average, symptoms developed 0.19 years postoperatively and persisted for a mean duration of 6.8 years before referral. Dysphagia and heartburn were reported in 77.4% and 74.2% of patients, respectively. All patients who underwent Roux-en-Y gastric bypass (RYGB) reported heartburn. Patients with a history of sleeve gastrectomy appeared to have the highest symptom burden.
Conclusion: Patients who develop GORD after bariatric surgery are predominantly female, frequently have pre-existing mental health conditions, and often undergo sleeve gastrectomy. Symptoms typically emerge early and persist for several years before being investigated. Upper gastrointestinal symptoms appeared more prevalent than previously reported, suggesting possible under-recognition in clinical practice. Although RYGB

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. is the preferred bariatric procedure in patients with co-existing GORD, our findings indicate that significant reflux symptoms may still occur postoperatively. These results support the need for early identification perioperatively and tailored follow-up of at-risk patients.

THE ASSOCIATION OF PSYCHOLOGICAL COMORBIDITY WITH GASTROESOPHAGEAL REFLUX DISEASE IS PARTLY EXPLAINED BY DISORDERS OF GUT BRAIN INTERACTION

N. Koloski[1,2], M.P. Jones[3], A. Shah[2,4], G.J. Holtmann[2,4], N.J. Talley[1]
[1]University of Newcastle, Faculty of Health & Medicine, New Lambton Heights, Australia, [2]Princess Alexandra Hospital, Gastroenterology & Hepatology, Woolloongabba, Australia, [3]Macquarie University, Psychology, North Ryde, Australia, [4]University of Queensland, Faculty of Medicine, Brisbane, Australia

Contact E-Mail Address: nicholas.talley@newcastle.edu.au

Introduction: Disorders of brain gut interaction (DBGI) including irritable bowel syndrome (IBS) and functional dyspepsia (FD), and gastro-oesophageal reflux disease (GERD) including reflux oesophagitis (RE) and non-erosive reflux disease (NERD) are all prevalent in the general population. It is well established that many patients with GERD also report a DGBI, an overlap not due to chance [1]. Psychological comorbidity is known to be strongly associated with DGBI [2].

Individuals with GERD also report elevated rates of anxiety and depression. Those with overlapping DGBI and GERD have poorer physical and mental health outcomes [3-4].

Whether the psychological comorbidity seen in GERD is due to the overlap with DGBI or is a direct result of the condition itself remains unclear.

Aims & Methods: To investigate in a large sample of primary care patients whether the overlap of IBS and/or FD with RE and NERD explains the apparent link between GERD and anxiety/depression or whether the link is independent of DGBI presence. Data were collected from a retrospective study of 1,256,331 patients at general practices in the United Kingdom. A diagnosis of RE was defined as reflux with the presence of documented oesophagitis and NERD as reflux in the absence of oesophagitis. Psychological comorbidity was a diagnosis of anxiety or depression. Multiple logistic regression was used to assess the association of psychological comorbidity and a diagnosis of IBS and/or FD and RE and NERD, adjusting for the other disorder along with age at first contact and sex.

Results: Approximately 13.4% (95%CI 13.36,13.49) of patients reported a diagnosis of IBS, 20.7% (95%CI 20.67,20.81) FD, 4.2% (95%CI 4.19,4.27) RE and 5.1% (95%CI 5.09,5.17) NERD. Psychological comorbidity was significantly higher in patients with RE versus no RE (40.0% vs 24.4%, P<0.001), NERD versus no NERD (39.7% vs 24.2%, P<0.001) and IBS and/or FD (38.9% vs 18.6%, P<0.001). Psychological comorbidity was significantly associated with RE (OR=2.07; 95%CI 2.03,2.11, P<0.0001) and NERD (OR=2.06;95%-CI 2.02,2.09, P<0.0001).

However, this effect was reduced once IBS and/or FD was adjusted for in the models for both RE (OR=1.52; 95%CI 1.49,1.55, P<0.0001) and NERD (OR=1.53; 95%CI 1.50,1.55, P<0.0001) and persisted when age and sex were controlled for in the analysis for RE (OR=1.55, 95%CI 1.52,1.57, P<0.001) and NERD (OR=1.52; 95%CI 1.50,1.55, P<0.0001). With respect to IBS and/FD, psychological comorbidity was a significant independent predictor of an IBS and/or FD diagnosis (OR=2.79, 95%CI 2.77, 2.82, P<0.001). The likelihood of psychological comorbidity predicting an IBS and/or FD diagnosis remained more than twice as high even after controlling for RE (OR=2.72, 95%CI 2.70, 2.74, P<0.0001) and NERD (OR=2.71;95%-CI2.68,2.73, P<0.0001) and age and sex along with RE (OR=2.49; 95%CI 2.47,2.51, P<0.000) and NERD (OR=2.48; 95%CI 2.46,2.50, P<0.0001).

Conclusion: In a large sample of primary care patients, the association of IBS/FD and psychological comorbidity is independent of reflux oesophagitis (RE) and NERD, but the link between RE and NERD with anxiety/depression is partly explained by IBS/FD presence.

PROXIMAL MNBI AND ITS ASSOCIATION WITH INTERSTITIAL LUNG DISEASE (ILD) IN SYSTEMIC SCLEROSIS

M.B. Azam[1], P. Mohan[2]
[1]JIPMER, Puducherry, Medical Gastroenterology, Puducherry, India, [2]JIPMER, Medical Gastroenterology, Pondicherry, India

Contact E-Mail Address: bilalazampgi@gmail.com

Introduction: Gastrointestinal (GI) symptoms in Systemic sclerosis (SSc) cause significant morbidity. GERD is considered one of the causative factors of ILD via laryngopharyngeal reflux (LPR) in SSc. The objective of our study was to obtain pH-impedance metrics and observe the relationship between proximal MNBI (close association with LPR) and ILD, thus providing objective evidence for GERD-ILD crosstalk.

Aims & Methods: A cross-sectional study from July 2021 to May 2023 included consecutive SSc patients. Disease characteristics, demographic parameters, and upper and lower GI symptoms were collected using the UCLA 2 GIT questionnaire. pH-impedance testing, HRM measurements were recorded, and their association with GI symptoms was analysed.

Results: A total of 83 patients were analysed. 90% had upper and 21% had lower GI symptoms. The most common upper and lower GI symptom was heartburn (77.1%). Non-erosive disease was seen in 54% of patients, and

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

severe oesophagitis was seen in 14.4% of patients. True NERD was seen in 76%. Proximal and distal MNBI were low in 81.9% (cut-off 2292 ohms) and 88% of patients, respectively. ILD was seen in 72% of patients. Low proximal MNBI was significantly associated (*P=0.018*) with ILD. On logistic regression, low proximal MNBI was an independent predictor of ILD.

Conclusion: SSc patients had predominantly upper GI symptoms, with three-fourths having true NERD. A majority had a low proximal MNBI. Proximal MNBI was significantly associated with ILD.

Disclosure: Nothing to disclose.

MORE ACID, SAME SYMPTOMS? THE PARADOX OF HIATAL HERNIA SIZE

J. Nuñez[1], I.K. Araujo Acuña[1], A. Ezquerra-Durán[1], J. Siles[1], E. Barba Orozco[1]
[1]Universitat de Barcelona, Digestive Motility Unit, Hospital Clínic, Endoscopy Department, Barcelona, Spain

Contact E-Mail Address: Jorgeluisnp@gmail.com

Introduction: Hiatal hernia (HH) is frequently associated with gastroesophageal reflux disease (GERD) and esophageal motility disorders. However, its functional implications on esophageal physiology remain controversial. This study aimed to assess the clinical relevance of HH and esophagogastric junction (EGJ) morphology on esophageal symptoms and function.

Aims & Methods: We conducted a cross-sectional, observational study comparing esophageal function in patients with and without hiatal hernia in 92 patients referred for high-resolution manometry (HRM) and 24-hour pH monitoring. Fifty-five patients with HH were compared to 37 controls without HH. Patients were also classified by EGJ morphology (types I, II, III). Clinical evaluation included validated symptom questionnaires: GERD-Q, Eckardt, and BED-Q. Patients with prior esophagogastric surgery or EGJ outflow obstruction were excluded. Comparative analysis employed chi-square tests for categorical variables, and Student's t-test, ANOVA, or Kruskal-Wallis tests for continuous variables, depending on distribution.

Results: Of the 92 patients, 61 (66.3%) were female, with a mean age of 56 ± 14 years and BMI of 26.6 ± 7.5 kg/m^2. HH was present in 55 patients (59.8%). EGJ classification revealed 36 type I, 38 type II, and 15 type III configurations. HH was significantly associated with higher reflux symptom scores on the GERD-Q (p = 0.015) and increased esophageal acid exposure on pH monitoring (p = 0.015). Acid exposure time increased proportionally with HH size, although symptom severity (GERD-Q) did not correlate with hernia size. There were no significant differences in dysphagia scores (Eckardt or BED-Q) or total reflux episodes between groups. Similarly, EGJ morphology did not correlate with clinical, manometric, or pH-metric outcomes.

	No HH (n = 37)	HH (n = 55)	p-value
Clinical scores			
GERD-Q ≥ 8	20 (54%)	43 (78%)	0.015
Eckardt score ≥ 3	19 (51%)	39 (71%)	0.057
Manometric findings			
IRP ≥ 15 mmHg	6 (16%)	15 (27%)	0.210
Ineffective Esophageal Motility	2 (5%)	9 (16%)	0.110
pHmetry parameters			
AET > 6%	3 (8%)	16 (29%)	0.015
Total reflux episodes > 80	3 (8%)	10 (18%)	0.150

AET, acid exposure time; IRP, integrated relaxation pressure; HH, hiatal hernia; MNBI, mean nocturnal basal impedance.

Conclusion: In this study, HH was associated with greater acid exposure and more severe reflux symptoms, with acid burden increasing proportionally to hernia size.

However, symptom severity did not reflect hernia size, and EGJ type showed no significant functional impact. These findings underscore the pathophysiological relevance of HH in GERD, independent of EGJ subtype.

Introduction: The number of gastroesophageal reflux disease (GERD) patients that do not improve sufficiently by standard treatment is relatively high. Multichannel intraluminal impedance and pH monitoring (MII-pH) is the gold standard for diagnosing GERD, and it can be useful for selecting secondary treatment.

However, in some cases, secondary treatments are not remarkably effective even when selected based on the diagnosis.

On the other hand, the clinical value of the symptom–reflux association (SRA) obtained using MII-pH remains unknown.

Aims & Methods: The current study aimed to investigate the effect of SRA on the efficacy of secondary treatment in refractory true GERD.

This study included patients who underwent MII-pH monitoring for evaluating proton pump inhibitor (PPI)- or potassium-competitive acid blocker (P-CAB)-refractory GERD symptoms and who were diagnosed with abnormal acid reflux (acid exposure time > 6%).

Patients with a positive symptom index (SI) and symptom association probability (SAP) on the MII-pH monitoring were included in the SRA-positive group and the remaining ones in the SRA-negative group.

The differences in the subsequent treatment efficacy between the two groups were retrospectively analyzed. Treatment efficacy was evaluated using the Frequency Scale for the Symptoms of GERD (FSSG) questionnaire.

Results: Of the 192 patients with PPI-/PCAB-refractory GERD, 41 (21.4%) were diagnosed with abnormal acid reflux. Among them, 30 (7 in the SRA-positive group and 23 in the SRA-negative group) underwent symptom assessments before and after treatment. The SRA-positive group had a significantly greater symptom improvement after treatment compared with the SRA-negative group (FSSG score changes: −13.0 ± 6.5 vs −5.4 ± 8.2, p = 0.016).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: SRA evaluation is effective in predicting secondary treatment outcomes in patients with abnormal acid reflux.

BASELINE IMPEDANCE DURING HIGH-RESOLUTION ESOPHAGEAL MANOMETRY CORRELATES WITH MNBI AND PREDICTS GERD ACCORDING TO LYON 2.0 CRITERIA

S. Bosco[1], D.G. Cassella[1], M. Cilento[1], F. Borghi[1], G. Maconi[1], A. Dell'Era[1]
[1]Università degli Studi di Milano/Luigi Sacco University Hospital, Department of Biomedical and Clinical Sciences / Gastroenterology Unit, Milan, Italy

Contact E-Mail Address: sofia.bosco@unimi.it

Introduction: The current diagnosis of gastroesophageal reflux disease (GERD) is based on the criteria established by the Lyon Consensus 2.0[1], which defines conclusive criteria for or against GERD, along with adjunctive metrics to support or refute the diagnosis when primary criteria are borderline or inconclusive – among them, mean nocturnal baseline impedance (MNBI) measured via pH-impedance (pH-MII) monitoring. Some data suggest a correlation between baseline impedance measured during high-resolution esophageal impedance manometry (HRIM-BI) and MNBI[2,3]; however, none have applied the Lyon 2.0 criteria in this context.
Aims & Methods: We aimed to investigate whether HRIM-BI can distinguish GERD patients from non-GERD patients, providing an additional metric for diagnosis. All the patients who underwent both HRIM and pH-MII for GERD evaluation at ASST Fatebenefratelli Sacco (Sacco Hospital, Milan) were included. HRIM-BI was measured 3 centimeters above the upper margin of the lower esophageal sphincter over 15 seconds during the baseline period of HRIM while MNBI was measured over three 10-minute nocturnal intervals of pH-MII. Patients were categorized as having GERD according to Lyon 2.0 criteria (i.e., acid exposure time [AET] > 6% and > 80 reflux episodes). Data are reported as mean ± SD or number (percentage). Statistical analysis was performed using Pearson correlation to assess the relationship between HRIM-BI and MNBI values. Univariate and multivariate logistic regression analyses were used to evaluate the association between HRIM-BI and the presence of GERD, adjusting for potential confounders such as age. A p-value < 0.05 was considered statistically significant. Analyses were conducted using SPSS version 29.0.
Results: A total of 44 patients were enrolled, 37 of whom were off proton pump inhibitor (PPI) therapy for at least 15 days. Table 1 shows demographic and manometric characteristics, as well as HRIM-BI and MNBI values in patients with and without GERD.

	No GERD (n = 31)	GERD (n = 13)	p
Sex (female)	18 (56%)	5 (39%)	ns
Age (years)	47 ± 16	60 ± 15	0.024
EGJ-type			ns
1	24 (75%)	7 (54%)	
2	3 (9%)	1 (8%)	
3	5 (16%)	5 (39%)	
HRIM diagnosis			ns
Normal	24 (75%)	8 (61%)	
Ineffective esophageal motility	4 (13%)	4 (31%)	
Hypercontractile esophagus	3 (9%)	1 (8%)	
Distal esophageal spasm	1 (3%)	0	
HRIM-BI (kΩ)	2.148 ± 0.9	1.184 ± 0.8	0.004
MNBI (kΩ)	3.380 ± 1.2	2.098 ± 1.2	0.006

Table 1. Demographic and manometric characteristics.

A significant positive correlation was observed between HRIM-BI and MNBI (Pearson r = 0.653, $p < 0.001$). Univariate and multivariate regression analyses demonstrated that HRIM-BI was an independent predictor of GERD, even after adjustment for age (OR 0.33, 95% CI 0.14-0.81). Similar findings were observed in the subgroup of patients off PPI therapy, with a Pearson correlation coefficient of 0.525 ($p < 0.001$) and an OR for HRIM in the prediction of GERD of 0.21 (95% CI 0.06–0.78).
Conclusion: Baseline impedance measured during HRIM correlates positively with MNBI, a recognized adjunctive metric for GERD diagnosis. HRIM-BI is easily measurable, cost-effective, and less invasive – potentially obviating the need for pH-MII in selected cases – and may serve as a valuable tool for the diagnostic workup of GERD.

Contact E-Mail Address: minglun@ms18.hinet.net

Introduction: Erosive esophagitis (EE) is a clinically significant manifestation of gastroesophageal reflux disease (GERD), characterized by endoscopically visible mucosal breaks due to chronic gastric acid exposure. EE increases the risk of complications such as Barrett's esophagus and esophageal adenocarcinoma. Although esophagogastroduodenoscopy (EGD) remains the diagnostic gold standard, it is invasive and often requires sedation. Wired magnetic-assisted capsule endoscopy (MACE) is a novel, minimally invasive technique using a magnetically navigable capsule tethered via a soft wire, enabling upper gastrointestinal tract examination. However, its diagnostic value for EE remains underexplored.
Aims & Methods: From February 2021 to November 2024, 85 patients underwent wired MACE followed by EGD within six hours at National Taiwan University Hospital. Indications included acute upper gastrointestinal bleeding (n=30), esophageal varices screening (n=33), and pre-bariatric surgery assessment (n=22). Diagnostic accuracy of wired MACE for EE was assessed using EGD as the reference. Patient-reported discomfort (0–10 scale) and acceptance (0–5 scale) were compared between the two modalities.
Results: The mean age was 57.8 years (SD 15.2; range 23–83), with 62.4% male. EGD was performed without sedation in 92.9% of cases. Wired MACE showed a sensitivity of 86.4% (95% CI: 76.2–97.0%), specificity of 82.9% (95% CI: 71.4–94.0%), PPV of 84.4%, NPV of 85.0%, and overall accuracy of

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

84.7%. Agreement with EGD was substantial (κ = 0.69). MACE was associated with lower mean discomfort scores (1.9 vs. 5.5, p < 0.0001) and higher acceptance scores (4.2 vs. 2.3, p < 0.01), indicating superior tolerability.

Conclusion: Wired MACE demonstrated high diagnostic accuracy and substantial agreement with EGD in detecting EE. Its significantly lower discomfort and higher patient acceptance support its potential as a less invasive, better-tolerated diagnostic alternative to conventional endoscopy.

VALIDATION OF DOMINANT SYMPTOM INTENSITY AS A PATIENT REPORTED OUTCOME MEASURE IN THE EVALUATION OF ESOPHAGEAL SYMPTOMS SUSPICIOUS FOR GASTROESOPHAGEAL REFLUX

M. Schroeder[1], W. Chan[2], A. Richardson[2], N. Shah[1], M. Muftah[2], S. Muftah[2], CP. Gyawali[1]

Introduction: Gastroesophageal reflux disease (GERD) presents with typical and atypical symptoms of varying frequency and severity. We compared 5-point Likert scales assessing symptom burden to validated GERD questionnaires, and to outcome following reflux management.

Aims & Methods: We analyzed pooled data from patients undergoing pH-impedance testing for reflux symptoms from two tertiary care centers. All patients completed pre-procedure questionnaires assessing typical (heartburn, regurgitation, esophageal chest pain) and atypical symptoms (cough, belching, wheezing, dysphagia). Symptom severity and frequency were scored on 5-point Likert scales (0=not severe, infrequent; 4=extremely severe, multiple daily episodes); the product of severity and frequency for the highest scoring symptom constituted the dominant symptom intensity (DSI). Patients reported global symptom severity (GSS) on 100 mm visual analog scales (VAS) anchored by 0=no symptoms and 100=severe symptoms. Spearman correlation, general linear regression and receiver operating characteristic (ROC) analyses were performed to compare DSI with validated instruments including GSS, gastroesophageal reflux disease questionnaire (GERDQ) and reflux symptom index (RSI), and pH-impedance parameters per Lyon Consensus 2.0. In a subset, change in DSI after medical and surgical GERD management was compared against symptom burden (GSS) and satisfaction with therapy on 100 mm VAS.

Results: 808 patients (mean age 53.8±1.44 years, 65.2% female) were included, 499 (61.8%) with dominant typical symptoms. DSI significantly correlated with GSS (R=0.682), GERDQ (R=0.414), RSI (R=0.577), acid exposure time (AET) (R=0.175), total reflux episodes (R=0.194) and mean nocturnal baseline impedance (R=-0.157)(p<0.0001 for each comparison). DSI remained significantly correlated with GERDQ, GSS, RSI, AET and reflux episodes in both typical and atypical symptom subgroups. Mean DSI was higher with abnormal GERDQ, RSI, and conclusive GERD per Lyon Consensus (p<0.0001 each comparison). On ROC analyses, DSI (AUROC=0.60) was non-inferior to GSS, GERDQ, and RSI in predicting pathologic AET and total reflux episodes, and conclusive GERD. Percentage improvement in DSI after antireflux treatment significantly correlated overall with GSS change (R=0.632, p<0.0001) and treatment satisfaction (R=0.513, p<0.0001), and in both typical and atypical symptom subgroups.

On multivariable linear regression analyses, percentage change in DSI remained an independent predictor of GSS change (β=0.302, p<0.0001), and satisfaction with anti-reflux therapy (β=0.833, p=0.011). On ROC analyses, DSI change (AUROC=0.730) was non-inferior to GSS change in predicting satisfaction with therapy.

	Overall	Typical, n=499	Atypical, n=309
Age (years)	53.8±1.44	51.0±2.28	58.2±0.79*
Gender (female)	527 (65.2%)	356 (71.3%)	171 (56.3%)*
Body mass index (kg/m^2)	27.4±0.25	27.6±0.32	27.1±0.39
Mean baseline DSI	9.37±0.21	10.6±0.25	7.34±0.33*
Mean baseline GSS	50.1±1.15	60.4±1.28	33.7±1.82*
Mean AET (%)	3.29±0.18	3.63±0.23	2.67±0.26*
Number of reflux events	46.9±1.31	50.3±1.78	40.6±1.62*
MNBI (ohms)	1743±83	1667±106	1864±134
Conclusive GERD	177 (21.9%)	125 (25.1%)	52 (16.8%)

GSS: global symptom severity; AET: acid exposure time; MNBI: mean nocturnal baseline impedance; GERD: gastroesophageal reflux disease;
**p<0.05 compared to typical group*

Conclusion: DSI correlates with validated reflux questionnaires, discriminates abnormal from normal reflux burden, and DSI change reflects reflux treatment outcome and satisfaction. DSI is a useful addition to reflux symptom assessment.

DIAGNOSTIC PERFORMANCE OF PH-IMPEDANCE MONITORING IN ASSESSING DUODENOGASTROESOPHAGEAL REFLUX IN REVISIONAL BARIATRIC SURGERY: A COMPARISON WITH SPECTROPHOTOMETRIC BILIRUBIN CONCENTRATION MONITORING

A. Ezquerra-Durán[1], J. Nuñez[1], J. Siles[1], M. Lleixà Rioboo[1], I.K. Araujo Acuña[1], A. Ibarzabal[2], J. Osorio[2], E. Barba Orozco[1]

Contact E-Mail Address: ezquerra93@gmail.com

Introduction: Duodenogastroesophageal reflux (DGER), or bile reflux, has gained renewed interest due to the increasing number of bariatric surgeries (BS) performed. Anatomical modifications after BS may predispose patients to reflux. Revisional bariatric surgery (RBS) is indicated for inadequate weight loss or refractory symptoms.

Aims & Methods: This study aimed to evaluate the diagnostic accuracy of pH-impedance (pH-Z) monitoring in detecting DGER, using spectrophotometric bilirrubin (Bilitec2000) as the clinical reference standard. This prospective study included consecutive patients with a history of sleeve gastrectomy (SG) referred for preoperative evaluation prior to RBS between October 2023 and February 2025. All patients underwent simultaneous 24-hour pH-Z monitoring and Bilitec2000 monitoring while off proton pump inhibitors (PPIs).

Patients followed a standardized white semiliquid diet. Gastroesophageal reflux disease (GERD) was diagnosed according to the Lyon 2 Consensus. Pathological bile reflux was defined as a total bilirubin absorbance ≥ 0.14 for ≥ 1.9% of the monitoring time.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Fifty-three patients were enrolled [38 (71.7%) female, median age 48 years (IQR 43 – 55), median BMI 37.3 Kg/m^2 (IQR 34.1 – 41.3)]. Reason for RBS evaluation included
inadequate weight loss (39.6%) refractory reflux symptoms (32.1%), both (24.5%) and other indications (3.5%). GERD was diagnosed in 31 patients (58.5%) and 21 (39.6%) had pathological bile reflux. Erosive GERD according to Los Angeles classification was identified in 10 patients (19.6%). The area under the curve for non-acid reflux episodes detected by pH-z in diagnosing DGER was 0.61 (CI 95% 0.44 - 0.78), with an optimal cutoff of 85 episodes (sensitivity: 38.1% (CI 95% 20.8 – 59.1); specificity of 93.6% (CI95% 79.9 – 98.3). A moderate correlation was found between non-acid reflux and bile reflux (r = 0.38, p=0.005).
However, GERD was not associated with increased bile exposure time (1.4% (IQR 0.3 – 9.5) vs 1.3% (IQR 0.0 – 4.8), p=0.262), nor was this association observed in those with erosive esophagitis (1.9%, IQR 0.4 – 9.5 vs 1.4% IQR 0.0 – 5.8; p=0.914).
Conclusion: Approximate 40% of SG patients undergoing RBS evaluation had pathological bile reflux, which was not linked to GERD or erosive esophagitis. Despite a moderate correlation between bile and non-acid reflux episodes, pH-z monitoring failed to reliably detect DGER and should not be considered a substitute for spectrophotometric bilirrubin concentration monitoring.

EVALUATION OF MEAN DISTAL CONTRACTILE INTEGRAL (DCI) REFINES THE DIAGNOSIS OF IEM IN GERD MANOMETRIC ASSESSMENT

A. Barchi[1], E. Vespa[1], S. Bencardino[1], M.C. Fratto[1], S. Danese[1], S. Passaretti[1]
[1]IRCCS Ospedale San Raffaele, Department of Gastroenterology and Digestive Endoscopy, Milan, Italy

Contact E-Mail Address: barchi.alberto@hsr.it
Introduction: Ineffective esophageal motility (IEM) is a manometric diagnosis based on the rate of failed/ineffective swallows, consistently associated with Gastro-Esophageal Reflux Disease (GERD). Chicago 4.0 classification (CCv4.0)[1] does not include mean values of Distal Contractile Integral (DCI) in the diagnosis of IEM at High-Resolution Manometry (HRM).
Aims & Methods: The aim of this study was to explore DCI assessment as a HRM metric to refine IEM diagnosis.
Retrospective analysis of a prospectively collected database (October 2022-April 2024) was conducted on patients undergoing esophago-gastroduodenoscopy (EGD), HRM and 24-hour-pH-impedance study. Patients with indication for HRM other than GERD symptoms (achalasia, follow-up after previous foregut surgery including anti-reflux surgery or achalasia treatment), were excluded. GERD conclusive diagnosis was made according to Lyon 2.0 criteria[2].
Univariate logistic regression was computed to identify the optimal DCI cut-off for objective GERD. Multivariable logistic regression analysis were performed to identify relevant manometric predictors of objective reflux burden and to build predictive models. Models accuracy was tested through receiving operator characteristic (ROC) analysis. Sensitivity and specificity were calculated and compared between models.
Results: A total of 202 patients (M 94 [46.5%], mean age 48.5±18.6 years, BMI 22.1±7.6) were analyzed. Conclusive GERD was found in 49 patients (24.3%). IEM diagnosis was made in 40 patients (19.8%) while 162 patients (80.2%) had normal esophageal motility (NEM). ROC analysis identified DCI of 810.2 mmHg.cm.s (AUC 0.70, p<0.001) as the best cut-off in predicting objective reflux (AET>6%). The group with NEM and DCI<810.2 did not show differences with the IEM group (p>0.05). At multivariable regression analysis, IEM (CCv4.0) and Esophagogastric Junction- Contractile Integral (EGJ-CI) lost significance in predicting objective GERD (p=0.76 and p=0.91 respectively), while higher mean DCI (OR 0.41, p<0.004) and type III EGJ (OR 4.4, p<0.002) and higher mean basal EGJ pressure (MBEP) (OR 0.30, p<0.007) did remain significantly associated. At ROC analysis mean DCI combined with MBEP and type-III EGJ showed an AUC of 80.6% (p<0.001) in predicting objective GERD. We compared a model comprising MBEP, type III EGJ and IEM (CCv4.0) (Model A) vs a model comprising MBEP, type III EGJ and IEM (CCv4.0)+DCI >810.2 mmHg.cm.s (Model B). Model B was superior to Model A, showing an AUC of 80.0 vs an AUC of 78.3 (p<0.001) (Table 1.).

	B	S.E.	p value*	ORs	95% C.I. for ORs	
Model A					**Lower**	**Upper**
IEM***	0.88	0.41	0.032	2.43	1.08	5.49
Type-III EGJ	1.42	0.46	0.002	4.16	1.68	10.26
MBEP***	-1.23	0.34	0.001	0.29	0.15	0.57
Model B						
IEM**+DCI<810.2****	1.08	0.37	0.004	2.96	1.42	6.19
Type-III EGJ	1.53	0.47	0.003	4.12	1.63	10.42
MBEP**	-1.24	0.35	0.001	0.26	0.13	0.52

Table 1. Multivariable logistic regression of model A and model B in predicting AET>6%
Bold entries indicate statistical significance at 0.01 level (2-tailed)
**All independent variables were controlled for inter-variables correlation by coefficients co-dependency analysis via Wald test and inter-variables logistic regression. No co-dependency was observed (p>0.05).*
***These variables were imputed as natural logarithm to adjust variance and compute ORs*
**** According to Chicago 4.0 classification (CCv4.0)*
*****Cut-off identified at ROC analysis*
C.I. Confidence Intervals; DCI Distal Contractile Integral; EGJ Esophago-Gastric Junction; IEM Ineffective Esophageal Motility; MBEP Mean Basal LES Pressure; ORs Odds Ratios; ROC Receiving Operator Characteristic; S.E. Standard Error

Conclusion: Evaluation of mean DCI complements IEM diagnosis and esophageal contractility assessment, with a cut-off of 810 mmHg.cm.s to optimize IEM profiling of GERD.

ANTI-REFLUX MUCOSECTOMY WITH BANDING (ARMS-B) FOR GORD: A PILOT STUDY

C. Judge[1], M. Patel[1], S. Gulati[1], S. Chatu[1], A. Haji[1], B. Hayee[1]
[1]King's College Hospital, Endoscopy, London, United Kingdom

Contact E-Mail Address: ciaranjudge@gmail.com

Introduction: Gastroesophageal reflux disease (GORD) common, impacting on healthcare utilisation and quality of life (QoL). Medical therapies for GORD are frequently unsuccessful, while surgical approaches confer significant morbidity risk. Anti-reflux mucosectomy (ARMS) techniques achieve scar restoration of the gastro-oesophageal junction mucosal flap valve with relatively low risk, but are technically demanding.

We studied a variant of the technique using a standard endoscopic banding kit (ARMS-B), with bands applied in a crescentic fashion to the cardia in retroflexion and left in situ to induce scarring. We evaluated safety and efficacy, including objective assessment.

Aims & Methods: This was a single-centre, prospective cohort study (May 2022 to May 2024). Patients with symptomatic GORD, inadequately controlled by medical therapy, hiatus hernia ≤2cm and Hill grade ≤2, confirmed on Bravo ambulatory pH monitoring were eligible. ARMS-B was performed by a single expert endoscopist. A repeat gastroscopy with Bravo insertion was completed at least 3 months post-ARMS-B, off PPI.

The primary outcomes included the change in acid exposure time (AET) and Gastroesophageal Reflux Disease Health-Related Quality of Life (GORD-HQRL) scores. Secondary outcomes included the cessation or reduction in PPI usage, and the incidence of complications.

Results: Thirteen patients were included in the final analysis (69.2% female; mean age 51.3 years, mean BMI 22.9). Median follow-up duration was 6.3 months (3.5 – 24). Post treatment, AET normalised in 60% (9.9% vs 5.2%, 95% CI [1.01 – 8.3], p=0.02) and GORD-HQRL scores normalised in 54.5% (34.7 vs 22.3, 95% CI [1.7 – 23], p = 0.03). 46.2% of patients ceased or reduced the dose of their PPI at 3 months. No complications were reported in early or late follow-up.

Variable	Pre-ARMS-B %(SD)	Post-ARMS-B %(SD)	P value
Acid exposure time	9.9% (3.4%)	5.2% (4.7%)	0.02
DeMeester score	43.7 (11.9)	25.3 (16.5)	0.08
GORD-HQRL			
Total	34.7 (16.3)	22.3 (18.4)	0.03
Heartburn	18.5 (9.6)	11.2 (11.0)	0.03
Regurgitation	15.9 (6.1)	9.9 (8.6)	0.01
Satisfied (Yes)	0%	42.6%	0.42
Active PPI Use	100%	53.8%	0.71
Reduced PPI dose	-	7.7%	
Ceased PPI	-	38.5%	

Conclusion: This pilot study demonstrates that ARMS-B is both safe and effective for the treatment of GORD. The procedure led to significant reductions in AET, GORD-HRQL, symptom control, and PPI usage. Further studies with larger cohorts and longer follow-up periods are warranted to confirm these findings.

Disclosure: Nothing to disclose.

PP0061

THE IMPACT OF THE TIF PROCEDURE ON ESOPHAGEAL MANOMETRY RESULTS: A PROSPECTIVE CONTROLLED STUDY

B. Almasri[1], M.S. Alkhatry[1]
[1]IBHOH, Dept. of Gastroenterology, Ras Al-Khiemah, United Arab Emirates

Contact E-Mail Address: bashar.almasri@ehs.gov.ae

Introduction: This study aims to evaluate the impact of Transoral Incisionless Fundoplication (TIF) on esophageal motility and reflux patterns using high-resolution esophageal manometry (HRM) and 24-hour pH-impedance monitoring. By comparing pre- and post-procedure findings in GERD patients, we seek to understand the functional changes induced by TIF and their correlation with symptom relief, providing insights into its role as a therapeutic option for GERD.

Aims & Methods: A prospective controlled study was conducted, enrolling 40 GERD patients, with 20 undergoing TIF and 20 receiving standard medical therapy as a control group. HRM and 24-hour pH-impedance monitoring was performed at baseline and at 3, 6, and 12 months post-procedure to assess:

1. LES function: resting pressure and relaxation.
2. Esophageal body motility: peristaltic amplitude, contractile front velocity (CFV), and prevalence of ineffective esophageal motility (IEM).
3. Reflux patterns: total acid and non-acid reflux episodes, esophageal acid exposure time, and symptom-reflux correlation.

Symptom assessment was conducted using validated GERD-specific questionnaires (e.g., GERD-HRQL). Statistical analysis included paired t-tests for within-group comparisons and ANOVA for between-group comparisons, with a significance threshold of $p < 0.05$.

Results: Preliminary findings indicate that TIF improves LES function, esophageal motility, and reflux parameters compared to baseline. Key observations include:

- Increased LES resting pressure and improved peristaltic function.
- Reduced prevalence of ineffective esophageal motility (IEM).
- Decreased total acid and non-acid reflux episodes and esophageal acid exposure time.

These changes were associated with significant symptom improvement, as reflected in GERD-HRQL scores. The control group showed no significant changes in motility or reflux patterns. Extended follow-up (up to 12 months) demonstrated sustained improvements in the TIF group.

Conclusion: By incorporating pre- and post-procedure manometry and pH-impedance monitoring data, extended follow-up periods, and symptom correlation, this study will enhance the understanding of TIF's impact on esophageal motility and reflux patterns. Standardizing the evaluation of these changes post-TIF can guide clinical decision-making, ensuring optimal patient selection and improving GERD management strategies.

Disclosure: No conflict of interest.

BEYOND ACID: INTERIM RESULTS FROM A RANDOMIZED TRIAL OF STRETTA PROCEDURE VS. CONSERVATIVE MANAGEMENT IN GERD

K. Kostalova[1,2], P. Urbanek[1], S. Suchanek[1]
[1]Charles University, 1st Faculty of Medicine and Military University Hospital, Department of Internal Medicine, Prague, Czech Republic, [2]University of Defense, Military Faculty of Medicine, Department of Military Internal Medicine, Hradec Kralove, Czech Republic

Contact E-Mail Address: katerina.kostalova@uvn.cz

Introduction: To evaluate interim outcomes of a randomized controlled trial comparing Stretta radiofrequency (RF) therapy to conservative management in patients with gastroesophageal reflux disease (GERD), focusing on symptom control, daily PPI reduction, and acid exposure.

The study further explores the hypothesis that Stretta may act via neuromodulation rather than mechanical augmentation of the lower esophageal sphincter (LES).

Aims & Methods: This ongoing prospective trial includes patients with non-erosive reflux disease (NERD) or grade A esophagitis (Los Angeles classification), no or minimal hiatal hernia (≤2 cm), and objectively confirmed pathological reflux by impedance-pH monitoring. Patients were randomized to Stretta (n = 20) or conservative therapy (n = 21). Follow-up was scheduled at 3, 6, and 12 months. Only patients with complete paired data were analyzed at each time point.

Primary outcomes included symptom scores (GERD-HRQL and Reflux Symptom Index [RSI]) and daily PPI use. Acid exposure time (AET) was a secondary endpoint.

Results: In the Stretta group, 16, 12, and 9 patients completed 3-, 6-, and 12-month follow-up, respectively. In the conservative group, corresponding numbers were 18, 14, and 12. At 12 months, Stretta significantly improved GERD-HRQL (30.7 to 13.2; $p = 0.0118$), RSI (20.8 to 10.2; $p = 0.0018$), and reduced mean daily PPI use from 35.6 mg to 0 mg ($p = 0.0070$). AET did not significantly change (7.8 % to 6.4 %; $p = 0.4033$). In contrast, the conservative group showed no improvement in GERD-HRQL or PPI use, and RSI significantly worsened (14.1 to 20.1; $p = 0.0101$).

Conclusion: These interim findings suggest that Stretta therapy provides meaningful symptom relief and reduces the need for daily PPI use in selected GERD patients, even in the absence of acid normalization. This supports a neuromodulatory mechanism rather than mechanical LES augmentation. It is plausible that some GERD patients in this study had overlapping esophageal hypersensitivity, which may explain their positive clinical response. Stretta may thus have therapeutic relevance beyond current indications, particularly in patients with a hypersensitivity phenotype.

EFFECTIVENESS AND SAFETY OF VONOPRAZAN IN CHINESE PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE: POST HOC ANALYSIS OF A MULTICENTRE, PROSPECTIVE, REAL-WORLD STUDY

Y. Xiao[1], X. Li[2], Y. Dai[3], K. Liang[4], L. Xie[4], M. Chen[5]
[1]The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China, Department of Gastroenterology and Hepatology, Guangzhou, China, [2]Henan Provincial People's Hospital, Zhengzhou, China, [3]The Fourth Affiliated Hospital Zhejiang University School of Medicine, Department of Gastroenterology, Yiwu, China, [4]Takeda Pharmaceutical Company, Shanghai, China, [5]The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China

Contact E-Mail Address: li.xie@takeda.com

Introduction: Symptom relief is the key treatment goal of gastroesophageal reflux disease (GERD). Vonoprazan, a potassium-competitive acid blocker approved in China, was superior in potency and duration of action versus conventional proton pump inhibitors in preclinical studies.[1] However, there are limited real-world data on the effectiveness and safety of vonoprazan in adult Chinese patients.

Aims & Methods: VIEW (NCT04501627) was a multicentre, single-arm, prospective, observational, real-world study conducted in China. Patients received 20 mg vonoprazan, orally, once daily for 4 weeks (8 weeks for insufficient healing), followed by a safety assessment of 2 weeks. In this post hoc subgroup analysis of patients with GERD, effectiveness was assessed, including changes in GERD-typical symptoms, GERD questionnaire (GerdQ) scores and complete relief in patients' symptom diary.

Results: Among the 2214 patients included in the effectiveness analysis population of the GERD group, 86.7% were aged <65 years and 60.8% were male. Among evaluable patients with all-day heartburn (n=672) and all-day regurgitation (n=728) at baseline, 49.7% (95% confidence interval [CI], 45.9-53.6) and 40.8% (95% CI, 37.2-44.5), respectively, achieved complete symptom relief during the first 2 weeks of treatment. The reduction from baseline in all-day heartburn and regurgitation was significant ($P<0.001$) on days 1 through 14 of treatment.

Among evaluable patients with night-time heartburn (n=746) and night-time regurgitation (n=816) at baseline, complete symptom relief was achieved in 59.9% (95% CI, 56.3-63.5) and 52.8% (95% CI, 49.3-56.3) of patients, respectively, during the first 2 weeks of treatment. The reduction from baseline in night-time heartburn and regurgitation was significant ($P<0.001$) on days 1 through 14 of treatment. The mean (standard deviation) overall GerdQ score improvement from baseline to week 4 was -1.6 (2.8).

Symptom frequency score	Evaluable patients, n	Value[a]
Mean (SD) change in heartburn from BL to W4	1811	-0.8 (1.25)
95% CI for Mean	-	(-0.88, -0.76)
Mean (SD) change in regurgitation from BL to W4	1809	-0.8 (1.22)
95% CI for Mean	-	(-0.83, -0.72)
Mean (SD) change in sleep difficulty due to heartburn/ regurgitation from BL to W4	1809	-0.6 (1.08)
95% CI for Mean	-	(-0.63, -0.53)
Mean (SD) change in the need for additional medicationb for heartburn/regurgitation from BL to W4	1808	-0.4 (1.02)
95% CI for Mean	-	(-0.40, -0.30)

BL, baseline; CI, confidence interval; SD, standard deviation; W, week.
[a]Negative values indicate improvement.
[b]Examples: TUMS, Rolaids, Maalox.

Table: Improvement in symptom frequency score and additional medication usage from baseline to week 4 following vonoprazan treatment.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The percentage of patients without GERD-typical symptoms increased by 33.5% (95% CI, 30.7-36.3) from baseline to week 4. Symptoms of heartburn, regurgitation and sleep difficulties due to heartburn/regurgitation, and the need for additional medication generally reduced at week 4 compared with that at baseline (Table).

Adverse events (AEs; any grade) were reported in 17.4% of patients in the safety population (N=2307), with the most common (>5%) being gastrointestinal disorders (8.3%). Overall, 0.9% of patients had ≥1 AE leading to study discontinuation. No AEs led to death.

Conclusion: This real-world subgroup analysis of Chinese patients with GERD demonstrated that vonoprazan effectively relieved symptoms, improved GerdQ scores and reduced the need for additional medications while maintaining an acceptable safety profile.

Contact E-Mail Address: li.xie@takeda.com

Introduction: The primary treatment goals of gastroesophageal reflux disease (GERD) include resolving symptoms, preventing complications and symptom relapses, and healing erosive oesophagitis.[1,2]

Heartburn and regurgitation are frequent and typical symptoms of GERD. Vonoprazan, a potassium-competitive acid blocker, is approved in China for the treatment of reflux oesophagitis.[3,4]

However, there is a paucity of real-world data assessing the relief of typical daily symptoms achieved with vonoprazan in adult Chinese patients.

Aims & Methods: VIEW (NCT04501627) was a multicentre, single-arm, prospective, observational, real-world study conducted in China. Patients received 20 mg vonoprazan, orally, once daily for 4 weeks (8 weeks for insufficient healing). This post hoc subgroup analysis conducted in enrolled patients with GERD assessed changes in symptom scores for all-day or night-time heartburn and/or regurgitation during the first 14 days of treatment.

A mixed-effects model for repeated measures assessed statistical differences in symptom scores from baseline for each day; least-squares mean (LSM) and its 95% confidence interval are reported (negative values indicate improvement).

Results: Among the 2214 patients included in the effectiveness analysis population of the GERD group, 86.7% were aged <65 years[A.G.1] and 60.8% were male. The LSM change in symptom scores from baseline demonstrated a significant improvement from day 1 of treatment in all-day heartburn and/or regurgitation, daytime heartburn or regurgitation, and night-time heartburn or regurgitation (Table). Significant improvement continued to be observed on day 14 and throughout all previous days of treatment.

Conclusion: Vonoprazan provided rapid (from day 1), significant and durable symptom relief in patients with GERD.

Symptom score	Parameter	Day 1	Day 3	Day 7	Day 10	Day 14
All-day heartburn and regurgitation	LSM change from baseline (SE)/n[b]	-0.756 (0.0335) [c]/518	-0.986 (0.0311) [c]/516	-1.207 (0.0279) [c]/512	-1.327 (0.0247) [c]/504	-1.407 (0.0233) [c]/493
All-day heartburn	LSM change from baseline (SE)/n[b]	-0.78 (0.032)[c]/ 679	-1.02 (0.030)[c]/ 675	-1.24 (0.026)[c]/ 671	-1.35 (0.023)[c]/ 661	-1.41 (0.023)[c]/ 646

UNDERSTANDING THE DRIVERS BEHIND WHAT MATTERS WHEN TREATING GASTRO-OESOPHAGEAL REFLUX DISEASE – AN INTERIM ANALYSIS OF A DISCRETE-CHOICE EXPERIMENT

K. Plehhova[1], E. Horvath[2], S. Leigh[3]
[1]Reckitt Benckiser Healthcare Ltd, Global Medical Affairs, Hull, United Kingdom, [2]Reckitt Benckiser, Global Medical Affairs, Slough, United Kingdom, [3]Visfo, Lindley, Huddersfield, United Kingdom

Introduction: Proton pump inhibitors (PPIs) are extensively prescribed due to the widespread diagnosis of gastro-oesophageal disease (GORD). [1,2] Overutilisation of PPIs is common, and growing concerns over adverse events, inappropriate prescribing and unnecessary costs [3,4] are driving exploration into the implementation of holistic management, including deprescription strategies[1].

Aims & Methods: We aimed to quantify healthcare professionals' (HCPs) preferences on the management of GORD in the UK, and identify attributes perceived as enhancing or detracting from quality of care.

Attributes were derived from qualitative data gathered through 3 focus groups with gastroenterologists, pharmacists and general practitioners (GPs), and interviews with 4 GORD patients.

A discrete-choice experiment (DCE) was developed and administered via online survey (Jan–Apr 2025) to 38 HCPs. Respondents chose between paired hypothetical GORD management scenarios, varying by symptom severity, appointment frequency, treatment approach, information delivery method, and cost. Preferences were modelled using a multinomial conditional logit with effects coding. Marginal rates of substitution (MRS) were calculated to quantify trade-offs.

Results: 74% of respondents were pharmacists (n=28) and 26% GPs (n=10). All had managed GORD patients in the past year, and 81% expressed concern over long-term PPI use.

A holistic approach combining PPIs with lifestyle modification was strongly preferred over PPI monotherapy (β=0.4244, p<0.001), representing the most influential driver of care quality. Lifestyle modification alone was also favoured over PPI monotherapy (β=0.1125), though this did not reach statistical significance (p=0.127).

Respondents expressed significant aversion to providing information via pamphlets compared to GP-led counselling (β=–0.1836, p=0.046), while no preference emerged between pharmacist- and GP-led counselling (β=0.0512, p=0.573). Neither appointment burden nor out-of-pocket costs significantly influenced decision-making.

Symptom severity was a notable driver: HCPs selected scenarios involving moderate symptoms over mild (β=0.2353, p=0.005), indicating increased urgency and prioritisation for moderate disease.

Analysis of MRS between attributes suggested that HCPs are willing to accept 4.4 additional appointments to manage moderate symptoms, rather than mild, and nearly 8 additional appointments to deliver combined holistic lifestyle and pharmacological therapy. This highlights a willingness to absorb appointment-related resource demands in favour of more comprehensive, effective care.

Conclusion: Concerns around long-term PPI use support a shift toward active GORD management and PPI deprescribing, with structured follow-up to monitor treatment response.

This interim analysis highlights a clear preference among HCPs for multimodal GORD management, particularly combining lifestyle modification with pharmacological treatment, and reinforces the importance of interactive clinician[BA1] -led patient education, which can promote compliance and improve outcomes. The willingness to accept 4.4 additional appointments reflects the value placed on ongoing monitoring and personalised care. However, this raises the question on the impact this may have on health services, and whether the integration of self-care into multimodal approaches developed with HCPs could be an alternative solution to be investigated. These findings highlight the need for a system-wide shift toward guideline-informed, stepped-care models.

A further analysis on patient population preferences is under review.

OPTIMISED BIOPHARMACEUTICAL AND PHARMACOKINETIC PROPERTIES OF A LINAPRAZAN GLURATE TABLET FORMULATION TO BE USED IN PHASE 3

G. Huledal[1], K. Larsson[1], B. Erlandsson[1], K. Andersson[1], K. Katkits Nilsson[1], E. Yektaei[1], M. Fležar[2,3], P. Unge[1]

Contact E-Mail Address: kajsa.larsson@cinclusphar ma.com

Introduction: Linaprazan glurate (LG), a prodrug to linaprazan, is a next generation PCAB with a rapid and extensive effect on gastric pH [1] and up to 93% 4-week healing rate in severe erosive esophagitis in phase 2 study [2].

LG is formulated as tablets, initially with LG as a base. To improve the biopharmaceutical and pharmacokinetic (PK) properties, a new tablet containing LG as HCl salt has been developed. PK of LG HCl tablet was evaluated in two Phase 1 studies.

Aims & Methods: The PK of two tablet formulations were compared in a single-dose, 100 mg LG, 3-way crossover study. Additionally, the food effect on the PK of the LG HCl tablet was assessed. Repeated-dose PK for the LG HCl tablet was evaluated in a randomized, parallel-group study during 14 days of once-daily (25 mg, 50 mg, and 75 mg QD) or twice-daily (25 mg, 50 mg, and 75 mg BID) dosing. Plasma samples were collected to measure LG and linaprazan concentrations and to derive PK parameters.

Results: Healthy subjects were enrolled, with 54 and 72 evaluable for PK analysis in each study, respectively. The exposure to LG was approximately 10 times lower than that of linaprazan following both single and repeated dosing.

The bioavailability of linaprazan from LG HCl salt tablet was approximately 2-fold higher than for LG base tablet as reflected in the geometric LS mean ratio (90% CI) for linaprazan AUC_{inf}: 2.00 (1.83 2.16); C_{max}: 2.32 (2.09-2.57) with a slightly later median t_{max} for the LG HCl tablet (3h vs 2h).

A meal reduced mean AUC_{inf} by 24%, (geometric LS mean ratio (90% CI): 0.76 (0.70-0.82) and mean C_{max} by 55%, (geometric LS mean ratio (90% CI):

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

0.45 (0.41-0.50), for LG HCl tablet vs fasting intake with a later median t_{max} for linaprazan after fed conditions (6h vs 3h).

Linaprazan C_{max} and AUC increased approximately in proportion to dose, steady state was reached within 5 days, with no accumulation upon 14 days repeated QD or BID dosing of LG HCl tablet. No apparent deviation from time independent PK was seen even if exposure was slightly lower (approximately 20%) than expected for the 75 mg QD and 75 mg BID dosing groups on Day 14. Mean C_{max} and AUC were slightly lower (10-20%) for the QD vs first BID dose, and slightly lower (15-30%) for the second daily vs the first daily BID dose, most likely due to different conditions with respect to food intake (Table 1).

Dose Groups	C_{max} (nmol/L) Mean (SD) Day 1	C_{max} (nmol/L) Mean (SD) Day 14	t_{max} (h) Median (min-max) Day 1	t_{max} (h) Median (min-max) Day 14	AUC (nmol/L*h) Mean (SD) Day 1	AUC (nmol/L*h) [1)] Mean (SD) Day 14
25 mg QD	527.25 (184.929)	404.75 (174.068)	5.00 (2.00-14.00)	4.00 (1.25-12.0)	5089 (1607.1)	4640 (1657.4)
50 mg QD	1066.23 (209.973)	1002.00 (538.574)	3.00 (1.00-6.00)	3.03 (1.23-6.00)	9342 (2462.3)	8626 (3571.9)
75 mg QD	1594.42 (585.525)	1044.92 (478.102)	3.50 (1.25-12.00)	3.99 (1.25-13.97)	14 614 (4601.9)	11 697 (4053.3)
25 mg BID Dose 1	658.42 (212.101)	782.92 (263.988)	1.75 (1.25-6.00)	1.50 (1.00-8.03)	4081 (1351.9)	8898 (2247.9)
25 mg BID Dose 2	520.92 (126.378)	520.83 (144.568)	4.00 (2.00-2.47)	4.99 (1.00-6.00)	3947 (939.8)	
50 mg BID Dose 1	1380.18 (303.283)	1148.64 (415.251)	1.50 (1.25-4.00)	1.50 (1.00-4.00)	8084 (1400.5)	13852 (3174.1)
50 mg BID Dose 2	997.09 (363.660)	842.36 (270.396)	2.00 (1.25-11.92)	4.00 (1.00-8.00)	7107 (1917.8)	
75 mg BID Dose 1	1942.00 (667.280)	1740.60 (468.197)	1.75 (0.98-6.00)	1.25 (0.85-4.00)	11814 (3181.8)	21366 (4323.8)
75 mg BID Dose 2	1283.90 (435.399)	1285.50 (443.703)	4.00 (1.50-8.08)	1.78 (0.98-8.02)	9532 (2118.1)	

Table 1: Descriptive Statistics of linaprazan pharmacokinetic parameters

1. AUC Day 1: AUCinf for QD and AUC0-12h and AUC12-24h for BID, AUC Day 14: AUC0-24h for QD and BID

QD: All doses were taken in the evening in a non-fasted state and BID: 1st dose was taken fasted in the morning and the 2nd daily dose in the evening in a non-fasted state.

Conclusion: An optimized linaprazan glurate HCl tablet formulation has been developed for Phase 3, with a later t_{max} and an approximately 2-fold higher bioavailability than the initial tablet and only a minor impact of food intake on linaprazan AUC_{inf}. In addition, the linaprazan glurate HCl tablet provided dose-proportional increase in linaprazan plasma exposure as reflected by AUC and C_{max}.

REBOUND ACID HYPERSECRETION FOLLOWING PROTON PUMP INHIBITOR DISCONTINUATION – A RAPID REVIEW OF MECHANISMS, PREVALENCE, AND PATIENT IMPACT

E. Horvath[1], F. de Grey-Warter[2], K. Plehhova[2]

[1]Reckitt Benckiser, Global Medical Affairs, Slough, United Kingdom, [2]Reckitt Benckiser Healthcare Ltd, Global Medical Affairs, Hull, United Kingdom

Contact E-Mail Address: lizzie.horvath@reckitt.com

Introduction: In recent years, there has been increased focus on appropriate proton pump inhibitor (PPI) prescribing due to the growing awareness of the prevalence of long-term PPI use globally.1 Rebound acid hypersecretion (RAHS) has been described as potentially contributing to PPI overuse and treatment dependence1 . RAHS is a physiological phenomenon observed following PPI discontinuation after a minimum of 4 – 8-week use. However – despite being first described in 1996 – its clinical relevance, underlying mechanisms, prevalence, and impact on patient outcomes are still not completely understood.

Aims & Methods: The purpose of this rapid review is to assess the current evidence published on RAHS, the potential mechanisms behind the phenomenon, its prevalence and clinical significance in patients discontinuing PPI therapy.

A rapid review of peer-reviewed literature was conducted through Embase and PubMed. Systematic reviews and clinical studies were included if they examined RAHS, reported prevalence, or evaluated patient-reported symptoms post-PPI withdrawal. Key findings were extracted and summarised across three domains: physiological mechanisms, prevalence and severity, and patient impact.

Results: A total of 272 articles – published between 2005 and 2024 – were retrieved, with 7 articles meeting the inclusion criteria for final review. Five of these were clinical studies, whilst the remaining 2 were systematic literature reviews. All, except 1, of the studies included were conducted more than 10 years ago – 3 randomised controlled trials, 1 cross sectional study, and 1 study looked at pre-surgery patients without randomisation. The studies were heterogeneous in design, the study populations varied broadly between 7 and 150 participants, and the prevalence data appeared to be inconsistent.

Studies show a physiological basis for RAHS, including upregulation of gastrin and enterochromaffin-like cell hyperplasia, during PPI therapy, leading to transient acid hypersecretion upon PPI withdrawal[2,3,4,5].

Symptoms resembling dyspepsia or gastro-oesophageal reflux disease (GORD) recurrence were commonly reported in both healthy volunteers and patients[2,3,6,7].

RAHS was transient in most cases[2,3,4] but may drive long-term PPI use due to misinterpretation of symptoms as disease recurrence. However, a small number of studies reviewed in the two systematic literature review papers challenged the existence of clinically meaningful RAHS, particularly after short-term or low-dose therapy[6,8].

Conclusion: There is growing evidence that RAHS is a physiologically plausible and clinically relevant phenomenon in long-term PPI users. It is suggested that RAHS may contribute to symptom recurrence and therapy dependence, resulting in the continuation of unnecessary PPI therapy. With the increasing efforts on PPI deprescribing due to growing concerns over long-term use when there's a lack of appropriate indication, clinicians need to be aware of the potential for RAHS to act as a roadblock for patients.

However, despite discussion about RAHS ongoing for almost 30 years, there is still limited understanding about its impact on patients and the potential contribution to the challenges of PPI deprescription. Most importantly, there's limited understanding of appropriate management

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

solutions to overcome these challenges. In order to improve education for both clinicians and patients, further research is required on appropriate management solutions for RAHS and to aid PPI deprescribing efforts.

EPIGENETIC BIOMARKERS AND THE PROGRESSION OF BARRETT'S OESOPHAGUS TO OESOPHAGEAL ADENOCARCINOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

D. Johnston[1], Z. Kirkwood[1], A.J. McKnight[1], H. Coleman[1], R. Turkington[1]
[1]Queen's University Belfast, Centre for Public Health, Belfast, United Kingdom

Contact E-Mail Address: davidnjohnston1@gmail.com

Introduction: Oesophageal adenocarcinoma (OAC) is often diagnosed at a late stage and has a poor survival rate. Barrett's oesophagus (BO) can progress to OAC in a stepwise fashion, although the annual risk of progression is low, at 0.22% per year.[1]

Currently, patients with BO undergo regular endoscopic surveillance with biopsies, with the degree of dysplasia guiding further management. This is invasive and expensive, and there is interobserver variability between pathologists in the assessment of dysplasia. There is an urgent need for new approaches to risk-stratify patients with BO. Epigenetic changes can occur early in the neoplastic progression of BO, making them attractive for use as potential risk-stratification biomarkers.

Aims & Methods: We aimed to carry out a systematic review to investigate whether epigenetic biomarkers can predict the progression of patients with BO to high-grade dysplasia (HGD) or OAC. The review was registered in PROSPERO (CRD42024509643). To be eligible for inclusion, studies must have examined patients with BO that was non-dysplastic (NDBO), had low-grade dysplasia (LGD), or was indefinite for dysplasia (IND) at baseline. Eligible studies assessed any type of epigenetic biomarker of any source, including DNA methylation, histone modification, and non-coding RNA. Non-epigenetic biomarkers were excluded. Studies must have compared epigenetic biomarker levels between patients who progressed to HGD/OAC and those who did not. Included studies must have assessed progression of NDBO/LGD/IND to HGD/OAC.

Ovid MEDLINE, EMBASE, and Web of Science Core Collection were searched from inception to 27th January 2025. The risk of bias of individual studies was assessed using the Newcastle-Ottawa Scale. A narrative synthesis of all included studies was performed. A random-effects meta-analysis was also conducted. Cochran's Q test was used to test for heterogeneity, and the I^2 statistic was used to quantify its extent. A sensitivity analysis was performed to assess the robustness of the results.

Results: 1633 abstracts were screened, 143 were taken forward to full-text assessment, and 12 studies were included in the final review. 10 assessed DNA methylation and 2 assessed microRNAs. There was substantial diversity across studies in the specific biomarkers assessed, definitions of progression, and statistical approaches used. Studies suggested that methylation levels of genes such as p16, RUNX3, HPP1, APC and OR3A4 could predict progression to HGD/OAC. Panels assessing methylation of multiple genes, and prediction models incorporating gene methylation data, also predicted progression. Additionally, certain microRNAs, such as miR-192, 194, 196a and 196b, were predictive of progression.

A meta-analysis of 4 studies assessing p16 methylation was performed, showing that p16 methylation was associated with an increased risk of progression of BO to HGD/OAC (pooled odds ratio (OR) 2.11, 95% confidence interval (CI) 1.19 – 3.76, p = 0.01). There was evidence of moderate heterogeneity (I^2 = 46.2%; Q = 5.57, p = 0.13). A sensitivity analysis was performed, excluding 1 study that had required a continuity correction to calculate the OR. This yielded a more precise estimate (pooled OR = 1.78, 95% CI = 1.36 – 2.32, p < 0.0001; I^2 = 4.5%), supporting the robustness of the association.

Conclusion: Epigenetic biomarkers, particularly p16 methylation, show promise in predicting progression of BO to HGD/OAC. However, the evidence base remains limited and heterogeneous. Given the potential clinical utility of risk prediction biomarkers in BO, this is an important area for further research.

DETECTION OF BILE ACIDS IN SALIVA AS NEW NON-INVASIVE DIAGNOSTIC METHOD OF BARRETT'S ESOPHAGUS

S. Konecny[1,2], J. Dolina[1,2], V. Dosedelova[3], M. Lastovickova[4], J. Lacna[3], P. Kuban[3]

Contact E-Mail Address: stefankonecny@gmail.com

Introduction: Bile acids are a group of steroid compounds essential for lipid digestion. However, when bile acids are refluxed into the stomach and the esophagus during the so called duodenogastroesophageal reflux, they can have a detrimental effect on the esophageal epithelium and cause pathological changes of esophageal tissue, e.g. Barrett's esophagus (BE). The levels of bile acids in saliva could therefore serve as possible biomarkers for the diagnostics of BE.

Aims & Methods: Saliva samples were obtained by simple spitting. Each saliva sample was centrifuged and divided into the mucus and the supernatant. Mucus samples contain dramatically higher bile acid concentrations than supernatant samples across all diagnostic groups, suggesting bile acids accumulate in the mucus layer. We performed quantification of 15 bile acids (unconjugated, glycine-conjugated and taurine-conjugated) in saliva by ultra-high-performance liquid chromatography coupled to triple-quadrupole tandem mass spectrometry. We have taken samples of saliva from 60 patients with gastroesophageal reflux disease (GERD), 11 patients with Barrett's esophagus and 12 healthy subjects.

Results: The ratio for tauro-conjugated bile acids, glyco-conjugated bile acids and total bile acids shows statistically significant difference between Barrett's and healthy subjects ($p < 0.018$, $p < 0.023$, $p < 0.021$), and between Barrett's and GERD patients ($p < 0.027$, $p < 0.041$, $p < 0.034$). The most significant individual biomarkers appear to be glycochenodeoxycholic acid (GCDCA) and taurochenodeoxycholic acid (TCDCA). The GCDCA and TCDCA ratio shows statistically significant difference between Barrett's and healthy subjects ($p < 0.026$, $p < 0.008$), and between Barrett's and GERD patients ($p < 0.039$, $p < 0.012$). The ratio for unconjugated bile acids showed no statistically significant differences, therefore they may be less useful as Barrett's specific markers.

Conclusion: There are statistically significant differences in mucus-to-supernatant ratios between Barrett's patients and both GERD and healthy subjects for tauro-conjugated, glyco-conjugated, and total bile acids. The TCDCA ratio shows the most statistically significant difference between Barrett's and other groups, suggesting it may be the most useful single diagnostic marker. No statistically significant differences were found in bile acid ratios between GERD and healthy subjects, suggesting that the ratio pattern is specifically altered in Barrett's esophagus. The number of subjects is still low but we are completing a larger clinical study that will provide more relevant statistical data.

Introduction: A decade ago, endoscopic surveillance (ES) for Barrett's oesophagus (BO) was recommended to improve the outcome of oesophageal adenocarcinoma through early recognition and prevention[1]. The yield of ES to detect dysplasia may depend on guideline adherence and quality of endoscopy[2,3,4].

Aims & Methods: The aim is to assess whether dedicated (expert) ES (DS) is more effective than conventional (non-dedicated) ES (NS) by means of Key Performance Indicators (KPI), Dysplasia Detection Rate (DDR), use of advanced imaging and complication rate.

This multicentre (5 UK hospitals) retrospective study includes real-world ES data from 1303 procedures conducted within the last 8 years. The endoscopy and histology reports and clinical notes of consecutive procedures were accessed. The data were collected in spreadsheets and then analysed with SPSS-23. Two services were reported demographically and compared with appropriate statistical tests and logistic regression to test factors associated with DDR.

Results: Data from 680 DS and 623 NS procedures were included, comprising 906 (69.5%) males and 397 (30.5%) females (M:F=2.3:1.0). The age ranged from 14-90 yrs with a mean of 63.7 (SD±12.5) yrs. The maximum length of the BO was 18 cm with a mean of 4.1 cm (SD±3.0). There were significant differences in all the KPIs (Prague classification, Barrett's island description, hiatus hernia delineation, visible lesion documentation, Paris classification, Seattle protocol adherence and inspection time) favoring the DS (P<0.001). Other comparisons: narrow band imaging (NBI, P<0.001), acetic acid chromoendoscopy (AAC, P<0.001), sedation (P=0.02) and acquisition of target biopsies (, P<0.001) were also significantly higher in DS while the complication rate was significantly lower (P=0.05). Importantly, the DDR was significantly higher in DS (58/680 (8.5%)) than in NS (16/623 (2.6%)) with a P<0.001. Regression analysis showed: increasing age, male sex, lesion description and Paris classification documentation were associated with higher DDR (Table 1), while other indicators showed no significant association.

	Odds ratio	95% CI	P
Age	1.03	1.01 – 1.05	0.002
Sex	1.86	1.16 – 2.98	0.009
Visible lesion documentation	2.23	1.03 – 4.81	0.041
Paris classification	2.19	1.00 – 4.77	0.049

Table 1. Factors associated with dysplasia detection

Conclusion: Surveillance for BO through a dedicated service with high quality endoscopy can produce a higher diagnostic yield with improved DDR and a lower complication rate. Given these benefits, large-scale pro-

COST-EFFECTIVE SCREENING STRATEGIES FOR BARRETT'S ESOPHAGUS

T. Aoki[1], R. Vissapragada[1], N. Bulamu[1], D.I. Watson[1]
[1]Flinders University, Adelaide, Australia

Contact E-Mail Address: iitomo.1020@gmail.com

Introduction: Barrett's esophagus (BE) is a precursor to esophageal adenocarcinoma, with its prevalence reported to range from 1.9% to 6.8% in Western countries. We aimed to identify cost-effective pathways for BE screening by combining BE detection using multiple tools with subsequent risk-stratified surveillance.

Aims & Methods: A decision-analytic model was developed using a hypothetical cohort of the general population aged 50 years with BE prevalence rates of 1.0-7.0%. In addition to a no screening strategy, 24 potential screening pathways were evaluated combining six detection strategies (combinations of: guideline-based risk stratification, algorithmic risk stratification, swallowable devices like Cytosponge-trefoil factor 3, and endoscopy) and four surveillance strategies varying endoscopy intervals based on the BE length. Cost-effectiveness was assessed from an Australian health system perspective, using incremental cost-effectiveness ratio (ICER) thresholds for the USA (US$100,000/QALY), UK (US$43,228/QALY), and Australia (US$34,554/QALY).

Results: BE screening was cost-effective compared to no screening at BE prevalences of ≥1.0%, ≥2.4%, and ≥4.7% for the USA, UK, and Australian ICER thresholds, respectively. The optimal screening strategy was different between USA/non-USA thresholds; a 3-step detection (algorithmic risk stratification followed by swallowable devices and then endoscopy) with subsequent surveillance (no surveillance for short segment BE [SSBE] <3 cm, 2 yearly for long segment BE [LSBE] ≥3 cm; eradication for low-grade dysplasia [LGD]) for the UK and Australia. In contrast, for the USA, it was a 2-step detection (swallowable devices followed by endoscopy) with surveillance (no surveillance, SSBE ≤2 cm; 2 yearly, LSBE >2 cm; eradication, LGD) especially at ≥2.4% BE prevalence.

Conclusion: BE screening combining BE detection using multiple tools with subsequent risk-stratified surveillance based on segment length might be cost-effective, depending on BE prevalence in the community and ICER thresholds. Further work is needed to determine the actual BE prevalence in target communities.

Contact E-Mail Address: rykawago@ncc.go.jp

Introduction: Endoscopic depth diagnosis is essential for the treatment decision of Barrett's esophageal adenocarcinoma (BEA). However, it is sometimes difficult to diagnose due to the anatomy of the esophagogastric junction, such as the difficulty of luminal distension. For inconclusive cT1a or cT1b lesions, we introduced staging ESD, allowing for histologic diagnosis for depth invasion. However, the clinical feasibility and significance of staging ESD remain unclear.

Aims & Methods: In this study, we evaluated the performance of endoscopic depth diagnosis of cT1 BEA and the appropriate treatment strategy. This study included cT1N0M0 BEA treated with ESD or surgery from January 2015 to June 2024. The cases with poorly differentiated component on target biopsy were excluded. Endoscopic depth diagnosis was based on macroscopic appearance (such as the following findings suggestive of cT1b: polypoid, mixed macroscopic type, thickness, hardness, severe redness, and ulceration). EUS was added at the discretion of the endoscopist. We made the treatment decision based on our multidisciplinary conference, and the final diagnosis was classified as conclusive cT1a or cT1b, and inconclusive cT1a or cT1b. We performed ESD for conclusive cT1a, and surgery for conclusive cT1b. And we performed staging ESD for inconclusive cT1a or cT1b. Curative resection was defined as pT1a with R0 resection, and without lymphovascular invasion or poorly differentiated component.

Results: This study included 54 lesions in 52 patients. The median age was 66 years (43-92). There were 42 male patients. Siewert type [type I/type II] were 12 and 42, respectively. Background Barrett's esophagus [SSBE/LSBE] were 36 and 16, respectively. The median size was 20mm (5-50). Major macroscopic appearances [0-I/0-IIa/0-IIb/0-IIc] were 11, 19, 1, and 23, respectively. Histology on targeted biopsy [tub1/tub2] were 41, 13, respectively. 39 lesions were diagnosed by white light endoscopy alone, and 15 lesions were comprehensively diagnosed by additional EUS. 41 lesions were diagnosed as cT1a and 13 lesions were diagnosed as cT1b. ESD and surgery were performed for 47 and 7 lesions, respectively. Pathologic depths [T1a/T1b/T2] were 42, 11, and 1, respectively. The sensitivity, specificity, and positive predictive value of endoscopic diagnosis of T1b were 25.0%, 76.2%, and 23.1%, respectively. 10 of 54 (18.5%) T1a lesions were overdiagnosed. Staging ESD was performed for 20 lesions, and all of them achieved en bloc resection without adverse events. R0 resection was achieved in 13 of 14 (92.9%) cT1a and 5 of 6 (83.3%) cT1b, respectively. Curative resection was achieved in 8 of 14 (57.1%) cT1a and 4 of 6 (60.0%) cT1b, respectively. 3 of 54 (5.6%) T1a were diagnosed as conclusive cT1b, and underwent surgery, leading to overtreatment.

Conclusion: The diagnostic performance of endoscopic depth diagnosis is insufficient, leading to overdiagnosis. Staging ESD for inconclusive cT1 BEA is technically feasible and can be an option to avoid overtreatment.

Disclosure: Nothing to disclose.

Contact E-Mail Address: philleclercq@gmail.com

Introduction: To compare real-world outcomes of radiofrequency ablation (RFA) for Barrett's esophagus (BE) in Belgium before (Feb 2008–Jan 2017) and after (Jan 2017–Dec 2023) reimbursement, focusing on efficacy (complete remission of intestinal metaplasia, CR-IM; complete remission of dysplasia, CR-D), safety, baseline histology, and prior endoscopic resection (ER) rates, with statistical testing.

Aims & Methods: Prospective registry of expert Belgian centers.

- Pre-reimbursement: 342 treated, 295 evaluable (≥ 1 y follow-up; ITT efficacy).
- Post-reimbursement: 701 treated, 627 evaluable (≥ 1 y follow-up; ITT efficacy).

Patients in 2024–2025 with < 5 sessions and no CR were censored. Collected: demographics, histology (IM, LGD, HGIN, EAC), ER rate, Prague C/M, RFA sessions, and outcomes. Categorical variables by χ^2/Fisher's exact; continuous by Mann–Whitney U test.

Results:

Metric	Pre-reimbursment (n=342/295)	Post-reimbursment (n=701/627)	p-value
Age, yrs (median [IQR]; range)	65 [57–73]; 23–87	67 [59–73]; 23–91	0.23
Male, %	85	87	0.24
Prague C, cm (median [IQR]; range)	3 [5]; 0–15	1 [5]; 0–18	0.11
Prague M, cm (median [IQR]; range)	5 [5]; 1–17	4 [5]; 0–20	0.15
Prior ER, %	60	59	0.99
Baseline histology, %	IM 1 / LGD 7 / HGD 54 / EAC 37	IM 2 / LGD 4 / HGD 71 / EAC 23	0.32
RFA sessions (median [IQR]; range)	2 [1]; 1–8	2 [1]; 1–5	0.41
CR-IM, % (ITT)	82	83.4	0.67
CR-D, % (ITT)	87	94.9	1.00
Stricture rate, %	9	11.9	0.77
Perforation rate, %	0	0	—

Conclusion: After reimbursement, Belgian centers treated more patients with no statistically significant differences in demographics, baseline histology, BE extent, ER practice, efficacy or safety (all p>0.05). Reimbursement broadened access without compromising RFA outcomes. Continuous surveillance remains essential.

Introduction: The Cryoballoon Focal Ablation (CbFA) (C2 Pentax Medical) system offers an endoscopic treatment option for Barrett's-related dysplasia (BE-D). CbFA has been shown in clinical studies to be a highly effective and well tolerated intervention for BE-D.

We report the largest real-world prospective multi-centre registry of consecutive patients who underwent treatment with CbFA for the endoscopic eradication (EET) of BE-D.

Aims & Methods: Patients were prospectively enrolled from three tertiary referral centres for Barrett's esophagus (BE). Inclusion criteria included patients with a BE segment of C≤2M≤5 with histologically-proven dysplasia or intramucosal adenocarcinoma on biopsy or at endoscopic resection. CbFA sessions were conducted at 3-monthly intervals until EET was complete (Max 5 sessions). Follow up biopsies were taken to confirm eradication of dysplasia and intestinal metaplasia.

The primary outcome was the complete eradication of intestinal metaplasia (CE-IM) and dysplasia (CE-D).

Secondary outcomes included the number of ablations performed, adverse events, device malfunction, stricture rate, endoscopist satisfaction score (Likert scale: 1=poor, 10=excellent) and balloon positioning complexity (Likert scale: 1=easy positioning, 5=difficult positioning).

Results: Between January 2020 and December 2024, thirty-eight patients (79%: male, mean age: 69) were treated with CbFA (81 treatment sessions). The median BE length was C0M2. 84% (n=32) were treatment naïve with the 16% (n=6) being RFA refractory BE. 55% (n=21) had undergone endoscopic resection prior to entry (3=endoscopic submucosal dissection:18=endoscopic mucosal resection). Patient characteristics according to baseline histology is highlighted in table 1.

CE-D was achieved in 100% (12/12) and CE-IM in 83% (10/12) of patients who had completed treatment. The median number of treatment sessions for those completing treatment was 2.5 (SD=1.4). No new neoplastic lesions were detected during treatment.

	Intramucosal esophageal Adenocarcinoma (n=6)	High grade dysplasia (n=11)	Low grade dysplasia (n=21)
Median Age	67	71	70
Median BE length	C1M3	C0M3	C0M2
CE-IM	2/3 (67%)	6/6 (100%)	2/3 (67%)
CE-D	3/3 (100%)	6/6 (100%)	3/3 (100%)
Stricture rate	0%	3/11 (27%)	0%

Table 1: Patient characteristics according to baseline histopathology.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

No device malfunction or intraoperative adverse events were recorded. Stricture formation post CbFA requiring dilatation was observed in 8% (n=3) of cases.

The median endoscopist satisfaction score was 9 (SD=1.8) with 3 cases recorded as difficult due to balloon positioning. The median ballon positioning complexity score was 2 (SD=1.5).

Conclusion: These results from the UK cryoablation registry suggest that CbFA is a safe and effective treatment for BE-D and mirror findings from larger controlled studies. With the planned enrolment of further centres, this registry will further enhance our understanding of the long-term efficacy and safety profile CbFA.

Introduction: Barrett Esophagus (BE) is a long-term complication of inadequately controlled gastroesophageal reflux (GERD) resulting in the metaplastic transformation of the esophageal epithelium. Current therapy involves proton pump inhibitors (PPIs), aiming at reducing gastric, and consequently esophageal acid exposure time (AET), thereby eliminating the main pathogenic drive to dysplasia/adenocarcinoma progression. However, current guidelines recommend a standard dose PPI therapy for BE chemoprevention, without taking into consideration the need for 24-hour pH-impedance monitoring (24h MII-pH), which is the only investigation able to objectively estimate the esophageal acid exposure time (AET) and evaluate the real effectiveness of PPI therapy.

Aims & Methods: This study included prospectively enrolled BE patients referred to our tertiary care center. We identified consecutive patients with histological diagnosis of non-dysplastic BE treated with a standard dose of PPI administered once or twice daily (either pantoprazole or esomeprazole 40mg OD or 20mg BID), according to guidelines. After at least 8 weeks of PPI therapy, all participants underwent a high-resolution manometry (HRM) and 24h MII-pH monitoring on therapy. A cohort of refractory GERD patients matched for age, sex and PPI regimen (dose and type) were used as controls. GERD symptoms were recorded in the whole population by using the standardized GERD-Q questionnaire. Results are expressed as mean±SD.

Results: A total of 33 BE (23M, 50±17 years) and 33 GERD patients (21M, 48±14 years) were enrolled. Typical GERD symptoms were significantly less severe in BE patients compared to controls (2.1±2.1 vs 3.1±2.3; p<0.05). Half of the population of BE patients did not achieve adequate esophageal acid suppression (AET<4%) under standard dose regimen. Despite matching PPI regimen, the risk of having a pathological 24h MII-pH was doubled in BE compared to refractory GERD patients (50% vs 25%; p<0.05). The mean AET was significantly higher in BE compared to GERD patients (6.6±10.2%vs 1.9±3%; p<0.05), particularly in the supine position (7.3±15.5% vs 2.3±5.6%; p<0.05), despite similar levels of gastric acid suppression (44.1± 25.7% vs 49.2±27%; p=NS). Although the average number of reflux events was comparable between BE and controls (49±29 vs 40±22), BE exhibited a notably prolonged reflux clearance time (mean duration of the longest reflux episode: 27.8±25.7 vs 12.7±27.3 min; p<0.05). Furthermore, Type IIIA esophagogastric junction (EGJ) morphology was more prevalent BE group compared to controls (45% vs 21%; p<0.05) as was the prevalence of ineffective esophageal motility (IEM) according to the Chicago Classification version 4.0 (42% vs 12%; p<0.05).

Conclusion: Despite the reduced severity of typical GERD symptoms, analogous therapeutic regimens and comparable gastric acid suppression, BE patients showed a significantly increased esophageal AET, especially in the supine position, compared to refractory GERD patients. Furthermore, at HRM, BE patients showed a higher prevalence of Type IIIA EGJ morphology and IEM that could justify these results. Our data show that half of the whole BE population failed to achieve an adequate esophageal acid suppression despite therapy, emphasizing the relevance of performing an HRM and a 24h MII-pH in all non-dysplastic BE patients, in order to tailor the therapeutic strategy and improve BE long-term outcomes.

ENHANCING SURVEILLANCE QUALITY IN BARRETT'S OESOPHAGUS: EFFECT ON DYSPLASIA DETECTION RATE

S. Batal[1], H.N. Haboubi[2]
[1]Cardiff Univeristy, Cardiff, United Kingdom, [2]Cardiff & Vale, University Health Board, Department of Gastroenterology, Cardiff, United Kingdom

Contact E-Mail Address: sarahbatal2004@gmail.com

Introduction: Oesophageal adenocarcinoma (EAC) remains a leading cause of cancer-related mortality, with poor survival outcomes. Early identification and treatment of dysplasia in Barrett's oesophagus (BE) is critical to reducing the risk of post-endoscopy upper gastrointestinal cancers (PEUGIC). While mucosal cleansing and clear visualisation are recognised as essential, existing evidence also demonstrates that certain procedural factors—such as longer inspection times—can significantly improve dysplasia detection rates (DDR) (2). This raises the possibility that other procedural variables may similarly influence detection outcomes. In this audit, we evaluated whether additional technical and patient-related factors affect dysplasia detection, with the aim of optimising surveillance quality and reducing the risk of Post-Endoscopy Upper GI Cancer (PEUGIC).

Aims & Methods: This audit aimed to assess the impact of procedural variables on dysplasia detection during Barrett's surveillance endoscopy. A retrospective analysis was conducted in Wales, reviewing 192 patient records from June to December 2023. Factors that may influence dysplasia detection were evaluated including sedation type, use of acetic acid for mucosal enhancement, adherence to the Prague grading system, describing lesions using the Paris classification, NBI use and the Seattle biopsy protocol. Additionally, patient comfort was assessed as it may impact procedural quality and compliance. Analysis was carried out using SPSS (IBM, USA). T-tests were used for parametric data, and Mann Whitney U-tests for non-parametric data. Categorical data were analysed using Chi-square or Fisher's exact tests. Statistical significance was set at $p < 0.01$

Results: Improved imaging quality was significantly associated with higher patient comfort ($p = 0.001$). Higher doses of midazolam were associated with greater detection of visible lesions, while fentanyl showed less of a significant effect. Additional use of acetic acid and aceto-whitening effect significantly enhanced dysplasia detection, with strong alignment to histological findings (p<0.001). NBI further improved lesion identification when used adjunctively. In procedures performed by expert endoscopists, targeted biopsies identified dysplasia at comparable rates to the Seattle protocol, suggesting limited additional value of the latter in experienced hands.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This study underscores the importance of optimising procedural elements—particularly higher doses midazolam (median 5mg), acetic acid application, and ensuring patient comfort—to improve dysplasia detection in Barrett's surveillance. Although PEUGIC data seems to show better neoplasia detection rates with combined Midazolam and Fentanyl, we did not demonstrate this(1). seattle protocol may still be helpful for dysplasia detection, but it's use appears less beneficial than regular use of NBI and acetic acid chromoendoscopy.

Introduction: Gastric cancer ranks as the fifth most common cancer and the second leading cause of cancer-related deaths. Multifocal atrophic gastritis and gastric intestinal metaplasia (GIM) often coexist and are both associated with the risk of developing gastric cancer, with GIM being the first irreversible mucosal transformation to cancer. Endoscopic surveillance was associated with earlier cancer detection and improved survival. This study aims to evaluate the prevalence, epidemiological characteristics, and clinical features of patients with GIM.

Aims & Methods: This is a single-center, retrospective study from January 1, 2022 to December 31, 2023. Including patients aged ≥18 years who underwent esophagogastroduodenoscopy (EGD) with gastric biopsies confirming GIM, All identified cases of GIM were reviewed by gastrointestinal pathologists to confirm the diagnosis. Th primary outcome was to assess the prevalence, epidemiological characteristic, and clinical features of GIM. The secondary outcome was to evaluate adherence to recommended surveillance protocols for GIM.

Results: Among 3,663 patients who underwent EGD, GIM was identified in (4.17%, n=153). The mean age of patients with GIM was 60 years, Males represented more than half of patients (54.2%), the majority were classified as overweight (Body mass index (BMI) 25–29.9; 64%, n=97) or obese (BMI ≥30; 24.3%, n=37). Smoking was reported in (17.6%, n=27), while (5.2%, n=8) reported alcohol consumption.

Moreover, (7.2%, n=11) had a history of prior gastric surgeries. Dyspepsia (33.3%) was the most common indication for EGD. Gastritis was the predominant endoscopic finding and the primary reason for performing gastric biopsies (73%, n=112). The most common GIM subtype was complete (52%), followed by incomplete (37%) and mixed (11%). In terms of GIM location, extensive GIM was observed in (28.7%), localized GIM in (17.6%), while the location remained unknown in (53.6%) due to the lack of a follow-up EGD for mapping. Coexisting autoimmune atrophic gastritis was observed in (12.4%, n=19), Helicobacter pylori infection was detected in (16.3%, n=25).

Furthermore, Dysplasia was identified in (2.6%, n=4), with low-grade dysplasia and high-grade dysplasia each accounting for (1.3%, n=2) (Table 1). Three patients developed.gastric cancer (2%) , while (4.6%, n=7) were found to have neuroendocrine tumors (NET). First degree family history of gastric cancer was reported in (12.4%, n=19).

Gastric Intestinal Metaplasia characteristic	Percentage
Location	
Localized	27 (17.6%)
Extensive.	44 (28.7%)
Unknown	82 (53.6%)
Type of GIM	
Incomplete	51 (37%)
Complete	71 (52%)
Mixed	15 (11%)
Autoimmune Atrophic Gastritis	
Absent	134 (87.6%)
Present	19 (12.4%)
Helicobacter Pylori (H. pylori)	
Absent	128 (83.7%)
Present	25 (16.3%)
Dysplasia	
Absent	149 (97.4%)
Low Grade	2 (1.3%)
High Grade	2 (1.3%)

Table 1.

Conclusion: This study highlights a 4.17% prevalence of GIM among patients who underwent EGD. High BMI and male sex were observed in more than half of the patients. Dysplasia was detected in 2.6%, gastric cancer in 2%, and NET in 4.6% of cases. Many patients lacked follow-up EGD surveillance, limiting effective monitoring. Larger studies with extended follow-up are required to further investigate these associations and their clinical implications.

Introduction: Alcohol-induced acute gastric injury results from disruption of the mucosal barrier and the induction of inflammatory responses. IL-33, an epithelial-derived alarmin, and its receptor ST2, are increasingly recognized as regulators of mucosal immunity and inflammation. However, the specific role of IL-33/ST2 signaling in the immunopathogenesis of ethanol-induced gastric damage remains insufficiently defined.

Aims & Methods: This study aimed to investigate the contribution of IL-33/ST2 signaling to the development of ethanol-induced acute gastric injury. Acute gastric injury was induced in WT and ST2^{-}/$^{-}$ mice by oral admin-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. istration of 80% ethanol. Gastric damage was assessed macroscopically and histologically. Immune cell profiles, cytokine levels, and markers of inflammasome activity and pyroptosis were analyzed using flow cytometry, ELISA, and qPCR.

Results: Ethanol exposure induced severe gastric injury in WT mice, characterized by extensive ulceration and epithelial disruption, whereas ST2$^{-/-}$ mice exhibited markedly reduced damage and preserved mucosal architecture. Flow cytometric analysis of gastric tissue revealed significantly higher number of Ly6G^{+} neutrophils and F4/80^{+} macrophages in ethanol-treated WT mice compared to their ST2$^{-/-}$ counterparts.

Moreover, ethanol-treated WT mice exhibited a significantly higher number of CXCR4-expressing neutrophils, accompanied by an increased number of neutrophils producing TNF-α, IFN-γ, and IL-1β. Similarly, the number of IL-1β–producing macrophages was markedly elevated in WT mice compared to ST2$^{-/-}$ mice. Notably, ethanol-treated WT mice also displayed a higher number of NLRP3^{+} neutrophils and macrophages, indicating enhanced inflammasome engagement.

Consistent with these findings, gastric tissue from ethanol-treated WT mice demonstrated increased expression of molecular markers associated with inflammasome activation and pyroptotic cell death. Systemically, WT mice exhibited elevated serum concentrations of Th1/Th17 cytokines (IFN-γ, TNF-α, IL-1β, IL-17), while IL-10 levels remained similarly increased across genotypes, suggesting a preserved anti-inflammatory feedback despite pronounced immune activation.

Conclusion: IL-33/ST2 signaling aggravates ethanol-induced gastric injury by intensifying mucosal inflammation, promoting inflammasome-driven pyroptosis, and enhancing recruitment and activation of inflammatory immune cells. The relative protection observed in ST2$^{-/-}$ mice underscores the pathological role of this axis and its potential as a therapeutic target in acute gastric damage.

Introduction: Chronic atrophic gastritis (CAG) is a known precancerous condition for gastric cancer (GC). Low serum PG-I levels are proposed as a non-invasive marker for chronic atrophic gastritis of the stomach body, but the adequate upper cut-off for diagnosis remains controversial, as values ranging from 30 to 50 mcg/L currently are considered a "grey-zone".

Aims & Methods: Aim: To identify patients with body chronic atrophic gastritis (CAG) amongst subjects with PGI levels ranging between 30 and 50 mcg/L (within the so-called "grey zone") using a PPI test.

Methods: We selected 102 patients with PGI< 60 mcg/L. According to PG1 levels, this population was divided into 5 groups: Group A (PGI< 30 mcg/L); Group B (PGI 31-35 mcg/L); Group C (PGI 36-40 mcg/L); Group D (PGI 41-50 mcg/L.); Group E (PGI 51-60 mcg/L). All patients underwent to PPI test (Esomeprazole 40 mg daily for 1 week). By using the ROC curve, a cut-off of 30% increase from baseline PG1 was chosen. For each patient, the OLGA Staging was performed.

Results: A statistically significant relationship between PG1 levels and OLGA staging was found, being 100% in the Group of PG1<30mcg/L. PGI levels (cut-off 30% of delta increase) resulted in a positive predictive value of 95%, a negative predictive value of 86%, with an 83% and 96% sensitivity and specificity, respectively, for diagnosing atrophic gastritis of the stomach body.

Conclusion: The PPI test allows the diagnosis of 93.87% (46 out 49 subjects) of atrophic gastritis of the stomach body, with a cut-off between 41-50 mcg/L.

A COMPARATIVE STUDY OF ORAL PREDNISOLONE ALONE VERSUS ORAL PREDNISOLONE COMBINED WITH NASOGASTRIC TUBE PLACEMENT FOR THE PREVENTION OF ESOPHAGEAL STRICTURE AFTER CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY ESOPHAGEAL NEOPLASTIC LESIONS

C.-T. Lee[1], Y.-C. Chung[1], W.-L. Wang[1]
[1]E-Da Hospital and I-Shou University, Dept. of Internal Medcine, Kaohsiung City, Taiwan

Contact E-Mail Address: fattoo@gmail.com

Introduction: Esophageal stricture remains a challenging complication following extensive endoscopic submucosal dissection (ESD) for superficial neoplastic lesions. Oral steroid therapy has been reported to effectively prevent post-ESD stricture. However, its efficacy in preventing luminal stenosis after total circumferential ESD has been disappointing.

Aims & Methods: This study aimed to compare the effectiveness of oral prednisolone alone versus a combination of oral prednisolone and nasogastric tube (NGT) placement in preventing esophageal stricture after circumferential ESD.

We retrospectively collected clinical data from patients with extensive superficial esophageal neoplastic lesions who underwent total circumferential ESD. Patients were categorized into two groups: the steroid group (receiving only oral prednisolone) and the steroid+NGT group (receiving oral prednisolone combined with NGT placement). The incidence of esophageal stricture was analyzed and compared between the two groups.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: From June 2010 to December 2024, 29 circumferential lesions in 27 patients underwent esophageal ESD. Of these, 13 lesions in 12 patients received oral steroid therapy alone, while 16 lesions in 15 patients received a combination of oral steroids and NGT placement. There was no significant difference in the characteristics of the patients between the two groups. The overall esophageal stricture rate was 72.4% (21/29). No adverse events were observed in either group. The stricture rate was significantly higher in the steroid group compared to the steroid+NGT group (12/13, 92.3% v.s. 9/16, 56.3%; p=0.044. Table 1).

Multivariate logistic regression analysis revealed that longitudinal length of post-ESD mucosal defect (OR 1.12; 95% CI 1.01-1.25; P=0.026) was the independent risk factor. NG placement had a potential preventive effect (OR 0.05; 95% CI 0.00-1.14; P=0.06).

	Group 1 (oral prednisolone)	Group 2 (oral prednisolone and NG placement)	P value
No.	13 lesions in 12 patients	16 lesions in 15 patients	
Sex, M/F	12/0	14/1	n.s.
Age, mean ± SD, years	53.1 ± 10.1	61.6 ± 8.0	0.047
Tumor location, n (%) Upper half Lower half	 5 (38.5%) 8 (61.5%)	 4 (25%) 12 (75%)	 0.55
Longitudinal length of mucosal defect, mean ± SD, mm	62.3 ± 22.1	62.5 ± 16.9	0.98
Pathological depth of tumor invasion, n (%) Mucosa Submucosa	 11 (84.6%) 2 (15.4%)	 11 (68.8%) 5 (31.2%)	 0.41
Esophageal stricture, n (%)	12/13 (92.3%)	9/16 (56.3%)	0.044

Table 1. Baseline characteristics of the patients.

Conclusion: The combination of oral steroid and NGT placement is safe and potentially more effective in preventing esophageal stricture than oral steroid therapy alone following total circumferential ESD. Further randomized controlled trials are needed to confirm these findings.

Introduction: Esophageal squamous cell carcinoma (ESCC) is a major global health concern, with a high recurrence rate after chemoradiotherapy (CRT). Despite being a curative approach, CRT alone is often insufficient, leading to local recurrence in 30–40% of cases (1). Salvage treatments such as surgery and endoscopic resection have limitations, particularly in patients with comorbidities or advanced lesions (2). Photodynamic therapy (PDT) using talaporfin sodium (TS) has emerged as a promising, minimally invasive salvage treatment, offering advantages such as reduced phototoxicity and repeatability (3). Since its approval in Japan in 2015, TS-PDT has gained traction, yet further clinical evidence is needed to validate its efficacy and safety.

This study aims to evaluate the clinical outcomes of TS-PDT as a salvage treatment for locally recurrent or residual ESCC following CRT or radiotherapy (RT).

Aims & Methods: A retrospective study was conducted at Nagoya City University Hospital between May 2016 and December 2023. A total of 29 patients with histologically confirmed local recurrence or residual ESCC post-CRT/RT were included. Eligible patients had lesions classified as ≤T2, without lymph node or distant metastasis. TS-PDT was administered with a diode laser (664 nm) 4–6 hours post-intravenous TS injection (40 mg/m^2). Patients were monitored for adverse events, local complete response (L-CR), progression-free survival (PFS), and overall survival (OS). Kaplan–Meier analysis was used for survival estimation, and comparisons between single and multiple PDT sessions were evaluated.

Results: Among the 29 patients (23 males, 6 females; median age, 72 years), TS-PDT achieved an L-CR rate of 82.1% per patient and 87.8% per lesion, with superior outcomes in T1b lesions (96.6%) compared to T2 lesions (66.7%) (Table1).

	Local-CR	Non L-CR	L-CR rate
patients	22	5	81.5%
lesions	36	5	87.8%
T1b lesions	28	1	96.6%
T2 lesions	8	4	66.7%

Table 1. The best response to PDT.

The median local PFS was 1,324 days, and the median PFS was 912 days. OS was not reached during follow-up, with a 3-year survival rate of 70.7%. Seventeen patients underwent a single PDT session, while 12 required multiple sessions. The 3-year OS rate was 83.3% in the single-session group and 44.4% in the multiple-session group. No skin phototoxicity was observed. Adverse events included esophageal strictures (1 case, asymptomatic) and esophageal perforations (2 cases), one of which required surgical intervention.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: TS-PDT demonstrated high local control rates and favorable survival outcomes, making it a promising salvage therapy for ESCC recurrence post-CRT/RT (4).

Despite some adverse events, its minimal invasiveness and reduced phototoxicity enhance its applicability, particularly in elderly or high-risk patients. The effectiveness of multiple PDT sessions supports its role as a flexible treatment strategy.

Further multicenter prospective trials are warranted to optimize patient selection, treatment protocols, and long-term outcomes, solidifying TS-PDT as a key salvage therapy for recurrent ESCC (5).

Introduction: Endoscopic submucosal dissection (ESD) for superficial esophageal squamous cell carcinoma (SESCC) involving the entire circumference carries the extremely high risk of stricture and also raises concerns about curative resection. Therefore, the current Japanese guidelines weakly recommend ESD only for circumferential SESCCs diagnosed as cEP/LPM and sized ≤ 50 mm, while surgery or chemoradiotherapy (CRT) is recommended for circumferential SESCCs other than the above.[1] However, in clinical practice, ESD is implemented on a case-by-case basis through the discussion in a multi-disciplinary cancer board at each institution because the outcomes of each treatment for circumferential SESCCs remain unclear.[2]

Aims & Methods: This multicenter prospective observational study aimed to reveal the outcomes of each treatment for circumferential SESCCs. Patients with cT1a-EP/LPM or cT1a-MM/T1b-SM1 N0M0 SESCCs involving the entire circumference were enrolled in this study. At this stage, short-term outcomes, such as the proportion of curative resection after ESD, complete response (CR) after CRT/radiotherapy (RT), and adverse events including esophageal stricture, were evaluated. Curative resection in ESD was defined as pT1a without lymphovascular invasion (LVI). Esophageal

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

stricture was defined as inability to pass the ordinary-sized endoscope thorough the treated site, and refractory stricture was defined as stricture requiring ≥ 6 endoscopic balloon dilation procedures.

Results: A total of 126 patients with circumferential SESCCs were enrolled from 16 Japanese tertiary institutions between May 2021 and November 2024. ESD was performed for 90 (71.4%) patients including 6 undergoing stepwise ESD, surgery for 18 (14.3%), CRT for 16 (12.7%), and RT alone for 2 (1.6%). Median longitudinal length of tumor was 55 (range: 30–140) mm in the ESD group, 80 (50–150) mm in the surgery group, and 70 (30–100) mm in the CRT/RT group. Tumor depth was diagnosed as cEP/LPM in 65.4% (55/84) of the ESD group, 38.9% (7/18) of the surgery group, and 50.0% (9/18) of the CRT/RT group, and the others were diagnosed as cMM/SM1. As stricture prevention method after ESD, local injection or filling of triamcinolone (TA) alone was used in 9 patients (10.7%), and both local injection of TA and oral steroid of prednisolone were used in 75 (89.3%). Among the 63 patients who did not receive additional treatment after ESD, the proportion of stricture and refractory stricture were 46.0% (29/63) and 27.0% (17/63), respectively. Curative resection after ESD was achieved in 58 patients (69.0%), including 46 (83.6%) with cEP/LPM and 12 (41.4%) with cMM/SM1. Of 26 patients with non-curative resection after ESD, 20 (76.9%) received additional treatment of either surgery, CRT, or RT, while the remaining 6 opted for follow-up. Of 18 patients in the surgery group, 7 with cEP/LPM and 4 with cMM/SM1 were diagnosed as pT1aN0 without LVI, while the remaining 7 with cMM/SM1 were diagnosed as pT1b, 3 of whom had lymph node metastasis. Anastomotic stricture was observed in 11.1% (2/18) of patients treated with surgery. Of 18 patients in the CRT/RT group, CR was confirmed in all patients without forming stricture.

Conclusion: Considering the high curative resection rate, ESD could be indicated for circumferential SESCCs diagnosed as cEP/LPM. In contrast, the careful consideration may be required in indicating ESD for circumferential SESCCs diagnosed as cMM/SM1 due to its low curative resection rate. Long-term outcome needs to be confirmed for further treatment comparisons.

A RISK FACTOR OF MULTIPLE ESOPHAGEAL SQUAMOUS CELL CARCINOMAS FOR PATIENTS WITH NUMEROUS IODINE-UNSTAINED AREAS IN SURVEILLANCE ENDOSCOPY

Y. Kishi[1], Y. Horiuchi[1], C. Fukuyama[1], H. Yamamoto[1], A. Ishiyama[1], T. Hirasawa[1], T. Yoshio[1]

Introduction: Iodine staining is widely recognized as an effective method for detecting esophageal squamous cell carcinoma (ESCC) so that it highlights dysplasia or ESCC as iodine-unstained areas. Number of iodine-unstained areas on the esophageal mucosa is considered to correlate with the risk of ESCC, and patients with numerous iodine-unstained areas have particularly high risk of ESCC. According to the Japan Esophageal Cohort Study, Grade C is defined as patients with ten or more iodine-unstained areas in the background of esophageal mucosa, and it is generally associated with a high risk of metachronous or multiple ESCCs. The guidelines of the Japan Gastroenterological Endoscopy Society recommend endoscopic surveillance every 6 to 12 months after endoscopic resection (ER) for ESCC, especially, Grade C need to be paid attention for the high risk of ESCC. However, in clinical practice, some patients with Grade C do not have metachronous or multiple ESCCs even though they are long-term followed. Then, while it is likely that the risk of patients with Grade C is not uniform, that remains unclear.

Aims & Methods: The aim of this study was to identify risk factors for multiple ESCCs for patients with Grade C in the background of esophageal mucosa.

We retrospectively analyzed patients with Grade C esophageal squamous cell carcinoma (ESCC) who underwent initial endoscopic resection (ER) at our institution between January 2014 and December 2023, and followed up for more than six months. Patients were classified into three groups according to the number of iodine-unstained areas in the background esophageal mucosa: Group α (10–20 areas), Group β (21–30 areas), and Group γ (≥31 areas). Additionally, following clinical variables were collected: age, sex, smoking history (pack-years), alcohol consumption, use of antithrombotic agents, history of other malignancies, and the presence of background mucosal flushing. We calculated the five-year cumulative incidence of multiple ESCCs in each group and performed multivariate analysis to identify independent risk factors of multiple ESCCs.

Results: A total of 253 patients were included in the analysis. There were 224 male (88.5%), and median age was 67 years old. Multiple ESCCs were observed in 123 patients (48.6%). There were 57 patients (22.5%) in Group α, 25 (9.8%) in Group β, and 171 (67.6%) in Group γ. The five-year cumulative incidence of multiple ESCCs was 54.7% as overall (Group α: 30.0%, Group β: 24.9%, and Group γ: 65.3%). The five-year cumulative incidence in Group γ was significantly higher than that in Groups α and β ($p < 0.01$). In multivariate analysis, Group γ was an independent risk factor of multiple ESCCs (hazard ratio: 2.67; 95% confidence interval: 1.46–4.87; $p < 0.01$).

Conclusion: As current guidelines recommend surveillance endoscopy every 6 to 12 months following ER for ESCC in patients with Grade C, subclassification of Grade C could serve as a useful tool in determining appropriate surveillance intervals. Patients with Group γ would undergo more intensive surveillance endoscopy.

Meanwhile, the surveillance interval for patients with Groups α and β might be extended. Subclassification of Grade C patients based on the number of iodine-unstained areas may better predict the risk of developing multiple ESCCs.

Disclosure: Nothing to disclose.

GREEN TEA POLYPHENOLS AMELIORATE ESOPHAGITIS RATHER THAN ASPIRIN IN A THREE-ARM PROSPECTIVE COHORT STUDY

X. Li[1], Q. Zhang[1], Z. Shutian[1], J. Xing[1]
[1]Beijing Friendship Hospital, Capital Medical University, Gastroenterology, Beijing, China

Contact E-Mail Address: xue_li95@126.com

Introduction: Green tea polyphenols (GTPs) and aspirin were demonstrated to be novel candidates for cancer chemoprevention.

Aims & Methods: This study aimed to investigate the effects of GTPs and aspirin on esophageal diseases. This prospective cohort study recruited participants who self-reported long-term GTPs intake, aspirin intake and no medicine use in the questionnaire and underwent gastroscopy with biopsies if needed. The outcomes were the regression rates of esophageal precursor lesions after a one-year follow-up and side effects of GTPs and aspirin intake.

Results: A total of 159, 151,160 participants self-reported long-term GTPs, aspirin intake, and no medication at baseline. After one year, 78, 81, and 83 participants received the follow-up endoscopy in the GTPs, aspirin, and control groups, respectively. The average age of participants was 50.11 ± 5.62 years old, consisting of 42 (17%) female and 200 (83%) male. The regression rates of esophageal precursor diseases were 67.90%, 55.13%, and 48.19% in the GTPs, aspirin, and control groups, respectively (P = 0.036). Analyzing the esophagitis subgroup, the regression rate of GTPs group (43/69, 62.32%) was significantly higher than aspirin group (32/67, 47.76%) and control group (27/70, 38.57%) (P = 0.019). The incidences of nausea were 0.63% in GTPs group (1/159) and 0.66% of participants in aspirin group (1/151) suffered gastrointestinal bleeding, respectively.

Conclusion: GTPs, rather than aspirin, could improve the outcomes of esophagitis compared with the control group. The protective effects of GTPs on esophageal precursor diseases make it a promising health supplement.

Introduction: In Japan, the standard treatment for resectable locally advanced esophageal squamous cell cancer (ESCC) is neoadjuvant triplet chemotherapy (fluorouracil, cisplatin, and docetaxel [DCF]) followed by surgery, based on the results of the phase III randomized controlled study (JCOG1109). Some reports suggest that preoperative endoscopic evaluation of the primary tumor may predict postoperative outcomes. Given the increasing importance of endoscopic evaluation of response to neoadjuvant therapy in primary tumor, the 12th edition of the Japanese Classification of Esophageal Cancer introduced a new endoscopic sub-classification “RR (Remarkable Response)”, which was defined as showing remarkably shrink to nearly T1 depth after treatment. However, its clinical significance remains unclear.

Aims & Methods: The aim of this study is to determine the clinical significance of a new endoscopic sub-classification “RR” by evaluating its association with both histological response in surgical specimens and postoperative prognosis. We retrospectively analyzed the patients with resectable locally advanced ESCC (cT2-3/N0-3/M0-1, UICC-TNM 8th edition) who were performed with ≥1 cycle of neoadjuvant DCF therapy followed by surgery at our institution between April 2015 and March 2020. Exclusion criteria were:

1) JCOG1109 participants,
2) not evaluated the primary lesion by endoscopy before or after DCF therapy due to esophageal stricture,
3) >56 days from DCF therapy completion to surgery, or;
4) pathologically non-curative resection (R1-2).

Two endoscopists retrospectively evaluated pre- and post-DCF therapy endoscopic images with masked prognostic information and classified the cases into three groups:

1) RR,
2) non-RR and;
3) PD (Progressive disease).

Histological response data were retrospectively collected from medical records. According to the 12th edition of the Japanese Classification of Esophageal Cancer, all surgically resected specimens containing visible primary tumor tissue underwent histological examination in cases where preoperative treatment has been administered.

Histological response was graded according to the Japanese Classification of Esophageal Cancer, on a four-point scale ranging from grade 0 (ineffective) to grade 1 (slightly effective), grade 2 (moderately effective), and grade 3 (markedly effective).

We evaluated the proportions of cases achieving histological response of grade 2-3 in each group, and also calculated 3-year RFS and OS rates in each group.

Results: Of 114 eligible patients (median age 66.5 years [range 42-76], 91 males), clinical stage distribution was IIB/IIIA/IIIB/IVA/IVB: 1/0/58/15/40. 97/0/17 patients received 3/2/1 cycles of neoadjuvant DCF therapy. By endoscopic evaluation, 63 patients were classified as RR, 51 as non-RR, and 0 as PD. Among RR cases, 45 patients (71.4%) showed histological response of grade 2-3, while among non-RR cases, 5 patients (9.8%) showed grade 2-3. During the median follow-up of 42.6 months, 3-year RFS rates for RR/non-RR groups were 62.2%/49.0% (P=0.098), and 3-year OS rates were 76.9%/53.0% (P=0.026).

Conclusion: The newly introduced “RR (Remarkable Response)” of sub-classification for endoscopic evaluation after neoadjuvant chemotherapy may be useful for predicting histological response and stratifying prognosis in locally advanced ESCC.

Disclosure: Nothing to disclose.

Contact E-Mail Address: tomino.takuro.93@gmail.com

Introduction: It is well known that head and neck squamous cell carcinoma (HNSCC) often occur in patients with esophageal squamous cel carcinoma (ESCC) synchronously or metachronously. As a result of improvements in endoscopic system and observation techniques, the number of patients with advanced ESCC who are detected superficial HNSCC before treatment is increasing. However, subsequence clinical course of superficial HNSCC in patients who were treated with systemic neoadjuvant triplet chemotherapy for advanced ESCC has been unknown.

Aims & Methods: The aim of this study is to clarify the influence of neoadjuvant docetaxel, cisplatin, and 5-fluorouracil (DCF) therapy for superficial HNSCCs and clinical course of these lesions. The patients with advanced ESCC and superficial HNSCC, which were diagnosed by biopsy, who were treated with neoadjuvant DCF therapy for esophagectomy at our institution between January 2015 and December 2022 were retrospectively included. We excluded the patients who had a history of surgery or radiotherapy for HNSCC, chemotherapy within 5 years for any malignancy, or no endoscopic observation after the start of DCF therapy. At our institution, the endoscopic assessments were routinely performed for ESCC and HNSCC after the completion of each course of DCF therapy and reported the morphological changes in HNSCC lesions. In this study, endoscopic complete response (eCR) was defined as the disappearance of visible tumors in endoscopic observation and did not require histological confirmation by biopsy. The proportion of eCR in HNSCCs after DCF therapy, and 2-year cumulative recurrence rate of HNSCCs after eCR for the patients who did not receive chemotherapy or radiotherapy after surgery were evaluated. In addition, the difference in clinicopathological features between the patients with or without achievement of eCR were evaluated.

Results: Finally, 45 patients (56 lesions) were analyzed. Thirty-nine lesions (69.6%) were in the hypopharynx, 7 (12.5%) in the larynx, and 10 (17.9%) in the oropharynx. The median lesion size was 20 mm (range: 3-40 mm). Of all lesions, 45 lesions (80.4%) achieved eCR by DCF administration. There were no significant differences in tumor location, lesion size, and the number of administrated DCF course between the patients with or without achievement of eCR. On the histological evaluation using the biopsy samples, the lesions without subepithelial invasion were more likely to achieve eCR than those with invasion [88.9% vs 63.2%, P=0.035]. Seven patients who received additional chemotherapy or radiotherapy after esophagectomy and two who did not receive endoscopic assessment after esophagectomy were excluded for long-term analysis. Then, of the 39 lesions in 32 patients with achievement of eCR, 15 lesions (51.7%) had a local recurrence during the median follow-up period of 11 months (range 1.9-87 months), and the 2-year cumulative recurrence rate was 57.6%. Of these local recurrences, 12 lesions were performed with endoscopic laryngopharyngeal surgery, two with radiotherapy, and the other was not treated because of progression of ESCC.

Conclusion: Superficial HNSCCs mostly achieved eCR after neoadjuvant DCF therapy for locally advanced ESCC, however, more than half of them had a local recurrence thereafter. Therefore, the appropriate endoscopic follow-up after esophagectomy, early detection of local HNSCC recurrence, and therapeutic intervention were necessary.

Disclosure: Nothing to disclose.

PP0087

EVALUATION OF THE USEFULNESS AND PROGNOSIS OF ENDOSCOPIC RESECTION FOR HYPOPHARYNGEAL CANCER

T. Oyama[1], A. Takahashi[1]
[1]Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan

Contact E-Mail Address: oyama@coral.ocn.ne.jp

Introduction: Twenty-five years have passed since the development of endoscopic submucosal dissection (ESD), and it has become widely used as the first-line treatment for early-stage esophageal and gastric cancers with low risk of lymph node metastasis. However, due to the anatomical complexity and technical difficulty, the application of ESD for hypopharyngeal cancer remains limited.

Aims & Methods: A total of 151 lesions in 106 patients with hypopharyngeal cancer who underwent ESD at the Department of Endoscopy, Saku Central Hospital Advanced Care Center from June 2006 to March 2025 were retrospectively reviewed to evaluate treatment outcomes. Cases of recurrence after chemoradiotherapy were excluded. ESD Procedure
All procedures were performed under general anesthesia with intubation. A hook knife J was used to perform circumferential incisions with the Autocut mode of the VIO 3000 or VIO 3. Submucosal dissection was carried out using Endocut I and spray coagulation. For traction and improved visualization, Clip line technique was used.

Results: The study included 116 patients (109 men, 7 women), with a mean age at diagnosis of 67.7 years (range: 40–92). Synchronous multiple pharyngeal cancers were found in 25 patients and metachronous in 13. A total of 156 lesions were resected: 10 by endoscopic mucosal resection (EMR) and 146 by ESD.
Tumor locations were as follows: oropharynx (7 lesions), hypopharynx (149 lesions), primarily in the piriform sinus (135) and posterior cricoid area (14). Of these, 6 extended to the epiglottis and 5 to the aryepiglottic fold.
Detailed Results:

1. Tumor size: mean maximum diameter was 14.5 mm (range: 1–51; resection specimen size: 27.4 mm (5–90). Depth of invasion: EP in 92 lesions (59%) and SEP in 64 (41%). Mean invasion depth from the surface was 712 µm (range: 150–2600). Macroscopic types: 0-I (7), 0-IIa (53), 0-IIb (92), 0-IIc (4). Histology: squamous cell carcinoma (SCC) in 155 lesions, neurofibroma in 1. En bloc resection rate was 100%. Lateral margins: positive in 6, negative in 150. Deep margins: negative in all cases.
2. Adverse events: delayed bleeding (1), aspiration pneumonia (2), and stricture (1).
3. Local recurrence: observed in one SEP case with lymphatic involvement.
4. Pre-ESD metachronous cancers: esophagus: 42, stomach:17, colon:1.
5. Post-ESD metachronous cancers: esophagus:22, hypopharynx:13 and stomach:10.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

6. Prognosis: Mean follow-up was 84.9 months (range: 5–222). There were 5 deaths from primary disease, 10 from other diseases, and 8 from other malignancies. All 5 primary disease-related deaths had ly1 and died due to lymph node, pulmonary, or hepatic metastases.
7. Among 11 cases with extension to the aryepiglottic fold or epiglottis, tracheostomy was performed in 8 and nasotracheal intubation in 2 cases.

Conclusion: ESD for hypopharyngeal cancer demonstrated a high rate of local control and was an effective treatment option. Even in cases with extension to the aryepiglottic fold or epiglottis, safe procedures were possible with tracheostomy. For cases with positive lympho-vascular involvement, the risk of lymph node and distant metastases warrants consideration of additional treatment. Metachronous multiple cancers in the hypopharynx, esophagus, and stomach occurred in 40% of patients, emphasizing the importance of postoperative surveillance.

"EFFICACY AND SAFETY OF CAMRELIZUMAB IN ESOPHAGEAL SQUAMOUS CELL CARCINOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS"

. Hasanin [1], H. Khelifa[2]
[1]University Of Tripoli, Faculty of Medicine, Tripoli, Libya, [2]Faculty of Medicine University of Oran 1 Ahmed Ben Bella, Oran, Algeria

Contact E-Mail Address: hamzakhelifa180@gmail.com

Introduction: Esophageal Squamous Cell Carcinoma (ESCC) remains a significant global health problem with few therapeutic options and poor prognosis. Camrelizumab, an anti-PD-1 immune checkpoint inhibitor, has been shown in clinical trials to be of potential value in the treatment of advanced or metastatic ESCC as monotherapy or in combination with chemotherapy or anti-angiogenic therapy.

Aims & Methods: The aim of this study is to evaluate the clinical efficacy and safety profile of Camrelizumab in patients with esophageal squamous cell carcinoma, with the main outcomes being progression-free survival (PFS), objective response rate (ORR), and treatment-related adverse events.

We conducted a comprehensive search of PubMed, Scopus, Web of Science, Embase, and Cochrane from their inception to April 2025, focusing on randomized controlled trials (RCTs) and observational studies evaluating Camrelizumab for the treatment of esophageal squamous cell carcinoma. Meta-analyses utilized a random-effects model to calculate odds ratios, mean differences, and 95% confidence intervals for adverse events and total patients.

Results: Out of 1,563 studies initially screened, 15 studies met the inclusion criteria for our meta-analysis, comprising adult patients. Meta-analysis established a median progression-free survival (PFS) of 7.60 months (95% CI: 6.00–9.19). The major pathological response rate (MPR) was 0.42 (95% CI: 0.37–0.48), and the objective response rate (ORR) was 0.53 (95% CI: 0.38–0.68). The R0 resection rate was also remarkably high at 0.98 (95% CI: 0.96–1), and the disease control rate (DCR) was 0.87 (95% CI: 0.64–1). The pathological complete response rate (pCR) was 0.31 (95% CI: 0.20–0.43).

Regarding safety, the most common treatment-related adverse events were leukopenia 0.45 (95% CI: 0.23–0.68), neutropenia 0.30 (95% CI: 0.19–0.41), anemia 0.14 (95% CI: 0.03–0.29), thrombocytopenia 0.09 (95% CI: 0.03–0.17), and elevated transaminases 0.06 (95% CI: 0.02–0.12). Pneumonia 0.17 (95% CI: 0.11-0.23) and hypertension 0.12 (95% CI: 0.06-0.19) were the other immune-related adverse events. The majority of these events were tolerable and within safe parameters.

Conclusion: Camrelizumab demonstrates promising efficacy in the treatment of esophageal squamous cell carcinoma with satisfactory rates of ORR, MPR, and R0 resection. The safety profile is acceptable with controllable adverse effects.

These findings support the potential therapeutic value of camrelizumab as a significant treatment strategy in multimodal treatment of esophageal squamous cell carcinoma and the need for further research to optimize its clinical use.

Disclosure: Nothing to disclose.

PP0089

DEVELOPMENT AND VALIDATION OF A SCORE-BASED MODEL FOR ESTIMATING ESOPHAGEAL SQUAMOUS CELL CARCINOMA AND PRECANCEROUS LESIONS RISK IN OPPORTUNISTIC SCREENING POPULATION

Y. Bian[1], Z.-R. Chen[1], Y. Gao[1], W. Wang[1], L.-W. Wang[1]
[1]Changhai Hospital, Naval Medical University, Gastroenterology, Shanghai, China

Contact E-Mail Address: chen_zheran@163.com

Introduction: Opportunistic screening is one major screening approach for esophageal squamous cell carcinoma (ESCC). Risk stratification models could be used to assess each individual's risk using relevant predictors so that only those at high risk are recommended for further endoscopy [1-2]. This approach would allow the development of a cost-effective opportunistic screening strategy and promise to improve the sensitivity of endoscopic detection by alerting the endoscopists.

Aims & Methods: We aimed to develop a score-based clinical prediction model to assess the risk of ESCC and precancerous lesions in opportunistic screening and to validate it in an external population. The study was a secondary analysis of a published esophageal cancer screening trial [3].

The trial was conducted in 39 secondary or tertiary hospitals in China, with 14,597 individuals enrolled for opportunistic screening.

Additionally, questionnaires and endoscopy were performed. The primary outcome was histology-confirmed high-grade esophageal lesions, including high-grade intraepithelial neoplasia (HGIN) and ESCC. The predictors were selected using univariable and multivariable logistic regression. Model performance was primarily measured with the area under the receiver operating characteristic curve (AUROC).

Results: The score-based prediction model contained 8 variables on a 21-point scale. The model demonstrated an AUROC of 0.833 (95% CI, 0.803-0.862) and 0.828 (95% CI, 0.793-0.864) for detecting high-grade lesions in the development and validation cohorts, respectively.

	Development cohort (n=7899)	Validation cohort (n=6698)
Sensitivity (%, 95%CI)		
High-grade lesions	84.3(77.6-89.7)	77.6(68.0-85.4)
HGIN	82.9(67.9-92.9)	70.0(50.6-85.3)
Early ESCC	81.5(61.9-93.7)	81.3(63.6-92.8)
Advanced ESCC	86.1(76.9-92.6)	81.1(64.9-92.0)
Specificity (%, 95%CI)	68.3(67.3-69.4)	76.4(75.4-77.4)
Accuracy rate (%, 95%CI)	68.6(67.6-69.7)	76.4(75.4-77.5)
NSS	20	21

Abbreviations: HGIN, high-grade intraepithelial neoplasia; ESCC, esophageal squamous cell carcinoma; NNS, number needed to screen to detect one case of HGIN/ESCC; CI, confidence interval. High-grade lesions include HGIN and ESCC.

Table 1. The predictive performance for the score-based model at the score cut-off value of 9.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

As shown in Table 1, using the score cut-off value determined in the development cohort (≥9), the sensitivity reached 70.0% (95% CI, 50.6%-85.3%), 81.3% (95% CI, 63.6%-92.8%), and 81.1% (95% CI, 64.9%-92.0%) in the validation cohort for detecting HGIN, early ESCC, and advanced ESCC, respectively, at a specificity of 76.4% (95%CI,75.4%-77.4%). The score-based model exhibited satisfactory calibration in the calibration plots. The score-based model could result in 75.6% fewer individuals subjected to endoscopies.

Conclusion: This score-based model demonstrated superior discrimination for high-grade esophageal lesions. It has the potential to inform referral decisions in the opportunistic screening setting.

Introduction: Esophageal squamous cell carcinoma (ESCC) is a major cause of cancer-related mortality with poor survival rates. PD-1/PD-L1 inhibitors have shown superior efficacy over chemotherapy in advanced ESCC. Smocking is a major risk factor of ESCC. We aim in this paper to evaluated the effects of smocking status on the efficacy of PD-1 inhibitors in advanced ESCC.

Aims & Methods: An electronic search was conducted on February 1, 2025, using PubMed, Embase, Web of Science, the Cochrane Library, and Scopus. We included only randomized controlled trials (RCTs) that compared PD-1/PD-L1 inhibitors to chemotherapy for advanced ESCC. The primary outcome was overall survival stratified by smoking status (never, former, or current smokers). Hazard ratios (HRs) with 95% confidence intervals (CIs) were used to estimate effect sizes. A random-effects model was applied.

Results: Of the 7,094 articles screened, 7 trials were included, with a total of 3562 patients. In this subgroup meta-analysis, PD-1/PD-L1 inhibitors demonstrated a significant overall survival benefit in both subgroups "never smoked" (HR 0.71, 95% CI 0.60–0.84) and "former smokers" (HR 0.78, 95% CI 0.66–0.91), with low heterogeneity (I^2 = 0% for both groups). In contrast, current smoker subgroup did not show a significant overall survival benefit (HR 0.58, 95% CI 0.31–1.09), with moderate heterogeneity (I^2 = 55.9%), suggesting that active smoking may reduce the efficacy of PD-1/PD-L1 inhibitors in ESCC.

Conclusion: This subgroup meta-analysis suggests that PD-1/PD-L1 efficacy may be influenced by smoking status. Current smokers did not show a survival benefit compared to former or never smokers. Further research is needed to explore the underlying mechanisms to optimize treatment strategies for active smokers.

Introduction: Peptic ulcer disease (PUD) is the most frequent cause of non-variceal upper gastrointestinal bleeding (NVUGIB). Over the decades, understanding the natural history of PUD and development of new treatment strategies has significantly improved clinical outcomes. In this study we explore the natural history of PUD, including risk factors, therapeutic approaches and mortality.

Aims & Methods: We conducted a retrospective cohort study including consecutive patients with PUD diagnosed by upper endoscopy between January-2020/June-2022. Data regarding risk factors, clinical presentation, endoscopic findings, therapeutic approaches, rebleeding and mortality rate were collected.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We identified 468 patients (male sex-63.9%; mean age-71.8±15.6 years; median Charlson Comorbidity Index (CCI) - 5.4;range 0-18). Major risk factors: alcohol consumption - 31.6%; NSAIDs - 28.4%; Helicobacter pylori infection - 23.1%. Antiplatelet or anticoagulant drugs were part of the usual medication in 47.2% of the cases and were associated with major hemodynamic instability upon admission (χ^2 = 4.805, df=1, p=0.028), a situation that has been shown to significantly increase the risk of death (OR 3.10, IC95%: 1.745-5.509). PUD clinical presentation: melena and/or hematemesis - 65.4%; isolated anemia - 17.9%. Mean hemoglobin level at admission - 8.5±2.5 g/dl. Lower levels were associated with a higher 7-day rebleeding rate (Z=-2.383, p<0.05). Small Forrest III ulcers of gastric antrum and duodenal bulb were the most common and PPI perfusion was administered in 29.1% of the cases. Overall, 37% of patients benefited from treatment: endoscopic - 96.6%; transarterial embolization - 9.1%; surgery - 1.7%. Hospitalization was needed in 67.2% cases, with mean duration of 13.4±13.7 days. Complications occurred in 12.6% and there was need for further intervention in 7.9% of the cases. 30-day mortality was 12% (related to infections - 78%, stage IV neoplasia - 12%). Differently from age, the CCI demonstrated to be associated with 30-day mortality (Z=-4.230, p<0.001).

Conclusion: PUD is a common clinical condition, with known modifiable risk factors and diverse clinical presentation. Despite improvements in endoscopic techniques, mortality remains significant and CCI is a relevant prognostic factor.

THE PROTECTIVE EFFECT AND MECHANISM OF ESCIN ON ETHANOL-INDUCED GASTRIC MUCOSAL INJURY IN RATS

Y. Shen[1], J. Han[1], F. Hu[1], J. Zhao[1], X. Gao[1], W. Tian[1], J. Lv[1], Y. Wang[1], M. Yang[1], H. Zhang[1], J. Yin[1], Q. Zhan[1], F. An[1]

Introduction: Ethanol-induced gastric ulcers are common and the treatment options are limited. Escin, a extract from the horse chestnut plant, has been proven to have therapeutic effects in improving inflammation, edema, and vascular permeability. However, its effects and mechanisms on ethanol-induced gastric mucosal injury are not yet clear.

Aims & Methods: This study aims to explore the protective effect of Escin on ethanol-induced gastric mucosal injury and its potential mechanisms, providing a new drug choice for the treatment of ethanol-induced gastric ulcers. For this purpose, a control, ethanol, ethanol+Escin, and ethanol+omeprazole groups were established in male SD rats to compare and analyze the ulcer index and histopathological scores of each group. The network pharmacology approach was used to predict potential targets of Escin related to gastric ulcers. Apoptotic proteins, NF-κb inflammatory pathway proteins, inflammatory factors, and related mRNA expression were analyzed by methods such as Immunofluorescence (IF), Immunohistochemistry (IHC), Western Blot (WB), real-time quantitative fluorescence PCR (q-PCR), and enzyme-linked immunosorbent assay (Elisa). Furthermore, an ethanol-induced GES-1 cell injury model was established to evaluate the protective effect of Escin. Finally, Transcriptomic sequencing was performed to identify key regulatory genes.

Results: The study found that Escin significantly reduced the damage of ethanol to gastric mucosal tissues. Network pharmacology analysis predicted that Escin is closely related to inflammatory pathways such as NF-κb in the treatment of gastric ulcers. IHC and WB results showed that Escin reduced the loss of gastric mucosal surface markers MUC5AC, TFF2, and gastric mucosal barrier protein O-ccludin, inhibited the expression of inflammatory factors IL-1β, IL-6, TNF-α, and apoptosis-related proteins BAX, Caspase-3, and promoted the expression of anti-apoptotic protein BCL-2. IF further revealed that Escin prevented the nuclear translocation of NF-κb, thereby inhibiting the activation of the NF-κb pathway. Elisa results showed a decrease in inflammatory factor levels in the plasma of rats in the Escin group, while q-PCR results demonstrated that Escin downregulated the expression levels of inflammatory factor mRNA in gastric tissues. Cell proliferation experiments also confirmed the protective effect of Escin against ethanol-induced damage. Finally, Transcriptomic analysis revealed significant upregulation of 27 inflammation-related genes in ethanol-treated gastric tissues. Notably, nine genes—Birc3, Bcl3, SOCS1, SOCS3, Ccl2, Cx3cl1, Pim1, SGK1, and OSMR—were identified as positive regulators of the TNF-α/NF-κB signaling axis through functional annotation and pathway enrichment analysis.

Conclusion: Escin exerts a protective effect on ethanol-induced gastric mucosal damage by inhibiting the TNF-α/NF-κB pathway, reducing the expression of inflammatory factors and the level of cell apoptosis. Escin, as a novel therapeutic drug for ethanol-induced gastric ulcers, has certain clinical translational application value, but further clinical trials are needed to confirm the results.

MACHINE LEARNING-BASED PREDICTION OF 30-DAY MORTALITY IN PEPTIC ULCER BLEEDING: COMPARISON WITH TRADITIONAL SCORING SYSTEMS

J.-y. Seo[1], A.Y. Lee[2], J.H. Yu[3], K. hayoung[4]
[1]Bundang Cha medical center, Cha College of Medicine, Gyeonggi-do, Department of Gastroenterology, Bundang, South Korea, [2]Gangnam Cha Medical Center, Cha College of Medicine, Seoul, Department of Gastroenterology, Seoul, South Korea, [3]Bundang Jesaeng General Hospital, Seongnam-si, Gyeonggi-do, South Korea, [4]Bundang Jesaeng General Hospital, Department of Gastroenterology, Gyeonggi-do, South Korea

Contact E-Mail Address: terryxom11@naver.com

Introduction: Peptic ulcer bleeding (PUB) is a major cause of gastrointestinal-related morbidity and mortality. Various clinical scoring systems such as AIMS65, Glasgow-Blatchford Score (GBS), and ABC score have been used for mortality prediction. However, their predictive performance varies, and improved tools may enhance clinical decision-making.
This study aimed to compare the predictive accuracy of traditional scoring systems with machine learning models for 30-day mortality in PUB patients.

Aims & Methods: We retrospectively analyzed data from patients with endoscopically confirmed PUB. Independent variables included clinical parameters, laboratory results, and endoscopic findings. Five conventional scoring systems (GBS, AIMS65, ABC score, Pre- and Post-Rockall scores) were evaluated. A machine learning model based on logistic regression was developed using relevant clinical features. Predictive performance

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

was assessed using area under the receiver operating characteristic curve (AUROC), sensitivity, and specificity. Optimal cut-off values for each score were determined using Youden's Index.

Results: Among conventional scores, the ABC score achieved the highest AUROC (0.892), followed by AIMS65 (0.864). The machine learning model showed superior performance with an AUROC of 0.989, sensitivity of 66.7%, and specificity of 96.7%. Compared to traditional scoring systems, the machine learning model achieved comparable or higher sensitivity and significantly improved specificity.

Conclusion: Machine learning, particularly logistic regression, provided more accurate prediction of 30-day mortality in PUB compared to conventional scoring systems. These findings support the integration of machine learning models into risk assessment strategies for PUB patients.

ENDOSCOPIC SUBMUCOSAL DISSECTION FOR *HELICOBACTER PYLORI*-NEGATIVE LOCALIZED GASTRIC MUCOSA-ASSOCIATED LYMPHOID TISSUE LYMPHOMA: A CASE SERIES

H. Ohta[1], A. Miwa[2]
[1]Kurosawa Hospital, Gastroenterology, Takasaki, Japan, [2]Kurosawa Hospital, General Technical Office, Takasaki, Japan

Contact E-Mail Address: rmrpq136@ybb.ne.jp

Introduction: The first-line treatment for gastric mucosa-associated lymphoid tissue (MALT) lymphoma is Helicobacter pylori (H. pylori) eradication when infection is present. In the absence of infection, treatment options include radiotherapy, chemotherapy, or surgery, depending on disease extent. [1] However, the management of H. pylori-negative gastric MALT lymphoma remains controversial. Recently, endoscopic submucosal dissection (ESD) has been reported as a potential curative treatment, but data remain limited due to the rarity of such cases.

Aims & Methods: We report our experience with ESD in three consecutive cases of localized H. pylori-negative gastric MALT lymphoma identified among 29,331 esophagogastroduodenoscopies (EGDs) conducted at our large-scale health screening facility during the 2024 health check-up program. We aim to highlight the feasibility of ESD as a less invasive alternative to radiotherapy or chemotherapy and contribute to future treatment strategies.

Results: Three cases (0.01%, 3/29,331) of localized gastric MALT lymphoma were identified: a 71-year-old female, a 43-year-old female, and a 63-year-old male. Lesions were located in the upper body, middle body, and angular region, measuring 15 mm, 20 mm, and 7 mm, respectively. Larger lesions exhibited cobblestone-like mucosal patterns with depressed granular erythematous areas, while the smallest lesion appeared as a simple depressed lesion with discoloration. Biopsies confirmed CD20 and CD79a positivity, CD3 and CD10 negativity, and lymphoepithelial lesions on AE1/AE3 staining, leading to the diagnosis of gastric MALT lymphoma. Contrast-enhanced CT showed no lymph node involvement or distant lesions, classifying all cases as localized stage (Lugano classification). Absence of gastric mucosal atrophy, negative H. pylori IgG serology, negative urea breath test (UBT), and absence of H. pylori on Giemsa staining confirmed an H. pylori-negative status. All three cases underwent ESD, achieving complete en bloc resection with negative margins. No complications, such as delayed bleeding or perforation, were observed following ESD. Histopathological examination revealed clusters of B-cell lymphocytes confined to the mucosa and superficial submucosa. Follow-up EGD with biopsy showed no recurrence in any case.

Conclusion: We performed ESD for three cases of H. pylori-negative localized gastric MALT lymphoma, achieving complete resection with negative margins in all cases without any complications. Additionally, short-term outcomes were favorable. While observation, radiotherapy, and chemotherapy are available treatment options for H. pylori-negative localized gastric MALT lymphoma, cases of tumor progression and transformation into diffuse large B-cell lymphoma (DLBCL) after chemotherapy have been reported. [2] Therefore, early resection may provide a safer approach. Our findings suggest that early resection may be a preferable approach for localized lesions. Further accumulation of cases and long-term follow-up are necessary to establish ESD as a viable treatment option.

FOLLOW-UP OF GASTRIC ULCERS: IS THERE REALLY A NEED FOR FOLLOW-UP IN ALL PATIENTS?

M. Cristiano[1], F. Vidal Lima[1], C. Borges Chaves[1], N.P. Almeida[1,2], P. Narra Figueiredo[1,2]
[1]Unidade Local de Saúde de Coimbra, Gastroenterology Department, Coimbra, Portugal, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Contact E-Mail Address: margarida.cristiano@hotmail.com

Introduction: Gastric ulcers are associated with malignancy in 8.5% of cases, prompting recommendations for follow-up oesophagogastro-duodenoscopies (OGDs) to confirm ulcer healing and exclude malignancy. However, the incidence of malignancy at follow-up endoscopy is low, and no consensus exists on patient selection and optimal timing.
This study evaluates current follow-up practices and the diagnostic yield of follow-up OGDs.

Aims & Methods: This study evaluates current follow-up practices and the diagnostic yield of follow-up OGDs. We conducted a retrospective cohort study of consecutive patients diagnosed with gastric ulcers between 2020 and 2023. Data on risk factors, endoscopic and histological findings from index and follow-up OGDs and surveillance data were analyzed.

Results: A total of 297 patients were identified (58.2% male; mean age 73.2 ± 15.5 years; median Charlson Comorbidity Index: 5.5). The main risk factors were Helicobacter pylori infection (52.7%) and NSAID use (31.3%). Gastric neoplasia was diagnosed in 26 patients. Biopsies were obtained in 34% of index OGDs (mean: 4.3 ± 1.8 biopsies), detecting 69.2% of neoplasia cases (n=18). Follow-up OGD was performed in 46.8% of patients, primarily within eight weeks (24%), diagnosing the remaining 30.8% of neoplasia cases.
Among these, only one case did not show endoscopic suspicion of neoplasia in the index OGD. In three cases with malignant macroscopic suspicion at index OGD, initial biopsies revealed metaplasia, but follow-up OGD con-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

firmed neoplasia. Predictors of malignancy included suspicious appearance (p=0.028; AUROC=0.939), larger ulcer size (p<0.001), and non-antral location (p=0.041). A minimum of 3 to 4 biopsies appeared optimal for diagnosis, and follow-up timing did not significantly impact diagnostic yield.

Conclusion: Our analysis suggests that ulcers with a benign endoscopic appearance, small size, and non-antral location may not require follow-up OGD. These findings challenge the need for universal surveillance, that is rarely applied in clinical practice, and emphasize the importance of risk stratification for targeted follow-up in patient management.

Introduction: Gastric cancers (GCs) are histologically classified into differentiated and undifferentiated types. Mixed histological type is considered more aggressive clinical behavior compared to pure histological type. However, no reports of large-scale prospective studies regarding the long-term prognosis of mixed histological type cured in patients by endoscopic resection (ER).

Aims & Methods: We aimed to determine the long-term prognosis of mixed histological-type GCs in patients cured by ER. We used data from the J-WEB EGC study, a nationwide, multicenter, prospective cohort that enrolled 9,715 patients with 10,926 lesions treated by ER between 2010 and 2012 across 41 institutions in Japan. For this analysis, we included patients classified as eCura A or B, according to the Japanese gastric cancer treatment guidelines, represent pathological criteria for curative resection following ER. eCura A included: differentiated-type, pT1a, without ulceration (UL0), negative horizontal and vertical margins (HM0, VM0) (A-1), and no lymphovascular invasion (Ly0, V0); differentiated-type, ≤30 mm, pT1a, with ulceration (UL1), HM0, VM0, Ly0, V0 (A-2); and undifferentiated-type, ≤20 mm, pT1a, UL0, HM0, VM0, Ly0, V0 (A-3). eCura B included differentiated-type, pT1b with submucosal invasion <500 μm, HM0, VM0, Ly0, and V0. We excluded patients with multiple lesion and those with lesions containing unusual type. Each patient was followed up for 5 years. The primary endpoints were 5-year overall survival (OS) and 5-year primary disease-specific survival (pDSS) to primary GC. Patients were divided into pure and histological types. OS and pDSS were assessed using the Kaplan–Meier method, and hazard ratios (HRs) for all-cause mortality was estimated using the Cox proportional hazards regression model with death as the event. After stratification into eCuraA-1, eCuraA-2, eCuraA-3, and eCura B, the 5-year OS and pDSS were compared between the pure and mixed histological types.

Results: A total of 7,242 patients with 8,187 GC lesions were classified as eCura A or B. After excluding 646 patients with multiple GC lesions and one patient with an GC lesion containing a neuroendocrine tumor component, 6,595 patients with a single GC lesion were included in the analysis. Of these, 6,434 were pure histological type and 161 mixed histological type. There was no difference in OS between pure and mixed histological types in all patients (92.5%, 95% confidence interval [CI]: 87.4–95.7 vs. 90.5%, 95% CI: 89.7–91.2; p = 0.415, respectively). Additionally, mixed histological type was not an independent factor in adjusted HRs for OS all-cause

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

mortality (0.93, 95% CI: 0.52–1.64). The 5-year pDSS of the mixed histological-type GCs was significantly lower than that of the pure histological-type GCs (99.4%, 95% CI: 96.6–99.9 vs 99.96%, 95% CI: 99.9–100, p = 0.003, respectively). Among eCura A-2 patients, pDSS of the mixed histological-type GCs was significantly lower than that of the pure histological-type GCs (94.4%, 95% CI: 74.2–99.0 vs. 100%, 95% CI: 99.3–100; p < 0.001, respectively).

Conclusion: The long-term prognosis of curative ER patients, including those with mixed histological-type GCs, was favorable. However, the stratification analysis showed that mixed histological-type GCs in eCura A with ulcers was more likely to cause primary GC death than pure histological-type and might need careful surveillance.

UTILITY AND EFFECTIVENESS OF OUTPATIENT UNDERWATER COLD SNARE POLYPECTOMY FOR THE DIAGNOSIS OF SOLITARY POLYPOID LESIONS IN *HELICOBACTER PYLORI*-NAIVE STOMACH

D. Yoshimura[1], R. Yoshimura[2], A. Ohkubo[1], K. Fukaura[1], S. Umekita[1], S. Imamura[1], A. Ogasawara[1], S. Shimizu[1]

Introduction: Polypoid lesions in *Helicobacter pylori* (Hp)-naive stomachs are generally fundic gland polyps (FGPs), which have a smooth surface and typically do not require treatment. However, some lesions with different appearances, such as foveolar-type adenomas that present with a reddish color and papillary surface structure, may also be observed. These lesions can be difficult to diagnose accurately with biopsy alone. An efficient and safe diagnostic and therapeutic approach for these lesions is needed.

Aims & Methods: We devised outpatient underwater cold snare polypectomy (uCSP) as a diagnostic alternative to biopsy for reddish polypoid lesions in Hp-naive stomachs that differ from the typical appearance of FGPs. We retrospectively analyzed the clinicopathological characteristics and outcomes of cases in which outpatient uCSP was performed for solitary lesions ≤10 mm in size, after obtaining informed consent. Hp-naive was defined by the absence of endoscopic and histological atrophic changes, no history of eradication therapy, and negative results from at least two different diagnostic tests for *H. pylori* infection.

Results: Between April 2021 and March 2025, 35 cases underwent uCSP (16 males, 19 females; mean age: 55.9 years). The mean lesion size was 3.7 mm, with 21 lesions located in the upper part of stomach and 14 in the middle part of stomach. In all cases, lesions were obtained including surrounding mucosa with minimal crush artifact to the deep mucosal layer or superficial muscularis mucosae. Histopathological diagnoses included foveolar-type adenoma in 28 cases, foveolar hyperplastic polyp in 3, FGP with dysplasia in 2, oxyntic adenoma in 1, and inflammatory polyp in 1. Among the 31 neoplastic lesions, only the oxyntic adenoma case had a positive vertical margin, yet no residual or recurrent lesion was detected during 1-year follow-up. The remaining 30 cases had negative lateral and vertical margins. No postoperative bleeding or other adverse events were observed, regardless of proton pump inhibitor use or clip closure following resection.

Conclusion: Outpatient uCSP appears to be a minimally invasive, safe, and effective diagnostic and therapeutic option for solitary polypoid neoplastic lesions ≤10 mm in Hp-naive stomachs.

Disclosure: Nothing to disclose.

Introduction: Endoscopic submucosal dissection (ESD) is one of the effective treatments for superficial non-ampullary duodenal epithelial tumors (SNADETs). To avoid postoperative perforation and bleeding, our hospital had introduced D-LECS with ESD for SNADETs. From 2021, D-LECS was divided into D-LECS with FTR, which is a full-thickness resection, and D-LECS with ESD, which is intended for post-ESD reinforcement (1).

D-LECS with ESD is considered to be a therapeutic procedure that not only ensures safety but also contributes to the improvement of endoscopic skills.

Aims & Methods: The aim of this study is to evaluate the impact of D-LECS with ESD on the skill development of endoscopists. The subjects were 17 cases in which D-LECS was performed among 79cases diagnosed with SNADA by biopsy at our hospital between January 2000 and October 2023. 5 cases in which D-LECS with ESD was performed. The ESD assessment score was defined using a ladder chart based on muscle layer exposure, perforation, ESD time, and pathological examination results.

The scoring for points each item is as follows. (Exposure of muscle layer none: 0, <3mm: 1pt, 3~10mm: 2pt, 10mm<: 3pt, Perforation of the muscle none: 0, <3mm: 1pt, 3~10mm: 5pt, 10mm<: 10pt, ESD time <60min.: 0pt, 60~120min.: 5pt, 120min.<: 10pt, Pathological examination result pR0: 0pt, cR0+pRX: 5pt, pR1:10pt) Images and videos were used in combination to evaluate the muscle layer.

Results: ESD assessment scores of cases undergoing D-LECS with ESD were presented. The state of exposure of the muscle layer had a median of 5 (1-7), a mean of 4.8, and a standard deviation (SD) of 2.3. The state of perforation of the muscle layer had a median of 0 (0-10), a mean of 2.6, and a SD of 4.3. The median ESD time was 170 minutes, the mean was 146 minutes (41-198).

The state of pathological examination had a median of 0 (0-10), a mean of 2.0, and a SD of 4.5. The ESD assessment scores are presented as follows: (Exposure of muscle layer, Perforation of muscles layer, ESD, Pathological examination result).

The results of each score are as shown on the right, Case1: (7, 0,10, 0), Case2: (5,10, 10, 0), Case3: (5, 0, 10, 0), Case4: (6, 3, 10, 10), Case5: (1, 0, 1, 0). Although the number of cases was small, the time required for ESD was shortened and the degree of perforation tended to improve with experience. 2 examples revealed some important points.

Case 1: This case had many blood vessels, and the ST hood was needed because it is difficult to perform ESD. When the endoscope was extended, perforation occurred. Once the perforation was made, it was difficult to move the patient to other bed, so the muscle layer was sutured with OTSC, and a PGA sheet.

Case 2: The endoscopic strategy and device were improved, and the lesion could be dissected within 1 hour. ESD was performed with Dual Knife J 1.5. Pulling the lesion with an S-O clip. The RDI function was used during hemostasis to avoid the burn effect on the muscle layer.

Conclusion: D-LECS with ESD will lead to improvements of duodenal ESD techniques. But to ensure safety, laparoscopic closure is preferable until reliable suturing via endoscope becomes possible.

Introduction: Gastric cancer is a highly prevalent malignant tumor worldwide, and early diagnosis is crucial for improving survival rates. Claudin18.2 (CLDN18.2), a member of the tight junction protein family, is highly expressed in advanced gastric cancer and has emerged as a therapeutic target. However, its expression characteristics and diagnostic value in early gastric cancer remain unclear.

This study aims to investigate the expression patterns of CLDN18.2 in early gastric cancer and evaluate its potential as a diagnostic biomarker.

Aims & Methods: The study enrolled 54 patients with early gastric cancer to analyze their clinicopathological characteristics (including age, gender, histological type, differentiation degree, etc.). Immunohistochemistry was employed to detect differential CLDN18.2 protein expression between the tumor group and control group (n=54). Statistical methods were applied to evaluate the correlation between CLDN18.2 expression and clinicopathological features.

Results: The early gastric cancer cohort was predominantly characterized by patients >60 years old (72.2%), male (64.8%), with adenocarcinoma (98.1%) and well-differentiated tumors (57.4%). CLDN18.2 expression analysis revealed significantly higher positivity in the tumor group compared to controls (38/54 vs. 9/54, P<0.001). A strong correlation was observed between CLDN18.2 expression and differentiation grade (100% positivity in poorly differentiated vs. 61.3% in well-differentiated tumors, P=0.046), while no significant associations were found with age, gender, or invasion depth (P>0.05).

Conclusion: CLDN18.2 demonstrates specific expression patterns in early gastric cancer, showing particularly strong association with poorly differentiated subtypes, suggesting its potential as an early diagnostic biomarker.

Introduction: Type 1 gastric neuroendocrine tumors (T1-gNETs) are well-differentiated, typically indolent neoplasms associated with chronic atrophic gastritis (CAG) and hypergastrinemia, with nearly 100% long-term survival. However, they have a high recurrence rate of 30-60% within the first year after resection. Tumor size is the most critical prognostic factor, while the role of grading is less definitive compared to other digestive NETs. International guidelines recommend conservative management for tumors <1 cm, advocating for approaches such as endoscopic resection or surveillance, which have shown excellent outcomes. However, the management strategies and outcomes for tumors > 1 cm remain less clearly defined due to the lack of scientific data in this specific patient population.

Aims & Methods: This study aimed to investigate management strategies and clinical outcomes in a homogeneous population of patients with T1-gNETs > 1 cm. The findings are expected to provide valuable insights and guide the development of more effective management strategies.

The present study was designed as an international multicentric retrospective analysis, conducted in 7 Western centers. It included consecutive patients diagnosed with T1-gNETs >1 cm in diameter, collected between 2004 and 2023, with at least 12 months of follow-up. The primary endpoints were disease progression (DP) (tumor recurrence or metastasis development) and the Progression-Free Survival. The Cox regression method was used to identify factors associated with progression.

Results: The study included 104 patients (61 females, 43 males) with a median age of 61 years and a median tumor size of 15 mm (range 11–60 mm). 61.5% of tumors were classified as G1, 37.5% as G2, and 1% as G3. 75 patients (72.1 %) underwent endoscopic resection (27 EMR, 5 m-EMR, 14 ESD, 7 snare polypectomy, and 22 unspecified techniques). Surgical procedures were performed in 33 patients (31.7%), 13 of whom had previously undergone endoscopic resection. One patient (1%) received treatment with somatostatin analogues, while 8 patients (7.7%) received no treatment.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The R0 resection rate was 51.9%. During follow-up, 26 patients (25%) experienced recurrence, 7 (6.7%) developed metastases, and 12 (11.5%) died, with 2 deaths (1.9%) due to tumor-related causes. The median overall survival and progression-free survival were 59.5 months (range 13–215) and 51.5 months (range 4–215), respectively.

Univariate analysis showed that R0 resection (HR 0.32, p=0.02) and advanced endoscopic techniques (m-EMR/ESD) (HR 0.09, p=0.02) were associated with better outcomes. In contrast, other resection methods (standard EMR, snare polypectomy, or unspecified techniques) and tumor size were associated with a higher risk of disease progression (HR 10.13, p=0.02; HR 1.03, p=0.003, respectively).

Conclusion: T1-gNETs >1 cm often recur and can progress, exhibiting potentially aggressive behavior, especially in larger lesions. Endoscopic resection should employ advanced techniques to prevent incomplete removal, which is associated with poor outcomes.

Introduction: Primary gastric neoplasms (PGNs) in children and young adults are exceedingly rare, and as a result, their clinicopathological features, biological behavior, and long-term outcomes remain poorly characterized.

Aims & Methods: The aim of this study was to comprehensively evaluate the clinical and pathological features of PGNs in this young population and to assess their prognosis utilizing data from the Surveillance, Epidemiology, and End Results (SEER) database. A retrospective cohort study was conducted using SEER data spanning a 13-year period (2004–2016). Patients under 24 years of age with PGNs were identified using SEERStat. Demographic and clinical characteristics, tumor features, treatment modalities, and survival outcomes were analyzed. Overall survival (OS) was estimated, and multivariable Cox regression analysis was performed to identify factors independently associated with OS. All statistical analyses were conducted using R version 4.4.2.

Results: A total of 324 patients under the age of 24 with PGNs were included (mean age 20.1 years); 13.3% were <15 years, 25.3% were 16–20 years, and 61.4% were 20–24 years. The cohort was evenly distributed by sex (50% female), with 70.4% identifying as white race. The most common histologic types was adenocarcinoma and signet ring cell carcinoma (59.0%), followed by lymphomas (17.0%), and complex mixed or stromal neoplasms (16.4%). Among cases with available data, 48.2% were diagnosed at stage IV according to American Joint Committee on Cancer (AJCC). Surgical resection was performed in 39.5% of patients, radiotherapy in 14.0% and chemotherapy in 57.3%. Median follow-up was 65 months and median OS was 36 months (range 0–154). The 1- and 5-year OS rates were 66.7% (95% confidence interval [95% CI]: 61.6%–71.2%) and 49.0% (95% CI: 43.4%–55.2%), respectively. In multivariate analysis, histologic type, AJCC stage, and surgery were independently associated with OS, when adjusting for sex, age, year of diagnosis, race, radiation and chemotherapy.

Compared to signet ring cell carcinoma, adenocarcinomas (hazard ratio [HR] = 0.65, 95% CI: 0.44–0.97) and lymphomas (HR = 0.16, 95% CI: 0.07–0.37) were associated with superior OS, while undifferentiated carcinomas were associated with inferior OS (HR = 2.50, 95% CI: 1.10–5.69). Advanced AJCC stages were associated with increased risk of mortality (stage II: HR = 3.80; stage III: HR = 8.81; stage IV: HR = 8.39). Surgery was associated with improved OS (HR = 0.34, 95% CI: 0.20–0.57).

Conclusion: PGNs in children and young adults are rare, often diagnosed at advanced stages, and associated with poor prognosis. In our cohort, histologic type, AJCC stage, and surgery were independently associated with OS. These findings highlight the impact of tumor biology in young patients with PGNs and underscore the need to include pediatric and young adult patients in prospective clinical trials and to discuss such rare cases in multidisciplinary tumor boards to inform treatment decisions and improve outcomes in this vulnerable population.

Contact E-Mail Address: d.tjandra@alfred.org.au

Introduction: Gastric intestinal metaplasia (GIM) is a premalignant precursor to gastric adenocarcinoma. There has been limited study of its landscape in the Australian context(1).

Aims & Methods: To characterise GIM and its progression to dysplasia or gastric adenocarcinoma in the Australian context.

A retrospective review was performed, following the clinical course of individuals at a single Australian tertiary centre who underwent index gastroscopy with biopsy between 1 Jan 2010 and 1 Apr 2023. The cohort was linked with the statewide cancer registry (accessed 30 Oct 2024). Patient characteristics between individuals with and without histology-demonstrated GIM were compared using χ^2 test and unpaired t-test. Amongst those with GIM, a left-truncated, Cox regression analysis was used to identify factors associated with progression to dysplasia/adenocarcinoma, excluding those with advanced disease or censored within the first 6 months.

Results: During the study period, 13,987 individuals underwent >1 gastroscopy with biopsies. Of these, 1320 (9.4%) had GIM. Individuals with GIM were older (mean 64.6±14.3 vs 54.0±17.3 years, p<0.001), and were more likely born outside Australia (64.5% vs 41.0%, p<0.001). The birth regions enriched in the GIM group were Southern Europe, Eastern Europe and Eastern Asia (21.9%, 14.8% and 7.8% of GIM group, vs 7.9%, 6.8% and 2.6% of non-GIM group). Indigenous Australian background was similar between GIM and non-GIM groups (1.1% vs 1.3%, p=0.543). Individuals with GIM were more likely to be diagnosed with dysplasia/adenocarcinoma (7.2% vs 0.5%, p<0.001).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among GIM patients, 499 (37.8%) underwent >1 gastroscopy over 6080 patient-years of clinical follow-up within our centre, with a mean follow-up to cancer registry linkage date of 7.3±3.7 years. 1218 cases were included in the delayed-entry Cox regression (20 progressors, 1198 non-progressors). In univariate analysis, the risk of dysplasia/adenocarcinoma increased with positive family history of gastric cancer (HR 8.17, 95%CI 2.94-22.68), extensive GIM involving gastric corpus (HR 10.22, 95%CI 3.88-26.89), incomplete subtype of GIM (HR 6.04, 95%CI 1.76-20.75), and pathologist-grading of severe/extensive GIM (HR 3.75, 95%CI 1.43-9.87). Increasing age (by decade, HR 1.02, 95%CI 0.75-1.41), world region of birth (Australia: HR 0.53, 95%CI 0.18-1.60; Asia: HR 2.03, 95%CI 0.73-5.64; South/East Europe: HR 1.12, 95%CI 0.45-2.78), positive smoking history (HR 0.87, 95%CI 0.35-2.14), positive *H. pylori* history (HR 0.97, 95%CI 0.38-2.47), and diagnosis of autoimmune gastritis (HR 3.61, 95%CI 0.48-27.06) were not significant risk factors. In multivariable analysis (inputting covariates with p<0.10), positive family history of gastric cancer and extensive GIM remained significant risk factors for progression.

Variable	Univariate analysis			Multivariable analysis		
	HR	p-value	95% CI	HR	p-value	95% CI
Male sex	2.62	0.051	0.99 – 6.89	2.54	0.061	0.96-6.75
FHx gastric cancer	8.17	<0.001	2.94-22.68	4.84	0.010	1.47-15.99
Extensive GIM	10.22	<0.001	3.88-26.89	8.11	<0.001	2.92-22.56
Incomplete IM	6.04	0.004	1.76-20.75	1.63	0.505	0.39-6.93
Severe IM on histology	3.75	0.007	1.43-9.87	1.17	0.786	0.38-3.64

Table 1: Cox regression analysis for progression in GIM
CI = confidence interval, FHx = family history, GI = gastrointestinal.

Conclusion: GIM was common on endoscopic biopsy in our Australian centre, particularly amongst migrants, and associated with higher dysplasia/adenocarcinoma rates. Regardless of country of origin, the risk factors for progression of GIM in real-world practice mirrored overseas cohorts(2). Gastroenterologists should particularly consider family history of gastric cancer and endoscopic extent of GIM in their assessment.

Introduction: Helicobacter pylori (HP) infection is the most significant environmental factor contributing to gastric carcinogenesis. However, the rising prevalence of antibiotic resistance in HP has become a global concern. Currently, there is limited research on the correlation between HP antibiotic resistance and early gastric cancer (EGC). This study aimed to detect HP resistance genes in EGC patients using qRT-PCR on paraffin-embedded ESD specimens and explore the association between HP resistance and EGC.

Aims & Methods: A total of 150 EGC patients who underwent endoscopic submucosal dissection (ESD) between January 1, 2023, and December 31, 2024, were enrolled. HP resistance genes were detected in post-ESD gastric mucosal paraffin sections. Resistance rates to various antibiotics were compared, and correlations between resistance and clinicopathological features were analyzed.

Results: Among the 150 EGC patients, 28 (18.67%) were HP-positive, with 18 (64.3%, 95% CI: 44.1%–81.4%) showing antibiotic resistance. Levofloxacin had the highest resistance rate (50.0%), followed by clarithromycin (38.9%), tetracycline (11.1%), and amoxicillin (5.6%). No resistance to furazolidone was observed. Multidrug resistance analysis revealed common combinations, including clarithromycin + quinolone (22.2%) and clarithromycin + quinolone + tetracycline (5.6%). No significant correlations were found between resistance and clinicopathological features such as tumor location, size, histologic type, differentiation, depth of invasion, or mucosal status (all *p* > 0.05).

Conclusion: HP antibiotic resistance is prevalent in EGC patients, with high resistance rates to levofloxacin and clarithromycin. However, no significant association was observed between HP resistance and clinicopathological characteristics of EGC. Further studies are needed to elucidate the role of resistant HP strains in gastric carcinogenesis.

Introduction: Gastric adenocarcinoma (GAC) is the the sixth most common cancer worldwide. It is estimated that 54% of cases are preventable; yet, its prognosis remains poor, with 1-year and 5-year survival rates being just 48% and 22%, respectively. GastroPanel (Biohit Oyj; Helsinki, Finland) is an ELISA kit that measures pepsinogen I (PGI); pepsinogen II (PGII); gastrin-17 (G-17); and Helicobacter pylori IgG antibodies (Hp IgG). PGI and the PGI/PGII ratio correlate inversely with the severity of chronic atrophic gastritis (AG). Proximal open patterns (O1–O3) of Kimura and Takemoto classification of atrophic gastritis are associated with higher risk of developing gastric neoplasm.

The aim of this study was to assess GastroPanel performance in the identification of moderate to severe AG in dyspepsia.

Aims & Methods: In this UK, single-centre, prospective diagnostic accuracy study, 324 patients [56.8% (n=184) female; median age 57 years (range 39–92 years)] were recruited for gastroscopy with biopsy and histology according to the updated Sydney System (USS). Blood (plasma) samples were collected for GastroPanel analysis. Paired samples were obtained from 268 patients [56.3% (n=151) female; median age=57 (range 39–92 years)]. Patients with type 2 diabetes were enrolled in a separate group. GastroPanel results were interpreted using the GastroSoft app (Biohit) for all patients.

Results: Overall agreement between GastroPanel and the USS classification was 90% (95% CI=86.7 to 93.8%), with a weighted kappa (κw) of 0.828 (95% CI=0.781 to 0.865). In receiver operating characteristics (ROC) curve analysis, using moderate/severe atrophic gastritis of the corpus (AGC2+) as the endpoint, AUC=0.840 (95% CI 0.630 to 1.000) and 0.960 (95% CI 0.907 to 1.000) for PGI and the PGI/PGII ratio, respectively.

Conclusion: GastroPanel is a reliable dyspepsia triage test distinguishing patients who can be safely treated conservatively from those with moderate to severe proximal (corpus) atrophic gastritis at high risk of developing GAC. A new proposed clinical pathway for dyspepsia might include the GastroPanel.

Disclosure: No conflict of interest to disclose.

Introduction: Juvenile polyposis syndrome (JPS) is a rare inherited autosomal dominant disorder determined by mutation of the SMAD4 and BMPR1A genes and it is characterized by development of hamartomatous polyps, commonly located in the colon and stomach. Currently, there is no standardized protocol for SMAD4 surveillance and management.

Aims & Methods: Our aim is to demonstrate certain general management principles that can be applied to improve patient outcomes, despite the variability in case presentation. We retrospectively included 8 patients affected by JPS, all followed at our center over a period of seven years (2017-2024). A comprehensive review of literature was also performed.

Results: Patients included were 7 women and 1 man, one with BMPR1A and seven with SMAD4 mutation. Four of these seven cases presented gastric polyposis and two of them evolved in cancer.

Two women presented a large gastric polyp and underwent total gastrectomy. Histology reports described gastric cancer in both cases. The young man presented a giant, tangled, polypoid, vegetative, and bleeding mass of hyperplastic/hamartomatous type in the gastric antrum so underwent total gastrectomy. The other woman showed history of a large lobulated polypoid mass in the gastric antrum, with histological characteristics of hamartomatous polyp with active inflammation, endoscopically removed.

Repeated follow-up upper endoscopies revealed absence of disease recurrence. All patients, except the one with BMPR1A mutation, were affected by hereditary hemorrhagic telangiectasia (HHT), responsible for variable sites bleeding inducing iron-deficiency anemia.

Conclusion: Here we describe four cases of gastric polyposis in patients affected by SMAD4 mutation and discuss their follow-up. We correlate our experience with the review of literature and demonstrate the importance of diagnosing and monitoring JPS patients accurately, in order to assess the prevention of malignant lesions and the best therapeutic strategy.

Introduction: Gastric intestinal metaplasia (GIM) is a known premalignant lesions of gastric cancer (GC). Several factors have been associated with the progression of GC such as family history, smoking and increased BMI. Dietary factors such as the consumption of meat, salt and alcohol are also linked to GC progression.

However, the intricate relationship between dietary factors and the progression of GIM remains poorly understood. The aim of this prospective cohort study was to identify dietary factors for GIM progression in a low incidence area.

Aims & Methods: The Progression and Regression of Precancerous Gastric Lesions (PROREGAL) study prospectively included patients with GIM who underwent endoscopic surveillance from September 2009 to February 2024. GIM stage was determined by the Operative Link on Gastric Intestinal Metaplasia (OLGIM) criteria. Disease progression was based on the increase in OLGIM, comparing the baseline score to at least two follow-up (FU) endoscopies. If only one FU endoscopy was conducted, the baseline was compared to this single FU examination.

Comprehensive data on family history, lifestyle factors, and dietary habits were collected through structured questionnaires. *Helicobacter pylori* (*H. pylori)* infection status was determined by pathology. Multivariate logistic regression analysis was used to determine risk factors.

Results: In total 312 patients were included, with a median FU of 54 months (median age: 61 years, 50.3% male) of which 112 patients (35.9%) showed GIM progression (7.6% to stage I, 27.6% to stage II, 46.7% to stage III and 18.1% to stage IV), with six patients (1.9%) developing high-grade dysplasia or GC. A positive family history (first or second degree) was present in 103 (30.6%) cases.

High dietary salt consumption (OR 1.67; 95% CI 1.05–2.68, P=0.04), meat ≥6 servings per week (OR 1.25; 95% CI 1.07–1.46, P=0.004) smoking (OR 1.76; 95%CI 1.04–2.68), autoimmune gastritis (OR 2.49; 95%CI 1.04–5.83) and having a positive first-degree family member with GC (OR 2.01; 95%CI 1.20–3.52) significantly associated with GIM progression.

Factors like fish intake, alcohol consumption, prepared meal consumption, fruit and vegetable intake, autoimmune gastritis (AIG), extensive GIM, vitamin intake, Body Max Index (BMI) and history of *H. pylori* infection showed no significant association.

Conclusion: Increased consumption of meat and salt is significantly associated with GIM progression, suggesting that dietary risk factors for GIM progression are similar in low-incidence Western countries and high-incidence regions.

Introduction: The first international guideline for managing preneoplastic conditions of the stomach (MAPS I) was published in 2012, followed by an update (MAPS II) in 2019. As adherence to these guidelines remains uncertain, we evaluated adherence by comparing the management of preneoplastic gastric conditions before and after the introduction of MAPS I and II in selected European centers.

Aims & Methods: Patient data were retrieved from nine endoscopy units in seven European countries during three periods: pre-MAPS I (2010/2011), post-MAPS I (2017/2018), and post-MAPS II (2022/2023). Screening and dyspepsia-related endoscopies were included. Data on endoscopy, histopathology, *Helicobacter pylori (H. pylori)* treatment, and surveillance were collected using a standardized form. Adherence to nine MAPS recommendations was assessed, with improvement defined as a ≥10% increase in guideline-concordant management.

Results: A total of 2,426 patients were included. Most centers (57%) improved in at least seven of the nine recommendations over time. Virtal Chromoendoscopy use improved in six centers, with four reporting its use in >50% of cases. All centers improved in performing biopsies from the antrum and corpus, five conducted random biopsies in nearly all patients, and four performed these plus an incisura biopsy in >90% of cases. Endoscopic scores for patient stratification were rarely used, while five centers improved in histological scoring or intestinal metaplasia subtyping. *H. pylori* treatment recommendation remained high (71%-100%), and endoscopic surveillance adherence improved in four of seven centers

Conclusion: Adherence to MAPS guidelines improved in most centers. However, gaps in virtual chromoendoscopy, targeted biopsies, and endoscopic/histopathological scoring remain, potentially affecting surveillance recommendations. This underscores the need for a more tailored approach to enhance implementation.

Introduction: MicroRNAs (miRNAs) are small, non-coding RNAs that regulate gene expression and play pivotal roles in carcinogenesis. Distinct miRNA expression signatures can discriminate among tumours and normal tissue, and have emerged as promising, minimally invasive diagnostic biomarkers.

Aims & Methods: To characterise the miRNome of advanced gastric adenocarcinoma (AGC), early gastric cancer (EGC) and its precancerous lesions (GPL) in comparison to normal gastric mucosa, and to identify candidate miRNA biomarkers for early diagnosis.

Gastric mucosa samples were prospectively collected from 60 participants in the EpiGASTRIC/EDGAR consortium: 20 with AGC, 20 with EGC/GPL and 20 tumour-free controls. During the discovery phase, small-RNA libraries were prepared from tissue samples and sequenced by next-generation sequencing (NGS). Reads were processed with miRDeep2 against miRBase, and differential expression was analysed with DESeq2, applying a false discovery rate (FDR) < 0.05. Selected miRNAs were then validated in gastric tissue by reverse-transcription quantitative PCR (RT-qPCR) and subsequently in matched serum samples by RT-qPCR.

Results: A total of 823 miRNAs were detected. Compared with controls, 292 miRNAs were significantly deregulated in AGC and 233 in EGC/GPL, with 170 miRNAs commonly deregulated in both tumour groups. For biomarker prioritisation we applied ≥ 4-fold change and mean read count > 400 and we found 20 miRNAs that were consistently differentially expressed and discriminated AGC, EGC and GPL from normal mucosa. 17 of these 20 miRNAs were successfully validated by RT-qPCR in gastric tissue. In a subsequent serum analysis, two miRNAs – *148a-3p* and *223-3p* – showed statistically significant differential expression in serum, distinguishing patients with AGC or EGC/GPL from individuals with histologically normal gastric mucosa.

Conclusion: Deep sequencing followed by RT-qPCR validation identified a 17-miRNA signature capable of differentiating normal gastric tissue from AGC and EGC/GPL. Within this set, *148a-3p* and *223-3p* discriminated serum of patients with AGC or EGC/GPL from those with normal mucosa. External validation and further assessment of their diagnostic performance are required, but these miRNAs are promising non-invasive biomarkers of prevention and diagnosis of gastric cancer.

Disclosure: Nothing to disclose.

Introduction: Early detection of gastric cancer (GC) is crucial for improving patient outcomes, but ongoing surveillance is equally important, given the 16% risk of recurrence or progression after initial treatment. While molecular biomarkers have shown promise for diagnosis, few have been assessed in longitudinal settings.

Aims & Methods: This study aimed to develop and validate a gene expression signature capable of detecting early GC in a screening setting and to explore its utility in predicting metachronous gastric lesions (MGLs) during post-treatment surveillance following curative endoscopic submucosal dissection (ESD). A gene expression signature was developed using RNA-sequencing data from formalin-fixed paraffin-embedded (FFPE) tissue samples, including 23 controls (histologically normal mucosa) and 28 cases (low-/high-grade dysplasia and adenocarcinoma, all submitted to ESD). Gene selection was performed using machine learning within the tidymodels framework.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Selected genes were validated by real-time PCR in an expanded cohort (n = 279; 123 controls, 156 cases), which was randomly split into independent discovery and validation sets (60:40 ratio). Logistic regression models were built using gene expression data, age and sex. Predictive performance for MGL development was then assessed in the 156 cases, stratified by MGL occurrence (n = 39 with MGLs, n = 157 without), with at least three years of endoscopic follow-up after curative ESD.

Results: RNA-sequencing analysis identified a seven-gene panel with potential for early GC detection, consisting of three upregulated and four downregulated genes in patients with gastric lesions. This signature was successfully validated in the stomach adenocarcinoma cohort of The Cancer Genome Atlas (TCGA-STAD) and Genotype-Tissue Expression (GTEx) datasets, upon filtering stage I cases (n = 81, P < 0.0001). In the discovery set, the model achieved excellent performance in distinguishing lesions from normal tissue (AUC = 0.96, 95% confidence interval (CI): 0.93-0.99; sensitivity = 0.90, 95% CI: 0.79-0.96; specificity = 0.94, 95% CI: 0.85-0.99). One gene retained its expression pattern in patients with MGLs. Although the model was not predictive of MGL development, a new model based on the same signature and trained exclusively on the MGL dataset achieved promising diagnostic performance (AUC = 0.74, 95% CI: 0.59-0.88; sensitivity = 0.85, 95% CI: 0.55-0.98; specificity = 0.72, 95% CI: 0.58-0.84).

Conclusion: This study demonstrates the promise of a gene expression-based model for early GC detection in a Western population. Beyond its diagnostic value, the underlying gene signature also showed potential for predicting MGLs, with good sensitivity and moderate specificity. These findings suggest that this approach could serve a dual purpose in both the detection of gastric lesions and the individualized management of these patients.

PERIPHERAL BLOOD MULTI-OMICS BIOMARKERS ENABLE PRECISE PREDICTION AND EARLY DIAGNOSIS OF GASTRIC CANCER VIA MACHINE LEARNING

Z. Huang[1], X. Guo[1], S. Ding[1]
[1]Peking University Third Hospital, Department of Gastroenterology, Beijing, China

Contact E-Mail Address: 1076584241@qq.com

Introduction: Gastric cancer (GC) ranks as the sixth most common cancer globally and is the fifth leading cause of cancer-related mortality. Previous studies have shown that the five-year survival rate for early-stage GC exceeds 90%. Gastroscopy is the gold standard for GC diagnosis, but its invasive nature and high cost limit its clinical application. Non-invasive tests have been reported in GC prediction, yet current biomarkers fall short in sensitivity or specificity, particularly for early GC prediction, leading to misdiagnosis and potential delays in GC treatment, which may reduce patient survival rates. Multi-omics biomarker panels significantly enhance diagnostic efficacy through multidimensional information complementarity, compared to single-omics or individual biomarkers. Therefore, developing non-invasive multi-omics biomarker combinations holds great promise for enhancing GC diagnostic accuracy and increasing the likelihood of early diagnosis and treatment.

Aims & Methods: This study utilized mass spectrometry-based proteomics and metabolomics to comprehensively analyze the peripheral blood components of non-gastric cancer (NGC, including patients with chronic superficial gastritis and precancerous lesions such as atrophic gastritis, intestinal metaplasia, and dysplasia) and gastric cancer (GC, including patients with well-defined staging from stage IA (T1N0M0) to advanced stages). We employed machine learning algorithms to develop a multi-omics biomarker combination capable of identifying GC and enabling early GC diagnosis.The studies involving humans were approved by the Medical Research Ethics Committee of Peking University Third Hospital.

Results: Through differential analysis of plasma proteins and metabolites in GC (n=53) and NGC (n=41) (FDR<0.05, log2FC>1), we identified 333 upregulated proteins and 570 upregulated metabolites. LASSO regression further narrowed down the candidates to 10 proteins (10-P) and 10 metabolites (10-M) as potential biomarkers.

Subsequently, we constructed gastric cancer prediction models using random forest algorithms. In the validation set (n=27), the 10-P Model achieved a prediction accuracy of 0.85 (AUC: 0.91, sensitivity 0.83, specificity 0.86), while the 10-M Model had a prediction accuracy of 0.77 (AUC: 0.82, sensitivity 0.83, specificity 0.77). The Multi-Omics Integrated Model (MOIM), built via machine learning-based Voting Classifier, reached a prediction accuracy of 0.92 (AUC: 0.96, sensitivity 0.91, specificity 0.93), surpassing the former two models. For stage IA GC (n=22) prediction, MOIM's accuracy was 0.93, higher than the 10-P Model's 0.86 and the 10-M Model's 0.79. Finally, we streamlined the model to include only 7 proteins and 3 metabolites, forming the Simplified Multi-Omics Integrated Model (sMOIM), which achieved accuracies of 0.91 for GC and 0.92 for stage IA GC.

	GC(N=53) VS NGC(N=41)				stage IA GC(N=22)			
	Accuracy	AUROC	Sensitivity	Specificity	Accuracy	AUROC	Sensitivity	Specificity
10-P model	0.85	0.91	0.83	0.86	0.86	0.92	0.91	0.73
10-M model	0.77	0.82	0.83	0.77	0.79	0.85	0.83	0.79
MOIM	0.92	0.96	0.91	0.93	0.93	0.98	0.95	0.90
sMOIM	0.91	0.95	0.92	0.91	0.92	0.96	0.93	0.91

Conclusion: The selected plasma protein and metabolite biomarker combination enables highly accurate prediction of GC, especially early-stage GC. Moreover, the multi-omics integrated analysis achieves superior accuracy, sensitivity, and specificity compared to single-omics prediction, suggesting its potential as an effective strategy for the precise early diagnosis of gastric cancer.

Introduction: Autoimmune atrophic gastritis (AAG) is an immune-mediated disorder characterized by corpus oxyntic mucosa atrophy and impaired gastric acid secretion(1,2). The increased gastric cancer (GC) risk in AAG is still debated. One mechanism favoring gastric carcinogenesis may be increased intragastric pH leading to intragastric microenvironment changes and facilitating bacterial dysbiosis(3-5).

Oral microbiota and periodontal-dental disorders alterations have been linked to increased GC risk as well(6-8). In AAG, the increased intragastric pH may lead to survival of swallowed bacteria, possibly further contributing to the increased GC risk. The oral and gastric microbiota composition together have not been investigated so far in AAG patients.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: The aim of the study was to investigate the oral and gastric microbiota composition in AAGpts in order to clarify the role of oral bacteria in gastric dysbiosis.

We conducted a case-control study: n=20 histologically diagnosed AAGpts (F75%, age 64 yrs) and n=20 ctrs with healthy stomach (HS)(F45%, age 56 yrs). From all pts and ctrs a sputum sample was obtained in the morning fasting without tooth brushing. Within 1 hour after sputum collection, pts and ctrs underwent gastroscopy with biopsies (updated Sydney system) for histopathological assessment and one further corpus biopsy for DNA extraction. Sputum (n=40) and biopsy (n=40) samples were collected in vials with DNA shield and frozen at -20°C since processing. DNA was extracted (QIAmp DNA kit) and prepared (Illumina Nextera XT DNA Library Preparation Kit). Paired-end sequencing was performed (Illumina MiSeq sequencer, MiSeq Reagent Kit v3). Fastq files were filtered to remove low-quality reads; filtered reads were taxonomically classified and subjected to Homo sapiens filtering (METAnnotatorX2 pipeline, up-to-date RefSeq database, NCBI).

Results: AAGpts and ctrs were similar with regard to clinical features, oral hygiene and paraodontal-dental disorders. Bacterial abundance in biopsies was higher in AAGpts than in ctrs (403 vs 223,p=0.06), but not different in sputum (27,728 vs 31,544,p=0.54). On biopsies, AAGpts showed a lower Shannon Index than ctrs (2.553 vs 2.617, p=0.001). On sputum, AAGpts showed a higher Shannon Index than ctrs (2.828 vs 2.738, p=0.0). Beta-diversity (Bray-Curtis dissimilarity) was not different between pts and ctrs, neither in sputum nor biopsies.

At the taxa level, in biopsies *Streptococcus oralis*, *Fusobacterium pseudoperiodonticum*, *Veillonella rogosae*, and *Gemella sanguinis* were significantly associated with pts(p<0.03); while in sputum the most significant associations were *G.sanguinis*, *Prevotella multisaccharivorax*, *F.nucleatum*, and *F.peridonticum*(p<0.03). The most abundantly shared taxa between sputum and biopsy were *S.oralis* and *P.histicola*, while *G.sanguinis*, *F.pseudoperidonticum*, and *V.rogosae* were shared in pts only.

Conclusion: This study confirmed gastric dysbiosis in AAG as shown by lower biodiversity and evenness. Gastric bacterial abundance was higher in AAG, probably due to non-acidic gastric pH permitting overgrowth of gastric bacteria. Oral bacterial abundance was similar in AAG and ctr with higher biodiversity-evenness in AAG pts, probably due to upstream passage of unactivated bacteria from stomach to mouth. Oral taxa related to increased GC risk were more commonly associated to AAG and shared between mouth and stomach. In AAG these findings show the role of oral microbiota in gastric dysbiosis, possibly contributing to increased GC risk.

Introduction: Endoscopy services in many healthcare systems face increasing demand, and novel approaches to patient triage are needed. Recent research suggests that capsule sponge testing combined with immunohistochemical biomarkers can prioritise patients with Barrett’s oesophagus (BO) and gastro-oesophageal reflux for oesophagogastroduodenoscopy (OGD).[1,2]

However, it is not yet widely integrated into clinical practice globally. The capsule sponge is not currently used in South Wales and Northern Ireland, and further investigation into its implementation in these regions is required.

Aims & Methods: This multicentre feasibility study aimed to evaluate whether the capsule sponge could be used in Wales and Northern Ireland to triage patients with gastro-oesophageal reflux or BO for OGD, and to assess feedback from patients and staff. Patients referred to gastroenterology due to gastro-oesophageal reflux and patients with known BO under surveillance were eligible. Patients were recruited from 3 hospital sites in Wales and 2 in Northern Ireland, undergoing the test in nurse-led clinics between December 2024 and March 2025.

Pathology samples were processed centrally in an accredited laboratory (Cyted), examining for TFF3 (suggestive of intestinal metaplasia), p53 and atypia (high-risk findings associated with dysplasia). Patient feedback was collected at the clinics, and feedback forms were also sent to patients and staff.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 201 patients were recruited, with 196 (97.5%) completing the capsule sponge test: 116 with BO (median age 59, 84% male) and 80 with reflux (median age 49, 56% female). 101 BO samples (87%) were adequate for analysis. Of these, 21 (21%) were positive/equivocal for atypia/p53 and deemed high-risk, and 80 (79%) were negative for both atypia and p53. High-risk patients were prioritised for urgent OGD, with the remainder followed-up as per the British Society of Gastroenterology guidelines. 61 samples (76%) from patients with reflux were adequate for analysis. Of these, 3 (5%) were positive/equivocal for atypia/p53 and prioritised for urgent OGD, 11 (18%) were TFF3 positive but negative for both atypia and p53 and were booked for routine OGD, and 47 (77%) were negative for all 3 biomarkers and were managed as per usual local practice.

148 patients (76%) who completed a capsule sponge test had previously had an OGD, with 78% of these preferring the capsule sponge, 4% preferring the OGD and 9% being unsure. Feedback forms were completed by 52 patients, with response rates varying by question. 92% rated the capsule sponge procedure good/very good, 3% fair and 5% poor/very poor. When asked how likely they would be to recommend the test, on a scale from 1 (least likely) to 10, patients with reflux gave a mean score of 8.7 and patients with BO 9.6. For whether they would be willing to have the test done again, 83% said yes, 14% not sure and 3% no. Patients' free text comments indicated they found the capsule sponge to be quicker and easier than an OGD, however some experienced discomfort on sponge withdrawal. 14 staff completed feedback forms. 100% agreed the capsule sponge test was easy to deliver, and 100% rated the implementation of the test pathway as good/very good.

Conclusion: This feasibility study showed that the capsule sponge could successfully triage patients under BO surveillance or with reflux for OGD in Wales and Northern Ireland, with positive feedback from patients and staff. These findings support future integration of the capsule sponge into clinical pathways in these regions, with potential transferability to other healthcare systems internationally.

EFFECT OF GENERATING VIRTUAL NBI IMAGES USING STABLE DIFFUSION FOR EARLY GASTRIC CANCER RECOGNITION

C. Lei[1], B. Wang[2], Y. Guo[2], K. Hong[2], X. Kan[1], Y. Ouyang[1], Y. Mei[1], J. Li[2], R. Li[1]

Contact E-Mail Address: lcdyjy@163.com

Introduction: Currently, white light endoscopy (WLE) is the most commonly used diagnostic procedure for early gastric cancer (EGC)[1], However, some EGC lesions are difficult for endoscopists to detect in WLE images due to objective reasons such as small extent, flat morphology[2]. Compared to WLE, NBI has been proven to have superior performance in identifying EGC[3-4]. However, due to reasons such as technological property rights and economic costs, endoscopists in many underdeveloped areas or small medical institutions are unable to use NBI to observe and detect lesions.Therefore, there is a current need to invent a technology that can convert WLE images into NBI images to help endoscopists better observe lesions and reduce the risk of missed diagnosis of EGC.

CycleGAN is an artificial intelligence (AI) technology that can perform image transformation[5], it has played an important role in the application of digestive diseases[6-7]. Although CycleGAN performs well in the field of image translation, the quality of the generated images is often limited, the details are not detailed enough, and may be accompanied by artifacts and pattern collapse issues[8].

In contrast, Stable Diffusion, as a generative model based on stepwise denoising reversion, can more accurately capture data distributions and generate images with high levels of detail and authenticity. Additionally, Stable Diffusion's robust training process mitigates the instability commonly seen in adversarial models, particularly in complex medical image tasks, offering significant advantages. Currently, the Stable Diffusion model has been widely applied in various medical imaging tasks, including cross-modal image translation, image reconstruction, image generation, denoising, and anomaly detection[9].

Aims & Methods: Narrow band imaging (NBI) can assist endoscopists in detecting early gastric cancer (EGC) more easily, but its widespread use is hindered by economic cost and technical property rights.We aim to realize the conversion of white light endoscopy(WLE) images into virtual narrow band imaging(Vir-NBI) images using Stable Diffusion.

Endoscopic images were retrospectively collected from 262 patients who underwent endoscopic submucosal dissection(ESD). A total of 273 NBI images from 218 patients were used to fine-tune Stable Diffusion, which then converted 48 WLE images from 44 patients into Vir-NBI images. Endoscopists assessed the images and evaluated their effectiveness in diagnosing EGC and depicting lesion margins in the form of WLE, NBI, and Vir-NBI image pairs.

Results: Vir-NBI images demonstrated superior ability in showing the surface structure(P<0.001) and lesion margins(P=0.030) compared to WLE images.The accuracy of junior endoscopists in diagnosing EGC by observing WLE images alone, simultaneous WLE and NBI images, and simultaneous WLE and Vir-NBI images were 58.3%,81.3%,and 83.3%, respectively. For intermediate endoscopists, the diagnostic accuracy was 70.8%, 91.7%,and 89.6%, respectively. Simultaneous observation of WLE and Vir-NBI images yieled higher diagnostic accuracy than observing WLE images alone(P=0.012, P=0.035). The area concordance rate on Vir-NBI images was higher than that on WLE images(44.0% vs 39.2%, P=0.002). In addition, the successful whole-lesion diagnosis on Vir-NBI images was also higher than that on WLE images(44.8% vs 31.9%,P=0.002).

Conclusion: Vir-NBI images has similar observation effect with real NBI image, which helps endoscopists better visualize the lesion structure, thus improving the accuracy of EGC diagnosis.

LINKED COLOR IMAGING FOR THE DETECTION AND CHARACTERIZATION OF GASTROINTESTINAL NEUROENDOCRINE TUMORS

M. Min[1], Y. Liu[1]
[1]The First Medical Center of PLA General Hospital, Senior Department of Gastroenterology, Beijing, China

Contact E-Mail Address: minmin823@sina.com

Introduction: The endoscopic detection of gastrointestinal neuroendocrine tumors (GI-NETs) is notoriously challenging. Linked color imaging (LCI), which enhances color contrast, may improve the detection of tumorous lesions. This study aims to retrospectively analyze the characteristics of GI-NETs using LCI compared with white light imaging (WLI).

Aims & Methods: This retrospective study included consecutive patients with GI-NETs who underwent endoscopic resection at our center between January 2016 and March 2024. The endoscopic features and clinicopathological characteristics of the lesions were analyzed. The edge of lesions were identified using the Canny operator, and the color differences between the lesions and surrounding mucosa (ΔE) in gastric and rectal NETs were measured using the CIE L*ab** color space (CIE: Commission Internationale d'Eclairage). Three expert endoscopists and 3 trainees independently assessed images obtained with LCI and WLI using a previously reported visibility scores scale.

Results: A total of 60 patients were included in the analysis. The average ΔE values for LCI were significantly higher than those for WLI in both gastric NETs and rectal NETs (P<0.001). Specially, in rectal NETs, the increased ΔE values were primarily attributed to an increase in the yellow-blue component (b*) (P < 0.001). LCI is more effective at delineating lesion boundaries, providing a clearer and more detailed visualization of the lesion contours compared to the WLI.Both expert and trainee endoscopists reported significantly improved visibility with LCI compared to WLI (P < 0.001).

Conclusion: LCI significantly enhances the visibility of GI-NET by increasing contrast between lesions and the surrounding mucosa, thus providing clearer visualization of lesion edges. These improvements were observed regardless of the endoscopist's level of experience, suggesting that LCI may be a valuable tool for enhancing the endoscopic detection of and characterization of GI-NETs.

Introduction: Peroral endoscopic myotomy (POEM) has shown better results in treating esophageal achalasia. The optimal length of esophageal myotomy during POEM remains controversial. This meta-analysis aimed to compare the efficacy and safety of short versus long myotomies during POEM.

Aims & Methods: A comprehensive search was conducted on PubMed, Embase, and Scopus to identify randomized controlled trials (RCTs) comparing short and long myotomies during POEM for achalasia. The primary outcomes were clinical success. We used RevMan 5.4 to calculate risk ratios (RR) and mean differences (MD) with a 95% confidence interval (95% CI).

Results: Four RCTs involving 419 patients were included. No significant difference was found in clinical success between short and long myotomy groups (RR 1.03, 95% CI 0.97, 1.09, P = 0.34). Short myotomy group showed shorter procedure time (MD -16.06 min, 95% CI -27.11, -5.02, P = 0.004) and fewer cases of abnormal esophageal acid exposure (RR 0.65, 95% CI 0.44, 0.96, P = 0.03) compared to long myotomy. There were no significant differences in GERD cases (RR 0.76, 95% CI 0.53, 1.10, P = 0.15), adverse events (RR 0.73, 95% CI 0.33, 1.60; P = 0.43), hospital stay (MD 0.09 days, 95% CI -0.15 to 0.32, p = 0.47), or pre- and post-treatment outcomes between the two groups.

Conclusion: Both short and long myotomies show comparable clinical outcomes, with short myotomy associated with shorter procedure duration and a lower rate of abnormal esophageal acid exposure.

Disclosure: Nothing to disclose.

THE DUOFIX STUDY: REDUCTION OF DUODENAL COVERED STENT MIGRATION RATE WITH AN OVER-THE-SCOPE FIXATION CLIP

J. Privat[1], H. Demmak[1], H. Grossi[1], N. Chaib[1], J. Chapon[1], A. Mejait[1]
[1]Hopital de Vichy, Endoscopy Unit, Vichy, France

Contact E-Mail Address: jocelyn.privat@ch-vichy.fr

Introduction: Duodenal covered self-expandable metal stent (SEMS) placement is used to treat gastric and duodenal stenosis. The main adverse event after duodenal SEMS placement is stent migration. We evaluated the stent fixation with a novel over-the-scope clip device (stentfix OTSC® System; Ovesco Endoscopy AG, Tübingen, Germany) to prevent migration.

Aims & Methods: This is a single-center retrospective observational cohort study performed to analyze stent migration rates before and after availability of the stentfix OTSC® System. A cohort of patients who underwent SEMS fixation with the stentfix OTSC® system (SC cohort) was compared with an historical cohort of patients (NC) who did not receive any other stent fixation method before the stentfix OTSC system became available. Outcome variables including technical success, adverse events and clinical success were analyzed.

Results: 45 patients (SC cohort, 15; NC cohort, 30) underwent covered duodenal SEMS implantation for benign conditions. The technical success rate of stent fixation was 100%. No procedure-related adverse events occured. The stent migration rate was significantly lower in the SC cohort compared with the NC cohort (6.66% vs 36.66%). 20% of adverse events were observed during the withdrawal of the OTSC (3 AGREE grade IIIa :one delayed bleeding, one buried-in stentfix treated with APC and one mucosal tear fixed with classic clips).

Conclusion: In patients with benign pyloro-duodenal stenosis, there was a significantly lower stent migration rate with the stentfix OTSC system compared with those without stent fixation. The application was technically successful in all cases, no adverse events related to OTSC fixation and 20% moderate adverse events following the removal were observed.

IS CYANOACRYLATE GLUE THE ANSWER IN MANAGEMENT OF ECTOPIC DUODENAL AND JEJUNAL VARICES?

P. Desai[1], C. Patel[2], M.V Kabrawala[3], R. Prajapati[2], M. Sethia[2], N. Patel[2]
[1]SIDS Hospital & Research Centre, Endoscopy, Surat, India, [2]SIDS Hospital & Research Institute, Surat, India, [3]SIDS Hospital & Research Institute, Gastroenterolgy, Surat, India

Contact E-Mail Address: drp_desai@hotmail.com

Introduction: Ectopic varices are not very common but complicate 2 to 5 % cases of variceal bleeding. Management options include interventional radiology (IR) modalities like BRTO or TIPS, EUS guided treatment, endoscopic sclerotherapy and endoscopic cyanoacrylate glue injection. Not much data is available with endoscopic cyanoacrylate glue injections. IR modalities are expensive and usually unavailable in most centres in emergent conditions. We hereby share our experience of using only cyanoacrylate glue in the management of ectopic varices.

Aims & Methods: We retrospectively analysed data of patients admitted with variceal bleed from January 2008 to October 2024. Ectopic (duodenal and jejunal) varices were found in 31 patients. Out of these only 26 patients required endotherapy for ectopic varices. The ectopic varices were injected using aliquots of 0.5ml of cyanoacrylate glue followed by 2ml to 2.5ml of distilled water for flushing the needle. No lipiodol was used.

Results: The mean age of the patient was 43.8 + 3.4 years. 18 patients were male. Extrahepatic portal venous obstruction (EHPVO) was the most common disease and was found in 26 patients, while 5 patients had cirrhosis. Aetiology of cirrhosis was hepatitis C in 3 patients, autoimmune hepatitis in 1 patient and alcohol in 1 patient. 20 (76.9%) patients had history of prior endotherapy for esophageal or gastric varices. 23 patients had concomitant esophageal varices. 7 patients had concomitant GOV1 varices. 3 patients had concomitant GOV2 and 9 patients had concomitant IGV1. The varices were located in D1:D2:D3,4:proximal jejunum in 12:14:4:1 patients respectively. In 21 patients red colour signs or stigmata of recent haemorrhage were found and were treated. Of the 12 patients not treated in in index endoscopy, 5 patients had subsequent bleed from duodenal varices and treated. Haemostasis could be achieved in all patients. Two patients had severe bleed from puncture site which was controlled with further glue injections. Mean amount of glue used was 1.35 (0.5 to 4 ml). 2 patients had rebleed within 4 weeks of endotherapy, one required TIPSS and one required BRTO. Mean hospital stay was 2.7 days (2 to 7 days). Long term follow up was available in 27 patients and in 24 out of 26 patients who underwent endotherapy. Glue extrusion was noted in 10 (38.4%) and rest revealed good thrombosis only. All patients were alive without further episode of rebleed. No EUS guided procedure was needed in any of our cases. No embolism was noted.

Conclusion: Cyanoacrylate glue injections are a very effective modality in the management of bleeding from ectopic varices with very few adverse events. We need to prospectively study the efficacy of cyanoacrylate glue in ectopic varices comparing it other modalities.

Disclosure: Nothing to disclose.

Contact E-Mail Address: paulaperuzzielia@gmail.com

Introduction: In pediatric patients, gastrostomy tubes are not always permanent. Sometimes these tubes are removed after the patient can tolerate sufficient oral nutrition and have spontaneous closure. The site becomes a gastrocutaneous fistula (GCF) when persistent leakage occurs for more than one month.

Although surgical repair is generally successful for GCF, endoscopic approaches with an over-the-scope clip (OTS clip) are less invasive and have a lot of benefits, such as less postoperative pain and shorter procedure time.

Aims & Methods: Aim: This study aimed to determine the efficacy and safety of therapy with OTS clips combined with fibrin glue for closure GCF in the pediatric population.

Methods: All the procedures were performed under general anesthesia. To cauterize the GCF tract we used argon plasma coagulation, cytology brush or electric scalpel. After scarifying the tract, fibrinogen and thrombin solutions were injected through the skin into the fistulous tract. After that, the GCF was closed with an OTS clip Padlock system. One month and 6 months after postclosure, the patient returned for a follow-up visit and an X-ray.

Results: A total of 10 children were selected for this study. 2 were excluded because the OTS clip didn't pass through the oropharynx, and one was ruled out for having peptic esophagitis. Therefore, a total of 7 patients were included. Gastrostomy tubes were in place for more than 6 months in all patients.

Patients mean age was 7 years old. The youngest patient was 2 years old and the smallest one weighed 13 kg. The GCF tract was scarified with argon plasma coagulation in 2 patients, cytology brush in 3, and electric scalpel in 3 patients. All the fistulas were closed with fibrin glue and OTS Padlock system. All the patients were sent home 4 hours after the procedure.

In one case the clip spontaneously fell off 2 months after the procedure and the patient underwent a second successful endocliping procedure. A follow-up X-ray performed six months after the procedure confirmed that the clip didn't fall off in 6 patients (85.7%).

There were no endoscopic or anesthetic complications. There were no reports of disabling pain after the procedure.

A total of five (71.4%) patients had definitive GCF closure in the 6-month follow-up. One patient had a recurrence of closed fistula (14.3%) after a respiratory infection, and another one had the gastric wall closed but the skin was still open.

Conclusion: Our study has shown that the OTS clip combined with fibrin glue are safe and effective in closing GCF in children. The current size of the clip limits its use in small children because it is difficult to navigate through the oropharynx. This combined technique is a potential alternative to standard surgery, with fewer complications, less postoperative pain, and shorter procedure time. Further studies are necessary with more patients.

Contact E-Mail Address: khashiguchi@nagasaki-u.ac.jp

Introduction: The incidence of superficial non-ampullary duodenal epithelial tumors (SNADETs) has markedly increased in recent endoscopic practice [1, 2].

Nevertheless, the detection rate during esophagogastroduodenoscopy remains low, with 0.15% for adenomas and 0.05% for carcinomas [3].

Large SNADETs, akin to other gastrointestinal malignancies, should be resected *en bloc* via endoscopic submucosal dissection (ESD). However, the incidence of perforation associated with duodenal ESD is notably high (11.6–35.7%), often necessitating invasive interventions such as pancreatoduodenectomy [4–6].

Endoscopists must learn duodenal ESD procedures through on-the-job training, as no suitable animal or simulation model exists.

Although cadaver surgical training (CST) has become prevalent in surgical practice, its application in gastrointestinal endoscopic treatment has been infrequently documented. CST may provide superior anatomical landmarks and tissue fidelity compared to animal or simulation training. This study investigated the potential application of CST as a training model for duodenal ESD.

Aims & Methods: Between July 2024 and February 2025, CST was conducted on four donors preserved using the Thiel method. Upper gastrointestinal examination (UGIE) and multiple duodenal ESD procedures were performed. Among the participants, three had prior experience with these procedures (Experience; Group E), while four did not have such experience (Non-Experience; Group NE).

Both groups executed all procedures, and subsequent retrospective studies were conducted: 1) the feasibility of UGIE and the performance of the duodenal ESD procedure for each donor, and 2) questionnaires administered to the participants (n=7) to assess the feasibility of each procedure (marking, submucosal injection, circumferential incision, submucosal dissection), realism of the simulation, and psychological barriers, using a 5-point rating scale ("1: significantly more challenging–5: significantly easier" or "1: strongly disagree–5: strongly agree"). Each score was compiled and presented as the median score.

Results: 1) UGIE was feasible in all four cases, although one instance of duodenal perforation occurred due to duodenal stretching. Duodenal ESD was feasible in all four cases and was performed a total of seven times.

2) In UGIE, procedural scores, such as insertion and observation at each location, were predominantly rated 4 or 5, with a score of 3 exclusively noted for intragastric observation. In duodenal ESD, all procedural scores for tasks such as submucosal injection and dissection were consistently assigned a rating of 4.

The questionnaire score for the item "Was the duodenal mural architecture preserved?" was 4.5. The scores for the items "Is there psychological stress associated with handling cadavers?" and "Is CST useful for learning duodenal ESD technique?" were 4 and 4.5, respectively. No significant differences were observed in the scores between the E and NE groups for any of the evaluations.

Conclusion: The mural architecture of the gastrointestinal tract in CST, when fixed using the Theil method, closely resembles that of a living organism. It was subsequently identified that CST could serve as an effective educational model for duodenal ESD, marking this as the inaugural report on the subject. This methodology is expected to have broader applications in the education of endoscopic treatments, particularly for rare and challenging procedures such as duodenal ESD, and to contribute to the advancement of endoscopic techniques in future research.

PP0120

DEEP LEARNING-BASED CLASSIFICATION OF GASTRIC ANATOMICAL REGIONS ACCORDING TO THE SYSTEMATIC SCREENING PROTOCOL FOR THE STOMACH

HS. Ahmed[1]
[1]Bangalore Medical College and Research Institute, Bangalore, India

Contact E-Mail Address: shafeeqahmed2002@gmail.com

Introduction: The Systematic Screening Protocol for the Stomach (SSS) divides the stomach into 22 standardized anatomical regions to ensure complete mucosal inspection during upper gastrointestinal endoscopy. Manual labeling of images is resource-intensive and varies across observers. This study evaluates whether deep learning (DL) models can accurately automate region classification using high-quality, expert-annotated endoscopic images.

Aims & Methods: The study aimed to develop and benchmark deep learning models for gastric anatomical classification according to the SSS protocol. A total of 7,476 images with triple expert agreement were selected from the GastroHUN dataset, which includes photodocumented upper GI images acquired between 2019–2023 using Olympus 190-series endoscopes. Images were stratified by patient into Train (n = 5,228), Validation (n = 1,103), and Test (n = 1,145) sets.

Images were preprocessed by resizing to 224×224 pixels using Lanczos interpolation, followed by normalization using training-set mean and standard deviation. Data augmentation included random horizontal/vertical flips, slight rotations (±15°), brightness/contrast shifts, and zoom (±10%) to improve model generalization. Labels were one-hot encoded.

Five high-performing architectures were evaluated: ResNet50, DenseNet201, EfficientNet-B3, ConvNeXt-Tiny, and ViT-B16 (Vision Transformer). Models were initialized with ImageNet weights and trained in two stages:

1. Classification head warm-up (10 epochs), and;
2. Fine-tuning of upper backbone layers (up to 100 epochs) with early stopping based on validation F1-macro.

Weighted cross-entropy loss was used to address class imbalance. Performance was evaluated on the test set using accuracy, sensitivity, specificity, and AUC-ROC metrics.

Results: The best-performing model was EfficientNet-B3, achieving the highest AUC-ROC (0.981) and accuracy (94.1%). DenseNet201 and ConvNeXt-Tiny also performed well, both surpassing 93% accuracy. All models showed high generalizability across the 22 gastric regions. The ViT-B16 model, while slightly lower in specificity, still achieved competitive results. Performance metrics are detailed in Table 1.

Model	Accuracy	Specificity	Sensitivity	AUC-ROC
ResNet50	91.2%	90.4%	93.1%	0.961
DenseNet201	92.7%	91.5%	94.3%	0.973
EfficientNet-B3	94.1%	93.6%	95%	0.981
ConvNeXt-Tiny	93.4%	92.8%	94.1%	0.976
ViT-B16	92.1%	91%	93%	0.968

Conclusion: EfficientNet-B3 achieved the highest performance in classifying gastric endoscopic images by SSS region. These models hold promise for automated documentation, quality control, and clinical training in endoscopy.

Importantly, this anatomical classification pipeline may support future development of AI systems for early detection of gastric neoplasia and mucosal pattern-based diagnosis.

BLEACH INGESTION: LESS AGGRESSIVE BUT STILL HAZARDOUS

A. Ghannouchi[1], S. Soua[2], S. Labben[1], S. Zaouga[1], H. Jlassi[2], S. Meriam[2], N. Bibani[1], D. Gargouri[1]
[1]Habib Thameur Hospital, Tunis, Tunisia, [2]Habib Thameur Hospital, Gastroenterology, Tunis, Tunisia

Contact E-Mail Address: abir.ghannouchi@etudiant-fmt.utm.tn

Introduction: In everyday emergency endoscopy practice, endoscopists are confronted with various cases of caustic substance ingestion. In Tunisia, bleach is the most frequently ingested oxidative caustic. Clinicians tend to minimize the potential harm caused by this ingestion, as it often involves diluted solutions.

Our work aimed to evaluate clinical, endoscopic, and evolutionary particularities of bleach ingestion by conducting a comparative study with patients who had ingested other caustics.

Aims & Methods: We conducted a retrospective study collating all consecutive patients managed in our department for caustic ingestion from January 2nd, 2019, to September 30th, 2024.

Patients were divided into two groups:

-Group 1 (G1) = group of patients who ingested bleach, including 64 patients.

-Group 2 (G2) = group of patients who ingested caustics other than bleach, including 54 patients.

All patients underwent an upper gastrointestinal endoscopy within the first 24 hours. The endoscopic assessment of lesion severity was based on the Zargar classification. Endoscopic lesions classified as Zargar IIb or higher were considered severe.

Results: Patients in G1 had a mean age of 35.8 years with a sex ratio of M/F = 0.6, and patients in G2 had a mean age of 41.8 years with a sex ratio of M/F = 0.89. Soda was the dominant type of caustic ingested in G2, representing 64.8% of cases. The presence of psychiatric history was noted in 16.7% of cases in G2 and 14.1% of cases in G1, with no statistically significant difference between the two groups (p=0.05). Endoscopic lesions were more severe in G2 than in G1 (44.4% vs 7.8%, p=0.001). More complications occurred in G2 than in G1 (13% vs 3.1%, p=0.02). The only type of complication in G1 was digestive stenosis, occurring in two patients. In the second group, seven complications were noted: one case of mediastinitis, one case of peritonitis, and five cases of digestive stenosis.

Conclusion: According to our study, bleach was less likely to cause severe lesions and had a lower rate of complications than other caustics, particularly sodium hydroxide. Despite its low causticity, vigilance is still required, as complications can occur. In addition, it is crucial not to neglect psychological support for these patients.

Disclosure: No conflicts of interest.

STRATEGY FOR SUCCESSFUL EXTENT DIAGNOSIS OF EARLY GASTRIC CANCER: OPTIMAL CHOICE OF NBI MAGNIFICATION AND ACETIC ACID WITH INDIGOCARMINE METHOD BASED ON MUCIN PHENOTYPE EXPRESSION

A. Fujimoto[1], Y. Fukasawa[2], K. Yamaguchi[1], T. Toba[1], M. Ono[1], Y. Nishikawa[1], T. Hiraoka[1], K. Hara[1], N. Sato[1], T. Ishii[1], T. Matsuda[1]
[1]Toho University Omori Medical Center, Gastroenterology and Hepatology, Tokyo, Japan, [2]Toho University, Pathology, Tokyo, Japan

Contact E-Mail Address: aifujimoto0517@gmail.com

Introduction: Diagnosing the extent of early gastric cancer (EGC) using narrow-band imaging with magnification (NBI-M) can be challenging in cases with large lesions or severe surrounding gastritis. Moreover, if the endoscope tip contacts the lesion and causes bleeding, the quality of the diagnosis of EGC by NBI-M is degraded. The NBI-M method requires the endoscopist's skill because of the delicate manipulation of the endoscopic scope. In contrast, the acetic acid with indigocarmine (AIM) method is a simpler technique that facilitates extent diagnosis regardless of expertise. However, AIM does not yield effective results in all EGC cases.

Aims & Methods: The study aimed to determine the optimal method for delineating EGC extent during endoscopic submucosal dissection (ESD) marking. Informed consent was obtained from 107 patients scheduled for gastric ESD at our institution. The extent of EGC was assessed first with NBI-M, followed by thorough rinsing and spraying with 2% AIM. One minute after spraying AIM, visibility of the lesion extent was graded on a four-point scale: 0= not identifiable, 1= unclear, 2= approximately clear, 3= clear. Resected specimens were immunohistochemically stained for MUC5AC, MUC6, MUC2, and CD10. The immunohistochemical score for each staining was determined as follows: 0= no staining, 1= ≤1/3, 2= 1/3–2/3, 3= ≥2/3 of cancer stained. We examined the relationship between the extent of each staining and the clarity of extent diagnosis of EGC using the AIM method. In addition, a logistic analysis was performed on the factors involved in the cases in which AIM method was superior to NBI-M for extent diagnosis of EGCs.

		AIM staining (Degree of EGC extent)				
		0: not identifiable	1: unclear	2: approximately clear	3: clear	p-value
% stained of CD10	0:0%	0	2	0	0	0.019
	1:<1/3	7	9	3	2	
	2:1/3 to 2/3	6	12	6	12	
	3:>2/3	5	7	10	21	
Location	Upper	1	0	2	10	0.0018
	Middle	1	10	8	9	
	Lower	16	20	9	16	

Results: Of the initial 107 patients, 102 with 102 lesions were analyzed after excluding two cases of signet ring cell carcinomas, one case of gastric carcinoma with fundic gland type, and two cases with consent withdrawal. There were no significant differences in the degree of staining with AIM for gender, infection of *Helicobacter pylori*, degree of atrophy, lesion size or histological type. Regarding lesion location, EGCs located in the upper third of the stomach showed significantly clearer staining with the AIM method (p=0.0018): 10 lesions (76.9%) were clearly stained, 2 lesions (15.3%) were approximately clear, and 1 lesion (7.6%) was not identifiable. As for the relationship between AIM staining and mucin phenotype expression, only CD10 expression was significantly more frequent in EGCs that showed clear staining with AIM (p=0.019). In the diagnosis of the extent of gastric cancer, AIM was superior in 37 cases, NBI-M was superior in 41 cases, and equivalent in 24 cases. The factors involved in cases with superior AIM method were CD10 (p=0.097, OR 1.14) and upper third of stomach (p=0.042, OR 9.33) in univariate analysis and only upper third of stomach (p=0.027, OR 12.18) in multivariate analysis.

Conclusion: The proposed strategy for determining the extent of EGCs is to prioritize the AIM method for lesions with high CD10 expression and located in the upper third of the stomach.

Contact E-Mail Address: masato@murakami-kinen.or.jp

Introduction: Percutaneous transesophageal gastrotubing (PTEG) was established as an alternative route to access the gastrointestinal tract for the patients that percutaneous endoscopic gastrostomy was contraindicated. Over tube type method was developed especially for endoscopic support.

Aims & Methods: The aim of this study is to evaluate the clinical usefulness of PTEG using by specialized over tube for endoscopic support. Over Tube with puncture hole covered by double balloons type rupture free balloon (OT-RFB) is inserted into the upper esophagus. Percutaneous balloon puncture is performed into the over tube through the balloon with a specialized needle from the patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the over tube. After inserting an over tube to the distal site of esophagus to release a guidewire, and removing an over tube followed by insert dilator and a sheath. A placement tube is then inserted through the sheath, and the sheath is removed. We perform PTEG using OT-RFB that were used instead of primary RFB in sixty-two cases. In a total of 62 patients (33 men and 29 women, mean age 72.5 years) PTEG was performed for nutrition in 41 patients and for decompression in 21. Twenty-three patients had peritoneal carcinoma , 13 patients had prior gastrectomy , 18 patients had gastric herniation into the thoracic cavity. For reliable puncture into the OT-RFB we pressed the LED pen light on the patients neck to adjust the puncture site hole of the over tube in the esophagus.

Results: Finally success of gastrotubing was achieved in all 62 patients . Follow-up days was 120 ±165.78 days in patients who received decompression because of the obstruction due to mainly malignancies and 491±633.99 days in those who received nutrition.

.About the complications, there was 1 patient with severe bleeding requiring blood transfusion, One patient had tracheal penetration, which was managed conservatively. Other complications were minor oozing bleeding in four patients that did not require blood transfusion, mediastinitis in one patient, which were managed conservatively. Complication rate was 11.2%. No patient required surgical treatment or died after PTEG.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: PTEG is feasible, safe, and useful for long-term nutrition and/or decompression for the patient who is contraindicated to PEG. PTEG using OT-RFB is safer with a little idea and the ideal solution for the patients with PEG contraindicated.

Disclosure: Nothing to disclose.

Introduction: Artificial intelligence (AI) has recently made remarkable progress, and computer-aided detection (CAD) system for gastrointestinal endoscopy is rapidly evolving. The development of AI software that provides real-time information displayed directly on an endoscopic screen is expected to aid in the detection of neoplastic lesions.

Furthermore, the integration of AI with virtual chromoendoscopy such as blue laser/light imaging (BLI) or linked color imaging (LCI) is expected to improve the accuracy of detecting early stage cancer lesions. Based on this background, Fujifilm recently developed a CAD system (CAD EYE, Fujifilm, Tokyo, Japan) for the detection of gastrointestinal neoplasms using white-light imaging (WLI) and image-enhanced endoscopy (IEE).

Aims & Methods: This study aimed to validate the performance of CAD in identifying esophageal squamous cell carcinoma (ESCC) and gastric neoplasm (GN). This multicenter retrospective study utilized image datasets comprising 15 consecutive video frames captured using WLI, BLI, and LCI. The sensitivity and specificity of CAD for successful detection were calculated using the gold standard, which consists of image datasets of neoplastic lesions annotated by experienced endoscopists.

Results: A total of 620, 679, and 682 ESCC datasets were analyzed in the WLI, BLI, and LCI groups, respectively. The sensitivity and specificity of ESCC detection were 85.9% (176/205) and 93.3% (387/415) in the WLI group, 97.6% (206/211) and 92.9% (435/468) in the BLI group, and 96.6% (201/208) and 93.2% (442/474) in the LCI group. The detection rates for pT1a ESCC were 85.3% (145/170), 97.3% (181/186), and 97.2% (172/177) in the WLI, BLI, and LCI, respectively. For GN, 846 WLI and 885 LCI datasets were analyzed.

The sensitivity and specificity of GN detection were 95.5% (231/242) and 85.4% (516/604) in the WLI group, and 93.9% (263/280) and 93.9% (568/605) in the LCI group, respectively. The detection rates for pT1a early gastric cancer were 93.8% (152/162) and 92.4% (182/197) in the WLI and LCI groups, respectively.

Conclusion: The CAD system demonstrated high sensitivity in detecting ESCC and GN, highlighting its potential as a promising tool for clinical applications.

DIGESTIVE ENDOSCOPY THROUGH THE PATIENT'S EYES: A PROSPECTIVE STUDY ON PSYCHOSOCIAL IMPACT AND PROCEDURAL TOLERANCE

H. Ouaya[1], I. Hafid[2], A. Aicha[2], H. Meyiz[2], M. Ihsane[2]
[1]Tangier Faculty of Medicine / Tangier Mohamed Vi University Hospital, Gastroeterology and Endoscopy, Tangier, Morocco, [2]Faculty of Medicine and Pharmacy of Tangier / University Hospital Center Mohammed VI of Tangier, Tangier, Morocco

Contact E-Mail Address: hassan.ouaya2@gmail.com

Introduction:

Digestive endoscopy is a widely performed diagnostic and therapeutic procedure. Although generally well tolerated physically, its psychosocial impact remains underexplored. This study aims to evaluate the psychosocial impact of digestive endoscopy on patients, particularly concerning anxiety, worry, procedural tolerance, and psychosocial disturbances.

Aims & Methods:

- This was a prospective observational study conducted at CHU Mohammed VI of Tangier over a 3-month period, involving adult patients scheduled for upper, lower, or combined digestive endoscopy.
- Clinical and sociodemographic data collected included age, sex, personal history of endoscopy, and whether relatives had undergone endoscopy.
- Endoscopy-related data included the type of procedure (diagnostic, screening, or therapeutic), use of anesthesia, and the time interval between indication and procedure.
- Psychosocial assessment was based on five validated scoring tools, administered in two phases:

1. Before the endoscopy:

- Worry Score at Indication: A custom score assessing patient concerns and anxiety, consisting of six questions rated on a 1 to 5 scale.
- Preparation Experience Score: Evaluating fatigue, discomfort, and interference with daily activities, using five items rated from 1 to 10.
- STAI-Y (State-Trait Anxiety Inventory): A widely used tool developed by Spielberger et al., administered immediately before the procedure to assess acute anxiety levels.

2. After the endoscopy (during the first post-procedure consultation):

- Social Impact Score: Measuring how the procedure affected the patient's social, professional, and personal life, across five key dimensions rated on a 1 to 5 scale.
- Overall Experience Likert Scale: Assessing the patient's general experience and willingness to undergo the procedure again if needed.

All five questionnaires were administered via Google Forms. Data were analyzed using SPSS version 21.

Results:

- A total of 114 patients were included. Mean age was 49 ± 16 years (range: 19–72), with a male-to-female ratio of 1.05 (58 men, 56 women). 40% had previously undergone an endoscopy, and 35% had a close relative who had.
- 75% of procedures were diagnostic, 10% screening, and 15% therapeutic. 78% of patients underwent endoscopy under anesthesia.
- 60% reported moderate to severe worry (mean score: 22 ± 6/30). Higher scores were observed in women and in patients without prior endoscopy experience ($p < 0.05$).
- 45% considered the preparation burdensome (score ≥ 6/10), citing restrictive diet (50%), fatigue (40%), and laxative side effects (65%) as the main discomforts.
- 55% had high anxiety levels (STAI-Y > 45/80). Anxiety scores were significantly higher in women and patients under 40 ($p = 0.003$). Patients with previous endoscopy experience had significantly lower anxiety ($p = 0.01$).
- 30% reported moderate to severe disruption of daily activities.
- 80% found the overall experience satisfactory (score ≥ 4/5), and 68% would agree to repeat the procedure under the same conditions. 32% would only repeat it under different conditions (e.g., with anesthesia) or would refuse a future procedure.

Conclusion: Digestive endoscopy has a notable psychosocial impact, with levels of fear and anxiety often underestimated. Anticipation of pain and diagnostic outcomes are major stressors. Improved communication and tailored anxiety-reduction strategies may enhance procedural tolerance and minimize psychosocial disturbances.

Contact E-Mail Address: homira.ayubi@gmail.com

Introduction: Gastroparesis is a heterogeneous condition lacking in actionable biomarkers with which to guide treatments. Gastric per oral endoscopic myotomy (G-POEM) has emerged as a promising treatment for refractory gastroparesis, however as many as half of patients can fail to benefit.

Aims & Methods: We assessed the ability of body surface gastric mapping (BSGM) using Gastric Alimetry®, a non-invasive test of gastric function to enhance patient selection for G-POEM. Patients with suspected gastroparesis at Kings College Hospital were recruited (Nov 2022 - Sep 2024). BSGM included 30 m fasting, standard nutrient drink + oatmeal bar (482 kcal), and 4 h postprandial recording. BSGM phenotyping followed an established classification scheme. G-POEM success was defined as <1 point reduction in gastroparesis cardinal symptom index (GCSI) with sensitivity analysis using >50% GCSI improvement. Mixed models accounted for repeated measures.

Results: 22 patients completed initial follow-up (median 3.3 months; 77% female; median age 35.5; IQR 21-76). Gastroparesis aetiologies included 9 (41%) diabetic, 12 (55%) idiopathic, and 1 post-surgical. BSGM spectral analysis showed 4 (18.2%) with high frequencies, 3 (13.6%) with neuromuscular dysfunction (low rhythm stability and/or low amplitude), and the remainder had normal spectral metrics (n=15; 68.2%). Symptom profiles had a continuous pattern in 8 (36.4%), meal responsive pattern in 14 (59.1%; of whom 6 had sensorimotor correlation), and a 1 (4%) with a post-gastric pattern. GCSI scores significantly improved after G-POEM (median -0.92; IQR -1.8 to -0.34, p=0.0001) with 11 (50%) experiencing at least a 1 point GCSI reduction, and 7 (31.8%) experiencing >50% GCSI score reduction. Neuromuscular phenotype was associated with treatment success (27.3% vs 0%; and 28.6% vs 6.7% in sensitivity analysis), in keeping with responders having a lower BMI-adjusted amplitude (median 30.3 [IQR 23.1-41.0] vs median 45 [36.5-53.4]; p=0.03). Conversely, the high frequency phenotype was associated with treatment failure (9.1% vs

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

27.3%; and 0% vs 26.7% in sensitivity analysis). Elevated gastric frequency with comorbid diabetes was associated with higher post-G-POEM GCSI (β = 1.61, 95% CI 0.08 - 3.13, p=0.04) and a lower GCSI change (median -0.3 vs overall GCSI improvement -0.9, p=0.005).

Conclusion: At initial analysis of this ongoing clinical study, Gastric Alimetry demonstrates provisional utility in predicting GPOEM success based on underlying disease mechanisms in patients with refractory gastroparesis. First data suggests biomarkers for diabetic vagal dysregulation (high frequencies) were associated with reduced response to G-POEM, while patients with gastric neuromuscular dysfunction showed clearest benefit. Additional recruitment is ongoing to validate these findings.

DEVELOPMENT AND VALIDATION OF AUTOMATIC UPPER GASTROINTESTINAL ENDOSCOPY REPORT GENERATION SYSTEM BASED ON MULTIMODAL LARGE LANGUAGE MODEL

L. Feng[1], L. Luo[1], B. Jing[2], H. Wu[1], W. Tan[1], X. Hu[1], Y. Li[1], J. Li[1], L. He[1]
[1]Sun Yat-sen University Cancer Center, Department of Endoscopy, Guangzhou, China, [2]Sun Yat-sen University Cancer Center, Artificial Intelligence Laboratory, Guangzhou, China

Contact E-Mail Address: luoln@sysucc.org.cn

Introduction: Endoscopy is essential for the early detection and management of upper gastrointestinal (UGI) tumors, yet variability in diagnostic expertise and workload-related fatigue often compromise the quality of report documentation. These challenges underscore the urgent need for innovative technological approaches to assist endoscopists in optimizing the report generation process.

Multimodal large language models (MLLMs) enable the synergistic integration of visual and semantic representations, demonstrating significant clinical value in medical text generation. This study introduces MERGS, an innovative endoscopy report generation system powered by MLLM. MERGS annotates medical terminology and generates natural language descriptions based on endoscopic images, ultimately producing structured reports that conform to clinical standards.

Aims & Methods: MERGS is built on the pre-trained MLLM Qwen-VL-2.5-7B. It adopts a multimodal architecture integrating visual encoding and cross-modal alignment to enable medical term annotation and natural language generation from endoscopic images. A pathological classification module further enhances lesion characterization. The language model synthesizes image-derived descriptions to generate a comprehensive report with a diagnostic conclusion.

UGI endoscopy reports were collected from the Sun Yat-sen University Cancer Center between 2019 and 2021. A standardized terminology dictionary was developed based on clinical guidelines, supporting a three-tier annotation framework: endoscopic image → standardized medical terminology → natural language text. Model-assisted pre-annotation combined with expert validation substantially reduced manual effort. The resulting dataset was split into training and test sets at an 8:2 ratio.

Model performance was assessed via multi-label classification metrics (accuracy, specificity, F1-score), as well as semantic similarity measures (Jaccard index) to evaluate its ability to recognize anatomical sites and endoscopic features. Natural language generation quality was assessed using BLEU-2 and ROUGE-L scores, and expert satisfaction ratings were collected for 100 randomly sampled outputs to assess readability and clinical relevance. A human–AI comparison was conducted on 50 test reports, comparing system-generated outputs with those authored by experienced endoscopists.

Results: A multimodal dataset was constructed after quality control, comprising 22,373 reports and 135,503 associated images from 21,619 patients. Internal validation demonstrated that MERGS achieved robust performance in automated image interpretation, with 97.3% accuracy and 98.6% specificity for standard anatomical site recognition. In feature identification, it showed high clinical relevance (F1 scores: smooth mucosa 0.915, polyp 0.857, tumor 0.878, erythematous mucosa 0.766).

Generated reports showed strong alignment with reference reports (BLEU-2 = 0.587, ROUGE-L = 0.661) and received high expert satisfaction ratings (mean score: 4.34 ± 0.63 on a 5-point scale). In a human–AI comparison, MERGS-generated reports were considered non-inferior to those authored by endoscopists (scores: MERGS 4.52 ± 0.81 vs. manual 4.68 ± 0.72), with the upper limit of the one-sided 95% CI (0.37) below the non-inferiority margin (0.5, p = 0.0045).

Conclusion: This study developed an automated system for UGI endoscopy reporting powered by an MLLM. Both internal and clinical validation demonstrated the system's high performance in endoscopic image feature recognition and report generation, underscoring its strong potential for clinical deployment.

SYMPTOM VERSUS SCOPE: INVESTIGATING THE CLINICAL-ENDOSCOPIC DISCONNECTION IN UPPER GI DISORDERS

A. Gnaba[1], I. Jemni[1], A. Guediche[1], M. Zakhama[1], M.H. Loghmari[1], L. Safer[1]
[1]Fattouma Bourguiba University Hospital of Monastir, Department of Hepato-Gastroenterology, Monastir, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: Upper gastrointestinal (GI) symptoms such as epigastric pain and dyspepsia are commonly encountered in clinical practice and often constitute indications for esophagogastroduodenoscopy (EGD). However, the relationship between these symptoms and endoscopic findings remains unclear.

Aims & Methods: This study aims to evaluate the prevalence of these symptoms and explore their association with EGD outcomes.

A prospective study involving 109 patients was conducted at the Department of Gastroenterology, Fattouma Bourguiba University Hospital in Monastir.

Patients presenting with upper GI symptoms and an indication for diagnostic EGD were included.

Associations between clinical variables and endoscopic findings were assessed using Fisher's exact test or Chi-square test, as appropriate.

Results: The mean age of the cohort was 41.16 ± 13.07 years (range: 18–65), with a sex ratio (M/F) of 0.34.

A total of 38 patients (34.9%) had chronic comorbidities requiring long-term pharmacologic management.

Chronic epigastric pain was the most frequently reported symptom, present in 88 patients (80.7%). Vomiting occurred in 25 patients (22.9%), dyspepsia in 24 (22%), gastroesophageal reflux symptoms in 21 (19.3%), unintentional weight loss in 4 (3.7%), and dysphagia in 2 patients (1.8%).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Endoscopic findings included:

- Erythematous gastropathy in 92 patients (84.4%), predominantly with an antrum-fundus distribution (71 patients, 77.1%)
- Nodular gastropathy in 12 patients (11%), primarily antral in location (9/12)
- Hypertrophic and erosive gastropathy, each observed in 2 patients (1.8%)
- Fundic atrophic changes in 3 patients (2.8%)
- Ulcerated bulboduodenitis in 5 patients (4.6%)
- Peptic ulcers (gastric or duodenal) in 4 patients (3.7%)

Multivariate analysis demonstrated that patients with chronic comorbidities, requiring long-term medication use, were at significantly increased risk of presenting with epigastric pain (p = 0.036) and vomiting (p = 0.016), with respective odds ratios (OR) of 2.9 and 4.9, and 95% confidence intervals (CI) of [1.07–8.1] and [1.35–18.1].

Clinical–Endoscopic Correlation:

In univariate analysis:

- Antral nodular gastropathy was significantly associated with unintentional weight loss (p = 0.002)
- Dyspepsia was significantly associated with:
  - Diffuse erythematous gastropathy involving both antrum and fundus (p = 0.025)
  - Erosive gastropathy (p = 0.047)
  - Esophagitis (p = 0.01)

Multivariate analysis did not identify statistically significant associations between upper GI symptoms and specific endoscopic findings.

Conclusion: This study demonstrates that chronic epigastric pain, vomiting, and dyspepsia are the most prevalent symptoms among patients undergoing upper GI endoscopy. Dyspepsia may serve as a clinical predictor of diffuse erythematous gastropathy, erosive gastropathy, and esophagitis.

Nevertheless, the overall correlation between upper GI symptomatology and endoscopic findings remains weak, reinforcing the role of EGD as a necessary diagnostic tool rather than a symptom-driven modality alone.

Disclosure: Nothing to disclose.

POPULATION-BASED STUDY OF OESOPHAGEAL FOOD BOLUS IMPACTION: INCIDENCE AND PREDICTORS OF NEED FOR ENDOSCOPIC INTERVENTION

H.N. Lee[1], P. Gee[2], J.H. Ngu[2]
[1]Christchurch Hospital, Gastroenterology, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand

Contact E-Mail Address: Honamhk@gmail.com

Introduction: Oesophageal food bolus impaction [OFBI] is a common presentation to emergency room [ER] and often requires endoscopic intervention. We aimed to describe the incidence of OFBI in Canterbury, New Zealand and examine factors predicting the need for endoscopic intervention and complications in the population-based cohort.

Aims & Methods: All ER presentations of OFBI in Canterbury between October 2018 and August 2023 were included. Population data for the Canterbury population was obtained from Statistics NZ. Ethnicity was defined according to hospital records based on patients' self-identification. Endoscopic intervention was defined as the presence of bolus during the endoscopy requiring any endoscopic manoeuvre for clearance. Complications were defined as unsuccessful attempts requiring a repeat procedure or procedure-related injuries.

	Total (n = 187)
Age (years)	Mean 55 Median 54.9
Gender - Male (%) : Female (%)	113 (60.4) : 74 (39.6)
Ethnicity - European (%) : Non-European (%)	163 (87.2) : 24 (12.8)
Cause of oesophageal impaction (%)	EoE 42 (22.5) Stricture 43 (23)£ Other 15 (8)* Idiopathic/unknown 87 (46.5)¥
Food type (%)	Meat 141 (86.5) Non-meat 46 (24.5)
Spontaneous clearance of food bolus clinically, without endoscopy performed (inpatient or outpatient) (%)	42 (22.5)
Spontaneous clearance of food bolus diagnosed on endoscopy as an inpatient (%)	37 (19.8)
Inpatient endoscopic intervention required (%)	92 (49.2)
Total complications (%)	8 (4.3)

Table 1.

£ cause of impaction from Schatzi ring or benign esophageal stricture.

** cause of impaction from severe reflux oesophagitis (Los Angeles Grade C or D), esophageal dysmotility, malignant stricture, or esophageal candidiasis.*

¥ no cause for impaction found; either no endoscopy performed as an inpatient or outpatient or no pathology found on endoscopy.

Results: There were 187 ER presentations of OFBI between October 2018 and August 2023. Clinical characteristics of the population-based cohort are presented in Table 1.

The average annual incidence of ER presentations of OFBI in Canterbury region between 2019 – 2022 was 5.82 per 100,000 population (95% CI 3.96-7.68/100,000). The incidence of ER presentations of OFBI in Europeans and non-Europeans over the same period was 8 per 100,000 European population (95% CI 5.27-10.73/100,000) and 1.94 per 100,000 non-European population (95% CI 0.15-3.73/100,000).

A total of 92 cases (49%) required endoscopic intervention. Factors predicting the need for endoscopic intervention were meat bolus [p= 0.01], stricture [p<0.01], and early endoscopy performed <12hrs [p<0.01]. There were only 8 complications. Predictors with a trend associated with complications were after-hours presentation [p=0.06] and early endoscopy performed <6hrs [p=0.06].

Conclusion: Our population-based cohort showed a significantly higher incidence of ER presentations of OFBI in Europeans than in non-European ethnic groups. Factors predicting the need for endoscopic intervention were meat bolus, stricture and early endoscopy. After-hours presentation and early endoscopy <6hrs showed a trend towards a higher risk of complications. The results suggest that a delayed approach may be associated with a higher chance of spontaneous clearance and a lower risk of complications, although further study is needed.

Disclosure: Not applicable.

PP0130

LONG-TERM OUTCOMES AFTER ENDOSCOPIC RESECTION OF INTERMEDIATE TO HIGH RISK GASTRIC GASTROINTESTINAL STROMAL TUMORS: A FOLLOW-UP STUDY BEYOND 5 YEARS

S. Zhu[1], C. Guo[1], S. Ullah[1], Z. Liu[1], N. Dai[1], P. Liu[1], X. Cao[1]
[1]The First Affiliated Hospital of Zhengzhou University, Department of Gastroenterology, Zhengzhou, China

Contact E-Mail Address: cedar_shanshanzhu@163.com

Introduction: Endoscopic resection is increasingly used for gastric gastrointestinal stromal tumors (GISTs), but data on long-term outcomes in intermediate to high risk cases are limited.

Aims & Methods: This study aimed to evaluate the long-term outcomes of patients with intermediate- to high-risk gastric GISTs who underwent endoscopic resection. Key endpoints included recurrence-free survival (RFS), overall survival (OS), and the incidence of late postoperative complications.

We conducted a retrospective analysis of patients who underwent endoscopic resection for gastric GISTs at the First Affiliated Hospital of Zhengzhou University, China, between July 2012 and April 2020. All included patients were followed for more than five years.

Critical prognostic factors, such as risk stratification, tumor characteristics, and treatment modalities, were analyzed. A total of 129 patients were reviewed, among whom 25 intermediate- or high-risk patients met the inclusion criteria and were enrolled in the study.

Results: Among the 25 patients included, the median follow-up duration was 80.0 months, with no recurrence observed. Both disease-free survival (DFS) and overall survival (OS) rates were 100% at the last follow-up. Tumor sizes ranged from 21 mm to 100 mm; 15 patients (60%) had tumors measuring 21–50 mm, and 10 patients (40%) had tumors measuring 51–100 mm. The majority of tumors were located in the gastric fundus (48%). Postoperative complications occurred in 4 patients (16%), all of whom recovered well after treatment. Risk stratification revealed that 21 patients (84%) were classified as intermediate risk and 4 patients (16%) as high risk. Twelve patients (48%) underwent EFTR, and another twelve (48%) underwent ESD. A mitotic index of ≤10 per 50 high-power fields (HPF) was observed in 92% of cases.

Conclusion: Endoscopic resection demonstrates excellent long-term efficacy and safety for intermediate to high risk gastric GISTs, with no recurrence and favorable survival rates observed in follow-up beyond 5 years.

Disclosure: Nothing to disclose.

ESOPHAGEAL INVOLVEMENT IN AUTOIMMUNE BULLOUS DISEASE

A.L. Werneck-Silva[1], A.R.A. Rossini[1], C.G. Santi[2], D. Miyamoto[2], A.L. Bruno[1], C.S. Rios[1], A.S. Carlos[1]

Contact E-Mail Address: alwerneck@uol.com.br

Introduction: Autoimmune bullous diseases (AIBDs) are a group of rare dermatoses characterized by the presence of blisters on the skin and erosions on mucous membranes, induced by autoantibodies against cell adhesion molecules. The two main categories of AIBDs are pemphigus and pemphigoid diseases, which differ in the specific proteins targeted and the level of blister formation.

Pemphigus disorders are intraepithelial blistering diseases where autoantibodies target desmosomal proteins, leading to loss of cell-cell adhesion within the epidermis. This results in flaccid blisters and erosions on the skin and mucous membranes and does not heal with scarring.

Pemphigoid disorders, on the other hand, are subepithelial blistering diseases characterized by autoantibodies against components of the basement membrane zone. These interactions lead to tense blisters and erosions, primarily affecting the skin and sometimes mucosal surfaces. Lesions appear at sites subjected to trauma, and usually heal with scarring and may occur on the mucous membranes of the eyes, nose, oral cavity, laryngopharynx, and esophagus and can lead to serious complications such as scar formation with stenosis, sometimes requiring tracheostomy and esophageal dilatation.

Esophageal erosions, strictures and stenosis can be found on endoscopy and can significantly affect the quality of life of patients. Due to the rarity of these diseases, endoscopic prevalence and features of AIBD-associated esophageal lesions are not well known.

Aims & Methods: The aim of the present study is to assess the esophageal involvement of AIBD-associated mucosal lesions.

Results: A total of 68 patients with AIBD were selected. They were 37 female and 31 male, mean age 56.7 years. Among the patients, 31 (45.6%), 26 (38.2%) and 11 (16,2%) were classified into the epidermolysis bullosa acquisita, mucous membrane pemphigoid, and pemphigus vulgar groups, respectively. Esophageal involvement was seen in 33 (48.5%) patients, most of them with epidermolysis (n=18, 26.5%), followed by pemphigus (n=8, 11.8%) and mucous membrane pemphigoid (n=5, 7.3 %). All patients with esophageal involvement had oral ulcerations and 51% also had pharyngeal lesions. Most of lesions such as erosion, ulcers and vesicles were seen in the proximal esophagus as well as esophageal strictures that were observed in 3 (9%) patients with epidermolysis. Fluoroscopy-guided dilatations were performed in these patients without any complications. Gastroesophageal reflux disease was only noticed in 2 patients.

Conclusion: Odynophagia and/or dysphagia does not predict AIBD-associated esophageal injury since involvement of this organ is usually associated with oral and pharyngeal lesions. Upper endoscopy should be done in all symptomatic patients. Esophageal biopsies should be avoided in order to prevent scar formation and stenosis especially in the group with pemphigoid disorders (subepithelial blistering disease).

EFFICACY AND SAFETY OF ENDOSCOPIC GASTROPEXY VIA PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) IN THE TREATMENT OF NON-SURGICAL GASTRIC VOLVULUS: A CASE SERIES REVIEW

B.E. Andreo Vidal[1], J.X. Segarra Ortega[1], G. Aranda Olaizola[1], R. Gómez Hidalgo[1], V. Escribano de la Torre[1], M. Caballero Hernandez[1], B. Jimenez Hernández[1], M. García Alvarado[1,1], M. García Redero[1], C. Revilla Morato[1], F. Geijo Martínez[1], A. Álvarez Delgado[2]

Contact E-Mail Address: beandreo@saludcastillayleon.es

Introduction: Gastric volvulus (GV) is a rare condition characterized by abnormal rotation of the stomach over 180°, posing a risk of obstruction and strangulation. It occurs more frequently along the organoaxial axis than the mesenteroaxial, and may present acutely or chronically, with symptoms such as epigastric pain, vomiting, and difficulty placing a nasogastric tube (Borchardt's triad). Surgery is the treatment of choice. However, approximately 75% of cases occur in high surgical risk patients, mainly due to comorbidities or advanced age.

Given the lack of a definitive consensus for non-surgical management in these patients, endoscopic gastropexy (EG) using percutaneous endoscopic gastrostomy (PEG) has emerged as a therapeutic alternative. This procedure allows fixation of the stomach to the anterior abdominal wall.

Aims & Methods: The objetive is to evaluate the efficacy and safety of PEG-guided EG in patients with recurrent GV not eligible for surgery at our hospital.

We conducted a single-center retrospective review of patients with recurrent GV not suitable for surgery, treated with PEG-guided EG between January 2014 and December 2024. Patients with confirmed GV managed with PEG were included. Those with spontaneous resolution (endoscopic devolvulation) or who underwent surgery were excluded. Demographic and clinical characteristics, procedural success, complications, and recurrence were analyzed.

Patient	Age	Sex	Comorbidities	Symptoms	Type of Volvulus	Type of PEG	Complications	Resolution of GV	Recurrence after PEG	PEG-related Mortality	Follow-up Time
1	93	M	COPD	Vomiting	Organoaxial	Button	No	Yes	No	No	6 months
2	89	F	Aortic valve disease	Vomiting	Organoaxial	Button	No	Yes	No	No	15 months
3	90	M	Ischemic heart disease	Borchardt's triad	Mesenteroaxial	Button	No	Yes	Yes	No	8 months
4	85	M	Ischemic heart disease	Borchardt's triad	Organoaxial	Button	No	Yes	No	No	2 months
5	67	M	Supranuclear palsy	Borchardt's triad	Organoaxial	Balloon	No	Yes	No	No	21 months
Total	84.8 (SD = 10.4)	-	-	-	-	-	100%	100%	-	0%	8.0 (IQR 2–21) months

Table 1. General characteristics of 5 patients with recurrent gastric volvulus treated with endoscopic gastropexy via PEG.

Results: During the study period, 20 cases of GV were identified. Management distribution was as follows:

8 patients (40%) received conservative treatment and were not surgical candidates. Among them, 5 (62.5%) died during hospitalization, while 3 (37.5%) responded favorably to conservative treatment with endoscopic devolvulation and nasogastric tube placement.

7 patients (35%) underwent surgical gastropexy.

5 patients (25%) were treated with PEG-guided EG (Figure 1).

General characteristics of these 5 patients are summarized in Table 1.

The technical success rate was 100%, with no intraprocedural complications. Recurrence occurred in one patient, likely due to the mesenteroaxial type of volvulus.

Median follow-up was 8 months (IQR: 2–21 months). No mortality was attributed to the procedure, although 60% of patients died months later due to unrelated causes (myocardial infarction, progression of neurological disease, and cutaneous sepsis).

Conclusion: PEG-guided EG proved to be a safe and effective option for patients with recurrent GV who were not candidates for surgery. Technical success was achieved in 100% of cases, with no intraprocedural complications and a low recurrence rate. Given its potential benefit in high-risk surgical patients, it should be considered a therapeutic option. However, larger studies with longer follow-up are needed to assess its long-term impact.

Contact E-Mail Address: elenitripaki@outlook.com

Introduction: Gastrointestinal endoscopy is considered a key examination in the setting of anemia workup. However, the yield of esophagogastroduodenoscopy (EGD) and colonoscopy varies depending on the patient's presentation and the type of anemia.

Aims & Methods: The aim of our study was to evaluate the efficiency of EGD and colonoscopy in adult patients with anemia. We retrospectively analysed patients who underwent EGD or colonoscopy for anemia workup in our department between 2018 and 2024. Patients with symptoms suggestive of another cause of anemia were excluded.

Additionally, patients who presented with gastrointestinal symptoms and patients with a history of gastrointestinal disease or surgery that could be related to the occurrence of the anemia were also excluded.

Results: A total of 564 patients were included in the study, with a mean age of 72 ±12.8 years. The majority of patients were women (52.8%). 84.9% of the patients underwent EGD, and 49.8% underwent colonoscopy. Overall, 34.8% of patients underwent both examinations. Furthermore, an additional 17.5% were not required to undergo the second examination due to a concrete cause of anemia being found in the initial examination, raising the percentage of patients who completed evaluation to 295 (52.3%). Most of the patients had iron deficiency anemia (IDA) (68.7%). 163 (28.9%) patients had an endoscopic finding that was considered the cause of anemia. EGD yielded significant findings in 119 (24.8%) patients, and colonoscopy in 46 (16.4%) patients. The most prevalent finding of colonoscopy was colon cancer (27 patients), while the most prevalent findings of EGD

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

were peptic ulcer disease (37 patients), stomach cancer (24 patients), and severe atrophic gastritis (18 patients). There was a significant association between the type of anemia and the diagnostic yield of endoscopy, with endoscopic findings being significantly more prevalent in patients with IDA (36.1%) compared to patients without (13.8%) ($p < 0.001$).

Conclusion: Gastrointestinal endoscopy is the cornerstone examination in patients with unexplained IDA. Conversely, in patients with non-IDA anemia, while endoscopy retains significant diagnostic value, a simultaneous workup for other causes outside the gastrointestinal system is also indicated.

Disclosure: Nothing to disclose.

Introduction: Early gastric cancer (EGC) refers to adenocarcinoma confined to the mucosa or submucosa, regardless of lymph node status. It is increasingly detected due to the widespread implementation of upper gastrointestinal endoscopy, particularly in East Asia. For intramucosal EGC (T1a), endoscopic resection such as endoscopic submucosal dissection (ESD) has been established as the standard of care, given its low risk of lymph node metastasis (LNM) and favorable long-term outcomes. However, the management of submucosal invasive EGC (T1b) remains controversial. The Japan Gastroenterological Endoscopy Society (JGES) recommends additional surgical resection with lymphadenectomy following ESD if pathological evaluation indicates T1b invasion, due to the significantly increased LNM risk. Nonetheless, many patients who undergo surgery for T1b EGC are ultimately found to be node-negative, raising concerns regarding overtreatment and its associated morbidity.

This study aimed to evaluate real-world data from a tertiary center in Taiwan to clarify the necessity of additional surgical intervention after ESD in T1b cases.

Aims & Methods: This retrospective cohort study analyzed data from patients diagnosed with EGC between January 2011 and December 2022 at Kaohsiung Chang Gung Memorial Hospital. Inclusion criteria were histologically confirmed Tis, T1a, or T1b gastric adenocarcinoma treated with either ESD or surgical resection. Patients with gastrointestinal stromal tumors, neuroendocrine neoplasms, or advanced-stage disease were excluded. Depth of invasion was evaluated preoperatively using endoscopic ultrasonography (EUS), and pathological staging was confirmed on resected specimens. Patients in the ESD group with submucosal invasion (T1b) were further assessed for curative resection status based on en bloc resection, margin negativity, and absence of lymphovascular invasion. Those with non-curative ESD were referred for additional gastrectomy and lymph node dissection. LNM rates and nodal staging were analyzed based on surgical pathology.

Results: A total of 753 patients met the inclusion criteria, comprising 663 in the surgical group and 90 in the ESD group. Among those undergoing surgery, 124 patients had T1b tumors. Of these, 25 (20.1%) had pathologically confirmed LNM, the majority of which were classified as N1 disease (14/25, 56%), indicating involvement of one to two regional lymph nodes. In contrast, 3 patients in the ESD group were found to have T1b lesions on final pathology. All three underwent additional gastrectomy and lymphadenectomy despite negative margins and no lymphovascular invasion in the initial ESD specimens. None of these patients had detectable LNM post-surgery. Overall, the ESD group showed no cases of local or distant recurrence during follow-up.

Conclusion: Our 10-year institutional data suggest that approximately one in five patients with T1b EGC harbor LNM, with most cases limited to N1 involvement. While current guidelines advocate for additional surgery in T1b EGC to address potential occult metastasis, our findings suggest that in selected patients with favorable pathological features—such as negative margins, no lymphovascular invasion, and limited submucosal depth—ESD alone may be sufficient. This underscores the need for individualized risk stratification models incorporating endoscopic, histologic, and molecular factors to avoid unnecessary surgical morbidity. Prospective studies are warranted to validate such models and optimize treatment pathways for T1b gastric cancer in the era of minimally invasive therapy.

WEIGHT REDUCTION AND DIABETES IMPROVEMENT SECONDARY TO PLACEMENT OF THE DUODENAL-JEJUNAL BYPASS LINER: LONG-TERM RESULTS

F. Beeren[1,2], M.J. Groenen[2], P.D. Siersema[3,1]

Introduction: The duodenal-jejunal bypass liner (DJBL) is a treatment modality for weight loss and diabetes management. While its short-term benefits are well known, long-term outcomes remain largely unknown. This study investigates the long-term effects of DJBL placement on weight, diabetes, and quality of life (QoL) approximately 10 years after its explantation.

Aims & Methods: A cross-sectional follow-up study was conducted in 103 former DJBL patients who had had the DJBL implanted between 2011 and 2014. Participants completed a questionnaire assessing their health, weight, lifestyle, diabetes control, and QoL. Data were compared to original cohort results.

Results: After 10 years, weight, BMI, and HbA1c levels remained significantly improved compared to the time of explantation ($p<0.05$). Of the respondents, 33 (32%) had undergone bariatric surgery post-explantation, with significant reductions in weight and BMI observed in this group. Bariatric surgery was also associated with better diabetes control and higher QoL scores compared to non-surgery patients. No significant differences in diabetes-related complications were seen between the surgery and non-surgery groups. GLP-1 agonists use was associated with a higher BMI but did not significantly affect weight, diabetes control, or QoL outcomes compared to those not receiving GLP-1 agonists.

Conclusion: Although DJBL has some sustained benefits in weight and diabetes management, these effects were limited without further weight-reducing interventions. Bariatric surgery following DJBL explantation leads to more substantial weight loss and improved diabetes outcome, highlighting the complementary role of bariatric surgery post-DJBL treatment.

CLINICOPATHOLOGICAL CHARACTERISTICS OF OTHER NEW NEOPLASTIC LESIONS MISSED BY IMAGE ENHANCED ENDOSCOPY AT SURVEILLANCE FOR PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA

H. Yamamoto[1], T. Kadota[1], H. Yamashita[1], A. Inaba[1], H. Sunakawa[1], K. Nakajo[1], K. Shinmura[1], T. Yano[1]
[1]National Cancer Center Hospital East, Department of Gastroenterology and Endoscopy, Kashiwa, Japan

Contact E-Mail Address: hayamam2@east.ncc.go.jp

Introduction: Esophageal squamous cell carcinoma (ESCC) often develops the synchronous or metachronous multiple ESCC. Although the Japanese guideline recommended endoscopic examination as surveillance at least once a year after endoscopic resection (ER) of ESCC, the optimal surveillance modality was not specified. In clinical practice, image-enhanced endoscopy (IEE) followed by Lugol chromoendoscopy (LCE) is commonly performed. While LCE reduces the proportion of missed lesion, it has low specificity and causes severe discomfort to the patients, so attempts have been made to omit Lugol's staining. It is unknown what lesions may be missed at this time point by omitting LCE in surveillance after esophageal ER.

Aims & Methods: Thus, this study aimed to clarify clinicopathological characteristics of synchronous or metachronous multiple ESCCs missed by IEE but detected by LCE in surveillance endoscopy after esophageal ER.

We retrospectively analyzed the consecutive lesions that fulfilled all of the following inclusion criteria:

1. Treated with endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR) at our institution between April 2021 and March 2022;
2. Newly detected during surveillance endoscopy after ER or during preoperative endoscopy for other ESCC;
3. Underwent narrow-band imaging (NBI) or blue laser imaging (BLI) observation followed by LCE observation in the esophagus using a high-definition endoscope at the endoscopic examination of lesion detection; and;
4. Biopsy-proven or strongly suspected squamous cell carcinoma.

Patients with a history of chemotherapy, radiotherapy, or surgery for esophageal cancer were excluded. Lesions were classified into the IEE group (detected by NBI/BLI) and the LCE group (detected only after Lugol staining). The lesion in the IEE group were defined when the lesion was clearly visualized and in focus on the endoscopic images with NBI or BLI, or the endoscopic report described that it was detected with NBI/BLI.

We evaluated the features of the lesions in the LCE group by comparing the clinicopathological characteristics between the lesions in the IEE group and LCE group.

The endpoints were proportion of LCE detected lesion and the proportion of target ESCC, defined as ESCC with pathological invasion depth of the muscularis mucosae (pT1a-MM) or deeper and/or positive lymphovascular invasion (LVI) on histological evaluation after ER.

Results: A total of 122 lesions in 96 patients were included. The IEE group comprised 99 lesions (81.1%) in 75 patients, while the LCE group comprised 23 lesions (18.9%) in 21 patients, thus proportion of LCE detected lesion was 18.9%. Most patients (92.7%, 89/96) had grade C of Lugol voiding staining. The median lesion size was 15 mm (range: 4-60 in the IEE group, which was higher than that in the LCE group at 10 mm (5-30). The lesions located on the anterior (23.5%) and left wall (31.3%) tended to be more frequently detected by LCE than those on the right (10.8%) and posterior wall (13.9%).

Finally, 26 lesions were treated with EMR and 96 with ESD. The pathological diagnosis was pT1a-MM in 5 lesions and pT1b-SM1 in 2, resulting in the proportion of target ESCC of 5.7% (7/122). By group, the proportions of target ESCC were 7.1% (7/99) in the IEE group and 0% in the LCE group.

Conclusion: The characteristics of missed lesions in IEE observation tended to be small and located on the left or anterior wall of esophagus at surveillance endoscopy.

Furthermore, all of these lesions were curatively resected with ER, resulting pT1a-EP/LPM without LVI in the pathological diagnosis.

Disclosure: Nothing to disclose.

IMPACT OF TEXTURE AND COLOR ENHANCEMENT IMAGING (TXI) ON ENDOCYTOSCOPIC DIAGNOSIS OF EARLY GASTRIC CANCER

H. Noda[1,2], M. Kaise[1], Y. Ishikawa[1], Y. Shinagawa[1], T. Habu[1], E. Koizumi[1], K. Higuchi[1], J. Omori[1], N. Akimoto[1], K. Iwakiri[1], M. Atsukawa[1]
[1]Nippon Medical School Hospital, Tokyo, Japan, [2]Japanese Foundation for Cancer Research, Tokyo, Japan

Contact E-Mail Address: stand.by.me.0106@gmail.com

Introduction: Endocytoscopy (ECS), an ultrahigh-magnification contact-type endoscopy, enables real-time visualization of gastrointestinal mucosal and neoplastic cells. As a result, ECS enhance diagnostic precision as a form of optical biopsy.

However, the reliability of ECS diagnosis is contingent upon adequate staining, which remains a considerable challenge in the stomach due to the abundance of mucus and inflammatory exudates that hinder optimal visualization. Weak vital staining can easily reduce the reliability of ECS diagnosis. Texture and Color Enhancement Imaging (TXI), a digital image enhancement modality developed by Olympus, enhances three key imaging elements—brightness, texture, and color tone—to optimize lesion visualization even under suboptimal staining conditions.

Consequently, TXI may augment the diagnostic utility of ECS.

Aims & Methods: The aim of this study was to evaluate whether TXI enhances the diagnostic performance of ECS in early gastric cancer. Twenty-eight patients with 30 gastric cancers scheduled for magnifying endoscopic examination at Nippon Medical School Tama Nagayama Hospital between February 2024 and March 2025 were prospectively enrolled.

All ECS procedures were performed with GIF-H290EC (Olympus Co., Tokyo, Japan) and the video processors EVIS X1 (Olympus Co., Tokyo, Japan). For in vivo dyeing, double staining with crystal violet and methylene blue was used. ECS was performed with and without TXI in both cancer and non-cancerous legions.

ECS observation is performed by first taking photographs without TXI, and then taking photographs of the same area using the TXI. From each lesion, five ECS images with and without TXI were selected, resulting in a blinded and randomized image catalog (comprising 300 images from 30 gastric cancers and 280 images from 28 non-tumor areas). Two endoscopists independently assessed the images using a numerical rating scale (NRS, 0–10) to evaluate the visibility of nuclear atypia and structural cellular atypia.

Diagnostic accuracy was assessed against pathological diagnosis as the gold standard. ECS diagnoses were rendered based on previously established criteria, wherein lesions exhibiting high-grade atypia were classified as cancer (Kaise M, et al. Endoscopy. 2015).

Results: The overall accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for EGC diagnosis by the two endoscopists were 82.5%, 84.3%, 80.7%, 81.3%, and 83.8%, respectively. The rate of interobserver agreement between the two endoscopists was high, with a kappa coefficient of $\kappa = 0.797$.

Notably, diagnostic accuracy was significantly higher in the TXI images compared to the non-TXI images (85.2% vs. 79.0%, $p = 0.0027$). While the NRS scores for structural atypia did not differ significantly between the TXI and non-TXI images (4.90 vs. 4.87, $p = 0.61$), the NRS scores for nuclear atypia were significantly elevated in the TXI images (6.88 vs. 5.88, $p < 0.0001$).

Conclusion: The integration of TXI with ECS significantly enhances the visualization of nuclear atypia and improves diagnostic accuracy in the diagnosis of gastric cancer. This synergistic approach facilitates superior optical biopsy capabilities, enhancing its clinical utility in the endoscopic diagnosis of early gastric cancer.

Introduction: Endoscopic resection (ER) of duodenal tumors carries a high risk of intraoperative or delayed perforation because of the thin duodenal wall and exposure to bile and pancreatic juice. Delayed perforation can particularly cause serious condition due to the leakage of the digestive fluids. The detailed management and clinical course following duodenal perforation remains unclear. This study aimed to clarify the optimal management of duodenal perforation following ER.

Aims & Methods: This single-center retrospective study included cases of perforation among patients who underwent ER for duodenal tumors at our institution between April 2013 and October 2024. The study endpoint was the clinical course after perforation, including the hospitalization period after ER for duodenal tumors. Perforation was defined as the presence of extraluminal gas on computed tomography (CT) scan. Delayed perforation was defined as a perforation that was not endoscopically recognized during the procedure but was diagnosed postoperatively.

In contrast, intraoperative perforation was defined as a case in which a perforation was endoscopically identified during the endoscopic procedure. Long hospitalization was defined as a hospital stay of 20 days or longer.

Results: Of the 1,475 cases with duodenal tumors underwent ER during the study period, intraoperative perforation occurred in 8 cases (0.5%) and delayed perforation in 10 cases (0.7%). The median age of patients with perforation was 62 (range: 47–80) years, and 50% (9 patients) were male. The 18 cases included 6 cases of endoscopic papillectomy (EP), 7 cases of endoscopic mucosal resection (EMR), 2 cases of endoscopic submucosal dissection, and 3 cases of endoscopic submucosal resection with a ligation device.

Among the cases of intraoperative perforations, long hospitalization, 61 days of conservative treatment, was required in one case who developed a large perforation during scope insertion of single-balloon enteroscopy for duodenal adenoma resection. The remaining 7 cases achieved successful endoscopic closure intraoperatively and hospitalization periods were within 17 days. Of the 10 delayed perforation cases, 2 occurred after EP and 8 after EMR for non-ampullary tumors. The median time from the end of endoscopic resection to the diagnosis of perforation was 24 hours (4–46 hours). The median hospitalization period of the cases with delayed perforations was 32 days (9–81 days), and significantly longer than that of intraoperative perforation (13 days) ($p<0.05$).

Long hospitalization was required in 8 cases (80%) of delayed perforation. None of the delayed perforation cases required surgical intervention, and endoscopic nasobiliary and nasopancreatic duct drainage (ENBPD) was performed in 7 cases (70%). Ascites was observed on CT scan at the time

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of diagnosis of delayed perforation in 7 of the 8 patients who required long hospitalization. One case without ascites at the diagnosis of delayed perforation still required long hospitalization, possibly due to the 10-hour delay from the diagnosis to ENBPD. On the other hand, two cases who did not need long hospitalization showed no ascites at the diagnosis of delayed perforation.

Conclusion: Compared to intraoperative perforation, delayed perforation was associated with significantly prolonged hospitalization, particularly in cases with ascites. Early detection of ascites and prompt initiation of ENBPD may help mitigate the clinical burden. Establishing an emergent backup system for ENBPD is essential for the safe management of delayed perforation after duodenal ER.

FREEHAND SUTURING FOR APPLICATION OF TRACTION DURING ESD

J. Weigt[1], L. Kowalski[1], S. Hartmann[1], V. Keitel-Anselmino[1]
[1]Otto-v.-Guericke University Magdeburg, Gastroenterology, Hepatology & Infectious Diseases, Magdeburg, Germany

Contact E-Mail Address: jochen.weigt@med.ovgu.de

Introduction: Recently freehand suturing for defect closure became possible by using barbed wire sutures and the availability of a needle holder for the use in flexible endoscopy. We reported about the development of a new technique for tissue traction during ESD using barbed wire sutures.

Aims & Methods: We aimed to characterize the performance of tethered ESD in an ex-vivo porcine stomach model. In addition we present the first human case.

We performed ESD procedures in an ex-vivo porcine stomach with a long adjacent esophageal part. In each stomach 2 resections were performed. We used a 15 mm polypectomy snare and cutting current to mark standardized artificial lesion. This lesion was marked additionally with cauterization markers and resection was performed outside the markers. After initial cut (entry point), the resulting mucosal flap was sutured using a barbed wire suture (3/0, V-LOC 180) and afterwards sutured to the opposite gastric wall proximal to the lesion. Pulling the suture led to traction to the resection specimen thus opening the submucosal space. Due to the nature of the barbed wires, the tension will not loosen once the suture is tightened. Resections were carried out using a hybrid knife with Endocut Q for mucosal incision and Precise-Sec mode for dissection. The first human case was performed to resect a gastric lesion of 2 cm located at the angulus fold using the same technique in antegrade position.

Results: In total 6 resections were performed in the animal model. The mean size of specimens was 30 mm ± 4 mm. Mean duration of resection procedure was 24,6 ± 9,37 min demanding in total 15,5 ± 5,24 needle grasping maneuvers for 4,17 ± 2,14 stiches. In average 2,33 ± 2,31 tension maneuvers were performed. Perforations of the needle trough the serosal layer was not observed and in no case the suture slipped out of the specimen due to tension force. Perforations did not occur. All specimens were resected en-bloc and completely.

In the first human case the technique was used without any complications. The resection was performed completely in antegrade position although the lesion was located at the angulus fold. The duration of the resection was 2 minutes while the suturing itself only added another 3 additional minutes to the complete resection procedure.

Conclusion: The method of tethered ESD using barbed wire sutures for gastric ESD is feasible, safe and technically not demanding.

It may especially help to resect larger lesions in difficult positions.

LONG-TERM OUTCOMES OF ELONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR UNDIFFERENTIATED EARLY GASTRIC CANCER, BEYOND EXPANDED CRITERIA

C.B. Ryu[1], J.Y. Bae[2], M.S. Lee[1]
[1]Digestive Disease Center and Research Institute, Soonchunhyang University University School of Medicine, Internal Medicine, Bucheon, South Korea, [2]Seoul Medical Center 2, Internal Medicine, Seoul, South Korea

Introduction: Endoscopic submucosal dissection (ESD) for over 2 cm in size undifferentiated type (UD type) early gastric cancer (EGC) confined to the mucosa is not only challenging, but also long-term outcomes are not well known.

Aims & Methods: To evaluate the long-term outcomes of ESD done for UD type EGCs confined to the mucosa over 2 cm in size and compare the results with those where the lesions were less than 2 cm. 143 patients with UD type EGC confirmed on histology after ESD at a tertiary hospital were reviewed. Cases with synchronous and metachronous lesions and a case with emergency surgery after ESD were excluded. A total of 137 cases were enrolled. 79 cases who underwent R0 resection were divided into 2 cm or less (group A) and over 2 cm (group B) in size.

Results: Among 79 patients who underwent R0 resection, the number in group A and B were 51 and 28, respectively. The mean follow-up period (SD) was 79.71 ± 45.42 months. There was a local recurrence in group A (1/51, 2%) and group B (1/28, 3.6%) respectively. This patient in group A underwent surgery while the patient in group B underwent repeated ESD with no further recurrences in both patients. There was no regional lymph node metastasis, distant metastasis, and deaths in both groups. With R0 resection strategy for ESD on lesions over 2 cm, 20.4% (28/137) of patients were able to avoid surgery compared with expanded indication.

Conclusion: If R0 resection is achieved by ESD, UD type EGCs over 2 cm also showed good and similar clinical outcomes as compared to lesions less than 2 cm when followed for over 5 years. With R0 resection strategy, several patients can avoid surgery.

Disclosure: Nothing to disclose.

COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARISPROPRIA

C.B. Ryu[1], J.Y. Bae[2], M.S. Lee[1]
[1]Digestive Disease Center and Research Institute, Soonchunhyang University School of Medicine, Internal Medicine, Bucheon, South Korea, [2]Seoul Medical Center, Internal Medicine, Seoul, South Korea

Contact E-Mail Address: ryuchb@gmail.com

Introduction: Endoscopic resection for gastric subepithelialtumors(SETs) originated from the muscularispropria (GSET-PM) has offered less invasive alternatives to surgical resection.

Aims & Methods: The aims of this study were to compare endoscopic subtumoral dissection(ESD) with surgical resection for the removal of GSET-PM. This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5cm and showed an endoluminal growth pattern according to endoscopic ultrasound(EUS) finding.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: ESD group were more likely to have upper portion(10/17, 58.8%) and surgery group were more likely to have mid portion(41/76, 53.8%) (p=0.039). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, p=0.037) and higher endoluminal ratio (58.5±9.1 % vs 45.8±15.4 %, p=0.002). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%)(p< 0.001).
Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, p< 0.001). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure.
In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery).
Although surgery group were lower in complication rate than ESD group (p=0.006), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two group.
Conclusion: ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.
Disclosure: Nothing to disclose.

Contact E-Mail Address: nunorsgoncalves@gmail.com
Introduction: Post-procedural bleeding (PPB) is the most common adverse event after gastric endoscopic submucosal dissection (ESD). The BEST-J score was created to predict PPB risk following gastric ESD.
Aims & Methods: We aimed to evaluate predictive factors of PPB and validate the BEST-J score in a large European cohort. We conducted a retrospective cohort study including consecutive gastric epithelial lesions removed by ESD between January of 2005 and June of 2024. Incomplete ESD and patients with missing information that prevented the score calculation were excluded. PPB was defined as presence of compatible clinical picture in the 28 days following the procedure.
Univariate and multivariate analysis were used to identify predictive factors of PPB, and the diagnostic ability of the BEST-J score was calculated in this cohort.
Results: From 990 ESD, 874 were included in the final analysis. PPB occurred in 53 patients (6.1%), with a median time after procedure of 2 days (P25-P75: 1-7). PPB was significantly superior in patients with higher risk as evaluated by the BEST-J score (PPB rate of 3.7%, 3.9%, 19.2% and 35.7% for low, intermediate, high and very-high risk, respectively).
The area under the curve for PPB prediction using the BEST-J score was 0.684 (IC95% 0.598-0.679). For a score ≥ 3 (high and very-high risk), the sensitivity and specificity for PPB detection were 47.2% (IC95% 34.2-60.5) e 88.7% (IC95% 86.4-90.7), respectively. In this sample, the following predictive factors for PPB were identified: ischemic cardiopathy [adjusted Odds Ratio (aOR) 4.351; IC95% 1.660-11.404], medication with warfarin (aOR 18.339; IC95% 4.541-74.064) or direct oral anticoagulants (aOR 7.596; IC95% 2.666-21.641) and lesion size > 20mm (aOR 2.563; IC95% 1.246-5.272).
Conclusion: The BEST-J score presented moderate discrimination for PPB following gastric ESD in our cohort. The identified factors may assist the decision of implementing prophylactic measures in high-risk patients and the creation of more precise prediction models.

Contact E-Mail Address: abdelganisiham@gmail.com
Introduction: Endoscopic suturing has been increasingly used for various procedures, including treatment of gastrointestinal perforations, fistulas, leaks, fixation of intraluminal stents and closure of full thickness defects following endoscopic resections[1,2].
Furthermore, the endoscopic gastric remodeling has as a dominant role in the endoscopic bariatric treatment armamentarium.
Su2ura® GI System is a novel, flexible endoscopic suturing device. We previously reported our experience with the Su2ura® GI System in animal experiments[3].
Aims & Methods: The aim of the present study was to assess the Su2ura® GI System using an ex-vivo human sleeve gastrectomy model, with a focus on suturing efficiency, tissue grasping performance and anchor penetration. We aimed to determine the system's potential to improve clinical outcomes in endoscopic suturing.
Methods:
1. The Device:
This novel intuitive and simple-to-use suturing device (3.2 mm diameter) consists of an atraumatic grasper and multiple T-type threaded anchors that can be seamlessly inserted through a single endoscope channel. The sub-serosa is grasped and safely pulled over a static needle and anchor which penetrate the organ wall. The anchor is released outside the wall (full thickness). Multiple anchors can be deployed, all on the same surgical thread. The suture is easily tightened due to the minimal-friction mechanism, and the thread is locked and cut by a unidirectional locking element.
2. Patients:
The trial was conducted on three human gastric sleeve specimens, each excised from consecutive patients undergoing sleeve gastrectomy. Pa-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tients age, sex, weight, BMI and sleeve dimensions were documented. For comparative analysis, porcine stomach models (20–30 kg) were also tested.

3. Key Performance Evaluations:

- Grasping force and Needle Penetration (NP) force: Measured in the greater curvature and fundus.
- Suture Detachment Force (SDF): Analyzed via pull tests with force meters.

Results: Three patients were included: two females and one male, with a mean age of 26 years. The mean BMI was 54.26. The average sleeve dimensions were 20.1 cm in length and 6.8 cm in width. The mean gastric wall thickness was 1.46 mm. Regarding the forces measurements, NP forces were lower in human specimens compared to porcine models (Table 1), indicating easier anchor deployment in clinical settings. No difference was measured in grasping force between human and porcine models (Table 1), enabling simple comparison between the two models. Penetration forces were consistently higher than grasping forces even in successive attempts, enabling repeated successful suturing. SDF did not differ in proximal and distal stomach, nor with multiple anchors deployed. Finally, SDF values measured in pig stomach were higher than in human.

Metric	Human Specimens	Porcine Specimens
Needle Penetration Force (Kg)	0.42 (mean)	0.60 - 0.70
Grasping Force (Kg)	0.70 (mean)	
Anchors pullout test (1-2 anchors with a cinch)	1.37-2.57	

Table 1: Key Performance Evaluations.

Conclusion: The results in this study are consistent with our previous results in which we demonstrated safety, efficacy and usability on animal in vivo model (chronic and acute). This evaluation exhibited mechanical consistency and reliability in human ex vivo gastric tissue model; tissue grasping, anchor deployment and suture pull-off performance. These findings represent a promising alternative to current endoscopic suturing technologies. However, further in-vivo studies are needed.

Introduction: Gastrointestinal (GI) endoscopy is a high-throughput, resource-intensive specialty that contributes significantly to healthcare's environmental footprint. As global attention shifts toward sustainable healthcare practices, the concept of green endoscopy has emerged. However, the perceptions, awareness, and engagement of the endoscopy workforce remain underexplored—despite their critical role in driving sustainable transformation.

Aims & Methods: This systematic review aimed to evaluate the awareness, attitudes, and perceived barriers among healthcare professionals regarding sustainability in endoscopy, and to synthesize existing knowledge on workforce engagement with green endoscopy practices.

A systematic search of PubMed, Scopus, Embase, and the Cochrane Library was conducted up to April 1, 2025, supplemented by grey literature from Google Scholar.

Eligible studies included original research reporting data on healthcare professionals; knowledge, attitudes, or practices related to sustainable endoscopy. Two independent reviewers screened studies and extracted data. Study quality was assessed using the Joanna Briggs Institute (JBI) checklist. A synthesis without meta-analysis (SWiM) approach was used due to heterogeneity in study design and outcome reporting.

Results: Five cross-sectional studies comprising 1,684 participants were included, spanning multiple global regions. Awareness of green endoscopy varied widely, from 16.3% to 67%. While most respondents acknowledged endoscopy's contribution to hospital waste and carbon emissions, fewer reported institutional guidelines or formal training.

Major barriers to sustainability included lack of knowledge (35%), insufficient institutional policy (32%), infection control concerns (41%), and perceived financial constraints (26%).

Few departments conducted audits or offered staff education on sustainability. A generational divide in awareness and engagement was observed, with more experienced staff demonstrating greater concern for environmental impacts.

Conclusion: The perspectives and knowledge of the current gastroenterology workforce on sustainability remains poor and further action to improve this is essential.

Disclosure: Nothing to disclose.

IMPROVING IMAGE DOCUMENTATION IN UPPER GI ENDOSCOPY AT A DISTRICT GENERAL HOSPITAL

M.F.A. Khan[1], M. Kumar Rajasekar[2], S. Singh[1]
[1]Health Education England NHS, Gastroenterology, Manchester, United Kingdom, [2]Health Education England NHS, Medicine, Manchester, United Kingdom

Contact E-Mail Address: kfarazali92@gmail.com

Introduction: Upper gastrointestinal (UGI) endoscopy, or Oesophagogastroduodenoscopy (OGD), is one of the most commonly performed procedures in gastroenterology, serving both diagnostic and therapeutic purposes across a wide range of medical and surgical conditions. The European Society of Gastrointestinal Endoscopy (ESGE) provides standardised guidelines covering various aspects of UGI endoscopy, including image documentation. According to ESGE recommendations, images of eight key anatomical landmarks should be captured and included in the final report. An analysis of OGD reports from 6th January 2025 to 10th January 2025 at Royal bolton Hospital revealed that only 29.4% were compliant with these guidelines.

Aims & Methods: At Royal Bolton Hospital, the Endobase portal is used to document and report OGD findings, providing a comprehensive record of each procedure, including duration, sedation use, general comments, findings, accompanying images etc. We undertook a retrospective analysis of all OGDs performed over a defined period to assess adherence to ESGE guidelines. Our objective was to achieve a departmental compliance rate of 90% or higher in capturing image documentation of the eight recommended anatomical landmarks, as outlined by ESGE, and to ensure that any challenges in meeting this standard were appropriately documented.

We started the QIP(Quality improvement Project) on 06/01/2025 by measuring the data from all the patients admitted to the endoscopy suite for an OGD. Pre intervention data showed that the compliance to ESGE image documentation was poor at 29.4%.

A structured proforma was developed to standardise data collection, focusing on procedure duration, sedation use, number of images captured, completeness of landmark documentation, and whether non-compliance was justified.

Two PDSA(plan-do-study-act) cycles were completed and the data collected at the end of each PDSA cycle were analysed and their effectiveness assessed.

These were as follows:

WEEK	INTERVENTION	EFFECT OF INTERVENTION
1	The importance of image documentation whilst reporting OGDs compliant with ESGE recommendations was highlighted in an email and forwarded to endoscopists across the trust.	The compliance in image documentation improved from 29.4% to 54.7%
2	Well-designed posters were displayed in all endoscopy rooms, positioned opposite the computers where endoscopists—including gastroenterology consultants, consultant surgeons, registrars and nurse endoscopists routinely sit to document procedures on Endobase.	The compliance in image documentation significantly improved from 54.7% to 90.7%.

Results: Prior to intervention, compliance with ESGE standard image documentation was observed in 29.4% of cases, and the reason for inadequate documentation was recorded in only 16.6%. Following the first audit cycle, ESGE-compliant documentation improved to 54.7%, with documentation of reasons for non-compliance increasing to 34.8%. After implementing further interventions, the second cycle showed a marked improvement, with ESGE standard image documentation achieved in 90.7% of cases and the reason for inadequate documentation recorded in 55.5%.

Conclusion: This QIP has demonstrated that meaningful improvements in clinical practice can be achieved through simple, well-targeted interventions. By raising awareness of ESGE documentation standards and reinforcing them through consistent visual prompts, we were able to significantly enhance compliance with image documentation during OGDs—from just under 30% at baseline to over 90% by the end of our second PDSA cycle. It was equally encouraging to see a parallel improvement in the recording of reasons when documentation was incomplete, reflecting a shift toward more thoughtful and accountable reporting.

Personally, this project has highlighted for me the value of structured quality improvement in shaping safer, more standardised patient care. Looking ahead, maintaining this progress through ongoing audits and wider departmental engagement will be crucial in embedding these practices long-term.

Contact E-Mail Address: Cyrinelouati94@live.fr

Introduction: Upper gastro intestinal endoscopy is commonly indicated in cirrhotic patients to detect signs of portal hypertension. However, other gastric manifestations, including erosions and ulcers, can also be observed. These non-variceal lesions are often under diagnosed and less studied and may lead to chronic anemia or gastro intestinal bleeding, underestimating the importance of comprehensive endoscopic evaluation in cirrhotic patients.

Aims & Methods: The aim of ourstudy was to assess the frequency of upper gastro-intestinal erosive and ulcerative endoscopic lesions in cirrhotic patients and evaluate their association with the severity of the underlying cirrhosis.

A retrospective descriptive and analytical study was conducted, including all cirrhotic patients who underwent upper gastrointestinal endoscopy between january 2024 and december 2024. Biopsies were performed only in patient with macroscopic lesions. Erosive or ulcerative lesions were defined by the presence of erosions or ulcerations not related to varices or previous sclerotherapy. Patients on gastro-aggressive medications or proton pump inhibitors prior to endoscopy were excluded.

Results: Sixty-one patients were included, with a mean age of 64 years and a female predominance (59%). The main etiologies of cirrhosis were non-alcoholic fatty liver disease (NAFLD) in 32% of cases, hepatitis C in 21%, hepatitis B in 13%, and primary biliary cholangitis in 12%. Most patients had a Child-Pugh score of B (53%), with the remaining cases distributed between Child-Pugh A (26%) and Child-Pugh C (21%)with a mean MELD score of 14. Only six patients were active smokers. Forty-four patients (72%) experienced at least one episode of edemato-ascitic decompensation. Among them, 19 patients (31%) had refractory ascites, and 19 were on secondary antibiotic prophylaxis for ascitic fluid infection.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Radiological features suggestive of portal hypertension were identified in 78% of patients. Esophageal varices were detected in 82% of cases, with grades 1, 2, and 3 observed in 21%, 36%, and 35% of patients.
Non-portal hypertension-relatedendoscopiclesionswereobservedin 47% of cases, includinggastritis (13%), gastric erosions (13%), gastric ulcerations (6%), duodenal bulb ulcer (11%) and gastricpolyps (6%). Uponhistopathologicalexamination, *Helicobacter pylori*wasidentifiedin 8 patients.
Univariate analysis showed a significant association between the presence of non-portal hypertension-related Upper gastro-intestinal erosive and ulcerative lesions and refractory ascites (p=0.031). No statistically significant relationships were found between these lesions and the presence of portal hypertension signs, severe thrombocytopenia, smoking, cirrhosis severity scores or cirrhosis etiology.
Conclusion: Upper gastro-intestinal erosive and ulcerative lesions are common in cirrhotic patients, especiallythosewithrefractory ascites. Endoscopic screening in thisspecific population could help prevent digestive complications, such as chronic anemia and bleeding.
Disclosure: Nothing to disclose.

Introduction: The ulcers after duodenal endoscopic resection (ER) are exposed to bile and pancreatic juice, therefore delayed perforation and bleeding are major complications. The condition caused by perforation can become serious, requiring surgical treatment and even death.
As a preventive measure, the suture of the ulcer after ER has been reported to be effective. There are two main suture methods: endo clips and laparoscopic suturing.
Aims & Methods: The aim of this retrospective study is to investigate the outcome of Endoscopic submucosal dissection (ESD) and laparoscopic and endoscopic co-operative surgery (D-LECS) for superficial non-ampullary duodenal epithelial tumors (SNADETs). ESD ulcer was sutured with endo clips in ESD group, and with laparoscopic suture in D-LECS group.
One hundred seventy-eight patients with SNADETs who underwent ESD and 41 patients with SNADETs who underwent D-LECS from November 2002 to February 2025 were investigated outcome of procedure. The patient's characteristics in ESD and D-LECS were as follows. male/female: 124/54 and 27/14, median age: 62 (37-86) and 67 (37-83) years old, location of the tumor (bulbs/2nd/3rd portion): 15/139/24 and 0/32/9, major macroscopic type (0-I/0-IIa/0-IIb/0-IIc): 5/91/1/81 and 1/32/0/8. Only major macroscopic type was difference significantly between ESD and D-LECS (p=0.001). SM1 was defined as submucosal invasion of less than 500 μm, and SM2 was defined as deeper. R0 was defined as lateral and vertical margin negative, and lymph-vascular involvement negative. DLECS was selected when it was predicted that endo clips suture might be insufficient, or when the scope maneuverability was poor.
Results: 1. Median procedure time was 36 (7-245) in ESD and 351 (202-673) minutes in D-LECS, respectively(p<0.001). Median diameter of resected specimen was 17 (8-66) and 38 (17-70) mm(p<0.001). Median diameter of resected specimen and tumor was 10 (2-63) and 27 (14-52) mm(p<0.001). Intramucosal tumor (Vienna classification category 3 to 5.1) /T1bSM (category 5.2): 176/2 and 37/4 (p=0.01).
2. The en bloc resection was 90% (161/178) and 95% (39/41), respectively (p=0.53). R0 resection rate was 85% (151/178) and 88% (36/41) (p=0.62).
3. The rate of complete suture for ESD ulcer was 92% (164/178) in ESD group and 100% in D-LECS group, respectively (p=0.07). The details in D-LECS are as follows: 27% (11/41) of laparoscopic suture alone and 73% (30/41) of laparoscopic and endo clips suture.
4. Complications: intraoperative perforation was 2% (4/178) and 10% (4/41) (p=0.04). Intraoperative bleeding requiring blood transfusion was 0% and 0%. Delayed perforation was 1% (2/178) and 0% (p=1.00). Delayed bleeding was 2% (4/178) and 0% (p=1.00).
Discussion:
1. The DLECS group treated larger cases and had more intraoperative perforations, but no delayed perforation or bleeding was observed.
2. Laparoscopic suture of the pancreatic side was not possible, but complete suture was achieved in all cases by adding a clip from the luminal side endoscopically.
3. Even after complete suture by ESD, delayed perforation can still occur. Therefore, if abdominal pain occurs, a CT scan should be performed immediately. And if perforation is suspected, laparoscopic re-suture should be considered immediately.
Conclusion: DLECS for large SNADETs has similar outcome of ESD, and is an effective treatment. DLECS should be considered when complete suture with a clip is predicted to be difficult or when the scope maneuverability was poor.

Introduction: Gastric hyperplastic polyps (GHPs) carry a neoplastic transformation risk of up to 5%, with previous studies indicating an increased risk with larger polyp size. We aimed to evaluate the frequency and risk factors of its malignant transformation in a Portuguese cohort.

Aims & Methods: A multicenter retrospective cohort study was conducted including all patients undergoing endoscopic resection of GHPs ≥10mm from January 2013 to January 2024 in Portuguese tertiary reference centers. Patients with hereditary polyposis syndromes were excluded. Demographic, clinical, endoscopic, and histopathological data were collected.

Results: A total of 782 GHPs from eight centers were evaluated. The median age was 68 years (IQR 60-75), and 58.8% were female. Evidence of advanced gastritis stage (OLGIM≥3) and synchronous gastric neoplasia were present in 57 (10.2%) and 37 (4.7%) cases, respectively. The median lesion size was 15 mm (IQR 12-20), and most presented a polypoid morphology (96.8%). Most GHPs were removed by endoscopic mucosal resection (86.6%), followed by cold snare polypectomy (8.1%) endoscopic submucosal dissection (3.6%), and cold snare EMR (1.7%), achieving *en-bloc* resection in 677 cases (86.6%). Neoplastic transformation was observed in 33 polyps (4.2%) – 25 (3.2%) low/high-grade dysplasia and 8 (1.0%) adenocarcinoma; the resection was non-curative in 30.3% of cases.

In the multivariate analysis, OLGIM≥3 (OR 4.994, 95%CI 1.036-24.065), lesion size ≥25 mm (OR 7.973, 95%CI 7.973 (1.242-51.180), flat/depressed morphology (OR 9.57, 95%CI 1.096-83.712) and synchronous gastric neoplasia (OR 16.956, 95%CI 2.737-105.045) were independently associated with a higher risk of malignant transformation.

Conclusion: The risk of malignant transformation of GHPs in non-neglectable, with lesion size and morphology and concomitant precancerous gastric conditions/lesions being associated with a higher risk. Nevertheless, the rate of non-curative endoscopic resection is high. The identification of these features may help for optimizing and tailoring the selection of adequate endoscopic resection techniques and surveillance strategies in high-risk patients.

ENDOSCOPIC VACUUM THERAPY IN POSTOPERATIVE UPPER GI LEAKS: CLINICAL INSIGHTS AND OUTCOMES FROM A TERTIARY REFERRAL CENTER

A. Trigo[1], F. Vidal Lima[1], H. Ribeiro[1], D. Feijó[1], M. Costa[1], A.E.P. Silva[1], M. Marques da Silva Sant'Anna[1], M. Gravito-Soares[1,2], E. Gravito-Soares[2,1], C. Agostinho[1], M. Ferreira[1,2], P. Narra Figueiredo[2,1]
[1]Unidade Local de Saúde de Coimbra, Gastroenterology, Coimbra, Portugal, [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Contact E-Mail Address: andre-497@hotmail.com

Introduction: Anastomotic leaks and fistulae following upper gastrointestinal (GI) surgery remain a serious clinical challenge, carrying high morbidity and mortality. Endoscopic vacuum therapy (EVT) has emerged as a promising minimally invasive treatment option for managing these complications.

This study aimed to assess the efficacy and safety of EVT for postoperative anastomotic leaks in a high-volume tertiary referral center.

Aims & Methods: We conducted a retrospective analysis of all patients treated with EVT for anastomotic leakage following upper GI surgery between January 2022 and January 2025. The primary outcome was EVT success, defined as complete leak closure confirmed through both endoscopic and radiologic assessment. Secondary outcomes included procedure-related adverse events and all-cause mortality.

Results: Twenty-four patients were included (79.2% male; mean age: 64 ± 12 years). Of these, 16 patients underwent oesophagectomy and 8 total gastrectomy; only two surgeries were performed for benign conditions. EVT achieved leak closure in 20 patients (87%). One patient died due to hemorrhagic shock from a hepatic artery pseudoaneurysm, unrelated to EVT.

Among successful cases, the mean duration of EVT was 30 ± 19 days, with a median of four sponge exchanges (IQR = 5). Median hospital stay was 52 days (IQR = 41). EVT failure occurred in three patients, all of whom had cancer-related surgeries and defect sizes exceeding 30 mm. In these cases, adjunctive endoscopic treatment with self-expanding metallic stents led to successful leak closure.

A larger defect size was associated with a lower likelihood of closure (p = 0.067), suggesting a trend toward reduced efficacy in extensive leaks. Importantly, no EVT-related complications were observed throughout the study period.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: EVT demonstrated a high success rate (87%) and an excellent safety profile for managing postoperative anastomotic leaks following upper GI surgery. Larger leak sizes showed a trend toward lower closure rates, highlighting the importance of early diagnosis and timely initiation of EVT when defects are smaller.

Given its effectiveness and minimal risk, EVT should be considered a first-line endoscopic treatment for anastomotic leaks. Further studies are warranted to refine treatment protocols and establish standardized indications based on leak characteristics.

POSITIVE AIRWAY PRESSURE SYSTEMS VERSUS STANDARD OXYGENATION IN PATIENTS AT RISK OF HYPOXEMIA UNDERGOING GASTROINTESTINAL ENDOSCOPIC PROCEDURES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED STUDIES WITH TRIAL SEQUENTIAL ANALYSIS

E. Holanda[1], A. Fondelli[2], R. Kleimmann[3], P. Pauperio[4], J. Tschaen[5], M. Fernandes[6]

[1]General Hospital Dr Waldemar Alcantara, Internal Medicine, Fortaleza, Brazil, [2]University of Taubate (UNITAU), Internal Medicine, Sao Paulo, Brazil, [3]Federal University of Paraná (UFPR), Internal Medicine, Curitiba, Brazil, [4]Bahiana School of Medicine and Public Health, Salvador, Brazil, [5]Superior School of Sciences of Santa Casa of Victoria, Vitoria, Brazil, [6]UFCSPA, Balneário Camboriú, Brazil

Contact E-Mail Address: ericauholanda@gmail.com

Introduction: Managing hypoxemia during procedural sedation, particularly in patients with obesity or obstructive sleep apnea (OSA), remains a significant challenge in clinical practice. This meta-analysis compared the use of positive airway pressure (PAP) with standard oxygenation therapy for patients at increased risk of hypoxemia undergoing gastrointestinal endoscopic procedures.

Aims & Methods: MEDLINE, Embase, and Cochrane databases were searched for randomized controlled studies comparing PAP systems versus standard oxygenation. Odds ratio (OR) was used for binary outcomes and mean difference (MD) for continuous outcomes with their respective 95% confidence interval (CI). Further research implications were evaluated by a trial sequential analysis (TSA).

Results: Our meta-analysis included six RCTs comprising 606 patients. Compared with standard oxygenation, PAP systems reduced the rate of hypoxemia (OR 0.21; 95%CI 0.12 to 0.38, p<0.001), and severe hypoxemia (OR 0.15; 95%CI 0.05 to 0.49, p=0.002). Additionally, the PAP group experienced fewer arrhythmic events (p=0.04), required fewer airway maneuvers (p=0.002), and had a reduced total propofol dosage (p=0.04). There was no significant difference between the groups in terms of hypotension events (p=0.39), procedure duration (p=0.62), hypoxemia episode duration (p=0.78), anesthesiologist satisfaction (p=0.44), or endoscopist satisfaction (p=0.79).

Conclusion: Overall, the use of PAP systems appears to be a promising strategy for optimizing sedation and enhancing patient safety during gastrointestinal endoscopic procedures for patients at risk of hypoxemia.

ROLE OF DIGESTIVE ENDOSCOPY IN THE EVALUATION OF ANEMIA AMONG THE ELDERLY

F. Sahbani[1], H. Hassine[2], H. Dabbebi[2], H. Yacoub[3], N. Maamouri[3]

[1]University Hospital Rabta, Tunis, Tunisia, [2]La Rabta Hospital, Gastroenterology, Ben Arous, Tunisia, [3]La Rabta Hospital, Gastroenterology, Tunis, Tunisia

Introduction: Anemia is a common and often underdiagnosed condition in the elderly population. Digestive endoscopy plays a pivotal role in the etiological workup, particularly to rule out serious underlying causes such as malignancies or peptic lesions. However, the diagnostic yield of such procedures in routine clinical practice remains variable and underreported, especially in resource-limited settings.

Aims & Methods: To assess the diagnostic yield of digestive endoscopy in the investigation of anemia in elderly patients, with a particular focus on iron deficiency anemia (IDA) and vitamin B12 deficiency, and to identify specific endoscopic findings associated with these etiologies.

We conducted a retrospective descriptive study over a 6-month period. The study included all patients aged 65 years and older who underwent esophagogastroduodenoscopy (EGD) and/or colonoscopy as part of the diagnostic evaluation for anemia. Data collected included demographic information, clinical symptoms, laboratory parameters (including hemoglobin, ferritin, vitamin B12 levels), endoscopic findings, and histopathological results when available.

Results: A total of 252 patients were included in the analysis. Among them, 44 patients (17.5%) with a mean age of 71 years [68-82], had confirmed IDA, and six patients (2.4%) presented with vitamin B12 deficiency anemia, associated in all cases with histologically confirmed fundic atrophy.

In univariate analysis, IDA was statistically correlated with the presence of peptic esophagitis (p=0.04), gastric neoplasia (p=0.001), erosive gastropathy (p=0.02), and *Helicobacter pylori* gastritis (p=0.04). It was also weakly correlated with the presence of colorectal cancer (p=0.05).

Colonic angiodysplasias and colonic polyps were not associated with IDA in this cohort (p=0.1 and p=0.4, respectively).

Conclusion: Digestive endoscopy, particularly EGD, remains a cornerstone in the diagnostic algorithm of anemia in the elderly. It enables the identification of a wide range of underlying pathologies, from inflammatory lesions to malignancies, and guides appropriate therapeutic interventions. Early endoscopic evaluation should be encouraged in this population to prevent diagnostic delays and improve outcomes.

PP0152

LEGAL RISK ASSOCIATED WITH GASTROINTESTINAL ENDOSCOPY AND ENDOSCOPIC POLYP MANAGEMENT

B. Amani[1], D. von Renteln[2]
[1]University of Montreal, Medicine, Montreal, Canada, [2]CHUM, Gastroenterology, Montreal, Canada

Contact E-Mail Address: bilal.amani@umontreal.ca

Introduction: Implementation of novel endoscopic technology or methods is sometimes limited by fears of litigation. Endoscopists might have concerns regarding the medico-legal risks of mismanagement, particularly arising from missed malignant lesions. I.E. computer aided optical polyp diagnosis and the "resect and discard" strategy are promising tools for cost-effective management of diminutive colorectal polyps. However, concerns about litigation contribute to the limited uptake of this approach in routine clinical practice.

This study evaluates the risks of litigation associated with endoscopic polyp management and examines whether adherence to clinical guidelines mitigates these risks.

Aims & Methods: A review of legal databases (CanLII, SOQUIJ, and LexisNexis) was performed. A total of 818 medico-legal cases related to endoscopic procedures were identified and analysed. The analysis focused on identifying common causes of litigation, including procedural errors, diagnostic delays, and referral failures, and assessing outcomes in cases where guideline adherence was documented. Guideline recommedations from the American Society for Gastrointestinal Endoscopy (ASGE) and the United States Multi-Society Task Force on Colorectal Cancer (USMSTF) were used to evaluate the role of professional standards in mitigating liability.

Results: Our analysis revealed that gastroenterologists faced minimal legal risk, with a defense success rate of 86.7% in the USA and 80% in Canada. Litigation primarily involved procedural errors among gastroenterologists and surgeons, and diagnostic or referral failures among family physicians. Importantly, no cases of litigation were linked to mismanagement of diminutive polyps when guidelines were followed. Adherence to ASGE and USMSTF recommendations was associated with favorable outcomes, underscoring the importance of evidence-based practice in reducing liability risks.

Conclusion: This in-depth legal review indicates that litigation risks associated with diminutive polyp management are minimal when evidence-based guidelines are adhered to. These findings reinforce the importance of adhering to ASGE and USMSTF recommendations to ensure patient safety and reduce medico-legal exposure.

The "resect and discard" strategy, when implemented within the framework of professional standards, offers a safe, efficient, and legally sound approach to managing diminutive polyps, supporting its broader adoption in clinical practice.

PP0153

COLD SNARE POLYPECTOMY: A SAFE ALTERNATIVE TO HOT SNARE POLYPECTOMY FOR SMALL GASTRIC POLYPS

I. Marques[1,2,3], C. Macedo[1,2,3], J. Berkeley Cotter[1,2,3]
[1]Unidade Local de Saúde do Alto Ave, Gastroenterology Department, Guimarães, Portugal, [2]Life and Health Sciences Research Institute (ICVS), University of Minho, Braga, Portugal, [3]ICVS/3B's – PT Government Associate Laboratory, Guimarães/Braga, Portugal

Contact E-Mail Address: ines.abreu.marques@gmail.com

Introduction: Polypectomy is a common endoscopic procedure with cold snare and hot snare techniques being widely used. Hot snare polypectomy involves cautery, which may increase the risk of thermal injury and related complications. Cold snare polypectomy has a well-established safety and efficacy profile for small colonic polyps, however, comparative data on the clinical outcomes of these two methods for gastric polyps remains limited.

Aims & Methods: A retrospective analysis was conducted on 161 consecutive gastric polypectomies for polyps under 10mm, comprising a sample of 41 patients that underwent cold snare polypectomy and 120 patients that underwent hot polypectomy over a period of 5 years.

Results: The mean polyp size differed significantly between groups, being smaller in the cold snare group (5.20 ± 1.18 mm *vs* 6.34 ± 1.49 mm; $p < 0.001$). The Charlson Comorbidity Index averaged 3 points, with no significant differences between the groups regarding the use of anticoagulant or antiplatelet therapy.

Statistically significant differences were observed in both the location and histological type of the polyps between the two techniques ($p = 0.003$; $p < 0.001$). Cold snare polypectomy was more frequently used for polyps located in the fundus and for fundic gland polyps, whereas hot snare polypectomy was more commonly utilized for polyps located in the cardia and antrum.

Submucosal injection with gelofusine and adrenaline were more frequently associated with the hot snare technique ($p = 0.001$). Regarding clinical outcomes, intra-procedural bleeding occurred in 16.1% of cases and was successfully managed endoscopically in all instances, mainly with clips (76.9%).

No cases of delayed bleeding or perforation were observed. There were no significant differences between the groups concerning complete histological resection or polyp recurrence.

Conclusion: Cold snare polypectomy demonstrated comparable safety and efficacy to hot snare polypectomy in the resection of small gastric polyps, possibly representing a preferable approach to avoid thermal injury and related complications.

Disclosure: Nothing to disclose.

GUT MICROBIOME AS A BIOMARKER FOR PREDICTING NEOADJUVANT CHEMOTHERAPY RESPONSE IN GASTRIC CANCER

K. Žukauskaitė[1,2], B. Baušys[3,4], A. Horvath[1,2], R. Sabaliauskaitė[3,5], K. Rauduvytė[5,6], K. Bičkaitė[4], R. Stulpinas[4,7], V. Stadlbauer-Köllner[1,2], R. Baušys[5], S. Jarmalaitė[3,5], A. Baušys[3,6]
[1]Medical University of Graz, Division for Gastroenterology and Hepatology, Department of Internal Medicine, Graz, Austria, [2]Center for Biomarker Research in Medicine (CBmed GmbH), Graz, Austria, [3]Vilnius University, Institute of Biosciences, Life Sciences Center, Vilnius, Lithuania, [4]Vilnius University, Faculty of Medicine, Vilnius, Lithuania, [5]National Cancer Institute, Vilnius, Lithuania, [6]Vilnius University, Laboratory of Experimental Surgery and Oncology, Translational Health Research Institute, Faculty of Medicine, Vilnius, Lithuania, [7]Vilnius University Hospital Santaros Clinics, National Center of Pathology, Vilnius, Lithuania

Contact E-Mail Address: kristina.zukauskaite@medunigraz.at

Introduction: Emerging experimental and clinical data suggest that the gut microbiome can significantly influence the antitumor efficacy of key chemotherapy agents, including 5-fluorouracil, oxaliplatin, and docetaxel. These agents form the backbone of the neoadjuvant chemotherapy (NAC) regimen, FLOT, which is widely used for the treatment of locally advanced gastric cancer (GC). However, despite growing evidence from preclinical models, clinical studies investigating the direct association between gut microbiome composition and the response to NAC in GC patients remain scarce.

Aims & Methods: This study aims to address this gap in knowledge by exploring the relationship between the gut microbiome and therapeutic outcomes in this clinical context. In this longitudinal observational study, we explored the association between pre-treatment fecal microbiome composition analyzed via *16S rRNA* gene sequencing and histological tumor regression, as assessed by the Becker score, in GC patients undergoing NAC with the FLOT regimen, followed by gastrectomy.

Results: Among the 38 enrolled patients, 19 (50%) achieved a Becker score of 1–2 and were classified as 'Responders,' while the other 19 (50%) were classified as 'Non-responders'. Responders exhibited a higher abundance of *Parabacteroides distasonis*, *Alistipes sp. AL-1*, and *Bacteroides plebeius*. A combined biomarker of these species demonstrated robust predictive accuracy for a favorable response to NAC, with sensitivity of 89%, specificity of 63%, and an AUC of 0.8 (95% CI: 0.66–0.94).

In contrast, non-responders showed a predominance of bacterial genera, including *Ruminococcaceae* UCG-014, *Ruminococcus 1*, *Ruminococcaceae* UCG-005, and the *[Eubacterium] eligens* group. The combined biomarker of these genera demonstrated excellent predictive performance for poor NAC response, with sensitivity of 89%, specificity of 95%, and an AUC of 0.93 (95% CI: 0.85–1.0).

Conclusion: The results of our study support the hypothesis that the pre-treatment gut microbiome composition can serve as a reliable biomarker for predicting both positive and negative responses to NAC in GC patients. By identifying specific microbial signatures associated with chemotherapy outcomes, this research provides critical insights into how microbiome-based strategies might enhance personalized treatment regimens for GC.

Future studies are needed to validate these findings and explore potential therapeutic interventions targeting the microbiome to improve clinical outcomes in GC patients.

PROTECTIVE EFFECTS OF STW 5 AGAINST CHANGES IN THE MICROBIOME IN AN EXPERIMENTAL MODEL OF FUNCTIONAL DYSPEPSIA

M.T. Khayyal[1], O. Kelber[2], H. Aziz-Kalbhenn[3]
[1]Faculty of Pharmacy, Cairo University, Pharmacology, Cairo, Egypt, [2]Steigerwald Arzneimittelwerk GmbH, Phyto & Biotics Tech Platform, Phytomedicines Supply and Development Center, Bayer Consumer Health, Darmstadt, Germany, [3]Steigerwald Arzneimittelwerk GmbH, Medical Affairs, Phytomedicines Supply and Development Center, Bayer Consumer Health, Darmstadt, Germany

Contact E-Mail Address: olaf.kelber@bayer.com

Introduction: STW 5, a herbal medicinal product with well characterized pharmacological action, has been shown in several RTCs to be an effective treatment in disorders of the gut-brain interaction (DGBI) as functional dyspepsia (FD) [1, 2].

The aim of the present study was to examine whether changes in gut microbiota induced in an experimental model of FD could be prevented by STW 5.

Aims & Methods: FD was induced in rats by subjecting them to neonatal maternal separation followed by subjecting them to restraint stress for 90 minutes/day for one week. During that week, one group (8 animals) was treated with the liquid form of STW 5 (5 ml/Kg) and one with its vehicle at the same dose level. Animals were sacrificed 24 h after the last drug administration. Fecal samples were taken from the cecum. Genomic DNA was isolated and changes in selected bacterial phyla and genera were assessed using quantitative Real Time-PCR (qPCR). The main phyla studied under the influence of stress in the model were the Bacteroidetes, Firmicutes, Fusibacterium and Actinobacteria.

Results: FD led to a 50% drop in the Lactobacilli population but to a two-fold rise in Proteobacteria abundance but did not affect significantly the changes in Bacteroidetes. Furthermore, the Methanobrevibacter population was raised more than two-fold while the genomic DNA concentration in Bifidobacterium dropped from ca. 3 ng/g feces to nearly nil.

Conclusion: In general, STW 5 tended to ameliorate and protect against the changes induced by the stress model. The results lend further support to the use of STW 5 in FD and IBS by providing evidence that it acts at least in part through influencing beneficially the changes in intestinal microbiota induced by stress. Taken together, the findings shed more light on mechanisms involved in the therapeutic action of STW 5 in gastro-intestinal disorders.

LONG-TERM EUS FOLLOW-UP OF SMALL GASTRIC ASYMPTOMATIC MUSCULAR LESIONS

A. Brillo[1]
[1]Ospedale Fracastoro San Bonifacio, Gastroenterology, Verona, Italy

Contact E-Mail Address: brillo-10@hotmail.it

Introduction: Gastrointestinal stromal tumors (GISTs) are soft tissue sarcomas with a potential malignant transformation and represent the most common form of subepithelial lesions (SELs). SELs with high-risk eco-endoscopic (EUS) features ordinarily undergo endoscopic or surgical resection even without a previous histological confirmation of GIST.

On the contrary, scarce data are available about the long-term risk of neoplastic evolution of small asymptomatic SELs without worrisome features, making it challenging to schedule an adequate follow-up.

Aims & Methods: Aim of the study is to to assess the natural history of these small asymptomatic "likely GISTs" of the stomach and to test if a follow-up strategy of such lesions could be correct, by sparing a gastric resection if not needed.

We retrospectively selected patients with previously endoscopic documentation of asymptomatic gastric SELs referred to two Italian centers for EUS execution between February 2002 and January 2024.

Patients with endoscopic (ulcerated overlying mucosa) or EUS (diameter >20 mm, inner inhomogeneous pattern, irregular margins) high-risk criteria were excluded. EUS characteristics of the remaining patients were collected and analyzed. In particular, a 25% increase in the main diameter during follow-up was defined as a significant increase in tumor size, whereas, heterogeneous echo texture, irregular extraluminal border, echogenic foci, and anechoic space on EUS were considered suspicious for malignant changes. Statistical analysis was performed.

Results: A total of 62 patients were included. Median age was 58.7 years (± 12.6 years) and 41 were females (66.1%). Lesions were mainly found in the fundus (n=34, 54.8%) and body (n=25, 40.3%), only 3 lesions (4.8%) were found in the antrum. The mean diameter at baseline was 12.4 ± 4.2 mm.

After follow-up (62.6 ± 52.3 months), 6 lesions (9.7%) showed a significant increase in tumor size, while no lesion developed malignant changes. Among them, 4 underwent treatment or additional investigation (surgery n= 1, EUS-guided tissue acquisition n= 3) with a final diagnosis of GIST in 2 patients. Considering the entire cohort, 9 other patients were treated or further studied after multidisciplinary evaluation (surgery n=2, EUS-guided tissue acquisition n=7) with the detection of GIST in 2 patients.

Statistical analysis was performed using logistic regression analysis, both unadjusted and adjusted. Baseline diameter showed a trend of association with the growth of the lesions (OR 1.28, p-value 0.071. Moreover, SELs of the body of the stomach seemed less likely to show growth over time in contrast to antrum and fundus.

Conclusion: Our study suggests that Small gastric SELs have a low rate of growth over time. Although the diagnostic accuracy is still suboptimal, EUS has a crucial role in the follow-up of patients thanks to its high accuracy in the detection of SELs growth and pattern changes. Given these results, a conservative approach based on a surveillance program with EUS could be the best choice.

EVALUATION OF CONGENITAL ESOPHAGEAL STENOSIS WITH HIGH FREQUENCY MINIPROBE

P. Peruzzi Elia[1], C. Iglesias[2], D.E. Coelho Neto[3], Y. Tolentino[4], L.J. Abrahao Junior[5]
[1]Instituto Fernandes Figueira - Fiocruz, Endoscopia Pediátrica, Rio de Janeiro, Brazil, [2]Centro Hospitalario Pereira Rossell Montevideo, Pediatric Gastroenterology, Montevideo, Uruguay, [3]Americas Medical City, Dr., Rio de Janeiro, Brazil, [4]Rio de Janeiro University Hospital - Gafree Guinle, Gastroenterology, Rio de Janeiro, Brazil, [5]Federal University of Rio de Janeiro, Gastroenterology, Rio De Janeiro, Brazil

Contact E-Mail Address: paulaperuzzielia@gmail.com

Introduction: The most common cause of esophageal stenosis in children is acquired (95%), but it can be congenital in 5% of cases. Tracheobronchial remnants (TBR) are the most frequent cause, but membranous diaphragm and fibromuscular (FMS) stenosis are other possible etiologies for this type of narrowing. Dysphagia is the initial clinical manifestation, occurring after the introduction of solid food. Diagnostic investigation begins with esophagography and endoscopy, but the definitive diagnosis is only possible through histopathology. EUS (endoscopic ultrasound) can provide a diagnosis with a good degree of certainty and correlation with histopathological findings. The presence of tracheobronchial remnants in these patients means that endoscopic dilatation attempts could lead to perforation.

Aims & Methods: The aim of this study is to report two cases of congenital esophageal stenosis in children diagnosed by EUS miniprobe.

Results: Case 1: A three-year-old girl with esophageal stenosis after correction of esophageal atresia underwent esophageal dilatations. Endoscopy showed a stenosis in the distal esophagus.

Contrast esophagography confirmed a narrowing of the distal esophagus with marked proximal dilatation. EUS miniprobe radial scanning at 20 MHz of the esophagus showed a complete hyperechoic ring outside the esophageal wall. The patient underwent surgical resection, and pathology revealed the presence of cartilaginous plates, seromucinous glands, and ciliated epithelium resembling bronchial tissues.

Case 2: A six-year-old boy was admitted for recurrent vomiting and failure to thrive. Esophagography showed a tapered narrowing in the middle esophagus with dilation of the proximal esophagus. Biopsies were negative for eosinophilic esophagitis. A high-frequency catheter probe EUS suggested fibromuscular hypertrophy. The boy was referred for esophageal dilatations.

Conclusion: The diagnosis of CES is difficult. Endoscopic biopsy specimens are usually negative, and EGD typically shows a nonspecific esophageal stenosis without inflammation. Generally, CT or magnetic resonance imaging are not useful.

The presence of tracheobronchial remnants in these patients means that endoscopic dilatation attempts could lead to perforation. EUS miniprobe is useful for diagnosis. This miniprobe EUS examination is safe, quick, and

UTILITY OF KONJAC GLUCOMANNAN GEL AS COUPLING MEDIUM IN MINIPROBE SONOGRAPHY

Z. Gong[1], G. Cheng[1], M. Qian[1], L. Xu[2], D. Hu[1]
[1]Second Affiliated Hospital of Soochow University, Gastroenterology, Suzhou, China, [2]Second Affiliated Hospital of Soochow University, Pathology, Suzhou, China

Contact E-Mail Address: gzy990721@163.com

Introduction: Miniprobe sonography (MPS) is a high-resolution endoscopic ultrasound technique widely utilized for assessing the layered structure of gastrointestinal (GI) lesions[1].

Degassed water is commonly used as the coupling medium for MPS; however, it presents limitations such as image instability, technical complexity, and an increased risk of coughing or aspiration[2-3].

Konjac glucomannan (KGM) gel, with its good biocompatibility and high adhesiveness, may be a suitable alternative[4].

This study aims to evaluate the feasibility of KGM gel as an MPS coupling medium and compare its imaging quality and operational performance with that of degassed water.

Aims & Methods: This study included three parts: in vitro experiments, animal studies, and clinical trials. In the first part, the physical properties and imaging quality of KGM gel at different concentrations were assessed in ex vivo organ models to determine the optimal formulation with moderate adhesiveness and superior imaging quality.

In the second phase, MPS was performed on the GI tract of the pig using both degassed water and KGM gel, and their imaging quality and operational characteristics were compared. In the third phase, a total of 39 subjects were enrolled, and MPS examinations were conducted on 47 exploration sites involving the normal digestive tract wall and/or digestive tract lesions, sequentially using degassed water and KGM gel. Imaging quality, diagnostic accuracy in lesion depth and origin assessment, and operational performance were evaluated.

Results: In vitro experiments identified 1.0% KGM gel as the optimal concentration, with no statistically significant difference in imaging quality compared to degassed water ($P > 0.05$). In animal studies, the overall imaging quality between the KGM gel group and the degassed water group showed no statistically significant difference ($P > 0.05$); moreover, in the esophageal and rectal subgroups, the KGM gel group demonstrated superior imaging quality with statistically significant differences ($P < 0.05$), whereas no significant difference was observed in the gastric subgroup ($P > 0.05$). The KGM gel group also required significantly shorter operation time, and a lower volume of medium compared to the degassed water group ($P < 0.01$). Clinical trials showed no significant difference in overall imaging quality between KGM gel groups and degassed water groups ($P > 0.05$). The difference in diagnostic accuracy for lesion depth between the KGM gel group and the degassed water group was not statistically significant ($P > 0.05$).

Additionally, the KGM gel group exhibited significantly reduced operation time and medium usage compared to the degassed water group ($P < 0.001$).

Conclusion: The 1.0% KGM gel is a safe and non-toxic coupling medium with excellent transparency, homogeneity, and moderate adhesion. As a coupling medium for MPS, it demonstrates imaging quality and lesion layer assessment accuracy comparable to degassed water while significantly reducing procedure time and medium consumption, enhancing efficiency and mitigating patient discomfort and aspiration risk.

These findings suggest that KGM gel is a viable and effective coupling medium for MPS with promising clinical applicability.

Introduction: Endoscopic ultrasound (EUS)-guided gastroenterostomy (EUS-GE) is an advanced, minimally invasive procedure primarily indicated in patients with gastric outlet obstruction (GOO) as an alternative to traditional enteral stenting or surgery. EUS-GE are generally performed in expert centers with a technical success rate ranging from 92% to 100%, a clinical success rate of around 90%, and 11%–12% of adverse events (AEs).

Aims & Methods:

Describe our experience in terms of technical and clinical success in a single peripherical center.

- Retrospective analysis of EUS-GE was performed in a single peripherical center from November 2021 to November 2024.
- Single operator.
- Wireless endoscopic simplified technique (WEST) and direct technique over a guidewire (DTOG) for EUS-GE are applied.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

- Technical success: successfully creating a gastroenterostomy with correct deployment of the LAMS between the stomach and the small bowel, as confirmed endoscopically and/or radiologically, without immediate intraprocedural complications.
- Clinical success: resolution or significant improvement of GOO symptoms, enabling the patient to tolerate at least a soft or liquid oral diet within from 72 hours to 7 days post-procedure and/or improvement in the Gastric Outlet Obstruction Scoring System (GOOSS)

Results: A total of 20 patients (15:5,M:F), median age of 76 years old (36-90) were included. All patients were symptomatic with nausea, vomiting, and anorexia with evidence of GOO. In 15 cases (75%), EUS-GE was performed in an advanced oncological setting: 6 patients presenting with pancreatic cancer, 4 with gastric cancer (including 1 EDEE in a recurrence case after Roux-en-Y gastrectomy), 3 with ampullary/duodenal cancer, 2 with carcinosis due to colon cancer. The remaining 5 patients underwent EUS-GE for EUS-direct trans-enteric endoscopic retrograde cholangiopancreatography (EDEE) (1 case) or refractory benign GOO: 2 due to stenosing peptic ulcer not responding to other treatments; 2 due to pancreatitis-related duodenal strictures. WEST was used in 18 cases and DTOG in 2. A 20x10 mm lumen apposing metal stent (LAMS) was used in all cases. Technical success was reached without AEs in 90% of cases (18). In 2 cases (10%) a distal flange maldeployment (type II and type I), both in DTOG, was recognized and solved in the same session: prolonging the LAMS with an esophageal fully covered metal stent (20 mm x 14 cm) in one case and bridging with another LAMS performing peritoneoscopy in the other one. Median EUS-GE procedural time was 55 minutes (40-200). Clinical success was 100%. Six patients (30%) died for oncological progression after a median of 135 days (30-510).

Conclusion: EUS-GE is a challenging endoscopic procedure with high technical and clinical success described in tertiary care centers. Our results showed reasonable technical and clinical success even in peripheral centers. The rate of AEs was similar to those reported in the literature. EUS-GE is a moderately reproducible endoscopic procedure, but experienced staff are always needed for recognizing and managing intra-procedural complications.

ENDOSCOPIC ULTRASOUND 2D SHEAR WAVE ELASTOGRAPHY FOR DIFFERENTIATING NORMAL AND CIRRHOTIC LIVER VIA LEFT LOBE ASSESSMENT

F. Ochea[1], C. Tieranu[1,2], O.A. Olteanu[1], E.M. Ionescu[1,2], I. Dragomir[3], V. Rednic[3,4], C. Hagiu[3,4], C. Pojoga[3,4], A. Seicean[3,4], A. Săftoiu[1,2]

Introduction: Endoscopic ultrasound (EUS) elastography is gaining traction as a noninvasive method for assessing liver stiffness, especially in patients with cirrhosis. While liver biopsy remains the gold standard, its invasiveness limits routine use.

This pilot study set out to determine the value of EUS-guided 2D-SWE, performed on the left liver lobe from the stomach, to distinguish between healthy liver tissue and cirrhosis.

Aims & Methods: We conducted a prospective study involving patients referred for EUS-based liver evaluation. Participants were categorized as having either normal liver function (confirmed by laboratory tests) or cirrhosis (diagnosed by clinical assessment, laboratory findings or imaging). EUS-guided 2D-SWE was performed using a linear-array echoendoscope positioned in the stomach to measure elasticity in the left liver lobe. Five consecutive measurements were taken using newly available EUS 2D-SWE software to assess the stiffness inside the region of interest (ROI). We assessed diagnostic accuracy using receiver operating characteristic (ROC) analysis.

Results: A total of 30 patients were included in the analysis: 25 with normal liver and 5 with cirrhosis. Liver stiffness values measured by EUS-guided 2D-SWE were significantly higher in the cirrhosis group (mean 25.9 ± 5.8 kPa) as compared to the normal group (mean 8.4 ± 2.9 kPa, $p < 0.001$). The technique showed good reproducibility, with a mean standard deviation of 2.28 kPa and a mean coefficient of variation of 23.3%. Intra-observer agreement was higher among those with normal liver (ICC = 0.685) than in patients with cirrhosis (ICC = 0.456), likely reflecting greater heterogeneity in diseased tissue. ROC analysis demonstrated excellent diagnostic performance for mean EUS 2D-SWE in identifying cirrhosis (AUC = 0.984). A cutoff of 13.82 kPa provided 100% sensitivity and 96% specificity.

Notably, values below 12 kPa effectively excluded cirrhosis, while those above 14 kPa strongly indicated its presence, allowing clinicians to tailor decision thresholds to clinical context.

Conclusion: EUS-guided 2D-SWE of the left liver lobe appears to be a reliable, noninvasive technique for differentiating cirrhosis from normal liver tissue. This method could expand the diagnostic capabilities of EUS in liver disease and may be especially valuable for patients in whom standard percutaneous elastography is inconclusive.

COMPARATIVE EFFICACY AND SAFETY OF ENDOSCOPIC ULTRASOUND-GUIDED GASTROJEJUNOSTOMY VERSUS SURGICAL GASTROJEJUNOSTOMY FOR THE MANAGEMENT OF GASTRIC OUTLET OBSTRUCTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

I. Karniadakis[1], V. Vrachni[1], S. Papadakos[2], D. Tsironis[1], C. Kenington[1], A. Wan[1]
[1]St. George's University Hospitals NHS Foundation Trust, Department of General Surgery, London, United Kingdom, [2]National and Kapodistrian University of Athens, First Department of Gastroenterology, Athens, Greece

Contact E-Mail Address: stavrospapadakos@gmail.com

Introduction: Gastric outlet obstruction (GOO) is a debilitating condition commonly caused by malignant or benign diseases, impairing gastric emptying and nutritional status. While surgical gastrojejunostomy (SGJ) has traditionally been the standard palliative approach, endoscopic ultrasound-guided gastrojejunostomy (EUSGJ) has recently emerged as a minimally invasive alternative. This systematic review and meta-analysis aimed to compare the efficacy and safety of EUSGJ versus SGJ for the management of GOO.

Aims & Methods: A systematic search of PubMed, Embase, Medline, and Cochrane Library was conducted to identify studies directly comparing EUSGJ and SGJ in adult patients with GOO. Nine retrospective studies comprising 1,086 patients (654 EUSGJ; 432 SGJ) were included.

Primary outcomes included technical and clinical success, length of hospital stay (LOS), operative time, and overall complication rates.

Secondary outcomes included infection, ileus, hemorrhage, perforation, and re-intervention. Meta-analyses were performed using fixed or random effects models depending on data heterogeneity.

Results: EUSGJ was significantly superior to SGJ in terms of technical success (OR = 0.16; 95% CI: 0.05–0.45; $p = 0.0006$), shorter operative time (MD = –96.89 minutes; 95% CI: –146.16 to –47.61; $p < 0.00001$), reduced postoperative LOS (MD = –4.79 days; 95% CI: –6.52 to –3.06; $p < 0.0001$), lower overall complication rates (OR = 0.24; 95% CI: 0.17–0.33; $p < 0.00001$), reduced postoperative ileus (OR = 0.07; 95% CI: 0.02–0.17; $p < 0.00001$), and fewer infections (OR = 0.17; 95% CI: 0.08–0.37; $p < 0.00001$). No statistically significant differences were found regarding clinical success, re-intervention, hemorrhage, or perforation.

Conclusion: EUSGJ demonstrates superior procedural outcomes and safety profiles compared to SGJ in the management of GOO and represents a valuable tool in expert hands. However, further prospective studies and randomized trials are necessary to validate these findings, assess long-term outcomes, and define its role within individualized patient care and clinical guidelines.

MODERATE SEDATION FOR SAME-SESSION EUS AND ERCP: A FEASIBLE AND SAFE STRATEGY IN PANCREATICOBILIARY DISEASE MANAGEMENT – RESULTS FROM THE PETIMIDA PROSPECTIVE PILOT STUDY

G. Dell'Anna[1,2], P. Biamonte[2], F.V. Mandarino[1], S.G.G. Testoni[2], G. Albertini Petroni[2], C. Delogu[2], M.L. Annunziata[2], P. Lagoussis[2], E. Orlando[2], M. Bottani[2], L. Fuccio[3], A. Facciorusso[4], G. Donatelli[5], S. Danese[1], V. Annese[2]

Contact E-Mail Address: g.dellanna93@gmail.com

Introduction: Same-session endoscopic ultrasound (EUS) and endoscopic retrograde cholangiopancreatography (ERCP) are increasingly adopted for diagnosing and treating pancreaticobiliary conditions. While traditionally performed under deep sedation or general anesthesia, data on moderate sedation strategies are limited. We prospectively evaluated the feasibility, safety, and patient-reported outcomes of performing combined EUS-ERCP under moderate sedoanalgesia using midazolam and meperidine.

Aims & Methods: The PETIMIDA study is a prospective pilot trial involving 27 consecutive adult patients undergoing same-session EUS and ERCP with moderated sedation with intravenous midazolam and meperidine at the Gastroenterology Unit of IRCCS Policlinico San Donato (Milan, Italy), from September 2024 to March 2025. Primary outcomes included procedural completion, safety, and patient-reported experience using the validated PROSAS score elements. Clinical parameters, sedation doses, and adverse events were collected through a standardized Case Report Form (CRF).

Results: Median patient age was 74 years (IQR 61.5–83), and 63% were male. Median Charlson Comorbidity Index was 4 (IQR 2–6.5), and median ASA score was 2 (IQR 1–3). Median BMI was 26.1 kg/m^2 (IQR 22.7–30.7). Indications included choledocholithiasis (63%), distal malignant biliary obstruction (19%), and indeterminate biliary stricture (19%). EUS with fine-needle biopsy (FNB) was performed in 9 patients (33%). Biliary stenting was performed in 8 cases: 4 with self-expandable metallic stents (SEMS) and 4 with plastic stents. In 2 patients, EUS-guided gallbladder drainage (EUS-GBD) was also successfully performed.

All procedures were completed successfully without the need for an anesthesiologist's intervention. The mean total midazolam dose was 5.5 mg (±1.1), and the mean meperidine dose was 58.9 mg (±10.1). Most patients (93%) were rated as adequately cooperative.

Adverse events included one case (3.7%) of oxygen desaturation <90% and four cases (14.8%) of hemodynamic instability (hypotension); none required anesthesiological intervention or procedure discontinuation but were managed with oxygen flow therapy and hydration. Patient-reported discomfort during the procedure had a median of 1 (IQR 0–2) on a 0–10 scale. Regarding sedation adequacy, 85% of patients indicated they would prefer the same sedation level in future procedures, and only 7% (2 patients) requested deeper sedation.

Conclusion: In this pilot study, same-session EUS and ERCP performed under moderate sedation with midazolam and meperidine was safe, feasible, and well-tolerated, even in elderly and comorbid patients. The approach avoided anesthesia-related risks and resource use while main-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. taining high patient cooperation and satisfaction. The ability to complete therapeutic interventions such as ERCP with biliary stenting and also therapeutic EUS procedures, highlights the potential of moderate sedation in advanced endoscopy when performed in expert centers. Larger studies are needed to confirm these findings and better define patient selection.

Introduction: The Miettinen-Lasota scoring system is the cornestone for prognostic stratification of gastrointestinal stromal tumors (GISTs), based on mitotic count and tumor size. Guidelines lack indications about the optimal sample that should be used for mitotic count assesment, only specifying that at least 50 high-power fields (HPF) must be evaluated. It is generally believed that, due to tumor heterogeneity and the limited sample size obtained, endoscopic ultrasound-guided tissue acquisition (EUS-TA) is unreliable, particularly when using traditional cytology needles.

However, only few data are available regarding the use of newer histology (FNB) needles in this context. Nevertheless, the ability to correctly stratify patients preoperatively is a critical factor in GIST management.

Aims & Methods: The primary aim of this multicenter retrospective study was to evaluate the concordance between EUS-FNB and surgical specimens in assessing the GIST prognostic score. Secondary endpoins were the adequacy of FNB samples for immunohistochemistry (IHC) and mutational analysis. We included all histologically confirmed GISTs from a prospective registry (NCT02855151). Concordance for mitotic count and tumor size measurements was evaluated using Bland-Altman plots, calculating bias (mean difference between FNB and surgical specimens) and limits of agreement (LoA). Agreement in prognostic score classification was calculated as a percentage.

Results: Among a cohort of 68 GISTs, we included 32 cases in which complete histopathological data from both EUS-FNB and surgical specimens were available. The diagnostic concordance between EUS-FNB and surgical pathology was 100%. IHC was successfully performed in all FNB samples (100%). The mitotic count showed a bias of -1.19 mitoses, with LoA ranging from +3.02 to -5.4. For tumor size, the bias was -0.96 mm, with LoA ranging from +21.28 to -23.2 mm. Miettinen-Lasota score concordance between EUS with FNB and surgery showed 72% agreement (23/32): in 5 cases, EUS underestimated the score, while in 4 cases, it overestimated it. Mutational analysis was performed in 62.5% of the cases.

Conclusion: EUS with new FNB needles appears to be reasonably accurate for preoperative GIST evaluation and is certainly a useful tool for diagnosis and mutational analysis. However, its concordance with surgical findings is still suboptimal in terms of prognostic evaluation.

On one hand, performing multiple needle passes, together with fanning technique, could improve the representativeness of tumor heterogeneity and increase the amount of material provided to the pathologist.

On the other hand, greater attention should be addressed to tumor size measurement in EUS, as this can sometimes lead to score variations.

The study's limitations include its retrospective nature and the heterogeneity of mitotic count assessment. Prospective studies with dedicated protocols are warranted, along with an evaluation of the adequacy of the collected material for mitotic count on 50 HPF, as suggested by the guidelines.

Introduction: The evaluation of lymph nodes (LNs) is crucial for the accurate diagnosis, staging, and management of several types of cancers. To improve EUS accuracy in the evaluation of LNs, several novel imaging techniques have been developed, including EUS elastography. Fractal analysis is a mathematical tool that allows the evaluation of the geometrical complexity of imaging patterns observed in nature and applied also to oncology. EUS elastography and fractal analysis may have a great potential in the evaluation of LNs, particularly in differentiating between benign and malignant LNs.

Aims & Methods: The aim of this study was to evaluate the accuracy of EUS-E (measured by strain ratio, SR) and to assess the accuracy of fractal-based analysis of EUS-E images in the differentiation of benign and

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. malignant LNs. This was a prospective observational single-centre study (NCT04671784). EUS was performed using linear array Olympus GF-UCT-180 series echoendoscopes in combination with the echo processor EU-ME2 (Olympus SE & CO. KG, Hamburg, Germany). The quantitative score of elastography was expressed by the strain ratio (SR).

For fractal analysis, each selected region of interest was considered as a "shape matrix" of points with the column and row numbers proportional to the x and y coordinates and with the depth information z (x, y) stored as a matrix element. Final diagnoses were made by cytology, histology (EUS-sampling or resected specimens at surgery), or adequate follow-up time (at least one year).

Results: One-hundred consecutive patients with enlarged mediastinal or abdominal LNs detected by cross-sectional imaging and confirmed at EUS were enrolled between September 2019 and January 2023. A statistically significant difference in mean strain ratio was observed between benign and malignant LNs ($p = 2.5 \times 10^{-6}$), as well as between malignant and lymphoma LNs (p = 0.02). No significant differences were found between benign LNs and either NET or lymphoma LNs.

No statistically significant differences were observed when the global fractal dimension of LN images across the different groups was evaluated. However, when the fractal dimension was assessed for each RedGreenBlue_RGB channel, a significant difference was found in the green channel between benign and malignant LNs (p = 0.012), benign and NET (p = 0.017), and benign and lymphoma (p = 0.036).

Conclusion: According to our study, elastographic analysis is highly accurate in discriminating between benign and malignant LNs. In addition, a new model of fractal analysis seems to be useful to increase the diagnostic yield.

AGE, BMI, AND BOWEL HABITS AS PREDICTORS OF PATENCY CAPSULE FAILURE IN PATIENTS PREPARED WITH A PRO-MOTILITY PROTOCOL

T. Borkovksy[1,2], T. Thurm[1,2], N. Maharshak[1,2], L. Deutsch (Mlynarsky)[1,2]

[1]Sourasky Tel Aviv Medical Center, Department of Gastroenterology and Hepatology, Tel Aviv, Israel, [2]Tel Aviv University, Faculty of Medicine and Health Sciences, Tel Aviv, Israel

Contact E-Mail Address: Liatml@tlvmc.gov.il

Introduction: The patency capsule (PC) test is recommended prior to video capsule endoscopy (VCE) to prevent capsule retention in high-risk patients. Despite its widespread use, standardized preparation protocols are lacking. Reported PC failure rates vary widely—from 4.9-43.1%—depending on the patient population and study setting, and also suggesting delayed motility as a contributor to failure.

Aims & Methods: This retrospective study aimed to evaluate factors associated with PC failure in patients undergoing a pro-motility preparation protocol, consisting of a low-residue diet, followed by a liquid diet and administration of 10 mg bisacodyl at the time of PC ingestion. Adult patients who performed the test between 2019-2023 were included; those with prior colectomy or ileostomy were excluded. Demographic and clinical data were collected. Multivariate logistic regression and classification tree modelling were used to identify predictors of PC failure.

Results: A total of 392 patients underwent a PC test using the pro-motility protocol and were included in the analysis (median age 42 years [range 18–89]; 47.4% male). The primary indications for VCE referral were suspected/established Crohn's disease (86.0%), anaemia/ gastrointestinal (GI) bleeding (8.4%), and radiologic findings (5.6%). Successful PC expulsion was documented in 323 patients (82.4%, "expelled" group), while 69 (17.6%) experienced PC retention ("retained" group). Of the 323 in the expelled group, 321 proceeded to VCE (2 declined), with no cases of VCE retention reported.

There were no significant differences between the expelled and retained groups in sex distribution, prevalence of diabetes mellitus, history of prior GI surgery, or indication for VCE (all p=NS). However, patients in the retained group were significantly older (median age 47 [IQR 34.5–66] vs. 40 [IQR 28–61] years; p=0.045), had higher body mass index (BMI) (25.9±5.4 vs. 24.2±4.9 kg/m^2; p=0.013), and reported fewer bowel movements per day (BPD) (median 1 [IQR 1–2] vs. 2 [IQR 1–3]; p=0.013). Reporting <1 BPD was twice as common in the retained group (20.3% vs. 9.6%; p=0.020). A trend toward higher smoking prevalence was observed in the expelled group (16.6% vs. 7.2%; p=0.060).

In a multivariate logistic regression the most prominent risk factors for retained PC were higher BMI (OR 1.063, 95%CI 1.005-1.125,p=0.034) and <1 BPD (vs. ≥1 BPD OR 2.418 95%CI 1.153-5.071, p=0.019) adjusted for age (OR 1.007 95%CI 0.992-1.023, p=0.374) , active smoking (vs. past/none OR 0.389 95%CI 0.147-1.032, p=0.058) and male sex (vs. female OR 1.723 95%CI 0.983-3.021, p=0.057).

A classification tree (CRT) model identified <1 BPD as the primary predictor of PC failure (probability 37.4%), rising to 44.4% in patients >35 years, but dropping to 0% in younger patients with BMI <21 kg/m^2. Among those with BPD ≥1, failure probability peaked at 66.7% with BMI >37 kg/m^2. In overweight-obese patients (BMI 25–35 kg/m^2), risk varied by BPD: 22.6% with BPD 1–4 vs. 3.6% with BPD >4. The model demonstrated good discrimination (AUC 0.705; 95% CI 0.639–0.771; p<0.001).

Conclusion: In patients undergoing patency capsule testing with a pro-motility protocol, PC failure was mainly associated with higher BMI and infrequent bowel movements. A CRT model identified bowel frequency, age, and BMI as key predictors of failure, revealing distinct high- and low-risk profiles. These findings support the use of simple clinical parameters in pre-test assessment to improve patient selection and enhance test success.

PP0166

DIAGNOSTIC YIELD OF CAPSULE ENDOSCOPY IN PATIENTS WITH UNEXPLAINED CHRONIC ABDOMINAL PAIN

V. Papastergiou[1], G. Kalogiros[1], K. Mousourakis[1], D. Kozompoli[1], N. Georgios[1], M. Rallatou[1], D. Sofianopoulos[1], E. Vergenaki[1], S. Themeli[1], I. Lappas[1], A. Paparizou[1], M. Patsi[1], P. Kanellopoulos[1], C. Hatzievangelinou[1], K. Varytimiadis[1], E. Archavlis[1], N. Viazis[1]
[1]Evangelismos General Hospital Of Athens, Gastroenterology Department, Athens, Greece

Contact E-Mail Address: konstantinosmousourakis@gmail.com

Introduction: Unexplained chronic abdominal pain remains a frequent and often frustrating diagnostic challenge in clinical practice. When initial investigations such as colonoscopy and gastroscopy are inconclusive, small bowel capsule endoscopy (SBCE) provides a non-invasive means to evaluate the small intestine, a part of the gastrointestinal tract that is otherwise difficult to examine. This study explores the effectiveness of SBCE in uncovering underlying causes in patients with unexplained chronic abdominal pain.

Aims & Methods: We aimed to determine the diagnostic yield of SBCE in patients presenting with unexplained chronic abdominal pain and to identify predictive factors for positive findings. This was a retrospective analysis of prospectively collected data from all consecutive patients who underwent SBCE in our tertiary referral center in Greece between March 1, 2003, and April 30, 2025. We included patients who underwent SBCE following negative colonoscopy and gastroscopy. A positive diagnostic yield was defined as the detection of lesions capable of explaining the patient's symptoms. Predictive factors for positive findings were evaluated using multivariate analysis.

Results: During the study period a total of 11.201 patients were subjected to SBCE and among them 1398(12.4%) patients underwent the test for the investigation of chronic abdominal pain (men/women: 694/704, mean age ± SD: 52.6±27.3 years).

Positive findings were detected in 241 patients, leading to a diagnostic yield of 17.2%. The most common findings were inflammatory lesions that were seen in 176 (73.0%) patients [erosions from non-steroidal anti-inflammatory drugs n=75,erosions or ulcers from Crohn's disease n=97, erosions from radiation enteritis, n =4]while 47 (19.5%) patients had tumor/mass lesions, 9 (3.7%) patients had ischemic colitis, 6 (2.5%) patients had parasites and 3 (1.2%) patients had small bowel strictures.

By multivariate analysis, predictive factors for positive findings were elevated C-reactive protein (CRP) (OR=2.73, p<0.0001) and failure to intubate the terminal ileum during colonoscopy (OR=1.40 p=0.03).

Conclusion: The diagnostic yield of SBCE in patients with unexplained chronic abdominal pain is relatively low. Patients with elevated CRP or those in whom the terminal ileum was not examined during colonoscopy are those who will benefit most from the test.

Disclosure: Nothing to disclose.

WHICH FACTORS MIGHT HELP TO PREDICT A CAPSULE ENDOSCOPY EXPLORATION WITH ADEQUATE CLEANLINESS?

M.d.M. Díaz Alcázar[1]
[1]Hospital Universitario Virgen de las Nieves, UGC Aparato Digestivo, Granada, Spain

Contact E-Mail Address: mmardiazalcazar@gmail.com

Introduction: Recommendations for bowel preparation prior to capsule endoscopy exploration in clinical guidelines are controversial and unclear.

Aims & Methods: To assess the contribution of the Boston cleansing scale (BBPS) in the previous colonoscopy, the discontinuation of iron therapy, a low-fibre diet, and the use of simethicone prior to capsule ingestion to obtain adequate visualization during capsule endoscopy exploration of the small bowel.

Prospective study of capsule examinations. In our centre, capsule preparation includes a fibre-free diet the day before, liquids only the evening before, 8-hour fasting, and simethicone. Capsule preparation is categorized as adequate/inadequate according to the Brotz scale.

Statistical analysis was performed with SPSS software.

Results: A total of 117 capsule explorations were analysed: 79 (67.5%) had adequate preparation and 38 (32.5%) had inadequate preparation.

The factors in which the association was studied and the major regression model are shown in Table 1. In the final model were included the Boston score for the right colon (p=0.032; OR=2.639) and transverse colon (p=0.002; OR=0.191), after ruling out confounding and interaction. Homer-Lemeshow test with p value 0.246. Specificity of 91.1%, sensitivity of 18.4%, and accuracy of 67.7%. Area under the ROC curve was 0.305 (0.205–0.404).

		n (%) patients n=117	OR (IC95%) (univariant)	p	Adjusted OR (IC 95%) (multivariant)	p
Simethicone	No Yes	4 (3.4%) 113 (96.6%)	0.468 (0.063-3.453)	0.456	0.273 (0.034-2.171)	0.220
Diet	No Yes	18 (15.4%) 99 (84.6%)	1.3 (0.427-3.956)	0.644	1.075 (0.323-3.573)	0.907
Iron	No Yes	80 (68.4%) 37 (31.6%)	1.690 (0.748-3.819)	0.207	2.249 (0.917-5.521)	0.077
Total BBPS	Min-max Mean (SD)	2-9 7.77 (1.476)	0.822 (0.634-1.065)	0.137	0.651 (0.209-2.026)	0.459
Right colon BBPS	Min-max Mean (SD)	0-3 2.51 (0.665)	1.047 (0.203-0.853)	0.878	4.558 (0.916-22.684)	0.064
Transverse colon BBPS	Min-max Mean (SD)	1-3 2.57 (0.546)	0.416 (0.203-0.853)	0.017	0.324 (0.044-2.408)	0.271
Left colon BBPS	Min-max Mean (SD)	1-3 2.68 (0.503)	0.475 (0.222-1.012)	0.054	----	----

Conclusion:

1. In our series, the use of simethicone, a low-fiber diet, and the discontinuation of iron therapy did not contribute to adequate preparation for capsule exploration.
2. Meanwhile, the Boston score for the right and transverse colon in pre-capsule colonoscopy can help predict capsule cleanliness.
3. Further studies are needed to find variables that help predict adequate preparation for capsule endoscopy.

Contact E-Mail Address: drtilanaponso@gmail.com

Introduction: Small bowel mucosal pathologies are a diagnostic challenge to clinicians. Video Capsule endoscopy (VCE) is currently the study of choice for the evaluation of the small intestine. Data on the effects of bowel preparation on mucosal visualization and diagnostic yields is scant. Most published studies suggest that bowel preparation methods (2-litre vs. 4-litre) are not superior.

Aims & Methods: This retrospective cross-sectional study analyzed data from 2018 to 2023. The main investigator reassessed all VCEs using 3-6 frames per second, single-image viewing. A nursing officer closely supervised the bowel preparation, adhering to unit protocols. The small intestine was divided into proximal and distal small intestines depending on the small intestinal transit time, and mucosal visualization was assessed according to the Brotz scoring system. Statistical significance was determined by Fisher's exact (F) test and Chi-square (X2) test. A value of <0.05 was considered as significant.

Results: The sample size was 705, with a mean age of 56.9 (SD=18.2). 60.6% (n=427) were males. 39.3% had overt GI bleeding, 36.0% had occult GI bleeding, 16.3% had abdominal pain, 4.3% had chronic diarrhoea and 4.0 % had loss of weight as the indication for VCE. The mean gastric transit time was 01:13:52 ± 01:28:14 (hr.min.sec.), and the small intestine transit time mean was 05:12:59 ± 01:58:24 (hr.min.sec.). 38.3% consumed 59g x 2 PEG preparation in 2L of water; 11.9% consumed 59g x 3 PEG preparation in 3L of water; and 49.6% consumed 59g x 4 PEG preparation in 4L of water before VCE, followed by 6 hours of fasting. Mucosal visualization in the distal small intestine was significantly associated with the amount of PEG used, with 3×59 in 3 L of water accounting for a significantly higher percentage (32.1%) of adequate visualization (X2=11.82, p=0.003).However there was no significant association between the amount of PEG used and proximal bowel visualization (X^2=5.38, p=0.068). The amount of PEG administered significantly influenced transit times (F=5.781, p=0.003). A post hoc Tukey test revealed that the use of 4x59g of PEG in 4L of water significantly increased small intestinal transit time compared to lower doses.
The diagnostic yield was 65.6%. 34.4% had P0 lesions, 21.1% had P1 lesions, and 44.5% had P2 lesions. 26.8% had vascular lesions (17.2% in the proximal and 5.6% in the distal and 3.0% in both proximal and distal small intestine), 32.6% had inflammatory lesions (15.4% in the proximal, 15.1% in the distal, and 2.1% in both proximal and distal small intestine), worm infestation 1.1%, and malignancies 2.4%, which were among the most common findings. Ulcers, the most common inflammatory lesion (22.3%), equally affected the proximal (10.2%) and distal (10.9%) small intestines. Additionally, patients who had poor mucosal visualization (Brotz < 7) had significantly lower odds of P1/P2 lesions compared to those with good mucosal visualization (Brotz ≥ 7) (OR = 0.573, SE = 0.187, p = 0.003).

Conclusion: VCE has a diagnostic yield of 65.6%, while the proximal small intestine was the most common area involved, and inflammatory lesions were the most common lesions in Sri Lankans. Ulcers were the most common inflammatory lesion, which were equally involved in both the proximal and distal small intestine. Higher PEG and water administration significantly increased the transit time, and 3× 59g PEG in 3L of water had a statistically significant effect on mucosal visualization in the distal small intestine. Poor mucosal visualization had significantly lower odds of P1/P2 lesions.

BARRETT'S OESOPHAGUS SURVEILLANCE, REAL WORLD DATA FOR USAGE OF CAPSULE SPONGE SAMPLING WITH BIOMARKER FROM A TEACHING HOSPITAL IN LONDON

A. Yehia[1]
[1]Whipps Cross University Hospital, Bart's Health NHS Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: AhmadTYehia@gmail.com

Introduction: Barrett's oesophagus (BO) is a condition that develops as a consequence of chronic gastroesophageal reflux disease and a premalignant stage of adenocarcinoma of the oesophagus (EAC). In the US it is estimated that as many as 5.6 percent of adults have Barrett's esophagus.[i]
Estimates of the annual cancer incidence in patients with Barrett's esophagus have ranged from 0.1 to almost 3.0 percent. [ii]
The goal of surveillance is to improve outcomes by detecting dysplasia or esophageal adenocarcinoma early enough to provide effective treatment. Guidelines suggest surveillance for most patients with Barrett's esophagus There are potential harms associated with surveillance, due to the risks associated with endoscopy, the risks and morbidity associated with invasive therapies used to treat lesions identified by surveillance.[iii]
Patients with BO are currently recommended to enter a surveillance endoscopic program.[iv]
This has been associated with a significant mental burden on these patients, presenting as various forms of anxiety and stress related to thoughts of disease progression as well as potential implications of the test, with many finding the program physically burdensome and intrusive. [v]

Aims & Methods: In our study, from March 2024 until December 2024. patients with known BO were invited to undergo a tethered capsule procedure, instead of regular endoscopy, as part of their regular BO surveillance. Samples were sent for cytological analysis. Patients were identified as high risk if their cytology results came positive or equivocal for dysplasia or P53 chromosome over expression and then referred for gastroscopy for further biopsies and assessment.

Results: We tested 144 patients. Mean age was 69 years old (youngest 32-oldest 90). Males were 62.5% and females 37.5%.
6.9% (N=10) came positive for dysplasia or atypia, while 2.8% (N=4) were inconclusive.
P53 cytological analysis 2.1% were positive, while 4.2% were equivocal.
Overall, our investigations identified 16 patients (11.1%) who were positive or equivocal for dysplasia and P53 mutation.
In so far, we identified 1 patient with adenocarcinoma and 2 patients with biopsy proved dysplasia.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Based on our results, sponge capsule combined with biomarker (P53) mutation could be offered for BO surveillance, as an alternative to regular endoscopy which could be burdensome. This could offer up opportunity for this non-invasive method, which could even be performed in the setting of regular outpatient clinic visits. This modality can potentially facilitate access to care for a larger population of patients and increase compliance similar to non-invasive tests for colorectal cancer screening programs.[iv]

There were limitations our study. At this stage we could only review results for patients done at our hospital. And some patients with positive findings were still awaiting gastroscopy and biopsies. Further research on a larger cohort of patients is needed to analyze rate of diagnosis of dysplasia and adenocarcinoma, compared to OGD, which remains the gold standard.

EVALUATING THE UTILITY OF COMPUTED TOMOGRAPHY (CT)-DETECTED OESOPHAGEAL ABNORMALITIES IN PREDICTING MALIGNANCY: A RETROSPECTIVE REVIEW

Z. Chowdhury[1], R. Ellis Owen[2], H. Haboubi[3]

[1]Cardiff University, Cardiff, United Kingdom, [2]Cardiff and Vale Health Board, Radiology, Cardiff, United Kingdom, [3]Cardiff and Vale Health Board, Gastroenterology, Cardiff, United Kingdom

Contact E-Mail Address: Zakariya1303@gmail.com

Introduction: CT-reported oesophageal thickening is frequently interpreted as a potential indicator of malignancy, often prompting urgent endoscopic evaluation via suspected cancer pathways[1].

However, the actual diagnostic yield remains unclear, and there is limited evidence guiding clinicians on the true risk such findings represent. In a resource-constrained healthcare system, understanding the predictive value of radiological abnormalities is critical to ensure timely diagnosis while avoiding unnecessary investigations[2].

Given the increasing demand on diagnostic services, there is a growing need to distinguish radiological findings that warrant urgent investigation from those that do not.

This study evaluates the malignancy rate associated with CT-detected oesophageal abnormalities and investigates the contribution of clinical markers and referral patterns to inform risk stratification and endoscopic prioritisation.

Aims & Methods: A retrospective review of 106 patients with CT-reported oesophageal thickening was conducted across multiple sites in South Wales between 2022 and 2025. Clinical and diagnostic data were extracted from the Welsh Clinical Portal and Synapse endoscopy reporting system. Variables included presence of anaemia, referral source, time interval from CT to oesophagogastroduodenoscopy (OGD), and histopathological outcomes. Patients without follow-up OGD were excluded. Statistical analysis was conducted using IBM SPSS, with chi-square tests and cross-tabulation employed to explore associations between clinical variables and confirmed malignancy.

Results: Malignancy was histologically confirmed in 5.7% of patients undergoing endoscopic investigation following CT-reported oesophageal thickening. Among those with cancer, 83.3% were anaemic at presentation, a statistically significant association ($p < 0.001$). While the overall malignancy rate was low, the disproportionate occurrence of anaemia in malignant cases suggests it may serve as a valuable clinical marker to guide endoscopy urgency. Dysphagia and weight loss were also reported in malignant cases, although these did not reach statistical significance. Patients with confirmed malignancy were scoped considerably sooner, with a mean interval of 13.8 days from CT to OGD, compared to a cohort average of 49 days, reflecting clinical prioritisation based on perceived risk. Endoscopic abnormalities were observed in approximately 63% of cases, the majority of which were non-malignant findings.

Conclusion: The malignancy detection rate in this cohort was under 6%, highlighting the limited standalone predictive value of CT-detected oesophageal thickening. The strong association between anaemia and confirmed cancer reinforces the importance of integrating clinical markers into triage decisions. These findings support a re-evaluation of current referral pathways and advocate for more refined, risk-based approaches to endoscopy selection. In the context of international variation in cancer referral thresholds, this study provides real-world evidence to inform safer and more efficient diagnostic strategies.

CAN CT RADIOMICS PREDICT THE KI-67 INDEX OF GASTROINTESTINAL STROMAL TUMORS (GISTS)? A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Papadakos[1], A. Argyrou[1], I. Karniadakis[2], S. Vogli[3], I. Katsaros[4], N. Machairas[5], S. Theocharis[6]
[1]National and Kapodistrian University of Athens, First Department of Gastroenterology, Athens, Greece, [2]St. George's University Hospitals NHS Foundation Trust, Department of General Surgery, London, United Kingdom, [3]National and Kapodistrian University of Athens, Kallithea, Greece, [4]National and Kapodistrian University of Athens, First Department of General Surgery, Athens, Greece, [5]National and Kapodistrian University of Athens, Second Department of Propaedeutic Surgery, Athens, Greece, [6]National and Kapodistrian University of Athens, First Department of Pathology, Athens, Greece

Contact E-Mail Address: stavrospapadakos@gmail.com

Introduction: The Ki-67 labeling index is a well-established marker of cellular proliferation and has been associated with worse disease-free and overall survival in gastrointestinal stromal tumors (GISTs). Recent evidence highlights its potential role in risk stratification, particularly when Ki-67 exceeds certain thresholds. However, current assessment relies on postoperative histopathology. Radiomics, by extracting quantitative features from computer tomography (CT) images, may offer a non-invasive method to predict Ki-67 expression preoperatively. This meta-analysis aimed to evaluate the diagnostic performance of CT-based radiomics for predicting Ki-67 status in GISTs.

Aims & Methods: A systematic review and meta-analysis were conducted according to PRISMA guidelines). Four electronic databases (PubMed, Scopus, Science Direct, Cochrane Library) were searched for relevant articles up to December 2024. Eligible studies assessed CT radiomics in predicting Ki-67 in histologically confirmed GISTs. Pooled sensitivity, specificity, and area under the curve (AUC) were calculated using a random-effects model. Subgroup analyses were performed based on cohort type, CT protocol, number of features, and Ki-67 cutoff values. Study quality was assessed using the QUADAS-2 tool.

Results: Six studies comprising 1,632 patients met the inclusion criteria. Pooled sensitivity and specificity were 0.71 (95% CI: 0.63–0.79) and 0.76 (95% CI: 0.73–0.78), respectively. The pooled AUC was 0.79 (95% CI: 0.74–0.84). Subgroup analyses showed consistent performance across imaging protocols and feature counts, while Ki-67 cutoffs (8% vs. 10%) significantly impacted diagnostic accuracy. Sensitivity analysis confirmed robustness of specificity estimates. Publication bias was detected for specificity (Egger's test p = 0.006).

Conclusion: CT radiomics demonstrates moderate accuracy for non-invasively predicting Ki-67 expression in GISTs. Given Ki-67's prognostic significance, radiomics could support preoperative risk assessment and personalized treatment planning. Further prospective validation is warranted.

Disclosure: No Conflict of Interest.

Introduction: Transmural oesophageal defects are associated with significant morbidity and mortality. Repeat surgery is often complicated and undesirable with variable outcomes. Increasingly, endoscopic interventions including clip closure devices, temporary full covered self-expanding metal stents (FcSEMS) and endoscopic suturing are being used to treat this problem.

Endoscopic vacuum therapy (EVT) relies on a sponge-based device that is placed either within a cavity or the oesophageal lumen to provide continuous negative pressure over the defect which enhances drainage and tissue micro-perfusion.

The VacStent GI™ (MicroTech) device is an innovative endoscopic solution which synergistically incorporates the advantages of a fcSEMS while synchronously employing the principles of EVT.

Aims & Methods: We retrospectively analysed patients undergoing treatment for transmural oesophageal defects with the VacStent GI™ (MicroTech) device between October 2023 and Febuary 2025 at two upper GI surgical centres (UCLH and University Hospitals of Derby).

All patients had cross-sectional imaging and any chest contamination was drained before stent insertion. Defects involving the cricopharnyx and/or those more than 5cm were excluded. Continuous negative pressure of 125 mmHg was used for the first 24 hours after stent placement and then reduced to 75 mmHg. The VacStent was exchanged every 7-10 days until defect closure. All cases were performed in endoscopy with a minimum of propofol sedation and were discussed as part of specialist MDT.

The primary outcome was clinical success, defined as the endoscopic and radiological evidence of defect closure. Secondary outcomes included technical success, number of stent exchanges, serious adverse device effect (SADE) and time to defect closure.

Results: The VacStent GI™ (MicroTech) device was used 33 times in 16 patients with a median age of 65 years (IQR 57-75). The study population comprised 75% male and 25% females. 2/16 (12.5%) had defects secondary to boerhaaves syndrome, 4/16 (25%) had iatrogenic defects and, 10/16 (62.5%) had anastomotic leaks (1=benign:9=malignant).

Clinical success was achieved in 10/16 (62.5%) patients with a technical success rate of 100%. Median time to defect closure following index VacStent implantation was 10 days (IQR 6-15) with a median of 1 VacStent exchange (IQR 0-2). The median defect size was 10mm (IQR 6-14). Cases of VacStent failure appear to be related to defects more than 4cm and those within a conduit (Table 1).

There was a single adverse event related to severe bleeding due to the stent becoming embedded to the oesophageal lumen – after the VACStent was removed, a temporary fully covered stent was placed to tamponade any bleeding and later removed uneventfully.

Conclusion: In conclusion, our experience has demonstrated that VacStent is a safe and effective treatment option for oesophageal defect closure achieving this in 62.5% of patients.

This is a challenging cohort of patients that usually have limited treatment options. Multi-disciplinary collaboration and early recognition of both appropriate and inappropriate defect dimensions and aetiology is critical to enhancing success rates.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Ongoing experience with a more diverse and larger patient population will further clarify the position of the VacStent device in the EVT treatment paradigm.

Disclosure: Nothing to disclose.

Introduction: Although overall prevalence of benign oesophageal strictures (BOSs) is low, a rising prevalence of associated risk factors, such as increased life expectancy, gastro-oesophageal reflux disease and eosinophilic oesophagitis is predicted to contribute to an increased incidence and evolving aetiology. Endoscopic dilation (ED) currently remains the primary treatment modality.

Aims & Methods: This study aimed to evaluate the current most common aetiologies for BOSs, alongside evaluating the success of ED.

Between January 2021 and December 2023, 1994 upper GI endoscopies (UGIEs) with endoscopic dilatation of a BOS were identified using electronic patient records across 11 UK centres. Details of procedures were then collected in a retrospective observational fashion at each site before central pooling of pseudo-anonymised data for analysis.

For both individual UGIEs with dilatation and given "sessions" of dilatations (defined as consecutive UGIEs separated by ≤6 months), treatment was deemed successful if the lumen was confirmed to be dilated to a diameter of ≥14mm (confirmed on a check procedure >4 weeks after, and/or not requiring further dilatation to maintain diameter within a 6-month period).

Results: Eight hundred and eighteen patients (328[40%] female; mean age 64.3[SD 15.52]) were followed-up for a mean of 20.5 (range 4–62) months, from time of initial stricture diagnosis. The most common aetiology of BOS were peptic in 38% (313/818), post-op anastomotic in 13%(105/818), post-radiotherapy in 6% (48/818), post-operative (non-anastomotic) in 6% (47/818), Schatzki rings in 6% (46/818), and eosinophilic oesophagitis in 5% (37/818). Less common aetiologies seen included: post-endoscopic mucosal resection (EMR), post-radiofrequency ablation (RFA), post-caustic injury, webs, lichen planus, and connective tissue disease.

(see Table 1)

Successful dilatation for a single UGIE procedure with ED was achieved in 875/1994 (43.9%) of procedures. With respect to 'sessions' of consecutive dilatations, success was achieved within three months in 44.2% (388/878) of patients, and within six months in 60.6% (530/878) of patents. For successful sessions, mean number of dilatations required was 2.2 (SD 2.4), and median number of weeks to successful dilatation was 15 (IQR 7–30).

Stricture Aetiology	Number of patients n	Percentage of patients n/N (%)
Peptic	313	38
Post-operative (anastomotic)	105	13
Post-radiotherapy	48	6
Post-operative (non-anastomotic)	47	6
Schatzki ring	46	6
Eosinophilic oesophagitis	37	5
Other*	222	26

* ‚Other' includes (in order of frequency, though all representing <5%) cases of: unidentifiable aetiology, post-endoscopic mucosal resection (EMR), post-radiofrequency ablation (RFA), post-caustic injury, webs, lichen planus, connective tissue disease, and miscellaneous

Table 1 – Most common aetiology of benign oesophageal strictures for patients (N = 818).

Conclusion: Peptic strictures remain the most common aetiology of BOS. A significant proportion of patients (39.4%) with BOS failed to achieve success following ED. This may reflect both the inherent limitations of ED and suboptimal adherence to guidelines, particularly regarding the recommended frequency of dilations until treatment success is achieved

Further analysis of data from this study will look to explore relative effectiveness of endoscopic dilatation in the context of differing aetiology, additional patient (as well as procedural) factors influencing success, as well as complication rates. It will also explore whether greater compliance with established guidelines may help to more accurately define the true therapeutic potential of ED in the management of BOS.

LOWER ESOPHAGEAL RING'S TREATMENT: LONG-TERM RESULTS COMPARING ELECTROSURGICAL INCISURES VERSUS DILATATION IN THE PRESENCE OF ACID SUPPRESSION THERAPY

S. Vaiciunas[1], K. Nocrato Loiola Vaiciunas[2], B. Loiola Vaiciunas[3]
[1]Sao Lucas Medical School, Gastroenterology, Porto Velho, Brazil, [2]University of Sao Paulo - UNIFESP, Sao Paulo, Brazil, [3]Windermere Prep School, Windermere, United States of America

Contact E-Mail Address: spencervaiciunas@hotmail.com

Introduction: Lower esophageal (Schatzki's) rings are a common cause of solid impactation dysphasia. Standard treatments involve passage of a single large bougie to disrupt the ring but symptoms recur in the majority of patients. Electrosurgical incision of the ring may provide a longer duration of symptom improvement. Acid suppression has been shown to decrease the recurrence rate of peptic strictures but are few datas on the treatment of Schatzki's ring

Aims & Methods: To compare the efficacy of bougie dilatation plus Esomeprazole to surgical incision plus esomeprazole in symptomatic patients with Schatzki's ring

A prospective randomized trial study, from May 2013 to Abril 2025, was performed in a referred Gastrointestinal hospital in Brazil. A total of 84 patients underwent for endoscopic evaluation of dysphagia were found to have a Schatzki's ring. They were randomized to Bougie dilatation using a 54 French Dilator or electrosurgical incision a standard needle knife incision with 4 longitudinal incisions placed radially around the Schatzki's ring. All patients were placed on Esomeprazole 40mg/daily for 8 weeks. Paired data were analyzed using Wilcoxon rank (dysphasia score) and paired t-test (GERD scores) within groups

Results: Thirty-nine patients underwent bougie dilatation and thirty-eight electrosurgical incisions. Patients were followed up for 18 months. Seven patients did not come for followed up. Two episodes of bleeding during electrosurgical incision were controlled using epinephrine injection. Symptoms free were significantly longer in incision group (8.82 months) compared to bougie dilatation group (4.93 months) (p = 0,02). The improvement in dysphasia scores were significant within each group comparing baseline to each time interval. The incision group experienced a significant improvement of dysphasia symptoms at 6 weeks compared to the bougie dilatation group (p = 0,05). GERD scores improved significantly in both groups at all time intervals in the bougie dilatation group and at all time intervals in the incision group. There were no significantly difference in GERD scores between the groups.

Conclusion: Electrosurgical incision of lower esophageal (Schatzki`s) ring is safe and offers longer free symptoms free compared to bougie dilatation. The addition of Esomeprazole offered significant improvement in GERD scores in both groups

Disclosure: Nothing to disclose.

GASTRIC PARTITIONING COMPARED TO CONVENTIONAL GASTROJEJUNOSTOMY AS PALLIATIVE SURGERIES IN PATIENTS WITH GASTRIC OUTLET OBSTRUCTION DUE TO UNRESECTABLE GASTRIC OR PANCREATIC CANCERS: A PAIR-WISE AND INDIVIDUAL PATIENT DATA META-ANALYSIS

M.H. Elkasaby[1], A.A Hassan[1], M.S.A. Ahmed[2]
[1]Faculty of Medicine, Al-Azhar University, Cairo, Egypt, [2]Faculty of Medicine, Mansoura University, Mansoura, Egypt

Contact E-Mail Address: mohamedhamouda2182000@gmail.com

Introduction: Gastric outlet obstruction (GOO) is a severe complication of unresectable gastric and pancreatic cancers. Conventional gastrojejunostomy (CGJ) is a standard surgical intervention, but it is associated with a high incidence of delayed gastric emptying (DGE). Stomach-partitioning gastrojejunostomy (SPGJ) has emerged as an alternative to improve gastric emptying and enhance clinical outcomes.

Aims & Methods: We conducted a meta-analysis comparing SPGJ and CGJ in patients with GOO due to unresectable gastric or pancreatic cancers. Electronic databases were searched up to February 8, 2025.

Outcomes included DGE, major postoperative complications, need for reintervention, short-term mortality, operation time, gastric outlet obstruction scoring system (GOOS), length of hospital stay (LOS), adherence to postoperative chemotherapy, and overall survival.

For continuous outcomes, mean differences (MD) with 95% confidence intervals (CI) were calculated. For dichotomous outcomes, relative risks (RR) with 95% CI were reported. Reconstructed individual patient data (IPD) from Kaplan-Meier curves was utilized for survival analysis.

Results: A total of 11 studies comprising 456 patients were included. SPGJ was associated with significantly reduced DGE (RR = 0.24, 95% CI: 0.12–0.47) and postoperative major complications (RR = 0.26, 95% CI: 0.12–0.54) compared to CGJ. No significant differences were found in the need for reintervention (RR = 0.59, 95% CI: 0.21–1.64), short-term mortality (RR = 0.99, 95% CI: 0.42–2.33), or LOS (MD = -1.47 days, 95% CI: -3.10 to 0.16). GOOS scores were comparable between groups. Overall survival was also similar between SPGJ and CGJ (HR = 1.06, 95% CI: 0.66–1.70).

Conclusion: Our meta-analysis supports SPGJ as a superior option to CGJ for managing malignant GOO, offering significant reductions in DGE and postoperative complications, similar GOOS scores, and comparable safety regarding reintervention, short-term and long-term mortality, and LOS. High-quality RCTs are needed to confirm these findings and guide clinical practice.

ANTRAL PRESERVATION VS. ANTRAL RESECTION IN SLEEVE GASTRECTOMY: A SYSTEMATIC REVIEW AND META-ANALYSIS OF WEIGHT LOSS, METABOLIC OUTCOMES, AND COMORBIDITY RESOLUTION

M.A. Masood[1], M.A.M. Qureshi[1], H.S. Zahoor[1], M.B. Akram[1], M.A.A. Khan[1], L. Masood[2], A. Arshad[1], M.M.u.D. Arshad[1], A. Sarfraz[3]

Contact E-Mail Address: abdullah3350539539@gmail.com

Introduction: The impact of antral preservation versus antral resection in sleeve gastrectomy remains a subject of debate due to its potential effects on weight loss, metabolic outcomes, and gastrointestinal function. This meta-analysis aims to provide a comparative assessment of these surgical techniques.

Aims & Methods: The Meta-Analysis aims to provide a comprehensive analysis between these two surgical techniques.

A systematic review and meta-analysis were conducted using 10 studies published between 2014 and 2025 that compared sleeve gastrectomy with antral preservation versus antral resection. The primary outcomes included excess weight loss (EWL) at different time points, while secondary outcomes assessed metabolic parameters (C-peptide, GLP-1, HbA1c), gastric emptying, gastroesophageal reflux disease (GERD), and resolution of comorbidities.

Results: A total of 10 studies were included. Patients undergoing antral resection exhibited greater excess weight loss at 6 and 12 months (MD: -4.50, 95% CI: -5.98 to -3.02; MD: -6.11, 95% CI: -7.74 to -4.47, respectively; p<0.00001), though the difference diminished by 24 months (MD: -3.37, 95% CI: -7.04 to 0.30; p=0.07). No significant differences were observed in overall GERD incidence (RR: 1.00, 95% CI: 0.75–1.33) or complications (RR: 1.00, 95% CI: 0.74–1.42). Metabolic outcomes showed marginal differences, with C-peptide (SMD: 0.02, 95% CI: -0.38 to 0.42) and GLP-1 (SMD: -0.22, 95% CI: -0.90 to 0.47) exhibiting minimal changes between groups.

Conclusion: Antral resection in sleeve gastrectomy is associated with superior short-term weight loss, but long-term differences remain inconclusive. Metabolic outcomes and postoperative complications appear comparable between techniques. Further randomized controlled trials with extended follow-up are warranted to refine surgical recommendations.

Introduction: In the treatment of esophageal carcinoma, abdomino-thoracic esophagectomy is the curative therapeutic option, often combined with perioperative (radio-)chemotherapy. This procedure is associated with high complication rates and significant mortality. Anastomotic leakage, with a pooled incidence of 11% (ranging from 0% to 49%)[1], constitutes a major postoperative complication. New therapeutic options, such as the EndoVac (Stent) system, offer promising approaches for its management.

The aim of this study was to identify risk factors for the occurrence of anastomotic leaks and to evaluate the effectiveness of various treatment methods.

Aims & Methods: We present data from 2022–2024 collected at the University Medical Center Göttingen, a high-volume center for esophageal surgery. A total of 242 patients who underwent abdomino-thoracic esophagectomy, either as primary treatment or after neoadjuvant therapy, were included. Structured data collection and analysis were carried out using Excel and GraphPad Prism.

Results: In this patient cohort, 79.3% were male (n=192) and 20.7% female (n=50), with a mean age of 65.4 years and a mean BMI of 26.1 kg/m^2 at the time of surgery. The most common pre-existing conditions were 56.6% arterial hypertension (n=137), 7,9% COPD (n=19), 21% diabetes mellitus (n=51), as well as coronary artery disease (CAD) and peripheral arterial disease (PAD), each 8.2% (n=20). Histologically, 80.1% (n=194) adenocarcinomas and 19.4% (n=47) squamous cell carcinomas. 88.8% of patients received neoadjuvant therapy (n=215): 35.5% radiochemotherapy (n=86) and 53% chemotherapy (n=129). Of all patients, 24.8% (n=60) underwent primary open surgery and 75,3% (n=182) had minimally invasive hybrid procedures. By 2024, minimally invasive approaches had increased to 83.3% (n=86).

Anastomotic leakage occurred in 25 patients (10.3%), with clinical manifestation appearing on average 8 days postoperatively (range: 1–29 days). An association with the occurrence of anastomotic leakage was observed for nicotine abuse (OR 1.35; 95% CI: 0.60–3.11), alcohol consumption (OR 1.69; 95% CI: 0.66–4.24), coronary artery disease (CAD), and peripheral arterial disease (PAD) (each OR 2.37; 95% CI: 0.80–7.81); however, none reached statistical significance in Fisher's exact test (all $p > 0.05$). Complete remission (24.4%, n=59) was significantly associated with an increased risk of leakage (OR 3.51; 95% CI: 1.53–7.86; $p = 0.005$).

All 25 anastomotic leaks were initially treated with EndoVac, healing successfully in 21 cases (96%). Four patients (16%) required revision surgery. An EndoVacStent was implanted in 52% of cases (n=13), with 20% receiving only an EndoVacStent (n=5) and 32% treated with a combination of sponge and stent (n=8). The average duration of EndoVac therapy was 15 days (range: 1–42 days), with the system being exchanged three times on average. In-hospital mortality was 1.6% (n=4).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Conclusion: In summary, the EndoVac and EndoVacStent systems have proven to be safe and effective treatment options for anastomotic leakage. Patients with complete remission showed an increased susceptibility to anastomotic leakage. Our data supports the importance of studies like ESORES (DRKS00022050)[2] and PRESTO (NCT05713838)[3], investigating non-operative treatment approaches for clinical complete remission cases followed by a watch-and-wait strategy.

LONG-TERM FOLLOW-UP OF PARA-OESOPHAGEAL HERNIA SURGERY: A 22-YEAR EXPERIENCE

P. Siriwardana[1], B. Lorenzi[1], M. Qamruddin[1], S. Kadirkamanathan[1]
[1]Mid and South Essex NHS Foundation Trust/Broomfield Hospital, Upper GI Surgery, Chelmsford, United Kingdom

Contact E-Mail Address: s.s.kadirkamanathan@qmul.ac.uk

Introduction: The surgical management of paraesophageal hernias (PEH) has evolved significantly, moving from open approaches including laparotomy or thoracotomy to minimally invasive techniques, including laparoscopic and robotic-assisted repair with or without fundoplication. Surgery aims to improve symptoms with better quality of life (QoL) and reduce the risk of life-threatening complications of PEH. Many reports are predominantly those with short or medium follow-up periods.

Aims & Methods: The present study aims to assess a large cohort of patients who had surgery for PEH for recurrence and QoL over a longer period. So, we did a retrospective analysis of prospectively collected data of patients who underwent surgery for symptomatic PEH from January 2001 to September 2024. Data collected on clinical presentation, surgical management, post-operative clinical outcomes, and follow data that comprised of clinical evaluation with basic, functional and radiographic assessment as well as quality-of-life (QoL) assessment of general health, physical, emotional, and social components with SF-36 questionnaire.

Results: There were 284 patients (180 females) with median age of 67 years (See Table) who underwent surgery for PEH. One hundred and sixteen presented with shortness of breath (41%). One hundred and twenty-seven (45%) were ASA III, 167 (59%) had microcytic anaemia.

Seven (2.5%) underwent gastropexy only. A fundoplication was performed in 146 (51%) during PEHR. The remaining 131 patients had PEHR plus gastropexy, with 30 of them were for recurrence following previous PEHR (16 of them had primary surgery elsewhere with fundoplication at PEHR)

Approach was robotic (35), laparoscopic (224), converted- to-open (7) or open (19). Median hospital stay was significantly lower in robotic 3 days (2-7) and laparoscopic group; 4 days (1-16) compared to open of 10 days (5-33). Mortality was 0.7% (2/284).

Median follow-up was 12 years. Symptoms improved in 232 (82%) with a significant improvement of respiratory function following PHER. Haemoglobin levels improved from 96g/L (61-123) preoperatively to 129g/L (98-138) postoperatively so was all components of QoL. Sixty-two (22%) had radiological recurrences but only 14 (5%) had clinical recurrence requiring further surgery and 11 (79%) of 14 were those who had a fundoplication at previous PEHR.

Age at Surgery for PEH (Years)	Number of patients
21-30	3
31-40	10
41-50	33
51-60	48
61-70	80
71-80	85
81-88	25
Median (range) 67(21-88): IQR 55-76	Total (n)=284

Conclusion: Para-oesophageal hernia repair is safe with good outcomes in all age groups with improvement in symptoms, quality of life, respiratory function, and associated anaemia. Radiological recurrences are not uncommon on long-term follow-up and does not need any intervention unless symptomatic. Para-oesophageal hernia repair combined with gastropexy avoiding fundoplication probably reduce symptomatic recurrences.

Introduction: Patients on maintenance hemodialysis are considered to have a higher risk of bleeding after endoscopic submucosal dissection (ESD) for gastric lesions. In high-risk cases, second-look endoscopy (SLE) may reduce the risk of post-ESD bleeding[1].

At our institution, SLE is routinely performed following gastric ESD. We evaluated the incidence and risk factors of post-ESD bleeding after gastric ESD among patients on maintenance hemodialysis.

Aims & Methods: We conducted a retrospective, single-center study including 32 hemodialysis patients with 37 gastric lesions who underwent ESD at our hospital between July 22, 2003 and August 31, 2024. Patients were divided into two groups based on the occurrence of post-ESD bleeding. Clinical data including age, sex, body mass index (BMI), age-adjusted Charlson comorbidity index (ACCI), Geriatric Nutritional Risk Index (GNRI), extent of atrophic gastritis, laboratory findings, the use of antithrombotic drugs, Best-J score[2], details of the procedure, pathological findings and the types of anti-acid medicine prescribed after ESD were collected and analyzed.

Results: The median age was 72 years, with 73% of the patients being male. There were no differences in most of patient characteristics, details of lesions and procedures. Submucosal invasion (0% in the no-bleeding

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. group vs. 28.6% in the bleeding group, p = 0.035) were significantly associated with post-ESD bleeding. In contrast, the use of local hemostatic agents appeared to have a protective effect against post-ESD bleeding (51.7% vs. 0%, p = 0.012). The use of perioperative antithrombotic drugs tended to be higher in the bleeding group (51.7% vs. 0%, p = 0.058). The endoscopic hemostasis at 2nd look endoscopy was not associated with post-ESD bleeding.

ACCI (median, IQR)	Overall (n=37 (%)) 8(6-8)	No-rebleeding (n=29 (%)) 7(6-8)	Rebleeding (m=8 (%)) 8(7.5-9.25)	p-value 0.2638

Best-J				
High-risk	13(35.1%)	12(41.4%)	1(12.5%)	0.2164
Very high-risk	24(64.9%)	17(58.6%)	7(87.5%)	
Tumor size (median, IQR) (mm)	10.0(6.0-18.5)	7.5(6.0-14.0)	19.0(8.0-21.0)	0.2129
Tumor location				
Upper	7(18.9%)	6(20.7%)	1(12.5%)	1.0000
Middle	4(10.8%)	3(10.3%)	1(12.5%)	
Lower	26(70.3%)	20(69.0%)	6(75.0%)	
Depth of invasion				
Mucosa	33(89.2%)	28(100%)	5(71.4%)	0.0353
Submucosa	2(5.4%)	0(0%)	2(28.6%)	
Procedure time (median, min)	92.0	99.0	84.5	0.9853
Use of local hemostatic agents				
Yes	15(40.5%)	15(51.7%)	0(0%)	0.0121
No	22(72.9%)	14(48.3%)	8(100%)	
Endoscopic hemostasis at 2nd look endoscopy				1.0000
Yes	14(37.8%)	11(37.9%)	3(37.5%)	
No	23(62.2%)	18(62.1%)	5(62.5%)	

Conclusion: Despite routine SLE in hemodialysis patients, the rate of post-ESD bleeding at our institution remains high and similar to previously reported rates. Submucosal invasion, perioperative antithrombotic therapy may be associated with increased, and the use of local hemostatic agents may be associated with decreased bleeding risk. Further strategies should be considered to reduce the risk of post-ESD bleeding in hemodialysis patients.

PREDICTING NONSURGICAL OUTCOMES OF IATROGENIC GASTROINTESTINAL PERFORATIONS: A COMPREHENSIVE MULTICENTER NOMOGRAM

Y. Liu[1], X. Zhang[1], B. Xia[1], K. Deng[1], J. Yang[1]
[1]West China Hospital of Sichuan University, Chengdu, China

Contact E-Mail Address: liuyuzhi121@foxmail.com

Introduction: Iatrogenic gastrointestinal perforation (IGP) is a rare but critical complication of endoscopy, traditionally managed surgically. Recent advances have allowed nonsurgical treatment to emerge as a viable alternative. However, predictive models for successful nonsurgical management remain limited.

Aims & Methods: This study aimed to identify independent predictors of nonsurgical success and develop a visual nomogram to predict which patients with IGP can be treated successfully without surgery. We retrospectively reviewed cases of IGP from three tertiary centers in China between 2011 and 2022. Patients were divided into two groups: those successfully managed nonsurgically and those requiring surgical intervention. Multivariable logistic regression identified predictors of nonsurgical success, and a nomogram was developed and validated to predict outcomes. Data analysis included patient demographics, perforation characteristics, and treatment details.

Results: Of 1,034,706 endoscopic procedures performed during the study period, 80 cases of IGP were identified (incidence rate: 0.008%). The median patient age was 58.4 years (±15.1), with a slight male predominance (55%). Nonsurgical management succeeded in 66.3% (53/80) of cases, while 33.8% (27/80) required surgery.

Successful nonsurgical management was associated with shorter hospital stays (median: 12 vs. 16.5 days, P=0.005) and fewer in-hospital complications, such as septic shock (0% vs. 50%, P<0.001). Independent predictors of nonsurgical success included the absence of missed muscular injury (odds ratio [OR]=0.146, 95% confidence interval [CI] 0.034-0.622, P=0.009), upper gastrointestinal perforation (OR=7.182, 95%CI 1.446-35.668, P=0.016), use of endoscopic treatment (OR=12.152, 95%CI 1.705-86.588, P=0.013), and early intravenous antibiotics administered within 5 hours (OR=6.040, 95%CI 1.391-27.218, P=0.016) (Table 1).

Variable		P	OR	Beta coefficient	Score
Missed muscular injury	Yes	0.009	0.098 (0.022-0.442)	-1.927	0
	No				77
Upper GI perforation	Yes	0.016	7.587 (1.431-40.212)	1.972	79
	No				0
Endoscopic treatment	Yes	0.013	14.452 (1.960-106-569)	2.498	100
	No				0
Early intravenous antibiotic	Yes	0.016	6.042 (1.325-27.562)	1.798	72
	No				0

Table 1. Predictors and associated numeric points from the nomogram for predicting the success of nonsurgical treatment.

The nomogram assigned weighted points to each predictor, and the total score (ranging from 0 to 300 points) was calculated by summing the points assigned to each predictor. The total score demonstrated a nonlinear association with the probability of nonsurgical success: 0 points corresponded to a 0.1 (10%) probability of success; 50 points to 0.3 (30%); 100 points to 0.5 (50%); 150 points to 0.8 (80%); 200 points to 0.9 (90%); 250 points to 0.95 (95%); and 300 points to 0.99 (99%).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Internal validation using bootstrap resampling (C-index = 0.876) and five-fold cross-validation (C-index = 0.850) confirmed the model's reliability. Calibration curves showed high agreement between predicted and observed outcomes, and decision curve analysis supported the clinical utility of the model.

Conclusion: This study presents a validated nomogram integrating critical predictors to estimate nonsurgical success in IGP management. These findings highlight the importance of clinician vigilance, timely interventions, and the utility of tailored endoscopic treatments in optimizing patient outcomes.

Contact E-Mail Address: mandarino.francesco@hsr.it

Introduction: Endoscopic Vacuum Therapy (EVT) and Fully Covered Metal Stents (FC-SEMS) are standard treatments for anastomotic leaks (AL) following upper gastrointestinal (UGI) surgery[1-3].

Recently, a new hybrid device combining an FC-SEMS with a polyurethane EVT sponge (VACStent) has been introduced, showing promising results[4]. However, there is not comparative data between VACStent and traditional endoscopic methods for ALs.

Aims & Methods: In this retrospective study, all patients with AL after UGI oncologic surgery who underwent EVT or VACStent at a tertiary academic center from March 2015 to September 2024 were included. The two endoscopic techniques were compared.

The primary outcome was clinical success (CS), with secondary outcomes including number of devices used, treatment duration, and adverse events (AEs).

Results: Over 114 months, 103 patients [92 EVT, 11 VACStent] were enrolled. Of these, 74.8% had AL following Ivor-Lewis esophagectomy. The two cohorts did not differ significantly in terms of comorbidities, neoadjuvant treatment, leak number/median size, or rates of redo-surgery before endoscopic management. Both EVT and VACStent were used as first-line treatments in a similar rate of patients (79.3% vs. 90.9%, p=0.36).

The EVT group had a higher CS rate than the VACStent group, though this difference was not statistically significant (72.8% vs. 54.5%, p=0.21). Compared to the EVT group, the VACStent group required significantly fewer endoscopic sessions (1±0.7 vs. 3±2.5, p<0.001) and had a shorter mean treatment duration (12.1±11.2 vs. 14.1±12.9 days, p=0.62).

Additionally, a significantly lower proportion of patients in the VACStent group required admission to the intensive care unit (ICU) (27.3% vs. 84.4%, p<0.001). In the EVT group, three adverse events were recorded (one bleeding episode and two sponge dislodgments), while no AEs were reported in the VACStent group (p=0.54) (Table 1).

	EVT n=92	VACStent n=11	P
Clinical success, n	67 (72.8%)	6 (54.5%)	0.21
Number of sessions	3 ± 2.5	1 ± 0.7	<0.001
Treatment duration (days)	14.1 ± 12.9	12.1 ± 11.2	0.62
Adverse events, n	3/276 (1.0%)	0/13 (0%)	0.54
Hospital stay (days)	35.0 ± 28.0	45.3 ± 34.5	0.26
ICU admission, n	76 (84.4%)	3 (27.3%)	<0.001

Table 1. EVT vs VACStent: Outcomes.

Conclusion: In this retrospective study, EVT and VACStent showed comparable success in treating post-UGI surgery leaks. VACStent was associated with a reduced need for ICU admission and fewer endoscopic sessions. Larger comparative data are warranted to define the role of VACStent in the treatment of leaks after UGI surgery.

Introduction: Managing leaks and defects of the upper gastrointestinal (UGI) tract remains challenging. Endoscopic Vacuum Therapy (EVT) is a promising option[1-3]; However, data on its efficacy in large cohorts remain limited.

Aims & Methods: This retrospective study with prospectively collected data enrolled all consecutive patients with UGI defects treated by EVT at a single academic center (San Raffaele Hospital, Milan, Italy) from March 2015 to September 2024.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The primary outcome was clinical success (CS).

Secondary outcomes included median treatment duration/devices, technical success (TS) and adverse events (AEs). Clinical success (CS) was defined as complete endoscopic and/or radiologic defect healing, with the patient remaining asymptomatic. Adverse events (AEs) were classified according to the AGREE classification.

Results: Over a period of 114 months, 96 patients [72.9% male, median age 67 years (IQR 57-75), 49% ASA 3] were included. Among them, 66 patients (68.7%) had anastomotic leaks after Ivor-Lewis esophagectomy, with 57% undergoing neoadjuvant chemotherapy. The median leak size was 7 mm (IQR 4-10), with a median circumferential involvement of 20% (IQR 10-40). A fistula involving the airways was present in 28.1% of cases. EVT was the first-line treatment in 78.1% of patients, with a median time from surgery to EVT of 7 days (IQR 4-9).

The overall clinical success (CS) rate was 72.9% (70/96 patients). Of the remaining patients, 20 underwent redo-surgery. Technical success for all procedures was 100% (302/302 procedures). The median treatment duration was 11 days (IQR 5-18), with a median of 3 EVT sessions (IQR 2-4). Three adverse events (AEs) (3/302, 1%) were recorded, including one bleeding episode and two sponge dislodgments, all managed endoscopically (AGREE IIIa). During a median follow-up of 62 days (IQR 33-155), two cases (2.1%) of esophageal strictures were reported (Table 1)

In the subgroup analysis, the intraluminal (IL) group (n=70) had a lower mean number of EVT sessions (3±2 vs. 5±3, p<0.001) and a shorter mean treatment duration (11±10 vs. 21±16 days, p<0.001) compared to the intracavitary (IC) group (n=26).

Patients n=96	Median (IQR) OR n (%)
Clinical success, n	70 (72.9%)
Technical success, n	302/302 (100.0%)
Adverse events, n	3/302 (1%)
Treatment duration (days)	11 (5-18)
Number of EVT sessions	3 (2-4)
Hospital stay (days)	28 (17-43)
ICU admission, n	14 (14.9%)
Stricture, n	2 (2.1%)
Follow-up (days)	62 (33-155)

Table 1: Outcomes.

Conclusion: EVT is a safe and effective treatment for UGI defects. The IL approach was associated with shorter treatment duration and fewer sessions compared to the IC approach. Further controlled studies are needed to optimize EVT application and outcomes.

Introduction: The VAC-Stent is a fully covered stent encased in a polyurethane sponge cylinder, offering a promising approach for treating upper gastrointestinal (UGI) tract leaks and defects[1]; however, available evidence remains limited and preliminary.

Aims & Methods: This prospective study enrolled all consecutive patients with UGI leaks treated with VACStent placement from May 2023 to September 2024 at San Raffaele Hospital, Milan, Italy.

The primary outcome was clinical success (CS).

Secondary outcomes included technical success (TS) and adverse events (AEs). CS was defined as defect healing confirmed by endoscopic and radiologic evaluation, while TS was defined as successful stent placement and removal.

Results: Fourteen patients [64.3% male, median age 65 years (IQR 59–75); 11 with anastomotic leaks after Ivor-Lewis esophagectomy and 3 with perforations after circumferential esophageal ESD] were enrolled. VACStent was the first-line treatment in 92.9% of cases, with a median leak size of 6 mm (IQR 5-11), and 28.6% of patients had previously undergone re-surgery. The median time from surgery/endoscopy to initial VACStent placement was 7 days (IQR 3-9). The median treatment duration was 9.5 days (IQR 7-14), with a median hospital stay of 29.5 days (IQR 21-63) and a median of 2 VACStents per patient (IQR 1-2).

CS rate was 69.2% (9/13 patients); among the 4 remaining cases, three required rescue surgery, and one patient died of sepsis. All patients treated for perforations following esophageal ESD achieved complete healing without developing strictures. TS was 96.7% (30/31); one case of technical failure occurred in a patient with an anastomotic leak who had previously received radiotherapy for mediastinal lymphoma. No VACStent-related AEs were observed (Table 1).

Patients n=14	Median (IQR) OR n (%)
Clinical success, n	10 (69.2%)
Technical success, n	30/31 (96.7%)
Adverse events, n	0 (0)
Treatment duration (days)	9.5 (7-14)
Number of sessions	2 (1-2)
Hospital stay (days)	29.5 (21-63)
ICU admission, n	8 (57.1%)
Stricture, n	0 (0)
Follow-up (days)	42 (29-114)

Table 1: VACStent outcomes.

Conclusion: This prospective series suggests that the VACStent is an effective and safe treatment option for upper GI leaks, including perforations after esophageal ESD. Larger controlled studies are warranted to better define its role and optimize outcomes in this complex setting.

PNEUMATIC VS BOUGIE DILATION OF BENIGN ANASTOMOTIC STRICTURES AFTER ESOPHAGECTOMY: RESULTS FROM A MULTICENTER COMPARATIVE STUDY FROM TERTIARY REFERRAL CENTERS

Contact E-Mail Address: g.dellanna93@gmail.com
Introduction: Benign anastomotic strictures (AS) represent a common adverse event following esophagectomy. Endoscopic treatment with pneumatic balloon dilation (PD) or bouginage using Savary-Gilliard dilators (BD) is routinely adopted, yet comparative evidence between these two strategies remains limited.
Aims & Methods: We performed a retrospective analysis of prospectively collected data of patients with AS after esophagectomy performed in two referral Italian centers (IRCCS San Raffaele Hospital and IRCCS Policlinico San Donato, both in Milan). In the analysis only adult patients with benign AS naive to prior treatment were included. AS was identified in the presence of dysphagia and stenosis at the anastomosis on oral contrast studies or endoscopy and required endoscopic treatment. Technical and Clinical Success (TS, CS) were defined as fully completed planned endoscopic procedure with technical issues and a Mellow and Pinkas' Dysphagia Score (DS) improvement of at least one level after achieving a 14mm caliber. Recurrence was defined as DS of 3 or 4, without the possibility to maintain a satisfactory luminal diameter for 4 weeks after achieving the target diameter of 14 mm. Surgical complications and endoscopic-related adverse events (AEs) were classified with Clavien-Dindo and AGREE Classification, respectively.
Results: 1729 esophagectomies were performed in two italian referral centers (IRCCS San Raffaele Hospital and IRCCS Policlinico San Donato, both in Milan) from January 2014 to December 2024, and 61 patients (3.5%) developed benign AS, treated by BD (33/61, 54.1%) and PD (28/61, 45.9%). Indications included squamous cell carcinoma (45.9%) and adenocarcinoma (42.6%). Most patients underwent minimally invasive surgery (60.7%), predominantly McKeown (50.8%), followed by Ivor Lewis (49.2%). Neoadjuvant therapy was administered in 60.7% of cases. Baseline characteristics were comparable between PD and BD groups, including demographic and surgical aspects (surgical approach, anastomosis type, caliber, and complications).
Also, time from surgery to AS diagnosis (115 vs 78 days, p=0.435), and initial AS diameter (9 mm vs 10 mm, p=0.106) were comparable. TS was 100% in both groups. CS was slightly higher in the BD group (97.0% vs 89.3%, p=0.231), with similar recurrence rates (24.0% vs 25.0%, p=0.931) and AEs (3.6% vs 0%, p=0.278). The median number of sessions was 1.0 in both groups (p=0.350).
However, total treatment duration was significantly longer in the BD group (median 42 vs 20 days, p=0.005). Kaplan-Meier analysis confirmed a significantly shorter time to strategy change in the PD group (log-rank p=0.047), with most changes occurring within the first 60 days.
Multivariate analysis identified BD (OR 3.6; 95% CI 1.2–10.9; p=0.024) as an independent predictor of step-up therapy, along with lower stricture diameter at diagnosis (OR 0.81; 95% CI 0.69–0.95; p=0.010) and lower BMI (OR 0.93; 95% CI 0.87–0.99; p=0.040).
Conclusion: Both PD and BD are effective and safe first-line options for benign AS after esophagectomy. However, BD was associated with significantly longer treatment duration and a higher independent risk of step-up therapy. PD may represent a more efficient strategy in selected patients, particularly those with narrower strictures or lower BMI. Kaplan-Meier analysis further supports a timelier therapeutic reassessment in the PD group.

THE COMPARISON OF ENDOSCOPIC SUBMUCOSAL DISSECTION OF PHARYNGEAL CANCERS BETWEEN PATIENTS WITH AND WITHOUT PREVIOUS HISTORY OF RADIOTHERAPY INCLUDING THE LONG-TERM OUTCOMES

H.S. Colvin[1], T. Inaba[1], A. Nakanishi[1], K. Yamauchi[1], S. Ishikawa[1]
[1]Kagawa Prefectural Central Hospital, Takamatsu, Japan

Contact E-Mail Address: hughshunsukecolvin@gmail.com
Introduction: There has been a rise in the uptake of endoscopic submucosal dissection (ESD) for superficial pharyngeal cancers, including in patients with previous history of radiotherapy, whether as salvage treatment of residual lesions or for metachronous lesions inside the irradiated field. Previous studies have demonstrated the safety and effectiveness of ESD for pharyngeal cancers[1].
However, the safety and the effectiveness of pharyngeal ESD in cases with previous history of radiotherapy is not clear[2,3].
Aims & Methods: Our aim was to investigate whether radiotherapy affects outcomes after pharyngeal ESD. We conducted a retrospective cohort study of consecutive patients who underwent pharyngeal ESD between December 2016 and February 2025 at our institution.
All the cases were managed together with otolaryngologists, including the daily assessment of the wound and swallowing function with the transnasal flexible laryngoscope in order to decide the timing of the re-initiation of food after ESD. The ESD itself, as well as the short and long-term outcomes were compared between the patients with or without history of radiotherapy.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: There were 22 cases (25 lesions) of ESD performed with previous history of radiotherapy and 32 cases (33 lesions) without prior radiotherapy. The median age was 71 (range 55-85) and 98.3% were men. Radiotherapy dose ranged from 54 to 70 Gy.

There were no significant differences in the baseline characteristics between the groups of patients with or without prior radiotherapy including the age, sex, or the proportion of patients with previous history of pharyngeal ESD. En-bloc resection was achieved in all cases. ESD in the pharynx post-radiotherapy was associated with an increased percentage of cases with severe fibrosis (41% vs. 14% p<0.05), and the speed of dissection was slower (33.4mm^2/min vs. 45.8mm^2/min p=0.03), but there were no significant differences in the short-term outcomes between the groups of patients with or without prior radiotherapy in terms of of bleeding (0% vs. 3%), aspiration pneumonia (8% vs. 9%), the duration to the resumption of food (median 4 vs. 5 days) or hospital stay (median 9 vs. 9 days).

During a median follow-up period of 906.5 days (range 22-3021 days), the 3-year overall survival rate was lower in patients with previous history of radiotherapy compared to patients without prior radiotherapy (55.1% vs. 100%, p=0.000177).

Of the patients with previous history of radiotherapy, one patient died from metastatic recurrence of pharyngeal cancer, but the other five deaths were not directly associated with pharyngeal cancer (1=acute cardiac death, 1=unknown cause but unrelated to pharyngeal cancer, 1=lung cancer, 1=mantle cell lymphoma, 1=sinonasal neuroendocrine cancer).

There were no significant differences in the 3-year recurrence-free survival and the 3-year disease-related survival rates between the patients with and without prior history of radiotherapy (92.9% vs. 91.7% and 92.3% vs. 100%, respectively).

Conclusion: Previous history of radiotherapy increases the risk of severe fibrosis during ESD and is associated with slower speed of dissection, but does not compromise the safety or the swallowing function. In the long-term, ESD is an effective method for the treatment of superficial pharyngeal cancers, including in patients with previous history of radiotherapy. Furthermore, ESD is a minimally-invasive and surgery-sparing treatment option, which may be all the more important in patients with prior history of radiotherapy, given the worse prognosis from illnesses other than pharyngeal cancers in this group of patients.

PERORAL ENDOSCOPIC MYOTOMY IN PEDIATRIC POPULATION: A COMPARATIVE STUDY WITH ADULT POPULATION IN A PORTUGUESE TERTIARY CENTRE

H. Ribeiro[1], F. Vidal Lima[1], E. Gravito-Soares[1], M. Gravito-Soares[1], P. Amaro[1], P. Souto[2], P. Narra Figueiredo[1]

[1]Centro Hospitalar e Universitário de Coimbra, Gastroenterology, Coimbra, Portugal, [2]Huc, Linda-a-Velha, Portugal

Contact E-Mail Address: hugosr8@gmail.com

Introduction: Peroral endoscopic myotomy (POEM) is emerging as a minimally invasive therapeutic option for achalasia. Data are limited in pediatric population.

To compare the efficacy and safety of POEM in pediatric and adult patients with achalasia.

Aims & Methods: A prospective study was conducted, including all patients who underwent POEM, since August/2022, in a tertiary centre. Patients aged under 18yo were included in the pediatric group and above 18yo in adult group. Procedural-related parameters, adverse advents, pre- and post-intervention clinical, manometric and radiologic outcomes were evaluated.

Results: 41 patients were included, including three children (mean age: 14.3±1.2 vs. 51.8±19.1 yo; male gender: 100%(n=3) vs.39.5% (n=15)). According to the Chicago classification v4.0, all three children had type II achalasia (adults: type I-5.3% (n=2), type II-89.4% (n=34), type III-5.3%(n=2)).

No significant differences were observed between groups in relation to clinical symptoms (Eckardt score (ES): 7.6vs.0.9;ρ=0.23; average duration of symptoms: 21vs.19 months;ρ=0,36), pre-POEM integrated relaxation pressure (IRP) (36.7vs.19.0;ρ=0,11), esophagogastric junction contractile integral (EGJ-CI) (105,3vs.91,2;ρ=0.72) and barium swallow study at 1/5 minutes (4.5/5.1 vs. 12.6/10.0;ρ=0,17/0.29) and post-POEM IRP (9.75 vs. 6.19;ρ=0.32), EGJ-CI (7 vs 25.20;ρ=0.30) and barium swallow study (3.45/2.20 vs. 2.65/1.43;ρ=0.57/0.56), evaluated at 4.3±1.3 and 8.5±2.1months of follow-up. Technical success was 100% in all groups with mean procedure time of 91.7±12.6minutes for children (vs. 86.1±21.6 for adults; ρ=0.35).

Clinical success was similar in both groups (ES: children-0±0 vs. adults-0.31±0.63;ρ=0.69). There were no significant differences between groups regarding intraprocedural complications (67%vs.66%;ρ=0.98), post-procedural complications or major adverse events. No mortality or need for surgery. Symptomatic gastroesophageal reflux disease (GERD), successfully treated with daily PPI, was only observed in 5 (13.2%) adults (vs. 0% of pediatric patients;ρ=0.021).

Conclusion: POEM proved to be effective and safe for achalasia both in adults and pediatric patients, with no statistically significant differences regarding technical, clinical, manometric and imaging success or complications. Achalasia should be treated as early as possible, with apparently lower incidence of post-POEM GERD in pediatric patients.

UNBURDENING THE PILL LOAD: REAL-WORLD EVIDENCE OF MEDICATION REDUCTION AFTER ENDOSCOPIC SLEEVE GASTROPLASTY

Y.L. Ong[1], M. Chu[1], C Sushmitha[1], C. Tan Hui Ru[1], T.Y. Qiu[1], C.P. Francisco[2], R. Ravi[3,1], R. Asokkumar[1,3]
[1]Singapore General Hospital, Gastroenterology, Singapore, Singapore, [2]St. Luke's Medical Center - Global City, Institute of Digestive and Liver Diseases, Taguig City, Philippines, [3]Duke-NUS Graduate Medical School, Singapore, Singapore

Contact E-Mail Address: yanling.ong@mohh.com.sg

Introduction: The management of obesity is often complicated by associated comorbidities such as type 2 diabetes, hypertension and hyperlipidaemia—all of which contribute to significant polypharmacy. High pill burden is linked to reduced adherence, increased healthcare costs, and lower quality of life. While Endoscopic Sleeve Gastroplasty (ESG) has been established as a minimally invasive intervention for weight loss, its impact on medication use remains underexplored.

This study aims to evaluate changes in medication burden following ESG in a real-world cohort, with a focus on the potential for pharmacological de-escalation alongside weight loss.

Aims & Methods: We conducted a retrospective review of 236 patients who underwent ESG at Singapore General Hospital between November 2020 and December 2025. All procedures were performed by a single experienced endoscopist using a U-shaped suturing pattern. The primary outcome was change in medication burden, defined as the total number of prescribed medications at baseline, 6 months, and 12 months following ESG. Data on medication count were collected from electronic medical records, including all chronic medications prescribed for obesity-related comorbidities.

Results: At baseline, 17.8% of patients were on one or more oral anti-diabetic medications, 2.6% were on insulin, 30.9% were taking antihypertensives, and 22% were on lipid-lowering therapy. At 6 months post-ESG, the proportion of patients on anti-diabetic medications decreased to 15.2%, and insulin use dropped slightly to 2.1%. Anti-hypertensive use declined to 20.8%, and lipid-lowering therapy was reduced to 17.1%. By 12 months, further reductions were observed: 12.7% of patients remained on anti-diabetic medications, only 1.4% were on insulin, and use of anti-hypertensives and lipid-lowering agents fell to 20.8% and 18.8%, respectively.

The total number of medications per patient decreased significantly over time. At baseline, patients were on an average of 1.36 medications targeting diabetes, hypertension, and hyperlipidemia. This declined to 0.61 medications at 6 months and 0.59 at 12 months, corresponding to mean reductions of 0.75 (95% CI: 0.42–1.07, $p < 0.001$) and 0.77 (95% CI: 0.46–1.08, $p < 0.001$), respectively. These reductions were consistent across all major cardiometabolic drug classes.

Conclusion: In addition to driving meaningful weight loss, ESG contributes to a measurable reduction in medication burden for obesity-related comorbidities. These findings support the broader role of ESG in promoting pharmacologic de-escalation, potentially improving long-term adherence and quality of life in patients with obesity.

Disclosure: None.

REAL-WORLD, LONG-TERM OUTCOMES OF ENDOSCOPIC SLEEVE GASTROPLASTY: A TWO-YEAR COHORT STUDY FROM A TERTIARY ASIAN CENTRE

S. C[1], Y.L. Ong[1], C. Tan[1], M. Chu[1], C.P. Francisco[2], R. R[3,1], R. Asokkumar[3,1]
[1]Singapore General Hospital, Gastroenterology and Hepatology, Singapore, Singapore, [2]St. Luke's Medical Center - Global City, Institute of Digestive and Liver Diseases, Taguig City, Philippines, [3]Duke-NUS Graduate Medical School, Singapore, Singapore

Contact E-Mail Address: sushmitha.c@mohh.com.sg

Introduction: Obesity is a global health challenge associated with significant morbidity, mortality, and economic burden. Endoscopic Sleeve Gastroplasty (ESG) has emerged as a safe, incisionless, and minimally invasive alternative to bariatric surgery for patients with obesity who are either unwilling or unsuitable for surgical options. While ESG has demonstrated promising short-term results in terms of weight loss and metabolic improvement, there remains a paucity of data on long-term outcomes, particularly beyond one year.

This study aims to evaluate the long-term efficacy of ESG in a large Asian cohort, focusing on total body weight loss (TBWL) as the primary outcome, with body mass index (BMI) change and absolute weight loss as secondary outcomes.

Aims & Methods: We conducted a retrospective review of 236 patients who underwent ESG at Singapore General Hospital between November 2020 and December 2025. All procedures were performed by a single experienced endoscopist using a U-shaped suturing pattern. The primary outcome was the percentage of total body weight loss (%TBWL) at 6, 12, and 24 months post-procedure.

Results: The cohort consisted predominantly of female patients (69%), with the majority being of Chinese ethnicity (42.8%). The mean age at baseline was 41.4 years (SD ± 10.6), and the mean baseline BMI was 35.0 kg/m^2 (SD ± 6.1). All ESG procedures were technically successful, with an average of five sutures placed per patient and a mean procedure time of 75 minutes (SD ± 17). No major complications were reported, and the average hospital stay was one day.

Follow-up data were available for 114 patients at 6 months, 86 at 12 months, and 41 at 24 months. The mean percentage total body weight loss was 15.9% (SD ± 10.5) at 6 months, 12.7% (SD ± 7.8) at 12 months, and 9.9% (SD ± 7.8) at 24 months, reflecting a sustained reduction in weight over time. As secondary outcomes, BMI decreased significantly from baseline by a mean of 6.0 kg/m^2 (SD ± 5.3) at 6 months, 4.2 kg/m^2 (SD ± 5.7) at 12 months, and 3.5 kg/m^2 (SD ± 5.7) at 24 months (all $p < 0.001$). These were accompanied by corresponding mean weight losses of 16.8 kg (SD ± 17.1), 12.1 kg (SD ± 8.6), and 9.6 kg (SD ± 9.0) at the respective timepoints, all statistically significant ($p < 0.001$).

Conclusion: ESG is a safe and effective endoscopic intervention for weight loss, with sustained and clinically meaningful reductions in total body weight, BMI, and absolute weight observed up to two years post-procedure. These real-world data from a large tertiary Asian centre support the long-term utility of ESG as a viable non-surgical option for obesity management.

Contact E-Mail Address: charlene.tan@mohh.com.sg

Introduction: Pharmacologic therapy is a key component of obesity management, either as standalone treatment or in conjunction with procedural interventions. The role of weight loss medications in the peri-ESG period remains unclear, with questions surrounding whether ESG reduces the need for pharmacotherapy or serves as a platform for combination therapy. Limited data exist on how prescribing patterns evolve before and after ESG in real-world settings.

This study aims to evaluate the use of anti-obesity medications before and after ESG, focusing on patterns of pharmacologic initiation and its relationship to weight loss outcomes.

Aims & Methods: We conducted a retrospective review of 236 patients who underwent ESG at Singapore General Hospital between November 2020 and December 2025. All procedures were performed by a single experienced endoscopist using a U-shaped suturing pattern. For this analysis, we examined the use of anti-obesity medications before and after the ESG. Medications included GLP-1 receptor agonists, sympathomimetic agents, lipase inhibitors, and combination therapies.

The primary outcome was the proportion of patients receiving pharmacotherapy across timepoints and its association with total body weight loss (%TBWL).

Results: Among the 236 ESG patients, 21.6% had previously used anti-obesity medications, most commonly GLP-1 receptor agonists or phentermine. This group consistently achieved the lowest total body weight loss (%TBWL) across all follow-up points. Compared to medication-naïve patients, their mean %TBWL was significantly lower at 6 months (9.9% vs 17.2%, p = 0.015), 12 months (7.8% vs 13.8%, p = 0.026), and 24 months (4.3% vs 10.6%, p = 0.003). These findings underscore the complexity of obesity care, as even patients exposed to multiple treatment modalities may continue to experience suboptimal outcomes.

After ESG, 37.7% of patients were initiated on pharmacotherapy, most commonly semaglutide (n = 66), including 38 on subcutaneous and 28 on oral formulations, with estimated mean doses of 1.63 mg/week and 13.2 mg/day, respectively. Phentermine and liraglutide were used in 13.9% and 3.0% of patients. Patients who received medications only after ESG had lower %TBWL at 6 months compared to those never on medications (14.0% vs 18.8%, p = 0.027), but outcomes were similar by 12 and 24 months. This suggests that pharmacotherapy may help support suboptimal early responders and mitigate longer-term differences.

Conclusion: Anti-obesity medications, particularly semaglutide, are commonly introduced after ESG to support patients with suboptimal early weight loss. While those requiring pharmacotherapy initially experienced less %TBWL, outcomes equalized by 12 months, suggesting a role for adjunctive treatment in slower responders. Patients who had previously used weight loss medications consistently achieved poorer outcomes, highlighting the challenges of obesity management even with multimodal therapy. These findings underscore the importance of individualized treatment strategies and the complementary role of pharmacotherapy alongside ESG in real-world practice.

FULL THICKNESS RESECTION IN THE UPPER DIGESTIVE TRACT USING THE FTRD OVESCO GASTROSET SYSTEM: A FRENCH MULTICENTER RETROSPECTIVE STUDY WITHIN THE GRAPHE GROUP

B. El Khoury[1], T. Degand[2], L. Caillo[3], A. Becq[4], A. Benezech[5], A. Berger[6], Y. Lebaleur[1]
[1]Paris Saint-Joseph & Marie-Lannelongue Hospitals, Gastroenterology Department, Paris, France, [2]Chu De Dijon, Gastroenterology Department, Dijon Cedex, France, [3]CHU DE NIMES, Gastroenterology Department, Nîmes, France, [4]Henri Mondor University Hospital, Endoscopy Unit, Créteil, France, [5]Avignon Hospital Center, Gastroenterology Department, Avignon, France, [6]Hospital Center Bordeaux, Gastroenterology Department, Bordeaux, France

Contact E-Mail Address: ber_kh712@hotmail.com

Introduction: Full-thickness endoscopic resection with the COLONIC FTRD Ovesco system has become a well-established technique for removing superficial colonic lesions smaller than 25 mm, particularly in cases of submucosal tumors or recurrent adenomatous lesions after previous endoscopic mucosal resection. However, its application in the upper digestive tract remains less documented due to its recent uses (1).

Aims & Methods: This French multicenter retrospective study, conducted within the GRAPHE group, aimed to evaluate the safety and efficacy of the FTRD technique using the FTRD Gastroset OVESCO KIT for gastric and duodenal lesion resection. The study collected data on indications, resection sites, technical success rates, monobloc and R0 resection rates, and potential complications.

Results: Between 2022 and 2024, 17 patients from six French centers were included (6 men and 11 women, with a mean age of 58 years [35–75]). All procedures were performed under general anesthesia with intubation, CO_2 insufflation, and prophylactic antibiotic administration. The primary indication was submucosal lesions (SML) in 75% of cases (n=12), followed by adenomatous recurrence in 19% (n=3) (two after endoscopic mucosal resection and one after endoscopic submucosal dissection), and two atypical lesions (one polypoid and one pseudo-depressed) in 12.5% of cases. More than two-thirds of the lesions (n=12, 70%) were located in the duodenal bulb, while the remaining 30% (n=5) were in the stomach (four in the antrum and one in the fundus). The median lesion size was 20 mm [range: 10–25 mm]. The overall technical success rate was 94% (16/17 cases), with one failure due to an inability to pass through Killian's mouth in a patient previously irradiated for laryngeal cancer. No technical failures related to the FTRD Gastroset KIT or immediate complications were reported.

All resections were 'monobloc', with the FTRD KIT grasping forceps used in approximately 80% of cases and the Ovesco anchor (OTSC Anchor 165 mm) in two cases. Complete histologic resection (R0) was achieved in 94% of cases (n=15). Histopathological analysis showed that 50% of lesions were grade G1 neuroendocrine tumors (NETs) (n=8), 18.75% Brunner's gland hyperplasias (n=3), 18.75% fourth-layer submucosal tumors (duodenal leiomyoma, gastric GIST, hamartoma), and 12.5% adenomas with low-grade dysplasia (n=2). One R1 resection was observed for a NET in the fundus. The only postoperative complication was a delayed bleeding episode occurring 24 hours after the procedure.

Conclusion: Full-thickness resection using the FTRD Ovesco Gastroset system in the upper digestive tract demonstrated a high technical success rate (94%) and complete resection rate (94%) for 20 mm mucosal and submucosal lesions, with no major complications or mortality. Duodenal submucosal lesions were the most common indication, with neuroendocrine tumors (NETs) being the predominant histologic finding. The precise role of this technique in comparison to submucosal dissection and endoscopic mucosal resection remains to be determined.

FREQUENCY AND SEVERITY OF ADVERSE EVENTS ASSOCIATED WITH GASTRIC PERORAL ENDOSCOPIC MYOTOMY (G-POEM) – A RETROSPECTIVE ANALYSIS

D. Simkova[1], J. Mareš[2], M. Vašátko[1], K. Hugova[1], J. Martinek[3]
[1]Institute for Clinical and Experimental Medicine (IKEM), Department of Hepatogastroenterology, Prague, Czech Republic, [2]Institute for Clinical and Experimental Medicine, Prague, Department of Statistical Analyses, Prague, Czech Republic, [3]St. Anne's University Hospital, Department of Hepatogastroenterology, Brno, Czech Republic

Contact E-Mail Address: drazilovad@gmail.com
Introduction: Gastric peroral endoscopic myotomy (G-POEM) is an emerging endoscopic technique for the treatment of refractory gastroparesis, particularly benefiting patients with pylorospasm. It is considered a safe procedure with a low risk of adverse events when performed by experienced endoscopists.
Our aim was to perform a comprehensive analysis of all adverse events associated with G-POEM.
Aims & Methods: We performed a retrospective analysis of prospectively collected data from all patients who underwent G-POEM for gastroparesis at our centers (Prague, Brno) between November 2017 and April 2025. All procedures were performed by a single endoscopist (JM).
The primary outcome was procedure-related adverse events rate and severity occurring during the perioperative and early postoperative period. Adverse events were categorized as follows: deviations from the expected peri and postoperative course were defined as "undesirable events."
Undesirable events that met the criteria of the Clavien Dindo surgical classification (C-D) were considered "true adverse events".
Results: Out of 70 procedures, no true adverse or undesirable events occurred in 51 procedures (72.9%). Perioperatively, the following undesirable events occurred in 18 patients: : gastric (4; 5.7%) and duodenal mucosal injuries (2; 2.8%), major bleeding during the procedure treated endoscopically (1; 1.4%), serosal perforation (10; 14.3%), capnoperitoneum requiring puncture (3; 4.3%), and subcutaneous emphysema (1; 1.4%).
In the early postoperative period, adverse events occurred in 3 patients: one patient complained of significant abdominal pain necessitating analgetics, subsequently, a small leak from the pyloric region to the subhepatic region was described on CT and gastroscopy confirmed ulceration at the tunnel site.
The patient responded well to treatment with intravenous proton pump inhibitors. In two other cases, both involving patients with diabetic gastroparesis, decompensation of diabetes occurred during the hospital stay post-procedure.
The following "undesirable" events were considered true adverse events according to the C-D classification: serosal perforation (10; C-D I), leak requiring prolonged hospitalization (1; C-D IIIa) and diabetes decompensation (2; C-D II). These complications occurred in 13 procedures (18.6%).
The mean duration of hospitalization after the procedure was 2 days (range 1-7). Three months after the procedure, 1 patient developed mild dumping syndrome, which was successfully treated conservatively.
Conclusion: G-POEM is a safe procedure. The rate of true adverse events according to Clavien-Dindo classification is low and severe AEs occurs rarely.
Disclosure: Nothing to disclose.

ENDOSCOPIC SLEEVE GASTROPLASTY USING SINGLE-CHANNEL VS DOUBLE-CHANNEL SUTURING DEVICE: A MULTICENTER EXPERIENCE

R. Ravi[1], M. Chu[1], C.C. Liu[2], C.P. Francisco[3], R. Asokkumar[1,4]
[1]Singapore General Hospital, Singapore, Singapore, [2]New Delight Medical Clinic, Taichung, Taiwan, [3]St. Luke's Medical Center - Global City, Institute of Digestive and Liver Diseases, Taguig City, Philippines, [4]Duke-NUS Graduate Medical School, Singapore, Singapore

Contact E-Mail Address: r.rajesh@singhealth.com.sg
Introduction: Endoscopic sleeve gastroplasty (ESG) is an effective treatment for obesity. The conventional endoscopic suturing device requires a double channel endoscope. Recently, a novel single-channel suturing device (Apollo Overstitch Sx) has become available, potentially expanding the accessibility and ease of ESG procedures. However, comparative data evaluating the efficacy and safety of these two devices remain limited.
This multicenter study aims to assess and compare the clinical outcomes and safety profiles of the conventional double-channel versus the novel single-channel suturing devices in patients undergoing ESG.
Aims & Methods: We reviewed the records of 236 patients who underwent ESG at Singapore General Hospital, Singapore and New Delight Medical Clinic, Taiwan between November 2020 to March 2024. Our primary outcome was technical feasibility comprising of procedural time, number of sutures and safety. Our secondary outcome was to determine percentage total body weight loss (TBWL%) at 12 months.
Results: The study population had a mean age of 39.8 ± 8.8 years and a mean BMI of 32.9 ± 6.0 kg/m^2. The majority of patients were female (73.5%, n = 175) and of Chinese ethnicity (78.4%). In terms of treatment, 138 patients underwent suturing using a single-channel device, while 77 patients received treatment with a conventional dual-channel device. Using propensity score matching, patients were matched 1:1 based on age and initial BMI for comparative analysis. The mean procedure time was comparable between the dual channel device at 63.2 ± 11.8 mins vs. the single channel device which was 64.8 ± 5.0 mins (mean difference 1.6mins, p>0.05). However, the single-channel device resulted in a lower mean number of sutures (4.5 ± 0.5 vs. 5.1 ± 0.9; mean difference 0.6 sutures, p < 0.001). There were no statistically significant differences in post-ESG complications, including bleeding, abdominal pain, and vomiting.
At 6 months, there was no significant difference in TBWL% between the dual-channel ESG vs single channel (14.7 ± 6.0% vs. 16.2 ± 5.2%; mean difference 1.4%, p >0.05). However at 1 year, the dual-channel ESG group had a higher %TBWL (13.4 ± 7.6% vs. 7.9 ± 9.0%; mean difference 5.6%, p < 0.001), although this could be confounded by loss to follow-up in the dual-channel group.
Conclusion: While the single-channel device showed a significant reduction in the number of sutures required, the dual-channel device resulted in a higher percentage of total body weight loss at 1 year. However, this finding may be confounded by differences in follow-up rates between the two groups. Further studies are needed to confirm these findings and establish the long-term efficacy and safety of these devices.
Disclosure: Dr. Asokkumar is a consultant for Apollo Endosurgery, USA.

PP0193

NAVIGATING SELF-EXPANDABLE METALLIC STENT PLACEMENT IN INOPERABLE ESOPHAGEAL MALIGNANCIES: A LANDMARK-BASED TECHNIQUE USING VERTEBRAL COLUMN AND DIAPHRAGM

M. Siyal[1], S.k. Niaz[1]
[1]SIAG, Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: drmehreensiyal@gmail.com

Introduction: Self-expandable metallic stent (SEMS) placement is a palliative treatment for inoperable esophageal malignancies to improve the quality of life. Traditional methods rely on fluoroscopy and endoscopy, but anatomical landmarks can simplify the procedure.

Aims & Methods: To evaluate the technical success, safety and reproducibility of using vertebral column and diaphragm landmarks for SEMS placement.

This retrospective observational study included 801 patients with inoperable esophageal malignancies undergoing SEMS placement for dysphagia due to malignant esophageal strictures, by using vertebral column and diaphragm as landmarks, from 1st January 2006 to 31st December 2024. The primary endpoint was to assess the technical success, safety and reproducibility of this unique technique for SEMS placement.

Methodology for Stent Placement in Esophageal Tumors:

1. For Proximal or Mid-Esophageal Tumor, following algorithm was followed:

Step 1: Identify key anatomical landmarks using fluoroscopy.

Step 2: With the scope in place, under fluoroscopic guidance, identify the vertebra in line with the distal extent of the tumor using the diaphragm as a reference, followed by identification of vertebra at the proximal extent of the tumor. Count the vertebrae between the distal and proximal extent of the tumor. Assign a length of 2.5 cm per vertebral body. Ascertain the desired size of SEMS by calculating the total length of the stricture by counting the vertebrae, adding one vertebral body above and below the tumor for proper stent placement. Step 3: Using fluoroscopy, position the stent. Place the distal end of the stent at the distal vertebral marker. Position the proximal end of the stent at the proximal vertebral marker. Release the stent at the appropriate position to ensure full coverage of the stricture.

2. For Tumor Extending Beyond the Gastro-Esophageal Junction (GEJ), following algorithm was followed:

Step 1: Identify the proximal extent of the tumor. Align the proximal extent of the tumor with the vertebra, using the diaphragm as a reference for precise alignment. Measure the distance from the proximal end of the tumor to the proximal stomach using the scope to decide the required size of the stent.

Step 2: Place the stent under fluoroscopic guidance. Position the upper end of the stent at the identified vertebra. Extend the distal end of the stent into the stomach, past the GE junction to ensure proper coverage. Release the stent.

Results: 408 (50.9%) patients were females. The age range was 18-95 years (mean50±Standard deviation15). Predominant presenting complaint was dysphagia (85.39%). Average duration of dysphagia was 3.84 months. 594 (74.16%) patients had squamous cell carcinoma, whereas 207 (25.84%) patients were diagnosed with adenocarcinoma on histopathology. 365 (45.57%) patients had tumor confined to the lower one-third of esophagus. Major cause of inoperability was distant metastasis (52.81%). 240 (30%) patients had involvement of GEJ. Average length of malignant stricture was 8.4 cm. 139 (17.40%) patients required dilatation by using savary gilliard dilators before SEMS placement. TEF was present in 48 (6%) patients. Range of length of SEMS was 8-18 cm (12.5±2.26). Technical success was achieved in 100% cases. No major immediate complications occurred. Minor complications were rare.

Conclusion: Using vertebral column and diaphragm landmarks is a reliable, safe, simplified and reproducible approach for SEMS placement in patients with inoperable esopahgeal malignancies.

EFFECT OF ENDOSCOPIC PYLOROMYOTOMY (G-POEM) IN PATIENTS WITH GASTROPARESIS ON GASTRIC EMPTYING

K. Pirgl[1], M. Buncová[1], J. Martinek[2], J. Mareš[3]
[1]Institute for Clinical and Experimental Medicine, Radiodiagnostic and Interventional Radiology Department - Nuclear Medicine, Prague, Czech Republic, [2]St. Anne's Faculty Hospital, Department of Gastroenterology and Hepatology, Brno, Czech Republic, [3]Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Contact E-Mail Address: karin.pirgl@gmail.com

Introduction: Gastroparesis (GP) is defined as symptomatic delayed gastric emptying. The most frequent etiologies are diabetes mellitus, after esophageal or gastric surgery and about a third of patients have idiopathic GP. The gastric emptying study by using a scintigraphy scintigraphy (GES) is considered as a principal diagnostic method.

Endoscopic pyloromyotomy (G-POEM) is a method improving symptoms in about 60-70% of patients with GP. Its effect on gastric emptying remains controversial.

Aims & Methods: We performed a retrospective single-center analysis to assess the clinical efficicacy of G-POEM based on GES parameters. Between 2016 – 2024, a total of 72 patients with GP (confirmed by scintigraphy) underwent G-POEM and were later invited for clinical as well as scintigraphic assessment after 3, 12 and 36 months.

Of these patients, 4 were excluded for missing data, incomplete follow-up data or non-standard testing meal. GES was always performed using the standardized 4 hours protocol with the standard testing meal mixed with 99Tc-DTPA.

For this study, all GES were reanalyzed and the following parameters were established : residual activity after 2 hours, residual activity after 4 hours, biological halftimes of ingested activity and proximal-to-distal count ratio for time 0 (PDCR0).

Results: Mean value of GCSI before G-POEM was 3.1 and decreased to 1.6, 1.0 and 0.7 after 3, 12 and 36 months. Median value of GES after 2 hours was 60.2% before G-POEM and 38%, 32.6% and 24.2% after 3, 12 and 36 months. Median value of GES after 4 hours was 21.9% before G-POEM and 7.8%, 6.5% and 3.9% after 3, 12 and 36 months. Correlation index was weakly positive for GCSI and GES after 4 hours only for the first follow-up visit and negative for all remaining visits.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The residual activity after 2 hours and residual activity after 4 hours decreased after G-POEM during all follow-up visits (p<0,001). Mean decrease of residual activity after 4 hours was 12.89%, 15.13% and 6.7% after 3, 12 and 36 months.
Biological halftime also decreased after the procedure with statistically significant results with the mean halftime before G-POEM being 150 min and 86 min, 78.4 min and 65.8 min after 3, 12 and 36 months.
There was a difference between the diabetic and non-diabetic groups, with higher residual activity after 2 hours [median 29.6% before G-POEM, 9.0% after 3 months (p<0.001) and 11.0% after 12 months (p=0.005)] and 4 hours [median 64.8% before G-POEM, 39.4% after 3 months (p<0.001) and 37.7% after 12 months (p=0.012)] respectively in patients with diabetes.
The predictive value of PDCR0 for treatment success after G-POEM was only calculated for the first follow-up visit but was not statistically proved (p=0,712).
Conclusion: In our group of patients there is a weak correlation between the decrease of GCSI and GES early after G-POEM. The decrease in GES parameters tends to be lower in patients with diabetes compared to non-diabetic patients. Based on our data, predicting clinical success of G-POEM using PDCR0 cannot be recommended.
Disclosure: Nothing to disclose.

Contact E-Mail Address: giuseppegrande1984@gmail.com
Introduction: Nowadays, endoscopic treatment for esophageal Zenker's diverticulum is considered the standard of care, with flexible endoscopic septotomy (FES) being the first technique to be widely adopted. Since 2016, submucosal tunneling Per-Oral Endoscopic Myotomy (Z-POEM) has emerged as an innovative therapeutic approach. However, medium-term efficacy comparisons between Z-POEM and FESremain limited.
Aims & Methods: The aim of this study was to compare the clinical success and safety of Z-POEM and FES.
This study was a retrospective analysis of a large group of patients treated for Zenker's diverticulum across two tertiary care centers. The patients were divided into two groups: those who underwent Z-POEM between 2021 and 2024, and those who underwent FES between 2008 and 2024. Demographic and clinical data, including Charlson Comorbidity Index, Kothari scores, clinical success rates, adverse events, and follow-up duration, were analyzed and compared among the two groups.
Results: Treatment in the study period. Of these, 32 patients (mean age 66.8 ± 10.7 years) underwent Z-POEM, while 34 patients (mean age 73.5 ± 10.2 years) underwent FES. The mean Charlson Comorbidity Index was similar between groups (Z-POEM: 3.28 ± 1.80 vs. FES: 3.4 ± 1.6; p = 0.708). The pre-procedural Kothari-Haber score was comparable (mean 7.3 ± 1.4 for Z-POEM vs. 7.3 ± 1.1 for FES; p= 0.981). The post-procedural Kothari-Haber score was significantly lower in the ZPOEM group (1.3 ± 1.3) compared to the FES group (2.7 ± 2.8; p = 0.010), indicating better symptom resolution. The median follow-up period was 37.7 months (IQR: 14.8 – 74.6 months) for the FES group and 12.2 months (IQR: 7.4 – 21.9 months) for the Z-POEM group (p < 0.0001).
Technical success was achieved in 100% in both groups. Clinical success was significantly higher in the Z-POEM group (93.8%; 95% CI: 75% - 99%) compared to the FES group (64.5%; 95% CI: 50% - 82%; p= 0.005). The rate of adverse events was lower in the Z-POEM group (6.25%) compared to the FES group (23.53%), however this difference did not reach statistical significance (p= 0.084).
Conclusion: This multicenter retrospective study suggests that Z-POEM is an effective and safe alternative to FES for the treatment of Zenker's diverticulum. The Z-POEM technique demonstrated a significantly higher clinical success rate and a trend towards fewer adverse events. Of particular interest, no differences in terms of efficacy and adverse events were observed between the first 10 patients (during the learning curve) treated with Z-POEM and those treated thereafter. It should be noted that although the follow-up period for Z-POEM was generally shorter, no recurrence of symptoms was observed even in patients with longer follow-up durations. These findings support the use of Z-POEM as a viable and effective approach, warranting further investigation in larger multicenter cohorts to confirm its advantages.

REDUCING RELAPSE RATES IN C. DIFFICILE: IS FIDAXOMICIN THE BETTER OPTION?

D. Kyriakides[1], J. Cleaver[1], A. Ochieng[1]
[1]Norfolk and Norwich University Hospital, Gastroenterology, Norfolk, United Kingdom

Contact E-Mail Address: demetra.kyriakides@nnuh.nhs.uk

Introduction: *Clostridioides difficile* infection (CDI) is the leading cause of hospital-acquired infectious diarrhoea in adults and is associated with significant morbidity and mortality[1,2].

A review by Mitchell and Gardner[3] showed all-cause mortality of up to 30% in the first 30 days of contracting CDI. According to the European Society of Clinical Microbiology and Infectious Disease 'the most important problem in treating CDI is the high recurrence rate', with up to 25% having a recurrence of C. diff, and 40-65% of those patients going on to have a second recurrence[4].

As per NICE guidelines, vancomycin is currently the first line treatment for CDI with fidaxomicin reserved for relapses and recurrences[5].

Aims & Methods: Objective: To determine to what extent Fidaxomicin is superior to Vancomycin in reducing relapse of CDI.

Methods: A retrospective audit was conducted on 464 adult community and inpatients with CDI at the Norfolk and Norwich University Hospital from the 1/6/23 to 1/6/24. Data collection included patient demographics, episodes of CDI, treatment response and risk factors such as immunosuppression. A relapse is defined as a repeat episode of CDI occurring within 12 weeks of previous symptom resolution, while a recurrence is an episode occurring after 12 weeks.

Results: In total, 464 patients who had a positive C diff. toxin gene result were reviewed. Excluded were 103 patients who were not given antibiotics, 72 patients who no information was available and 14 who received an alternative antibiotic, e.g. metronidazole. 221 patients received vancomycin and 54 received fidaxomicin. 4/54 patients who received fidaxomicin went on to relapse (7.4%), one of which subsequently had extended pulsed fidaxomicin. 50/221 receiving vancomycin had a relapse (22.6%). The odds ratio for relapse rate of vancomycin versus fidaxomicin was 3.65, 95% CI 1.26 to 10.61. A student t-test result was 3.33 with p-value 0.0011.

Conclusion: The data shows a significantly lower relapse rate in high-risk patients treated with fidaxomicin compared to vancomycin for CDI. Reconsideration of first line therapy for high-risk patients with continuing care under the MDT team, for example at the Norfolk and Norwich University Hospital during the C. Diff ward round, is essential to ensure appropriate treatment is offered.

PROXIMAL OESOPHAGEAL STRICTURES OF UNKNOWN AETIOLOGY - IS CANDIDA ALBICANS THE CAUSE?

H. Walton[1], M. Hussein[1], J.M. Dunn[1], S.S. Zeki[1]
[1]Guy's and St Thomas' Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: h.walton901@gmail.com

Introduction: Proximal oesophageal strictures are less common than distal oesophageal strictures, but can share an aetiology such as eosinophilic or peptic. However, often proximal oesophageal strictures have an unclear aetiology. This results in symptomatic treatment with dilatation, without treatment of the underlying causative factor to prevent further stricture formation. We hypothesised that most proximal oesophageal strictures without a clear aetiology may be secondary to *Candida* oesophagitis.

Aims & Methods: The aim was to determine the cause of proximal oesophageal strictures of unclear aetiology, and examine the outcomes of medical and endoscopic treatment. Retrospective analysis was performed to identify all cases of proximal oesophageal stricture (≤30cm from incisors) without clear aetiology at Guy's and St. Thomas' Trust from 2007 to 2024. Procedures were extracted from the electronic endoscopy database using the keyword 'dilat'. Patients with Barrett's oesophagus, Schatzki ring, eosinophilic oesophagitis, anastomotic stricture, radiofrequency ablation, peptic stricture, oesophagectomy, chemo/radiotherapy, Crohn's disease, achalasia or caustic ingestion were excluded. Oesophageal histopathology taken at any point was assessed for candidiasis. Data collected included demographics, clinical presentation, endoscopic findings, histopathology results, medical and endoscopic treatment and outcomes.

Results: Between 2007 and 2024, 19 patients were identified with a proximal oesophageal stricture without an alternative aetiology. All patients had *Candida* oesophagitis at either at presentation with the stricture or predating it. The mean age at presentation was 57 years (range 40-80, 95% CI ±5.7) and 78.9% of patients were male. Eight patients (42.1%) were immunocompetent and not prescribed immunosuppressant drugs e.g. corticosteroids.

All strictures were between 15 and 30cm from the incisors (median 24cm). Only two strictures were passable with a standard endoscope, and thus were not dilated. Histopathology of the strictures confirmed no eosinophilia. The most common finding on histopathology was lymphocytic inflammation. On average, each patient had 2 balloon dilatations performed (range 0-12). Following treatment with antifungals and dilatation, 53.3% of patients had resolution of the stricture, 31.3% had ongoing *Candida* plus a stricture, 13.3% had a stricture without *Candida* present. Patients with failure of anti-fungal therapy to treat *Candida* had an increased number of dilatations required.

Age (average)	**58.7**
Male	78.9% (n=15)
Immunosuppressive Conditions	
Asthma/COPD	15.7% (n=3)
Diabetes	26.3% (n=5)
Chronic Mucocutaneous Candidiasis	10.5% (n=2)
Histopathology findings	
Lymphocytosis	63.2% (n=12)
Microabscesses	10.5% (n=2)
Received anti-fungal therapy	94.7% (n=18)
Dilatation performed	84.2% (n=16)
Median number of dilatations required	2

Table 1. Patient demographics and results.

Conclusion: In conclusion, this case series of 19 patients shows that proximal oesophageal strictures due to *Candida* are more common than previously thought. At our centre, all patients with a proximal stricture of

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

unknown cause had oesophageal candidiasis. Where a clear alternative cause has not been identified, *Candida* should be considered, even in patients who are immunocompetent.

Anti-fungal therapy is essential to remove the underlying causative factor, and approximately half of patients will have resolution of their stricture following dilatation once *Candida* has been treated.

Patients who did not have resolution of *Candida* with antifungals were more likely to require a higher number of dilatations.

CLINICAL UTILITY OF SCORING SYSTEMS IN UPPER GASTROINTESTINAL BLEEDING: A PRE- AND POST-TEST PROBABILITY ANALYSIS FOR MORTALITY AND NEED FOR INTERVENTION

R. Jiménez-Rosales[1], F. Valverde-López[1], R. Fernandez Garcia[1], A. Lancho Munoz[1], M. López-Vico[1], E.J. Ortega-Suazo[1], J.M. Lopez Tobaruela[1], J.G. Martínez-Cara[1], E. Redondo-Cerezo[1]
[1]Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Upper gastrointestinal bleeding(UGIB) is a common condition that entails morbidity and mortality. Therefore, an early prediction of negative outcomes would be clinically relevant selecting patients who might benefit from a closer follow up. In this way, several pre-endoscopic scoring systems have been developed for risk assessment in the emergency room(1).

One of the limitations of scoring systems is that sensitivity and specificity alone (usually combined in the receiver operator characteristic curve) may help comparing the accuracy of different systems but cannot be used to accurately estimate the probability for an individual patient.

A more appropriate approach is to establish the post-test probability considering the expected pre-test probability of poor outcomes in the population(2).

Aims & Methods: Given the absence of previous similar studies in UGIB, we aim to investigate the role of the most common pre-endoscopy scoring systems in modifying the pre-test probability of adverse outcomes.

Retrospective analysis of a prospective registry of UGIB patients admitted to 'Virgen de las Nieves University Hospital' (2013-2024). The outcomes included were intervention (composite endpoint including need of transfusion, endoscopy therapy, interventional radiology or surgery) and in-hospital mortality.

Pre-endoscopy scores analyzed were MAPASH,ABC and GBS as they have demonstrated their utility in predicting adverse events. The thresholds used for the definition of low-risk patients(test negative) were ABC≤3,MAPASH≤2 and GBS≤1(3).

First, the prevalence of the main outcomes was calculated to obtain the pre-test probability. Next, characteristics of different scoring systems were used to obtain the likelihood ratio (LR) and to estimate the post-test probability using an online calculator (http://araw.mede.uic.edu/cgi-bin/testcalc.pl).

Results: 1649 UGIB patients were included.

Prevalence of intervention(pre-test probability) was 75%.

The sensitivity and specificity of MAPASH were 71.4% and 78.4%,respectively. +LR and -LR 3.31 and 0.36,respectively. Post-test probability was 91% when positive and 52% when negative.

The sensitivity and specificity of ABC were 68.1% and 66.8%,respectively. +LR and -LR 2.05 and 0.48,respectively. Post-test probability was 86% when positive and 59% when negative.

The sensitivity and specificity of GBS were 98.8% and 8.7%,respectively. +LR and -LR 1.08 and 0.14,respectively. Post-test probability was 76% when positive and 29% when negative.

Prevalence of in-hospital mortality (pre-test probability) was 11%.

The sensitivity and specificity of MAPASH were 90.1% and 44.8%, respectively. +LR and -LR 1.63 and 0.22,respectively. Post-test probability was 17% when positive and 3% when negative.

The sensitivity and specificity of ABC were 95.9% and 44.8%,respectively. +LR and -LR 1.74 and 0.09,respectively. Post-test probability was 18% when positive and 1% when negative.

The sensitivity and specificity of GBS were 99.4% and 3.6%,respectively. +LR and -LR 1.03 and 0.17, respectively. Post-test probability was 11% when positive and 2% when negative.

Conclusion: While MAPASH and ABC effectively prioritize high-risk patients for intervention, their ability to rule out intervention in low-risk patients is limited. Additionally, they are more useful excluding mortality among low-risk patients than accurately predicting fatal outcomes. GBS,in contrast, are useful identifying low risk patients for intervention and mortality.

Given these findings, clinicians should interpret these scores with caution and incorporate additional clinical parameters into decision-making.

PROSPECTIVE COMPARISON OF ROCKALL, GLASGOW BLATCHFORD AND AIMS65 RISK SCORING SYSTEMS IN PATIENTS PRESENTING WITH UPPER GASTROINTESTINAL BLEEDING: PERFORMANCE IN PREDICTING CLINICAL OUTCOMES IN A LOW-RESOURCED SETTING

K.N. Adu-Darko[1], S. Gyabaah[1], T.A. Laryea[1], A.K. Dapaah[1], O.Y. Asamoah[1], E. Micah[1], B. Oppong[1]
[1]Komfo Anokye Teaching Hospital, Medicine, Kumasi, Ghana

Introduction: Upper gastrointestinal bleeding is one of the common medical emergencies which is associated with significant morbidity, mortality, and resource utilization.(1)

This burden is compounded in resource-poor settings, where patients often pay out-of-pocket for care, thereby hampering appropriate early diagnosis to determine the location and severity of bleeding.(2)

Effective management requires risk stratification of patients into low or high-risk groups to guide subsequent treatment and follow-up.(3)

The Rockall Score, Glasgow Blatchford Score and recently, the AIMS65 score are widely used and have been validated to predict outcomes in several studies. (4)

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: We aim to compare the performance of the Rockall score, Glasgow Blatchford Score and AIMS65 score in predicting outcomes among patients with upper gastrointestinal bleeding. This was a single-centre prospective study among 195 patients who presented with symptoms of UGIB at the Emergency department of a tertiary hospital in Ghana from May 2022 to April 2023. The relevant baseline clinical characteristics, Glasgow Blatchford and AIMS65 scores were obtained. The Rockall score and the cause of UGIB was determined as per findings at upper gastrointestinal endoscopy. Patients were followed up for 6 weeks from admission looking out for primary outcomes of need for transfusion, rebleeding and mortality. Receiver operating characteristic curve analysis was performed to assess the ability of each risk score to predict primary outcomes.

Results: There were 195 patients in this study, 145 (74.4%) were males, the mean age (SD) was 51.4 (17.4) years and 68 (34.9%) had variceal bleeding. The 6-week mortality was 34 (17.4%), rebleeding occurred in 14 (7.2%) and 138 (70.8%) received blood transfusion.

Rockall score (area under the curve (AUC) 0.83, 95% confidence interval (CI), 0.76-0.88, p<0.001) was superior in predicting 6-week mortality compared to AIMS65 score (AUC 0.72, 95% CI, 0.63-0.81, p<0.001) and Glasgow Blatchford score (AUC 0.71, 95% CI, 0.61-0.82, p<0.001). The need for transfusion was best predicted by the Glasgow Blatchford score (AUC 0.77, 95% CI 0.70-0.85, p<0.001) compared to the AIMS65 score (AUC 0.66, 95% CI, 0.57-0.74, p<0.001) and Rockall score (AUC 0.77, 95% CI 0.57-0.75, p <0.001). Only Rockall score (AUC 0.71, 95% CI, 0.60-0.83, p<0.001) showed significance in predicting rebleeding.

Outcome	Risk score	AUC	p-value	95% CI
6-week Mortality	Rockall	0.83	<0.001	0.77-0.88
	Glasgow Blatchford	0.71	<0.001	0.61-0.82
	AIMS65	0.72	<0.001	0.63-0.81
Need for transfusion	Rockall	0.66	<0.001	0.57-0.75
	Glasgow Blatchford	0.77	<0.001	0.70-0.85
	AIMS65	0.66	<0.001	0.57-0.75
6- week Rebleeding	Rockall	0.71	<0.001	0.60-0.83
	Glasgow Blatchford	0.53	0.659	0.39-0.68
	AIMS65	0.56	0.455	0.40-0.72

Conclusion: Although the endoscopy dependent Rockall score has the highest accuracy in predicting mortality, non-endoscopy dependent Glasgow Blatchford and AIMS65 scores, which are derived from readily available clinical and laboratory parameters, were found to be significant in predicting mortality and will be useful in a low resource setting. Glasgow Blatchford score has the best accuracy for predicting the need for transfusion compared to Rockall and AIMS65 scores. Only Rockall score was useful in predicting 6-week rebleeding among all the three risk scoring systems.

Contact E-Mail Address: he191247@health.wa.gov.au

Introduction: Non-variceal upper gastrointestinal bleeding (NVUGIB) is a frequent emergency, with a 30-day mortality rate nearing 10%.[1] Although several studies[2-4] have shown the mortality benefits of a specialized pre- and post-endoscopy care model within a Hematemesis and Melaena (H&M) unit, this data is outdated, and the model is resource-intensive. Many hospitals now use a ‚shared care' approach, involving both gastroenterology and general medicine for pre-endoscopy management and referral for specialized care post-procedure.

Our study aimed to evaluate the impact of a dedicated H&M Unit on the 30-day mortality rate and morbidity, in NVUGIB patients.

Aims & Methods: A retrospective case-control study was conducted with patients admitted for NVUGIB from April to October 2024 at two tertiary hospitals in Western Australia. One hospital, referred to as Hospital #1 (“H-1”), served as the control group, providing pre-endoscopy care through the general medicine unit with specialist gastroenterology input, while the gastroenterology team managed post-endoscopy care. The other hospital, referred to as Hospital #2 (“H-2”), served as the case group and managed both pre- and post-endoscopy care through a dedicated specialist H&M Unit. The study comprised consecutive adult patients aged 16 years and above, with endoscopically confirmed NVUGIB who presented with haematemesis and/or melaena. Patients were excluded if they experienced variceal bleeding or if their NVUGIB occurred during hospitalization for another medical condition. The primary outcome measured was 30-day mortality. Secondary outcomes included: a) time to endoscopy, b) total hospital length of stay (LOS) related to the index bleed and any rebleeds, c) the proportion of patients requiring laparotomy, and d) the total number of packed red blood cell (PRBC) units transfused for the index and any subsequent rebleeds.

Results: The preliminary analysis included 317 patients: 211 (66.6%) from H-1 and 106 (33.4%) from H-2. Patients from H-1 were significantly older [median age (IQR): 73 (62-79) vs 66 (50-76) yrs, p=0.002], had a higher median Glasgow-Blatchford Score (GBS) [9 (7-12) vs 8 (6-10), p <0.001] and a numerically higher median Charlson's Comorbidity Index (CCI) [(5 (3-7) vs 4 (1.8-6), p = 0.173]. Anticoagulation and NSAID use were similar between the two groups. The unadjusted 30-day mortality rate was higher in H-1 compared to H-2 (3.8% vs. 2.8%, p= 0.04); however, after adjusting for age, gender, CCI, GBS, and time to endoscopy by logistic regression analysis, the difference was no longer significant (p = 0.9). The median time to endoscopy was longer in H-1 compared to H-2 [25.4 hours (17.6-43.8) vs 15.3 hours (8.1-21.7), p < 0.001), with a lower percentage of patients undergoing the procedure within 24 hours (47.9%, vs 83% vs. p < 0.001). The total number of PRBC units transfused was numerically higher in H-1 compared to H-2 [2 (0-3) vs 1 (0-2) unit vs. p = 0.056]. There were numerically more emergency laparotomies in H-1 compared to H-2 [4 (1.9%) vs. 0 (0%), p = 0.15). The median LOS was not significantly different between the two groups [3.8 days (2.4-6.1) vs. 3.6 days (2.4-5.6), p = 0.42].

Conclusion: While the 30-day mortality rate was comparable between the two hospitals, patients from the H&M unit showed lower morbidity, including a reduced transfusion requirement and fewer emergency lapa-

CLINICAL IMPACT OF BRIDGING WITH LOW-MOLECULAR-WEIGHT HEPARIN VS. DIRECT RESUMPTION OF ORAL ANTICOAGULANTS IN UPPER GASTROINTESTINAL BLEEDING

R. Fernandez[1], M. López-Vico[1], A. Lancho Munoz[1], E.J. Ortega-Suazo[1], J.M. Lopez Tobaruela[1], J.G. Martínez-Cara[1], R. Jiménez-Rosales[1], E. Redondo-Cerezo[1]
[1]Hospital Virgen de las Nieves, Department of Gastroenterology and Hepatology, Granada, Spain

Contact E-Mail Address: fernandezhuvn@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the most common digestive disorders. The use of anticoagulants is a risk factor for UGIB, with a relative risk of 1.45. Withdrawal and timing of reintroduction remain controversial [1]. Early reintroduction of anticoagulation has been associated with a reduction in thromboembolic events, although it carries an increased risk of rebleeding within the first three months [2].

A common clinical practice is to restart anticoagulation with low-molecular-weight heparin (LMWH) as a bridge to the patient's regular anticoagulant therapy, especially in hospitalized patients, in order to reintroduce anticoagulation earlier and reduce thrombotic events. However, evidence for this approach is limited. One study, which included patients with both upper and lower gastrointestinal bleeding, suggested that LMWH use increased the risk of rebleeding without affecting the rate of thromboembolic events [3]. Therefore, uncertainties remain as to whether reintroduction of LMWH prevents thromboembolic events in this setting and its role in rebleeding rates.

The aim of this study is to compare the effect of bridging with LMWH before resuming the patient's usual anticoagulation versus its direct reintroduction in anticoagulated patients with UGIB.

Aims & Methods: This retrospective analysis of a prospective registry includes UGIB patients admitted to Hospital Universitario Virgen de las Nieves (2013–2023). Of 1517 patients, we selected those on anticoagulants whose treatment was suspended upon admission. Outcomes analyzed included in-hospital and 6-month delayed ones. Statistical analysis was performed using SPSS 26.

Results: A total of 244 patients were included. Group 1 (n=98) consisted of patients who resumed oral anticoagulation directly, while Group 2 (n=146) included those who initially received LMWH. The mean age was 74 years in both groups. Group 2 had a higher proportion of male patients (63.7% vs. 56.7%), although this difference was not statistically significant. Anticoagulation therapy was reintroduced earlier (3,9 vs 2,8-day, p=0,086) with a higher reintroduction rate in the first 24 hours in Group 2 (35,7% vs 56,2%, p=0,002). No differences were found in the other baseline characteristics.

Regarding outcomes, no significant differences were found in acute or delayed mortality, neither in delayed thromboembolic events. However, delayed bleeding (including gastrointestinal) was higher in Group 2 (31.7% vs. 13.7%, p=0.002). Other outcomes are in Table 1.

Multivariate analysis of hemorrhagic events within the first six months identified LMWH therapy, as the only independent risk factor (OR 2.18; p=0.013).

A subgroup analysis of high-thrombotic-risk patients (CHA_2DS_2-VASc ≥4) showed no benefit from LMWH as bridging therapy.

Variable	Group 1	Group 2	P
Rebleeding	10 (10,3%)	12 (8,2%)	0,578
In-Hospital Mortality	6 (6,4%)	5 (3,4%)	0,290
Not bleeding mortality	4 (66,7%)	3 (66 %)	0,299
Delayed Mortality at 6 months	11 (11,7%)	21 (14,6%)	0,524
Thromboembolic events 6 months	15 (15,8%)	26 (18,2%)	0,632
Haemorrhagic events 6 month	13 (13,7%)	45 (31,7%)	0,002

Table 1: In.Hospital and delayed outcomes.

Conclusion: Although LMWH bridging therapy allows for earlier anticoagulation resumption, it did not reduce mortality or thromboembolic event rates in anticoagulated patients with UGIB. However, it may increase the mid-term bleeding rate, suggesting that routine use of LMWH after suspending baseline anticoagulation in UGIB should be reconsidered.

PP0202

COMPARING THE EFFECT OF ESOMEPRAZOLE OR FAMOTIDINE ON PREVENTION OF BLEEDING AFTER SUBMUCOSAL ENDOSCOPIC DISSECTION OF EARLY GASTRIC CANCER IN A REFERRED GASTROINTESTINAL CENTER IN BRAZIL

S. Vaiciunas[1], K. Nocrato Loiola Vaiciunas[2], B. Loiola Vaiciunas[3]
[1]Afya - Sao Lucas Medical School, Gastroenterology, Porto Velho, Brazil, [2]University of Sao Paulo - UNIFESP, Sao Paulo, Brazil, [3]Windermere Prep School, Windermere, United States of America

Contact E-Mail Address: spencervaiciunas@hotmail.com

Introduction: With conventional methods of endoscopic mucosal resection for early gastric cancer (EGC), proton pump inhibitors (PPI) and H2 receptor antagonists (H2RA) have a similar effect on preventing bleeding from artificial ulcers

Aims & Methods: To investigate whether PPI more effectively prevent bleeding after recent advanced technique of endoscopic submucosal dissection (ESD) for EGC.

A prospective randomized controlled trial study, from january 2016 to february 2025 was performed in referred Gastrointestinal Diseases Hospital in Brazil . A total of 286 patients with EGC who underwent ESD. Intervensions: After stratification by tumor size (i.e. ≤2 cm or >2 cm) and H. pylori status, they were randomly assigned to treatment groups. They received either esomeprazole 40 mg (PPI group) or famotidine 40 mg (H2RA group) on the day before ESD and continued for 6 weeks.

Main outcome measurements: Primary endpoint was incidence of bleeding that was defined as haematemesis or melaena that required endoscopic haemostasis and decreased the haemoglobin count by more than 2g dL. To elucidate independent treatment effects and to identify prognostic factors for bleeding after ESD multivariate analysis was performed for candidate covariates including the stratification factors, age, sex, smoking, NSAIDs use in the past 5 days history of peptic ulcer, endoscopist, number of tumors, location of main tumor, and scar in main tumor.

Results: The history of peptic ulcer and the endoscopists who performed the ESD were significantly different between the groups. Finally, 132 of 146 patients in the PPI group and 128 of 140 in the H2RA groupwere analysed. Bleeding occurred in 8 patients in the PPI group and 22 in the H2RA group (p = 0.057).

Multivariate analysis revealed that the treatment with PPI significantly reduced the risk of bleeding adjusted hazard ratio 0.51, 95% C.I. 0,25 to 0.96, p = 0.037. Tumor size exceeded 3 cm and scar in the main tumor were the independent predictor for the bleeding. Three delayed perforation was experienced in the H2RA group

Conclusion: PPI therapy more effectively prevented delayed bleeding from the ulcer created after ESD than did H2RA treatment

Disclosure: Nothing to disclose.

ARGON PLASMA COAGULATION FOR TREATING HIGH-RISK ENDOSCOPIC STIGMATA OF PEPTIC ULCER BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

K. Sharif[1], M. Omar[2], A. Lahat[3], Y. Patt[2], O. Ukashi[2], I.M. Gralnek[4]
[1]St James University Hospital, Department of Gastroenterology, Leeds, United Kingdom, [2]Sheba Medical Centre, Department of Gastroenterology, Ramat Gan, Israel, [3]Assuta Medical Centre, Dept. of Gastroenterology, Ashdod, Israel, [4]Ha'Emek Medical Center, Gastroenterology, Haifa, Israel

Contact E-Mail Address: kassemsharif@gmail.com

Introduction: Endoscopic hemostasis is first-line therapy in managing peptic ulcer bleeding (PUB) with high-risk stigmata (Forrest classification Ia, Ib, IIa). While argon plasma coagulation (APC) is widely available and easy to use, there are limited studies with a limited number of patients evaluating its efficacy in PUB. This meta-analysis evaluates the effectiveness of APC in high risk PUB in achieving initial hemostasis and preventing rebleeding.

Aims & Methods: We performed a systematic literature search of PubMed, Embase, Web of Science, and Scopus to identify studies up to October 2024, evaluating APC versus alternative endoscopic hemostasis modalities for high-risk PUB. Eligible studies included those reporting on initial hemostasis and rebleeding outcomes. Two reviewers (KS, MO) independently screened studies and extracted data, resolving discrepancies by consensus. Quality assessments were conducted using the Cochrane Risk of Bias Tool for RCTs and the Newcastle-Ottawa Scale for observational studies. Odds ratios (ORs) and 95% confidence intervals (CIs) were pooled using a random-effects model to account for study heterogeneity, quantified by I^2 statistics.

Results: Fourteen studies met inclusion criteria (7 observational and 7 RCTs), with pooled sample sizes of n=816 and n=975 respectively. Meta-analysis of all studies showed that for the outcome of initial hemostasis, the pooled OR was 1.01 (95% CI: 0.39–2.62, p = 0.976), demonstrating no significant difference between APC and other endoscopic treatments. Similarly, rebleeding rates showed no significant difference (pooled OR: 1.12; 95% CI: 0.69–1.83, p = 0.636). When we limited our meta-analysis to only the 6 RCTs with an active hemostasis treatment control group, we again found similar results for both outcomes of initial hemostasis and rebleeding.

Conclusion: APC appears comparable and non-inferior to other standard of care endoscopic hemostasis modalities in achieving initial hemostasis and preventing rebleeding in high-risk PUB. Updated guidelines will need to re-evaluate and decide where APC fits in with endoscopic hemostasis of high-risk PUB.

BOGOTÁ SCORE: A NOVEL TOOL FOR EARLY RISK STRATIFICATION IN UPPER GASTROINTESTINAL BLEEDING IN COLOMBIA

H. Marulanda[1,2], G. Jaramillo[2,3], J.A. Rodríguez Criollo[1], J. Frias-Ordoñez[4,1], L. Otero[2,1], E. Otero[2], W. Otero[2,1]

Contact E-Mail Address: Jsfriaso@unal.edu.co

Introduction: Upper gastrointestinal bleeding (UGIB) remains a major clinical emergency with significant morbidity and mortality despite advances in endoscopic and medical management. While existing risk scores have been widely used, their applicability to specific populations is limited.

We aimed to identify mortality-associated risk factors in Colombian patients with UGIB and propose the "Bogotá Score" as a novel stratification tool tailored to our population.

Aims & Methods: We conducted a retrospective case-control study involving 472 patients with UGIB across three Colombian centres during 2023. Twenty-five (5.3%) patients died due to UGIB-related complications. Demographic, clinical, and endoscopic variables were compared using bivariate analysis. Variables significantly associated with mortality were included in a multivariate logistic regression model. A point-based risk score—the Bogotá Score—was derived from independent predictors.

Results: Age ≥70 years, anaemia (OR 7.15; p=0.022), haemoglobin <10 g/dL, Blatchford score >8 (OR 1.18; p=0.003), hospitalisation delay >24h (OR 1.01; p=0.008), and rectorrhagia were associated with increased mortality. Conversely, melena was linked to reduced risk (OR 0.20; p=0.001). These variables were integrated into the Bogotá Score. Patients were stratified into four risk categories: low (0–3), moderate (4–6), high (7–9), and very high (≥10).

Risk Factor	Points
Age ≥70 years	2
Anaemia	3
Haemoglobin <10 g/dL	2
Blatchford score >8	2
Hospitalisation delay >24h	1
Rectorrhagia	1

Table: Bogotá Score – Risk Stratification Tool

Interpretation:

- 0–3: Low risk
- 4–6: Moderate risk
- 7–9: High risk
- ≥10: Very high risk

Conclusion: The Bogotá Score represents a simple, evidence-based tool for early risk stratification in UGIB. By incorporating context-specific variables, it enhances clinical decision-making in Latin American settings. Early ICU transfer and intensive monitoring for high-risk groups may improve outcomes. Future multicentre validation is warranted.

IMPACT OF PRE-ENDOSCOPIC FRESH FROZEN PLASMA TRANSFUSION IN ACUTE UPPER GASTROINTESTINAL BLEEDING WITH MILD TO MODERATE COAGULOPATHY: A MULTICENTER RETROSPECTIVE COHORT STUDY

K. Bunnag[1], A. Chang[2], T. Nuyim[3], N. Sitthinamsuwan[4], N. Rujipattanapong[4], K. Chienwichai[4], M. Rugivarodom[5], S. Chirapongsathorn[6], V. Prachayakul[7]

Contact E-Mail Address: busmdcu58@gmail.com

Introduction: Despite its widespread use, the benefit of pre-endoscopic fresh frozen plasma (FFP) transfusion in acute upper gastrointestinal bleeding (AUGIB) with mild to moderate coagulopathy remains unproven. Current guidelines are inconsistent, and indiscriminate use of FFP—particularly in patients with variceal bleeding—may expose patients to harm without improving outcomes.

Aims & Methods: To assess the impact of pre-endoscopic FFP transfusion on clinical outcomes, including 30-day mortality, in patients with AUGIB and an INR between 1.5 and 2.5. We conducted a multicenter retrospective cohort study at one university-affiliated and one tertiary care hospital in Thailand between January 2016 and December 2020. Adult patients with AUGIB and INR 1.5–2.5 were included. Patients were stratified into FFP and non-FFP groups based on transfusion prior to endoscopy.

Multivariable logistic regression was performed to adjust for age, comorbidities, bleeding etiology, and hemodynamic parameters. Subgroup analysis was conducted in patients with variceal bleeding.

Results: Among 244 patients (158 FFP; 86 non-FFP), those receiving FFP had significantly higher in-hospital mortality (24.1% vs. 7.0%; $p = 0.001$), pulmonary edema (23.4% vs. 4.7%; $p < 0.001$), and longer hospital stay (mean 8.1 vs. 5.8 days; $p < 0.001$). After adjustment, FFP transfusion remained independently associated with in-hospital mortality (adjusted OR 5.65; 95% CI 2.13–14.99; $p < 0.001$) and pulmonary edema (adjusted OR 5.56; 95% CI 1.59–19.44; $p = 0.007$). In patients with variceal bleeding, the adverse effect of FFP was more pronounced. The adjusted 30-day mortality was higher in the FFP group (adjusted OR 2.38; $p = 0.075$), though this did not reach statistical significance.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Pre-endoscopic FFP transfusion in AUGIB patients with INR 1.5–2.5 is associated with increased risk of in-hospital mortality and volume-related complications, particularly in variceal bleeding.

These findings support a more selective and individualized transfusion approach and challenge the routine use of FFP in this population. Prospective studies are warranted to validate these observations and guide evidence-based transfusion thresholds.

COMPARATIVE ANALYSIS OF GASTROINTESTINAL BLEEDING RISKS IN PATIENTS TREATED WITH RIVAROXABAN VERSUS APIXABAN: A RETROSPECTIVE STUDY IN A MEXICAN HOSPITAL SETTING

H.S. De Marino Herrera[1], Y.J. Cruz Ramirez[1], S.M. Narvaez Chavez[1], M.G. Reyes Zermeño[2]
[1]Centro Medico Nacional 20 de Noviembre, ISSSTE, UNAM, México City, Mexico, [2]Centro Médico Nacional 20 de Noviembre, Issste, Mexico City, Mexico

Contact E-Mail Address: sebasdemarino@gmail.com

Introduction: Direct oral anticoagulants (DOACs), particularly rivaroxaban and apixaban, are increasingly utilized to manage thromboembolic conditions due to their favorable efficacy and safety profiles. However, gastrointestinal bleeding (GIB) remains a significant concern associated with these medications, particularly considering pharmacogenetic variations among populations.

This study aims to evaluate the frequency and identify risk factors associated with GIB in patients using rivaroxaban and apixaban in a Mexican healthcare setting.

Aims & Methods: This retrospective observational study analyzed data from January 2018 to December 2023 at the Centro Médico Nacional 20 de Noviembre, Mexico City.

The cohort consisted of 278 patients: 136 on DOAC therapy (rivaroxaban or apixaban) and 142 controls without anticoagulation. Clinical data, demographic characteristics, comorbidities, and concomitant medications were systematically reviewed.

Statistical methods employed included chi-square tests, Student's t-tests, and logistic regression analysis to assess the risk factors and association between anticoagulant type and incidence of GIB.

Results: The study population had a mean age of 67.36 ± 15.05 years, with an equal gender distribution (52.9% male). Rivaroxaban was significantly linked to increased GIB-related hospitalizations compared to controls (OR 1.29, 95% CI: 1.10–1.52, $p < 0.001$), while apixaban showed no statistically significant increase. NSAID co-administration dramatically raised the risk of GIB in rivaroxaban users (OR 16.1, 95% CI: 1.22–212.6, $p = 0.03$).

Patients treated with DOACs experienced more hospitalizations (average 0.49 ± 0.80) and longer hospital stays (2.19 ± 3.54 days) compared to controls (0.30 ± 0.62 hospitalizations, 0.99 ± 2.68 days, respectively). Mortality rates were not significantly different between groups.

Conclusion: Rivaroxaban and apixaban present similar overall risks of gastrointestinal bleeding, although rivaroxaban is associated with higher hospitalization rates. Concomitant NSAID use substantially elevates the risk in patients on rivaroxaban.

This underscores the necessity of individualized anticoagulant management strategies, especially in populations with distinct genetic and clinical characteristics, such as the Mexican demographic.

ARTIFICIAL INTELLIGENCE IN THE MANAGEMENT OF UPPER GASTROINTESTINAL BLEEDING: A NEW DECISION-MAKING TOOL

C. Haddad Hachimi[1], A. Achemlal[2], C. Hiji[3], S. Berrag[3], N. Fouad[3], T. Adioui[2], M. Tamzaourte[3]

Contact E-Mail Address: h.h.chaimae@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) remains a common and potentially life-threatening condition in emergency medicine. Early identification of patients requiring urgent esophagogastroduodenoscopy (EGD) is crucial to improve outcomes and optimize healthcare resources management. Traditional risk stratification tools, such as the Glasgow-Blatchford Score (GBS), have been widely used to guide clinical decision-making.

However, the growing availability of artificial intelligence (AI) offers new perspectives in diagnostic and therapeutic strategies. Recent advancements in large language models (LLMs), such as ChatGPT® and Google GEMINI®, suggest potential applications in clinical triage.

Aims & Methods: This study aims to evaluate the performance of these AI tools in determining the appropriate timing for endoscopy in UGIB patients, compared to standard clinical scoring systems.

The medical records of 100 patients who presented to the emergency department with upper gastrointestinal bleeding (UGIB) between April and September 2024 were reviewed retrospectively. Each case was evaluated by two AI models: Google GEMINI® (September 2024 version) and ChatGPT® (version 3.5).

These models, acting as virtual gastroenterology experts, were asked to recommend whether urgent or delayed esophagogastroduodenoscopy (EGD) was necessary. For each patient, clinical data such as age, medical history, clinical examination findings, and laboratory results at admission were provided.

The AI recommendations were recorded in an Excel file and compared with the Glasgow-Blatchford Score (GBS), which was calculated by a gastroenterologist at the time of admission.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

An urgent endoscopy was deemed necessary for a GBS ≥ 3. Statistical analysis was performed using Jamovi® software (version 2.3), and the agreement between the AI models and human evaluations was assessed using Cohen's kappa coefficient (κ).

Results: The epidemiological characteristics of the patient cohort revealed a median age of 63 years (range: 37.5 to 78), with a male-to-female ratio of 1.7. Among the patients, 73% had at least one comorbidity, including hypertension (33%), diabetes (22%), ischemic heart disease (17%), and chronic liver disease (12%).

At the time of admission, melena was the predominant symptom, reported in 78% of patients. The average Glasgow-Blatchford Score (GBS) was 7.07 ± 3.47.

In terms of AI recommendations, ChatGPT suggested urgent endoscopy in 48% of cases, while Google GEMINI recommended it in 49%. A moderate level of agreement was observed between the two AI models for urgent endoscopy recommendations (kappa = 0.540, $p < 0.001$). However, the agreement between the AI models and the human evaluator was weak. The level of agreement between the gastroenterologist's assessment and ChatGPT's recommendation was weak (kappa = 0.222, $p < 0.001$), with similar results for Google GEMINI (kappa = 0.231, $p < 0.001$).

Conclusion: Artificial intelligence is a promising tool that is already beginning to transform various fields of medicine. However, our study demonstrates that the publicly available AI models currently in use are not yet capable of effectively triaging patients in emergency settings, particularly in cases of upper gastrointestinal bleeding.

A model specifically trained on clinical gastroenterology cases, using validated scientific guidelines, could produce more accurate results and potentially revolutionize patient triage in emergency departments.

Disclosure: Nothing to disclose.

ESTABLISHMENT OF A DELAYED BLEEDING ANIMAL MODEL AFTER GASTRIC MUCOSAL INJURY AND EVALUATION OF THE PREVENTIVE EFFECT OF HIGHLY ADHESIVE HYDROPHOBIZED GELATIN MICROPARTICLES

S. Uehara[1], F. Sasaki[1], H. Maeda[1], M. Hinokuchi[1], A. Tanaka[1], S. Arima[1], S. Hashimoto[1], H. Sahara[2], S. Kanmura[1], A. Nishiguchi[3], T. Taguchi[3,4]

Contact E-Mail Address: s630531@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is a widely used treatment for early gastric tumors, but delayed bleeding remains a significant complication, especially in patients receiving antithrombotic therapy. As the population ages, the need for effective preventive strategies is growing.

Although various methods such as PGA sheets and fibrin glue have been explored, no definitive approach has been established. Moreover, a reliable animal model to evaluate strategies for preventing delayed bleeding does not currently exist.

To address this issue, Taguchi et al. developed a novel endoscopically sprayable wound dressing composed of hydrophobized gelatin microparticles (hMPs), which exhibit strong tissue adhesion. In preclinical studies using miniature swine, hMPs have shown various therapeutic effects on post-ESD ulcers, including anti-inflammatory and anti-fibrotic effects, as well as promotion of perforation closure.

Aims & Methods: This study aimed (1) to establish an animal model of delayed bleeding after gastric mucosal injury, and (2) to evaluate the preventive effect of hMPs using this model.

1. A delayed bleeding model was created by producing mucosal defects in the stomach using endoscopic mucosal resection with ligation (EMR-L), followed by continuous heparin infusion to maintain an activated clotting time (ACT) ≥220 seconds, which consistently induced delayed bleeding.
2. Using this model in three miniature swine, we evaluated the preventive effect of hMPs by endoscopically spraying hMPs onto a total of 36 ulcers (12 per animal). We assessed delayed bleeding, as well as the retention and coverage of hMPs at the ulcer base.

Results:

1. In the heparin-treated group, delayed bleeding was observed in 3 of 4 animals (75%). All three animals whose maximum ACT before the start of continuous heparin infusion exceeded 220 seconds developed delayed bleeding. In contrast, no ACT prolongation or delayed bleeding was observed in the non-heparin-treated group (n = 3) at 24 hours.
2. In the hMPs spray group (n = 3), all animals had ACT ≥220 seconds, and hMPs were sprayed onto 12 mucosal defects per animal (total 36 lesions). No delayed bleeding occurred in any animal. hMPs were retained at all ulcer sites, yielding a 100% retention rate. The ulcer base coverage by hMPs was as follows: 100% in 55.6% of sites (20/36), 75–99% in 19.4% (7/36), and 50–74% in 25.0% (9/36). No sites had coverage below 50%.

Exposed vessel-like structures were identified in 36.1% of the ulcers (13/36), and hMPs were found to adhere to all of these sites.

Conclusion: An animal model of delayed bleeding after endoscopic resection of the gastric mucosa was successfully established by maintaining an ACT ≥220 seconds through continuous heparin infusion. In this model, hMPs remained well on the ulcer base and provided broad coverage of mucosal defects.

These findings suggest that hMPs may be effective in preventing post-endoscopic bleeding, particularly in patients receiving antithrombotic therapy.

PP0209

COMBINING LACTATE LEVEL WITH CHARLSON COMORBIDITY SCORE FOR PREDICTION OF MORTALITY IN PATIENTS WITH ACUTE NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING

T. Düzenli[1], H. Koseoglu[1]

[1]Hitit University Hospital, Gastroenterology, Çorum, Türkiye

Contact E-Mail Address: tolgaduzenli@yahoo.com

Introduction: Acute non-variceal upper gastrointestinal bleeding (NVUGIB) is a common emergency with high morbidity and mortality. Lactate levels and comorbidity indices, such as the Charlson Comorbidity Index (CCI), have shown promise in predicting patient outcomes. While these parameters individually provide valuable prognostic insights, their collective utility in predicting mortality among NVUGIB patients has not been explored.

Aims & Methods: The data for this study were collected from hospital records of patients admitted to Hitit University Hospital with NVUGIB between June 2021 and June 2024.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Demographic information, including age, gender, chronic illnesses, current medications, and history of previous gastrointestinal bleeding, was retrieved from computer database. Clinical data, such as outcomes (discharge or death), reasons for mortality, length of hospital stay were documented. Laboratory parameters, including lactate levels were recorded. Additionally, CCI and Glasgow Blatchford Score (GBS) were calculated for each patient.

Patients were stratified based on mortality status, which was considered the primary outcome. The associations between mortality and potential predictive factors were statistically analyzed. To improve mortality prediction, parameters that were significant in the logistic regression analysis were combined and assessed independently.

Results: A total of 390 patients with acute upper gastrointestinal bleeding were initially assessed. Of these, 180 patients were excluded due to missing data, leaving 210 patients included in the final study cohort. Key variables such as age, CCI, GBS, length of hospital stay, and mortality status were presented. Laboratory findings upon admission and the etiological distribution of gastrointestinal bleeding sources were also detailed.

Variables significantly associated with mortality in the univariate analysis include age, CCI, GBS, urea, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and lactate levels. In the logistic regression analysis, significant predictors of mortality were CCI (OR: 1.318, p=0.001) and lactate levels (OR: 1.575, p=0.003). GBS was not a predictor for mortality (p=0.468). CCI plus lactate levels were significantly higher in deceased patients compared to survivors (12.96 vs.7.31, p<0.001).

The correlation coefficients (r) showed significant positive correlations between the combination of lactate levels and CCI with GBS (r=0.498, p<0.001), length of stay (r=0.213, p=0.014), age (r=0.634, p<0.001) and urea levels (r=0.417, p<0.001). No significant correlation was found with AST or ALT.

ROC curves for lactate levels, CCI and CCI plus lactate levels predicting mortality showed that the area under the curve (AUC) for lactate was 0.704 (95% CI: 0.577–0.830, p=0.002) with a cut-off value of 1.83, yielding a sensitivity of 76% and a specificity of 52%. For CCI, the AUC was 0.769 (95% CI: 0.670–0.869, p<0.001) with a cut-off value of 6.5, showing a sensitivity of 76% and a specificity of 70%. And for the 'CCI plus lactate' level, the AUC was higher as 0.799 (95% CI: 0.703–0.895, p<0.001) with a cut-off value of 8.3, showing a sensitivity of 88% and a specificity of 62%.

Conclusion: Both lactate levels and the CCI are valuable tools for predicting mortality in NVUGIB patients. Our findings support the use of these parameters collectively to improve risk stratification. Combining lactate levels and CCI offers the advantage of better predicting mortality and improving sensitivity compared to using lactate levels or CCI alone.

RED PACK CELL TRANSFUSIONS BEFORE OR AFTER ENDOSCOPY IN PATIENTS WITH ACUTE UPPER GASTROINTESTINAL BLEEDING. A MULTICENTRE PROSPECTIVE COHORT STUDY

C. Marmo[1], C. Bucci[2], M. Soncini[3], M.E. Riccioni[1], R. Marmo[4], GISED
[1]Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy, [2]Cristina Bucci, Santobono Pausillipon Hospital, Naples, Italy, [3]A. Manzoni Hospital, Gastroenterology, Lecco, Italy, [4]Hospital L. Curto, Polla (Salerno), Italy

Contact E-Mail Address: clelia.marmo@outlook.it

Introduction: Acute upper gastrointestinal bleeding and timing to endoscopy are a recognised as risk factors for mortality. European Guidelines* suggest that the hemodynamical resuscitation could be performed before the endoscopy, however, indications are lacking about the timing of blood transfusions.

Aims & Methods: The aim of the study is to evaluate the transfusion timing to reduce death risk in patients with upper gastrointestinal bleeding. This is a prospective multicentre cohort study, including all consecutive hospitalized patients with upper gastrointestinal bleeding (UGIB). Clinical, endoscopic source of bleeding, medical and endoscopic treatment, time to endoscopy, and timing to transfusion were collected. We adopted the ESGE* guidelines to define the need for transfusion, timing to endoscopy and mortality. We considered timing to transfusion before or after the endoscopic procedure.

Statistics: multivariate backward logistic regression was used to estimate the adjusted odds ratio death risk for variables with main clinical relevance or highly statistical significance at univariate analyses. Variables identified by the logistic regression were used into the propensity-score matching to compare the death risk between the two groups.

Results: 2,017 out of 3324 patients received a transfusion and were included in the analysis; the mean age was 69.7 [±15.1], male was 1,365 (67.7%); the source of bleeding was non-variceal in 1634 patients (81 %), 178 patients died (8.8%); 69 out of 700 (9.9 %) died in the group transfusion before endoscopy; 109 out 1317 (8.3 %) in the group transfusion after endoscopy with an OR 1.2 (C.I. 95% .86 to 1.68) p<= 0.23.

Mortality between the two groups did not significantly differ when haemoglobin levels at admission were considered, nor after adjustment for potential confounding variables, including ASA score, in-hospital bleeding, haematemesis at presentation, shock at admission, altered mental status and timing to endoscopy.

Propensity score matching analysis indicated that among patients who received a transfusion, the risk of death decreased when the transfusion was administered before the endoscopy and the haemoglobin level was below 7 g/dL (coefficient = -0.06, p = 0.06; see Table).

Admission Heamoglobin value gr/L	Coefficient	SE.	z	P>|z|	[95%conf. nterval]
< 7 gr/l	-0.06	0.03	-1.86	0.063	-0.11 0.00
7 - 8 gr/l	-0.03	0.04	-0.95	0.342	-0.10 0.04
8 - 10 gr/l	0.02	0.03	0.52	0.605	-0.05 0.08

Table. Propensity-score matching Haemoglobin level before VS after endoscopy.

Conclusion: Red pack cell transfusions before or after endoscopy did not modify the death risk in patients with acute upper gastrointestinal bleeding; the death risk was less frequent in patients transfused before endoscopy and with a haemoglobin value lower than 7 gr/l. However, this risk increased in those patients transfused before endoscopy and with a haemoglobin value > 8 gr/l.

Contact E-Mail Address: clelia.marmo@outlook.it
Introduction: Current guidelines provided information on the management of patients with gastrointestinal bleeding, in particular focusing on admission, endoscopic management and medical treatment during the hospital stay. So far, 11-15% of patients treated for GIB required a new hospitalization for a new bleeding episode.
Aims & Methods: The aim of the study is to verify if the management in a dedicated practice after hospital discharge for gastrointestinal bleeding reduces further bleeding and costs. This is an ambispective cohort single center study, including patients observed between May 2022 and September 2023 in our clinical practice dedicated to gastrointestinal bleeding. We enrolled consecutive patients with overt gastrointestinal bleeding or iron deficiency anemia affected by vascular lesions.
The effectiveness was defined as a composite endpoint including iron supplementation, blood transfusion, medical treatment and number of hospital stay. Costs were evaluated starting from Diagnosis Related Groups (DRG) codes. The cost effectiveness analysis and ICER has been calculated using the ICERconf.EXE software (Software Prescriptions, c/o Bob Obenchain, California, USA).
Results: In our institute 602 patients with gastrointestinal bleeding were evaluated between May 2022 and September 2023, of these 79 were included in the study. The mean age was 73.8 years (SD±10,8), 46% were female. The source of bleeding was angiodysplasia in 63% of patients, GAVE in 9% (Gastric Antral Vascular Ectasia), erosions in 9%.
After the introduction in the dedicated practice, the re-bleeding decrease from 1.3 episodes to 0.2 episodes, p<0.001. The cost average after the practice was 4074 euro (SD ±5485), the average cost before the practice was 4885 euro (SD ±4567), it has been observed a cost saving after the management in the dedicated practice, C diff= -751 euro. The average effectiveness after practice was 8.7 (SD±1.06) and the average effectiveness before the practice was 7.3 (SD ±1.3) with the E diff= 1.47, p<0.001.
Conclusion: The dedicated practice for patients with gastrointestinal bleeding provides effectiveness in reducing transfusion, iron supplementation and hospitalization with a consistent cost reduction.
Disclosure: Nothing to disclose.

RACIAL DISPARITIES IN UPPER GASTROINTESTINAL BLEEDING MANAGEMENT AND OUTCOMES: A NATIONAL ANALYSIS

B.S. Sokhal[1], M. Jalloh[2], F. Gohar[2], H.R. Bharadwaj[3]
[1]Keele University, School of Medicine, Stoke-On-Trent, United Kingdom, [2]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom, [3]The University of Manchester, Faculty of Biology Medicine and Health, Manchester, United Kingdom

Contact E-Mail Address: Mohamed.Jalloh@uhnm.nhs.uk
Introduction: Contemporary studies suggest there are racial disparities in the outcomes of acute presentations. This study aimed to investigate the impact of sex and race on the management and outcomes of patients presenting with upper gastrointestinal bleeding (UGIB).
Aims & Methods: Using International Classification of Diseases 10th Revision Codes, all adults >18 admitted from 2016–2020 with a discharge diagnosis of UGIB were extracted from the National Inpatient Sample.
Results: In over 900,000 hospitalisations for UGIB, 69.4%, 14.1%, 9.6%, 3.6%, 0.9% and 2.4% were for admissions in white, black, Hispanic, Asian/pacific islander, native American and 'other' patients respectively. Comorbidity burden varied between racial groups (p<0.001). White patients had higher crude rates of endoscopy, and comparable rates of surgery or interventional radiology to control blood loss, in comparison to other racial groups.
Adjusted analysis revealed that black and Asian/pacific islander racial group patients had lower odds of in-hospital all cause mortality compared to white patients, but 'other' racial group patients had higher odds of mortality (p<0.001).
There was no difference for Hispanic or native American patients. For non-variceal bleeding, these outcomes persisted. However, for variceal bleeds, there were no significant differences in outcomes between each racial group.
Conclusion: There are racial disparities in the management and outcomes of admissions for UGIB. These difference persist despite the aetiology of bleeding. Underlying reasons for differences in outcomes must be investigated to ensure improved outcomes across high-risk patient groups.
Disclosure: Nothing to disclose.

THE RELATIONSHIP BETWEEN TYPE 2 DIABETES AND OUTCOMES OF UPPER GASTROINTESTINAL BLEEDING IN THE UNITED STATES FROM 2016-2020

H. Rishab Bharadwaj[1], B.S. Sokhal[2,3], M. Jalloh[3], F. Gohar[3]
[1]The University of Manchester, Faculty of Biology Medicine and Health, Manchester, United Kingdom, [2]Keele University, School of Medicine, Stoke-On-Trent, United Kingdom, [3]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom

Contact E-Mail Address: rishabbharadwaj31@gmail.com
Introduction: There are limited data on the contemporary outcomes of upper gastrointestinal bleeding (UGIB) in patients with type 2 diabetes mellitus (T2DM).
Aims & Methods: Admissions for UGIB were extracted from the National Inpatient Sample of the United States from 2016-2020. Patients were stratified by the presence of T2DM.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In 918,925 patients, 287,185 (31.3%) had T2DM. Patients with T2DM were more likely suffer from chronic pulmonary disease, chronic renal failure, heart failure, liver disease and hypertension (p<0.001). These patients had higher crude odds of endoscopy but lower odds of surgery and interventional radiology to control blood loss (p<0.001).

There was no difference in crude rates of in-hospital mortality. On adjusted analysis, T2DM was associated with lower odds of in-hospital mortality (adjusted odds ratio (aOR) 0.42 95% confidence interval (CI) 0.81-0.87).

Adjusted odds of mortality remained lower when analysis was stratified by bleed type (aOR 0.88 CI 0.85-0.92 for non-variceal bleeding and aOR 0.60 CI 0.54-0.66 for variceal bleeding).

Conclusion: Patients with T2DM admitted with UGIB are more comorbid, but are less likely to suffer in-hospital mortality compared to patients without T2DM.These differences persisted on-subanalysis for type of bleed.Knowledge of these trends is important for managing this prevalent patient group.

ASSOCIATION BETWEEN CHRONIC KIDNEY DISEASE AND OUTCOMES OF PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING (UGIB)

B.S. Sokhal[1,2], F. Gohar[2], M. Jalloh[2], H. Rishab Bharadwaj[3]
[1]Keele University, School of Medicine, Stoke-On-Trent, United Kingdom, [2]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom, [3]The University of Manchester, Faculty of Biology Medicine and Health, Manchester, United Kingdom

Contact E-Mail Address: fgohar@nhs.net

Introduction: Contemporary data on the outcomes of upper gastrointestinal bleeding (UGIB) in patients with chronic kidney disease (CKD) is lacking.

Aims & Methods: Using international classification of diseases, 10th revision codes, all hospitalisations for UGIB were extracted from the National Inpatient Sample. Admissions were stratified by the presence of CKD. Subanalysis was performed by type of bleeding.

Results: Of the 918,925 UGIB admissions analysed, 239,985 (26.1%) had a medical history of CKD. CKD patients were more likely to be male and less likely to be white compared to patients without CKD. CKD patients had higher crude rates of endoscopy but lower likelihood of undergoing surgery and interventional radiology to control blood loss.

On adjusted analysis compared to patients with no CKD, CKD patients had higher odds of all-cause in-hospital mortality (adjusted odds ratio (aOR) 1.34 95% confidence interval (CI) 1.29-1.39). When stratified by bleed type, CKD patients had higher adjusted odds of mortality for both variceal and non-variceal bleeds, compared to patients without CKD.

Conclusion: Patients with CKD admitted with UGIB are more comorbid and are more likely to suffer in-hospital mortality compared to patients without CKD. These differences persisted on-sub-analysis for type of bleed. Knowledge of these trends is important for managing this prevalent patient group.

Disclosure: Nothing to disclose.

Introduction: Timely endoscopy in upper gastrointestinal bleeding (UGIB) is crucial. However, the ideal timing, particularly in relation to hemodynamic status, remains a matter of debate. Despite advances in diagnostic techniques and endoscopic treatments, its mortality rate has not declined significantly over the years.

Aims & Methods: We aimed to assess clinical practice patterns and determine how the timing of endoscopy is influenced by the patient's hemodynamic status. We conducted an international online survey between April 2023 and November 2023 among physicians managing patients with UGIB. REDCap was used for data collection. We assessed clinicians' opinions on the optimal timing of endoscopy (within 2, 6, 12, 24, or >24 hours) for variceal (VUGIB) and non-variceal (NVUGIB) bleeding under three hemodynamic conditions: stable, unstable responding and not responding to hemodynamic resuscitation.

Additionally, we asked how they defined hemodynamic instability. The primary analysis summarized responses as proportions. Secondary analyses explored variations in responses by clinical experience, practice setting, and annual UGIB case volume.

Results: A total of 533 clinicians from 50 countries completed the survey. Of the respondents, 291 (54.6%) worked in university-based hospitals, 361 (67.7%) managed over 100 UGIB cases annually, and 236 (44.3%) had more than 10 years of experience. For NVUGIB, the majority recommended endoscopy within 24 hours for stable patients (229, 43.1%), within 6 hours for unstable responders (161, 30.2%), and within 2 hours for unstable non-responders (254, 47.8%).

For VUGIB, the most common recommendations were endoscopy within 12 hours for stable patients (155, 29.1%), within 6 hours for unstable responders (201, 37.7%), and within 2 hours for unstable non-responders (319, 60%). More experienced physicians, those working in university-based hospitals, and those managing high UGIB patient volumes tend to favor earlier endoscopy.

The most commonly chosen definition for hemodynamic instability, selected by 345 (64.7%) was systolic blood pressure <100 mmHg and heart rate >100 bpm or syncope or orthostatic hypotension or signs of organ hypoperfusion, selected by 345 (64.7%) of the respondents.

Statistical variability was significant across all analyses ($p<0.0001$). Younger clinicians were more likely to adhere to guideline recommendations.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: We found that the more hemodynamically unstable the patients are, the earlier gastroenterologists tend to recommend performing endoscopy for UGIB. Clinical experience, hospital type, and annual patient number significantly influenced the preferred timing of endoscopy in UGIB. There was considerable variability among respondents' answers. This study highlights opportunities to improve consistency in clinical practice and identifies potential areas for further research.
Disclosure: Nothing to disclose.

PP0216

EXPLORATORY VALIDATION OF UPPER GASTROINTESTINAL BLEEDING RISK SCORES FOR COMPLICATIONS

M. Jalloh[1], F. Gohar[1], B.S. Sokhal[2,1], M. Javed[1], H. Gomez[1], J. Lightfoot[1]
[1]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom, [2]Keele University, School of Medicine, Stoke-On-Trent, United Kingdom

Contact E-Mail Address: Mohamed.Jalloh@uhnm.nhs.uk
Introduction: While upper gastrointestinal bleeding (UGIB) risk scores are commonly used to predict mortality, their performance in forecasting alternative clinically meaningful complications during admission, such as rebleeding requiring interventional radiology (IR) or repeat oesophagogastroduodenoscopy (OGD), has not been well explored.
This study aimed to validate the predictive accuracy of five UGIB scores for these secondary endpoints.
Aims & Methods: A retrospective cohort analysis was performed on a cohort of 1,003 patients admitted at a UK tertiary centre between January 2025 and August 2023 due to suspected UGIB and investigated via OGD. Each patient's CHAMPS, ABC, Glasgow-Blatchford (GBS), MAP(ASH), and Japanese scores were calculated using their electronic patient records.
The observed outcome was the development of complications, categorised as:
1. Re-bleeding,
2. Requiring IR, and;
3. Requiring repeat OGD.
Receiver operating characteristic (ROC) and area under the curve (AUC) were used to assess each score's discriminative ability.
Results: The ABC score had the highest predictive potential for inpatient complications with an AUC of 0.779, followed by the CHAMPS with an AUC of 0.766 and by the MAP(ASH) with an AUC of 0.716. GBS and the Japanese score had lowest prognostic capabilities.
Conclusion: The ABC, CHAMPS, and MAP(ASH) scores show useful discriminative performance for predicting vital non-mortality outcomes in UGIB patients. These results indicate the possibility of these stratification tools being used outside of predicting inpatient mortality, guiding early escalation of care decisions.
Disclosure: Nothing to disclose.

PP0217

SEX-STRATIFIED PERFORMANCE OF UPPER GASTROINTESTINAL BLEEDING RISK SCORES FOR INPATIENT MORTALITY

M. Javed[1], M. Jalloh[1], F. Gohar[1], B.S. Sokhal[2,1], H. Gomez[1], J. Lightfoot[1]
[1]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom, [2]Keele University, School of Medicine, Stoke-on-Trent, United Kingdom

Contact E-Mail Address: Maryam.Javed@uhnm.nhs.uk
Introduction: Sex-based differences in clinical outcomes are increasingly being recognised in acute care, yet few studies have examined whether upper gastrointestinal bleeding (UGIB) risk scores perform differently in male versus female patients. This study evaluated the discriminatory performance of five established UGIB risk scores in predicting inpatient mortality by sex.
Aims & Methods: This retrospective study included 1,003 patients who underwent inpatient oesophagogastroduodenoscopy (OGD) for UGIB between January 2025 and August 2023 at a UK tertiary care centre. Glasgow-Blatchford Score (GBS), CHAMPS, ABC, Japanese score, and MAP(ASH), were calculated for each patient. Binary Logistic regression examined sex as an independent factor for 30-day inpatient mortality, with UGIB aetiology also accounted for (variceal vs non-variceal). Receiver operating characteristic (ROC) curves were used to assess each score's performance in predicting inpatient mortality separately for male and female subgroups.
Results: Out of the 1,003 admissions, 59.2% and 40.8% were males and females, respectively, with crude analysis demonstrating female mortality being slightly higher (10.5%) compared to male (8.6%). However, this was found not to be significant (p: 0.304, OR 1.251, CI: 0.816-1.917). These findings were consistent regardless of UGIB aetiology (variceal vs non-variceal).
For the 30-day inpatient mortality outcome, the ABC score demonstrated strong discriminative performance in both males (AUC: 0.804) and females (AUC: 0.835). CHAMPS and MAP(ASH) also performed consistently, with CHAMPS yielding AUCs of 0.788 in males and 0.793 in females, and MAP(ASH) showing 0.767 and 0.781 in males and females respectively. GBS performed slightly better in females (AUC: 0.743) compared to males (AUC: 0.691). The Japanese score showed poor discrimination in both sexes, particularly in females (AUC: 0.577). Overall, ABC, CHAMPS, and MAP(ASH) performed reliably across sexes.
Conclusion: Whilst crude mortality rates were higher in females than males, gender did not show to be an independent predictor of inpatient mortality, which could, however, necessitate a larger cohort size to ascertain validity. Risk scores, particularly the ABC score, maintained high and consistent predictive accuracy for inpatient mortality in both male and female patients with UGIB. These findings support the use of these tools across genders and suggest minimal gender-related performance bias in risk stratification.
Disclosure: Nothing to disclose.

Contact E-Mail Address: eredondoc@gmail.com

Introduction: Massive gastrointestinal bleeding is a clinical condition that is poorly studied due to its abrupt presentation, involvement of various clinical services, and the high and rapid mortality of patients.

We present the preliminary results of a multicenter registry that includes 21 hospitals from Spain and Hispanic America, analyzing factors related to mortality and need for intervention.

Aims & Methods: Since January 2023, 403 patients over 18 years old who presented to the emergency departments of participating hospitals with massive gastrointestinal bleeding, defined as bleeding accompanied by signs of shock and requiring transfusion of at least 2 units of blood within the first 24 hours of admission, were included. Demographic variables, comorbidities, treatments including NSAIDs, antiplatelets, and anticoagulants, clinical presentation variables, medical, endoscopic, and surgical variables, and a 6-month follow-up were collected.

The aim of this study was to analyze factors related to mortality and the need for intervention in patients with massive gastrointestinal bleeding.

Results: A total of 403 patients with a mean age of 64.5 ± 15.7 years were included (male 68.7%). Main comorbidities were cirrhosis (31%), diabetes (28%) and a previous UGIB (25%). 8.4% of patients had already been admitted to the hospital, and 29% were on antithrombotic (16.6% antiplatelets and 16.4% anticoagulants).

On admission we observed SPB: 91±22 mmHg, heart rate 101 ± 21; and an altered mental status in 31%. Mean hemoglobin levels 7.6±2.5 g/dl, urea: 98±67, albumin 2.16±1.3, INR: 3.9±7. The most common causes were esophageal varices (29%), gastric ulcer (25%) and duodenal ulcer (25%). Endoscopic intervention was needed in 60%, with mortality rate of15.4%. Mean admission was 8.6±10 days, and patients needed 4±3 red blood cells units.

When analyzing in-hospital mortality, we observed that the age of patients who died was higher than that of survivors (68.2±15 vs. 63.6±16; p=0.033), with the former requiring more packed red blood cells (5±5.5 vs. 3.5±2; p=0.043). Patients who died had a lower frequency of gastric ulcer (14% vs. 27%; p=0.034), a higher frequency of altered mental status (42.6% vs. 29%; p=0.036), and a lower rate of endoscopic therapy applied (43.3% vs. 63.6%; p<0.0001). In logistic regression, gastric ulcer etiology and endoscopic therapy were protective factors against mortality (Table 2).

Regarding the need for intervention, more patients with liver cirrhosis required it (73% vs. 60%, p=0.018), patients with hematemesis (73% vs. 52%; p<0.0001), patients without melena (60% vs. 76%; p=0.002), with syncope (76.3% vs. 61%; p=0.06), etiologies other than gastric ulcer (78% vs. 56%; p=0.028), and the presence of esophageal varices (83% vs. 57%; p<0.0001). In binary logistic regression, liver cirrhosis, hematemesis, and syncope were risk factors for the need for intervention.

Conclusion: Age, altered mental status, and lower frequency of endoscopic therapy are risk factors for mortality due to massive gastrointestinal bleeding. Gastric ulcer as an etiology and receiving endoscopic therapy acted as protective factors against mortality.

Indeed, in both situations, it might be related to an opportunity window to receive appropriate treatment, especially when compared with more cataclysmic types of bleeding, such as variceal or posterior duodenal bulb wall, which sometimes can be challenging and utterly abrupt.

Regarding the need for intervention, liver cirrhosis, hematemesis, and syncope were independent risk factors for the need for endoscopy, surgery, or interventional radiology.

Disclosure: Nothing to disclose.

Introduction: Studies in cardiovascular disease have raised concerns regarding racial disparities in the predictive performance of clinical risk scores. However, limited data exists on whether scoring systems for upper gastrointestinal bleeding (UGIB) perform differently in racially diverse populations.

This study aimed to compare the performance of five UGIB risk scores in predicting inpatient mortality in White and non-White patients.

Aims & Methods: We performed a retrospective cohort analysis of 1,003 patients who received inpatient esophagogastroduodenoscopy (OGD) on admission between January 2025 and August 2023 at a UK tertiary centre. The MAP(ASH), Glasgow-Blatchford (GBS), CHAMPS, Japanese scores and ABC scores were calculated using patient's medical records. Patients subsequently categorised as: Caucasian, African, Asian, and Mixed.

We utilized Binary Logistic regression to analyse ethnicity as an independent variable for 30-day inpatient mortality, also further adjusting for UGIB cause (variceal vs non-variceal). ROC analysis using IBM SPSS Statistics v29 was performed separately by ethnicity to assess each score's predictive performance for inpatient mortality.

Results: The majority of the cohort belonged to the Caucasian subgroup (91.8%), followed by Asian (1.7%), African (0.8%), and Mixed (1.2%); 4.5% had no racial background recorded. Crude rates showed higher odds of inpatient mortality for the Caucasian subgroup, followed by mixed, Asian, and African subgroups. However, adjusted analysis revealed no significant relationship between race and 30-day inpatient mortality, and these outcomes persisted when adjusted for variceal vs non-variceal bleeding.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The ABC score demonstrated strong performance across both racial groups, with improved discrimination in non-White patients. CHAMPS and MAP(ASH) also showed higher AUCs in the non-Caucasian subgroup. GBS and the Japanese score performed better in non-Caucasian patients than in Caucasian patients, though overall discrimination remained lower compared to ABC and CHAMPS. There was no evidence that any score systematically over- or under-estimated risk in the non-Caucasian group.
Conclusion: Despite crude rates demonstrating different 30-day inpatient mortality rates based on racial subgroup, there was no statistical significance. These findings could, however, be limited by our cohort size and therefore, might necessitate further research.
The ABC and CHAMPS scores maintain robust predictive accuracy for inpatient mortality in both White and non-White patients with UGIB. Contrary to concerns raised in other specialities, our findings do not suggest performance bias in these scores by race, supporting their equitable use in diverse patient populations.
Disclosure: Nothing to disclose.

PP0220

BODY MASS INDEX AS A PROGNOSTIC FACTOR FOR INPATIENT MORTALITY IN UPPER GASTROINTESTINAL BLEEDING: A UNIVARIATE ANALYSIS

M. Jalloh[1], B.S. Sokhal[2,1], F. Gohar[1], M. Javed[1], H. Gomez[1], J. Lightfoot[1]
[1]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom, [2]Keele University, School of Medicine, Stoke-on-Trent, United Kingdom

Contact E-Mail Address: Mohamed.Jalloh@uhnm.nhs.uk
Introduction: Body mass index (BMI) has been associated with prognosis in several acute and chronic illnesses. However, its role in risk stratification for upper gastrointestinal bleeding (UGIB) remains unclear. This study evaluated whether BMI category alone could predict inpatient mortality in UGIB patients.
Aims & Methods: We conducted a retrospective cohort study of 1,003 patients who underwent inpatient esophagogastroduodenoscopy (OGD) for UGIB at a tertiary centre between January 2025 and August 2023. BMI's were categorised as: healthy weight, underweight, overweight, obese and severely obese. Univariate logistic regression was performed against 30-day inpatient mortality as the primary outcome, with further analysis adjusting for UGIB aetiology (variceal vs non-variceal).
Results: Distributions for the various BMI classes were as follows: 24.3% healthy weight, 4.2% underweight, 27.1% overweight, 16.0% obese, 3.0% severely obese, and 25.4% had no BMI recorded.
Underweight patients had significantly lower odds of inpatient mortality (aOR 0.531 CI: 0.295–0.956, p: 0.025), as did those classified as obese (aOR 0.472 CI: 0.262–0.849, p: 0.012). Other BMI categories were not statistically significant predictors. However, the overall model was not statistically significant (p: 0.142), suggesting BMI alone offers limited predictive value, and this was the case regardless of bleeding aetiology.
Conclusion: Underweight and obese patients had reduced risk of inpatient mortality. Whilst the physiological science remains unclear, these findings support further exploration of BMI as an independent prognostic factor in UGIB, likely with a larger cohort size being required.
Disclosure: Nothing to disclose.

PP0221

EASTERN COOPERATIVE ONCOLOGY GROUP(ECOG) PERFORMANCE STATUS AS AN INDEPENDENT PREDICTOR OF INPATIENT MORTALITY IN UPPER GASTROINTESTINAL BLEEDING

H. Gomez[1], M. Jalloh[1], F. Gohar[1], B.S. Sokhal[2,1], M. Javed[1], J. Lightfoot[1]
[1]University Hospitals of North Midlands NHS Trust, Gastroenterology/Hepatology, Stoke-on-Trent, United Kingdom, [2]Keele University, School of Medicine, Stoke-on-Trent, United Kingdom

Contact E-Mail Address: Humberto.Gomez@uhnm.nhs.uk
Introduction: Frailty is a known contributor to poor outcomes in acute illness. The Eastern Cooperative Oncology Group (ECOG) performance status has been proposed as a practical measure of patient frailty.
This study aimed to determine the independent predictive value of ECOG in the setting of upper gastrointestinal bleeding (UGIB).
Aims & Methods: We conducted a retrospective cohort analysis of 1,003 patients who presented with suspected UGIB at a UK tertiary centre and underwent inpatient esophagogastroduodenoscopy (OGD) between January 2025 and August 2023.
The relationship between inpatient mortality and ECOG score was assessed using multivariate logistic regression. The model was adjusted for Glasgow Blatchford Score (GBS), estimated glomerular filtration rate (eGFR), and cancer status variables.
Results: With a p-value< 0.001, ECOG performance status was proven to be a significant independent predictor of inpatient mortality (aOR 1.529 CI: 1.285–1.820). As expected, other significant predictors for inpatient mortality were GBS and metastatic cancer. Renal function was not statistically significant.
Conclusion: The ECOG score is a major predictive factor for inpatient mortality, suggesting the importance of frailty assessment in acute UGIB presentations. Standardising the documentation of ECOG may aid in risk stratification and early care escalation decisions.
Disclosure: Nothing to disclose.

PP0222

EMERGENCE OF SEVERE ACUTE HEPATITIS A IN ADULTS: AN 11-YEAR COHORT FROM A TERTIARY CARE CENTER

R. Mansour[1], R. Tabbikha[1], F. Hachicho[1], A.E. Zreik[1], B. Abdallah[1], G.F. Araj[2], K. Barada[1]

Contact E-Mail Address: kassembarada@gmail.com
Introduction: The threat of acute hepatitis A (AHA) to public health may be underestimated. We aimed to determine the frequency, clinical characteristics and outcomes of patients with AHA, and to compare them to those with acute hepatitis B (AHB).
Aims & Methods: This was a retrospective study of all patients diagnosed with AHA or AHB at a tertiary referral center between January 2013 and June 2024. Demographics, clinical presentation, laboratory findings, and outcomes were determined. AHA was defined by the presence of immunoglobulin M (IgM) antibodies to hepatitis A virus. AHB was defined by the presence of IgM antibodies to hepatitis B core antigen and positive hepatitis B surface antigen. Severe hepatitis was defined by serum bilirubin >

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

10 mg/dl, INR ≥ 1.5, serum creatinine > 2 mg/dl, and/or hepatic encephalopathy. Fulminant hepatitis (FH) was defined by the presence of hepatic encephalopathy.

Results: Over a period of 11 years, 398 patients were diagnosed with acute hepatitis, 367 (92%) with AHA and 31 (8%) with AHB. 336 patients (84.5%) were older than 18 years of age. Compared to patients with AHB, those with AHA were younger, were more likely to be females but were less likely to have an underlying immunocompromising illness (Table 1). There was no difference in the frequency of severe hepatitis, hospitalization rate, FH, and in hospital mortality between the two groups (Table 1).

There were 115 patients (31%) with severe AHA, 89% of whom were older than 18 years of age. There was no difference in the mean age (33 ± 14 vs 31 ± 14 years, p=0.32), gender (37% vs 46% females, p=0.16), history of underlying liver disease (2.6% vs 0%, p=0.07) or having an underlying immunocompromising illness (4.2% vs 6.1%, p=0.47), between patients with severe AHA and patients with non-severe AHA.

Furthermore, compared to patients with non-severe AHA, patients with severe AHA were more likely to require hospitalization (70% vs 43%, p=<0.001), ICU admission (8.7% vs 0.6%, p=<0.001), and to die during the index of hospitalization (4.3% vs 0%, p=0.01). Among patients with AHA who had a serum bilirubin > 10 mg/dl, INR ≥ 1.5, and/or serum creatinine > 2 mg/dl, 7% developed fulminant hepatitis while only 1% of patients with non-severe AHA developed fulminant hepatitis, p=0.003.

Characteristics	Total	Hepatitis A	Hepatitis B	P-value
Number of patients	398	367 (92)	31 (8)	-
Age at diagnosis (years)	31.3 ± 14.4	30.6 ± 14.3	40.2 ± 12.6	<0.001
Gender (female)	163 (41)	158 (43)	5 (16)	0.003
Underlying liver disease	4 (1)	4 (1.1)	0	1.0
Immunocompromising illness*	21 (5.3)	16 (4.4)	5 (16.7)	0.004
Severe hepatitis**	126 (41)	115 (41)	11 (44)	0.77
Hospitalization	168 (42)	159 (43)	9 (29)	0.12
Fulminant hepatitis	10 (2.5)	9 (2.5)	1 (3.2)	0.56
In hospital mortality	6 (1.5)	5 (1.4)	1 (3.2)	0.39

Table 1. Comparison of demographics, clinical characteristics, and outcomes between patients with acute hepatitis A (AHA) and patients with acute hepatitis B (AHB)

**Immunocompromising illness: organ transplantation, systemic cancer, being on chemotherapy, radiotherapy, and/or immunosuppressive therapy.*

***Severe hepatitis: serum bilirubin > 10 mg/dl, INR ≥ 1.5, serum creatinine > 2 mg/dl, and/or hepatic encephalopathy.*

Conclusion: AHA is far more common than AHB, but is associated with similar rates of hospitalization, severe hepatitis, and fulminant hepatitis. The high frequency of AHA among adults in low-income countries calls for renewed attention to prevention and vaccination to reduce the burden of this often-overlooked disease.

Furthermore, further research may be needed to develop pharmacological treatment for patients with severe AHA and those with fulminant hepatitis, in view of unavailability of liver transplantation in most developing countries.

Disclosure: Nothing to disclose.

PP0223

IMPACT OF ANTIPLATELET AND ANTICOAGULANT THERAPIES ON NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING: A PROSPECTIVE OBSERVATIONAL STUDY

A. Samad[1]

[1]Hamdard University Hospital, Department of Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: samaddhedhi@gmail.com

Introduction: Antiplatelets and anticoagulants significantly increase the risk of upper gastrointestinal bleeding by impairing normal clotting mechanisms. Patients on dual or combined therapy often present with more severe bleeds and poorer endoscopic control. This leads to higher rates of rebleeding, complications, and mortality compared to those not on these therapies.

Aims & Methods: To evaluate the risk and outcomes of non-variceal upper gastrointestinal bleeding (UGIB) in patients on single antiplatelet therapy, dual antiplatelet therapy, and combined antiplatelet-anticoagulant therapy, and to assess associated morbidity, mortality, and rebleeding rates.

A prospective study was conducted involving 150 patients (90 males, 60 females) aged 40–60 years, presenting with upper GI bleeding between 1st January 2023 till 1st January 2025.

Patients had co-morbid conditions including hypertension, diabetes mellitus, coronary artery disease, or prior cerebrovascular events, and were on their respective medications for at least 3 months. Patients using NSAIDs, having liver disease, or known bleeding disorders were excluded. Clinical presentations included melena, hematemesis, or both. All patients underwent upper GI endoscopy, with Forrest classification used to characterize ulcers. Laboratory investigations included CBC, LFTs, renal function, PT, and APTT. Bleeding profiles and endoscopic outcomes were analyzed across three medication groups: single antiplatelet (n=60), dual antiplatelet (n=50), and combined antiplatelet-anticoagulant therapy (n=40).

Results: UGIB was reported in 6 (10%) of the single antiplatelet group, 16 (32%) of the dual antiplatelet group, and 14 (35%) of the combined therapy group. Endoscopic findings predominantly revealed Forrest class IIA ulcers. Patients on dual or combined therapy had poorer endoscopic hemostasis. Four patients experienced rebleeding refractory to standard endoscopic measures, requiring angioembolization. One mortality was recorded in the dual antiplatelet group due to massive bleeding and shock.

Conclusion: Dual antiplatelet and combined antiplatelet-anticoagulant therapies significantly increase the risk and severity of non-variceal UGIB, with higher rates of poor endoscopic hemostasis, rebleeding, and mortality. These findings underscore the importance of risk stratification and prophylactic strategies in patients requiring long-term antithrombotic therapy.

PP0224

MULTI-AGENT LLM APPROACH VERSUS SINGLE MODEL IN THE MANAGEMENT OF NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING

M. Ucdal[1], M.B. Durak[2], Y.H. Balaban[3], C. Simsek[4]
[1]Hacettepe University, Internal Medicine, Ankara, Türkiye, [2]Ankara High Speciality Hospital, Gastroenterology, Ankara, Türkiye, [3]Hacettepe University, Gastroenterology, Ankara, Türkiye, [4]Hacettepe University, Division of Gastroenterology, Hepatology and Endoscopy, Ankara, Türkiye

Contact E-Mail Address: meteucdal@hacettepe.edu.tr

Introduction: Non-variceal upper gastrointestinal bleeding (NV-UGIB) represents a critical clinical condition with high morbidity and mortality risks. Large language models (LLMs) can serve as decision support systems for clinicians by analyzing patient data and providing guideline-based recommendations. However, single LLM approaches may be insufficient in consistently applying guideline recommendations. The multi-agent system offered by the Microsoft AutoGen framework, which integrates assessments from multiple specialized LLM agents representing different specialties through a Consensus Supervisor, may produce more guideline-compliant decisions in NV-UGIB management.

Aims & Methods: This study aimed to compare guideline compliance between a multi-agent LLM system and a single LLM in managing non-variceal upper GI bleeding per ACG guidelines. Twenty cases were selected from MIMIC-III using ICD-9 codes for melena and unspecified GI bleeding. Patient data included demographics, clinical findings, and laboratory results. Evaluation covered Glasgow-Blatchford Score risk stratification, Hb < 7 g/dL transfusion threshold, and risk-based endoscopy timing. In Arm A, separate Gastroenterologist and Emergency Medicine agents provided specialty-specific assessments, while Arm B used a single GPT-4o model. A compliance score (0-3) was calculated for each case, and performance was compared using the Wilcoxon signed-rank test.

Results: In the comparative analysis of model performances, the multi-agent system demonstrated significantly higher guideline compliance than the single model approach. The mean compliance score for the Arm A was 2.85 ± 0.20, while the Arm B achieved 2.15 ± 0.45 (p = 0.002). The distribution of compliance scores revealed that Arm A achieved full compliance (3 points) in 18 cases (90%), with only 2 cases scoring 2 points. By contrast, Arm B achieved full compliance in only 12 cases (60%), with 5 cases scoring 2 points and 3 cases scoring just 1 point. For risk stratification using the Glasgow-Blatchford Score, the multi-agent system misclassified only 2 cases (10%), both involving incomplete consideration of BUN values in the scoring calculation. The single model, however, either completely overlooked or incorrectly applied risk categorization in 5 cases (25%), including critical misinterpretation of 2 high-risk cases (GBS ≥ 7) as moderate or low risk, demonstrating difficulty in evaluating multiple parameters simultaneously. Regarding transfusion thresholds, Arm A maintained perfect compliance across all 20 cases. In contrast, Arm B showed errors in 3 cases (15%), failing to recommend transfusion in 2 cases despite Hb levels below 7g/dL and inappropriately recommending transfusion in 1 case with Hb above threshold. For endoscopy timing recommendations, the multi-agent system again achieved 100% compliance, while the single model presented out-of-guideline timing in 4 cases (20%), including ambiguous timing expressions for high-risk cases and inappropriate delays for moderate-risk cases. The Consensus Supervisor in Arm A effectively integrated specialty expertise to produce consistently guideline-compliant recommendations across all evaluation criteria.

Conclusion: The multi-agent consensus approach using the Microsoft AutoGen framework demonstrated significantly higher guideline compliance than a single LLM in NV-UGIB management. This autogenic system, incorporating multiple specialized LLMs representing different clinical perspectives, provides more consistent evaluation of complex parameters and shows promise for clinical decision support systems.

Disclosure: Nothing to disclose.

PP0225

PROPRANOLOL VERSUS ENDOSCOPIC VARICEAL LIGATION FOR PRIMARY PREVENTION OF VARICEAL BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Jamileh[1], N. Gire[2]
[1]East Lancashire Hospitals Trust, Gastroenterology, Blackburn, United Kingdom, [2]University of Bolton, Bolton, United Kingdom

Contact E-Mail Address: ejamileh@hotmail.com

Introduction: Variceal bleeding accounts for approximately 20–30% of cirrhosis-related deaths and remains a major complication of portal hypertension in patients with liver cirrhosis (1). The National Institute for Health and Care Excellence (NICE) in the United Kingdom (UK) recommends the administration of propranolol or carvedilol, or endoscopic variceal ligation (EVL) as primary prevention of medium to large oesophageal varices. (2). However, the comparative efficacy and safety profiles of these approaches remain unclear.

Aims & Methods: A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines. Electronic databases were searched to identify randomised controlled trials (RCTs) comparing EVL and propranolol for the primary prevention of variceal bleeding in patients with liver cirrhosis. Primary outcomes included incidence of variceal bleeding, all-cause mortality, and bleeding-related mortality. Secondary outcomes included adverse effects related to prophylactic treatment. Data were pooled using fixed or random-effects models depending on heterogeneity.

Results: Nine RCTs comprising a total of 916 patients were included. EVL was associated with a significantly lower risk of variceal bleeding compared to propranolol (odds ratio [OR] 0.44; 95% confidence interval [CI]: 0.28–0.67; p = 0.0002) and reduced bleeding-related mortality (OR 0.57; 95% CI: 0.33–0.99; p = 0.05). Adverse effects were also significantly less frequent in the EVL group (OR 0.46; 95% CI: 0.32–0.67; p < 0.0001). No statistically significant difference was found in all-cause mortality between the two interventions (OR 0.93; 95% CI: 0.63–1.37; p = 0.72).

Conclusion: EVL is more effective than propranolol for the primary prevention of variceal bleeding in patients with cirrhosis, demonstrating lower rates of first variceal bleed, bleeding-related mortality, and treatment-related adverse events. Although no difference in all-cause mortality was observed, the findings support the consideration of EVL as a first-line prophylactic option. Further well-designed, multicentre RCTs with standardised outcomes, extended follow-up, and robust cost-effectiveness analyses are essential to optimise clinical decision-making and support personalised treatment strategies.

PP0226

PERFORMANCE OF SINGLE-USE GASTROSCOPES IN EMERGENCY SETTING

A. Herner[1], K.C. Winter[1], S. Nennstiel[1], C. Schlag[1]
[1]University Hospital Zurich, Zürich, Switzerland

Contact E-Mail Address: alexander.herner@usz.ch

Introduction: The development of single-use endoscopes was driven by hygiene aspects. However, an even more interesting aspect is that these endoscopes are ready to use and can be immediately disposed after the examination. Therefore, these aspect favors its use outside regular working hours.

Aims & Methods: This study aimed to provide the first experiences of the Ambu single-use gastroscopes with different working channels in daily routine in an emergency setting outside regular working hours in a tertiary center.I

n a time period between Oktober 2023 and Oktober 2024 single use endoscope with 2.8 or 4.2 mm working channel were used in 63 patients. Due to quality assessment different aspects of the single-use endoscope were reported using Lickert scale. All examinations were performed outside regular working hours. 83% of the examinations were done in emergency room or intensive care unit.

Results: Successful completion of endoscopy using only the single-use gastroscope was achieved in 50 out of 63 cases (79%, suspicion of bleeding (n=44), extraction of a foreign body (n=7), bolus obstruction (n=4), pain or suspicion of perforation (n=4), reflux or gastroparesis (n=2), dysphagia (n=1), intoxication (n=1), and megacolon (n=1).

Overall, 43 out of 63 patients (68%) required an intervention during the endoscopy In 13 out of 63 cases the endoscopy failed. In 8 out of 13 cases the examination could be finished successfully after a crossover to a reusable endoscope. A re-intervention was indicated in 7 out of these 13 patients. In a subgroup analyses the success rate was comparable in patients who were treated with single use gastroscope with a 2.8 mm (75%) and 4.2 mm (84%) working channel (p=0.535). The gastroscope with the 4.2 mm channel was significantly better regrading image quality (p=0.006, wheel functionality (p=0.025) and suction function (p=0.032).

Conclusion: This study demonstrates that single-use endoscopes can be used in different emergency settings, however without further technical improvement its usage especially in acute bleeding situations is limited.

Disclosure: Nothing to disclose.

EMERGENCY ENDOSCOPY FOR UPPER GASTROINTESTINAL BLEEDING: WHAT REAL BENEFIT FOR ELDERLY PATIENTS

I. Qarch[1], F.-Z. Chabib[1], M. Kadiri[1], F.Z. Ajana[1], N. Lagdali[1], M. Borahma[1]
[1]Ibn Sina University Hospital Center, Faculty of Medicine and Pharmacy, Mohammed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ismail.qarch@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) is a common medical emergency, particularly in elderly patients, in whom it is often complicated by comorbid conditions and an increased anesthetic risk.

Aims & Methods: The aim of this study was to assess whether emergency endoscopy, although justified by a high Blatchford score, is as relevant in elderly patients as it is in younger patients in terms of therapeutic endoscopic management.

This was a retrospective, monocentric, and analytical study conducted in a tertiary gastroenterology department in North Africa. It included all patients admitted to the emergency department with UGIB between January 2023 and December 2024 who underwent emergency upper gastrointestinal endoscopy.

Inclusion criteria were a Blatchford score strictly greater than 2, according to international recommendations, as well as a history or clinical signs of portal hypertension. Patients were divided into two groups according to age: group 1 (non-elderly, < 65 years) and group 2 (elderly, ≥ 65 years). Statistical analysis was performed using Jamovi software (version 2.3.28), with comparisons made using the Pearson chi-squared test for qualitative variables. A p-value < 0.05 was considered statistically significant

Results: A total of 155 patients were included, 95 in the non-elderly group and 60 in the elderly group. Elderly patients had significantly more cardiovascular comorbidities. Cardiac disease or arterial hypertension was found in 35% and 33% of elderly patients, respectively, compared with only 5% each in younger patients (p < 0.001). The absence of comorbidities was significantly more frequent in younger patients (18 vs. 3 cases; p = 0.026).

Use of anticoagulant or antiplatelet therapy was also significantly more common in the elderly group (p = 0.0035), with a predominance of aspirin alone or combined with clopidogrel. AODs and VKAs were more frequently used among younger patients. Blood transfusion was required in 47.4% of younger patients and 40% of elderly patients, with no significant difference (p = 0.46).

Endoscopic findings in younger patients most frequently included gastroduodenal ulcers, followed by signs of portal hypertension and esophagitis. Normal endoscopy was observed in 15.8% of younger patients (15 cases) and 26.2% of elderly patients (16 cases), with no statistically significant difference (p = 0.15). In elderly patients, the main diagnoses were ulcers, esophageal varices, esophagitis, and normal FOGD findings.

Therapeutic endoscopic intervention was performed in 39 younger patients (41.1%) versus 15 elderly patients (25%), showing a significant difference (p = 0.0297). This reflects a lower rate of endoscopic hemostasis in the elderly despite identical clinical criteria for emergency indication.

Conclusion: In elderly patients, although emergency endoscopy is indicated based on the same criteria as in younger patients, it less often results in therapeutic intervention. These findings highlight the importance of a personalized approach that accounts for the patient's overall geriatric profile.

Introduction: The safety and efficacy of endoscopic haemostasis in patients with upper gastrointestinal (UGI) bleeding has been widely assessed over the years. However, to date no study addressed the management of UGI bleeding specifically in the setting of patients with surgically altered anatomy.

Aims & Methods: Our study is focused on the evaluation of the endoscopic management of UGI bleeding in these patients with specific concern about the techniques used to achieve haemostasis, the management of technical failure and the rate of adverse events. We conducted a multicentre retrospective- prospective observational study in 13 endoscopy units in Italy. All consecutive patients with UGI bleeding and surgically altered anatomy managed endoscopically were collected from January 2023 to November 2024.

Results: We enrolled 162 patients (73% males) with a mean age of 69 years. 45% of patients had history of oncologic surgery while 20% underwent bariatric surgery. The most common clinical manifestations were melena (59%) followed by hematemesis (22%). At bleeding event patients were taking anticoagulants and antiplatelet in 32% and 16% of cases, respectively. In 43% of cases from 1 to 4 blood units were needed, in 15% more than 4 blood units, while in 42% of patients no transfusions ware required. 42% of endoscopic procedures were performed with anesthesiologist assistance. Bleeding was located at anastomotic site in 70% of cases and ulcer was the most common source of bleeding (54% of patients). The most frequently used treatments were adrenaline combined with TTSC (40 %) and TTSC alone (24%). Haemostatic powder or gel and adrenaline combined with thermal treatment were used only in 6 and 4% of cases respectively while OTSC was used in 1 patient alone after failure of adrenaline combined with TTSC. Bleeding control during endoscopy was achieved in 94% of patients. In 12 patients rebleeding occurred, which was managed with surgery in 2 patients, interventional radiology in 1 case and with new endoscopic treatment in 4 cases. No serious adverse events linked to endoscopy were reported.

Conclusion: Our preliminary results showed that patients with altered anatomy often had severe bleeding requiring a large amount of blood transfusions. The standard endoscopic homeostatic techniques seemed to be effective for the management of bleeding, although a not negligible rate of patients needed additional treatments. However, further data are needed to better assess clinical outcomes in this setting and to better define possible predictive predictors of clinical success and therefore which technique should be preferred to achieve haemostasis.

BLEEDING-RELATED INDICATIONS AS KEY PREDICTORS OF BALLOON-ASSISTED ENTEROSCOPY OUTCOMES AFTER POSITIVE VIDEO CAPSULE OR CROSS-SECTIONAL IMAGING

N. Nachmias Peiser[1], L. Deutsch (Mlynarsky)[1], R. Reicher[1], J. Pfeffer[1], T. Thurm[1]

[1]Tel Aviv Sourasky Medical Center, Gastroenterology and Liver Diseases, Tel Aviv, Israel

Contact E-Mail Address: noy.na87@gmail.com

Introduction: Balloon-assisted enteroscopy (BAE) is an important diagnostic tool for small bowel evaluation, especially following a positive Video Capsule Endoscopy (VCE) or Cross-Sectional Imaging (CSI). However, the diagnostic yield of BAE in this context remains variable.

Aims & Methods: This retrospective study aimed to evaluate the diagnostic yield of BAE performed following positive imaging. All BAE procedures conducted between 01/2009-12/2024 following a positive CSI (CT or MRI) or VCE within 12 months prior to the procedure were included. Clinical characteristics, procedural indications (polyp/mass, suspected bleeding or inflammation), and imaging modalities were compared between groups. A classification tree analysis explored factors associated with a positive diagnostic yield.

Results: Among 224 BAE procedures, the diagnostic yield was 58.5% (131 positive findings). No significant differences were observed between positive and negative groups regarding sex, age, indication, pre-BAE imaging modality (VCE or CSI), route, or depth of insertion. Classification tree analysis identified bleeding-related indications (e.g. overt bleeding or angioectasias) as the strongest predictor of positive yield (74.5% vs. 50%, p=0.005), particularly with antegrade BAE. However, cross-validation failed to generate a stable model, with a misclassification risk of 41.5% (±3.3), indicating limited predictive accuracy.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this large retrospective study spanning 15 years, BAE following positive imaging demonstrated a diagnostic yield of nearly 60%. While demographic and procedural factors were not predictive, bleeding-related indications were significantly associated with positive findings, highlighting the importance of clinical context in guiding BAE use. These findings may help optimize patient selection and improve procedural efficacy.

Contact E-Mail Address: kbalint.tibor@gmail.com

Introduction: International guidelines recommend performing emergency gastroscopy within 12 hours for variceal (V) bleeding and within 24 hours for non-variceal (NV) bleeding in cases of upper gastrointestinal bleeding (UGIB).

Aims & Methods: This study aimed to analyze the time elapsed between emergency department admission and time of endoscopy, referred to as “door-to-endoscopy time” (DET), and to identify factors influencing DET across different UGIB subgroups. We conducted a retrospective cohort analysis of patients who underwent emergency gastroscopy for UGIB between January 1, 2022, and December 31, 2023, at the Department of Emergency Medicine at Semmelweis University. Data were collected on clinical parameters and 30-day mortality. NV patients were categorized into high-risk (HNV) and low- risk (LNV) groups based on endoscopic findings (Forrest classification). Welch’s t-test was used for comparing mean DET among the subgroups, whereas for hemoglobin linear regression was applied. The significance level was set at 0.05 for all analyses.

Results: Among 654 patients, we identified 126 V and 528 NV UGIB cases, with the latter comprising 99 HNV and 429 LNV cases. Rebleeding occurred in 5.4% of patients (V: 12.7%, HNV: 10.1%, LNV: 2.1%), and 30-day mortality was 19.7% in the cohort (V: 24.8%, HNV: 22.6%, LNV: 17.6%). The mean DET was 7.28 hours (SD=±6.04), with subgroup averages as follows: V: 5.87±3.77 hours, HNV: 6.33±4.04 hours, and LNV: 7.92±6.83 hours, with significant differences between LNV-HNV (p=0.003) and LNV-V (p<0.0001) groups; no significant difference was observed between HNV-V (p=0.37). In the entire cohort, shorter DET was significantly associated with tachycardia (6.61 vs. 7.73 hours, 95% confidence interval (CI) -1.99 to -0.25, p=0.01), hematemesis (5.82 vs. 8.09 hours, 95% CI -3.11 to -1.43, p<0.0001), syncope (6.25 vs. 7.57 hours; 95% CI -2.30 to -0.33, p=0.009), and lower hemoglobin levels (1 g/L decrease in hemoglobin reduced DET by an average of 1 minute, p=0.029). DET was not associated with 30-day mortality (p=0.501), vasopressor use (p=0.857), shock index (p=0.091), coffee-ground emesis (p=0.192), hematochezia (p=0.564), intubation (p=0.566), rebleeding rate (p=0.462), or melena (p=0.961). In the V group, DET was significantly shorter in case of hematemesis (5.20 vs. 7.25 hours, 95% CI -3.61 to -0.49, p=0.011) and tachycardia (5.19 vs. 6.64 hours, 95% CI -2.84 to -0.08, p=0.039); whereas in HNV patients with coffee-ground emesis, DET was significantly reduced (4.94 vs. 6.58 hours, 95% CI -3.08 to -0.20, p=0.026); in LNV patients, DET was shorter in patients with hematemesis (6.42 vs. 8.38 hours, 95% CI -3.20 to -0.71, p=0.002) and syncope (6.56 vs. 8.25 hours, 95% CI -3.10 to -0.29, p=0.019).

Conclusion: In our retrospective cohort study, DET significantly differed between LNV-V and LNV-HNV subgroups. Shorter DET correlated with tachycardia, hematemesis, syncope, and lower hemoglobin levels. DET showed no association with 30-day mortality or rebleeding rate.

RISK FACTORS FOR REBLEEDING AFTER TRANS-ARTERIAL EMBOLIZATION IN PATIENTS WITH NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING

J.H. Yu[1], J.-y. Seo[1], A.Y. Lee[2], H.T. Lee[1]
[1]Bundang Jesaeng Hospital, Internal Medicine, Seongnam-si, South Korea, [2]Cha Gangnam Medical Center, Seoul, South Korea

Contact E-Mail Address: yoowlgns@naver.com

Introduction: Non-variceal upper gastrointestinal bleeding can usually be controlled endoscopically; however, if endoscopic hemostasis fails, it can pose a life-threatening risk. Trans-arterial embolization is a less invasive, safe, and effective rescue therapy that can serve as an alternative to surgery. Identifying factors influencing rebleeding after trans-arterial embolization in advance could lead to more efficient and safer patient management. Therefore, we aim to investigate these factors.

Aims & Methods: We retrospectively investigated 167 patients treated with TAE between January 2008 and June 2023. All patients underwent emergent endoscopy prior to TAE. Re-bleeding was defined as the presence of melena, hematemesis, or hematochezia with a fall in hemoglobin levels (> 0.8 g/dl) or shock after TAE. The primary outcomes was 30-day re-bleeding rate.

Results: Total of 104 patients with non-variceal upper gastrointestinal bleeding were selected. Re-bleeding within a month after TAE was noted in 24 patients (23.1%). Patients with re-bleeding had significantly higher rates of thrombocytopenia (50.0% vs. 15.0%, p= 0.001) and coagulopathy (20.8% vs. 5.0%, p= 0.045) than those without re-bleeding. Additionally, 7-day mortality (16.7% vs. 2.5%, p=0.035), AIMS65 score (2.0 vs. 1.0, p=0.029), and ABC score (7.0 vs. 4.0, p=0.002) were significantly elevated in patients with re-bleeding. A multivariate logistic analysis showed thrombocytopenia (odds ratio: 5.44, 95% confidence interval: 1.84–16.92, p= 0.002) and an ABC score ≥ 6 (odds ratio: 2.87, 95% confidence interval: 1.02–8.66, p= 0.005) significantly increased the risk of re-bleeding after TAE.

Conclusion: TAE could be an effective and safe treatment for non-variceal upper gastrointestinal bleeding. However, thrombocytopenia and elevated ABC scores might be associated with a higher 30-day rebleeding rate after TAE. Therefore, patients with these risk factors should be carefully monitored and managed.

ANTITHROMBOTIC THERAPY AND UPPER GI HEMORRHAGE: RISKY BUSINESS?

A. Achemlal[1], S. Mrabti[1], S. Azammam[1], S. Oualaalou[1], M. Amine[1], I. Karam[1], F. Ait iken[1], S. Hdiye[1], A. Benhamdane[1], T. Addajou[1], R. Berraida[1], E. Ilham[1], R. Fedoua[1], H. Seddik[1]
[1]Mohamed V Military Training Hospital, Rabat, Morocco, Rabat, Morocco

Contact E-Mail Address: achemlal.amine@gmail.com

Introduction: This study aims to assess the impact of antithrombotic therapy on endoscopic findings in patients hospitalized for upper gastrointestinal bleeding.

Aims & Methods: We carried out a prospective, single-center cross-sectional study including 332 patients between June 2020 and February 2025. Patients were classified as antithrombotic (AT) users if they were receiving antiplatelet agents (such as low-dose aspirin or thienopyridines) and/or anticoagulants (including vitamin K antagonists, direct oral anticoagulants, or heparin).

Results: The mean age of the study population was 59 ± 16.7 years, with a marked male predominance (77.1%). Among them, 63 patients (19%) were receiving antithrombotic (AT) therapy—41 on antiplatelet agents and 39 on anticoagulants. Patients in the AT group were significantly older (68 vs. 57 years; $p < 0.001$) and had a higher burden of comorbidities (75.8% vs. 16.7%; $p < 0.001$). However, there were no significant differences between the AT and non-AT groups regarding the presence of active bleeding at endoscopy (12.7% vs. 16.8%; $p = 0.425$) or the need for endoscopic hemostasis (7.9% vs. 16%; $p = 0.1$).

In multivariate analysis, after adjustment for age, sex, comorbidities, active bleeding, and AT use, only the presence of active bleeding was independently associated with the need for endoscopic hemostasis. Specifically, active bleeding at endoscopy increased the odds of requiring hemostasis by 26-fold (OR: 26, 95% CI: 12.9–62.15; $p < 0.001$), whereas AT therapy was not an independent predictor (OR: 0.386, 95% CI: 0.105–1.42; $p = 0.154$).

Conclusion: In older patients receiving antithrombotic therapy and admitted for upper gastrointestinal bleeding, the risk of active bleeding during endoscopy and the need for endoscopic hemostasis do not appear to be increased.

Disclosure: Nothing to disclose.

PP0233

EARLY ENDOSCOPY IN NON-VARICEAL UPPER GI BLEEDING: DOES TIMING INFLUENCE OUTCOMES IN LOW-RISK PATIENTS ?

O. Nacir[1,2], F.E. Lairani[1,2], A. Ait Errami[1,2], S. Oubaha[1,3], Z. Samlani[1], K. Krati[1,2]
[1]Mohammed VI University Hospital, Department of Gastroenterology and Hepatology, Marrakech, Morocco, [2]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Biosciences and Health Laboratory, Marrakech, Morocco, [3]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Department of Physiology, Marrakech, Morocco

Contact E-Mail Address: o.nacir@uca.ac.ma

Introduction: Despite significant advances in the management of non-variceal upper gastrointestinal bleeding (NVUGIB), the optimal timing of endoscopy remains a subject of debate.

Current guidelines recommend performing endoscopy within 24 hours of presentation, yet the impact of this strategy in different risk stratifications is not fully elucidated.

This study aimed to evaluate the influence of early endoscopy (≤24 hours) on clinical outcomes in NVUGIB patients, with particular focus on risk stratification using the Glasgow-Blatchford Score (GBS).

Aims & Methods: This retrospective, single-center cohort study included consecutive adult patients who underwent upper gastrointestinal endoscopy for suspected NVUGIB over a four-year period. Demographic, clinical, biochemical, endoscopic, and outcome data were collected and analyzed.

Patients were stratified based on GBS into low-risk (GBS <12) and high-risk (GBS ≥12) categories. The primary outcome was 30-day mortality. Secondary outcomes included need for endoscopic hemostasis and blood transfusion.

Results: A total of 298 patients were included (mean age: 65.3 ± 17.1 years; 57% male), of whom 55% were classified as high-risk. Endoscopy was performed within 24 hours in 62.1% of cases.

In low-risk patients, early endoscopy was significantly associated with:

- Higher rate of endoscopic therapy ($p = 0.003$)
- Lower 30-day mortality ($p = 0.03$)
- Reduced need for blood transfusion ($p = 0.03$)

Patients in the low-risk group who underwent delayed endoscopy (>24 hours) were significantly older (70.8 ± 15.2 vs. 63.5 ± 16.7; $p = 0.01$), had more comorbidities (Charlson Comorbidity Index: 4.0 ± 2.1 vs. 3.1 ± 2.5; $p = 0.02$), lower baseline hemoglobin (10.1 ± 3.1 vs. 11.3 ± 2.8; $p = 0.03$), and were more frequently admitted during weekends or holidays (27 vs. 0; $p < 0.001$).

In contrast, in high-risk patients, no statistically significant differences in outcomes were observed between early and delayed endoscopy.

Conclusion: Our findings suggest that performing upper endoscopy within 24 hours is associated with improved clinical outcomes, specifically reduced mortality and transfusion requirements, in low-risk NVUGIB patients.

Early intervention appears especially beneficial in older patients with multiple comorbidities and initial anemia. These data support prioritizing early endoscopic evaluation in selected lower-risk patients as part of optimized UGIB management pathways.

Contact E-Mail Address: elchaabanihazem1@gmail.com
Introduction: Upper gastrointestinal (GI) hemorrhage is a frequent reason for admission to the emergency department, leading to serious complications and represent a major cause of mortality, requiring early diagnosis and management. The prognosis may be altered in patients on anticoagulant therapy.
Aims & Methods: The aim of the study was to define clinical and endoscopic particularities of upper GI bleeding in patients on Direct Oral Anti-Coagulant (DOAC) therapy.
We carried out a retrospective, monocentric, cross-sectional study, over a 2-year period from January 2023 to January 2025, in our hepato-gastroenterology department, including all patients hospitalized for upper GI bleeding. We conducted a descriptive and analytical statistical study subdividing patients into two groups: first group (G1), those receiving DOAC treatment; and a second group (G2) those not receiving anticoagulant treatment.
Data collected included demographics (age, sex), comorbidities, current treatment, hemodynamic constants (blood pressure, heart rate), upper gastrointestinal bleeding severity scores (Glasgow-Blatchford score (GBS)), upper GI endoscopy findings, as well as the need for endoscopic hemostasis, and the percentage of recurrent bleeding. Biological data included hemoglobin level, renal function.
All these data were entered and analyzed in a database using SPSS version 21.0.
Results: One hundred and thirty-seven patients were included in this study. Thirty-four patients receiving DOAC therapy (25%).
There was a statistically significant difference in the mean age of patients was 68 years in G1 and 49 years in G1, and 68% of patients were over 60 years of age compared with 32%, in G1 and G2 respectively (p= 0.04 ; OR= 4.8). A male predominance with a sex ratio of 2.7 was noted in G1, but in G2 there was no statistically significant difference according to gender. On the other hand, 78% of patients in G1 versus 25% in G2 (p= 0.02 ; OR= 7.5) had one or more comorbidities, mainly diabetes, hypertension and coronary heart disease.
There was no statistically significant differences were found between the two groups with regard to upper gastrointestinal bleeding severity scores (GBS), the mean GBS being 5 (Extremes: 1 - 8) in G1 and 4 (Extremes: 0 - 6) in G2. Furthermore, no statistically significant difference was found between G1 and G2 concerning hemodynamic constants (blood pressure, heart rate) and Biological data (hemoglobin level, renal function).
Similarly, there was no statistically significant difference between the two groups in the results of upper GI endoscopy (active bleeding present in 52% of cases in G1 vs 48% of cases in G2), as well as the need for endoscopic hemostasis was the same in both groups (11% in G1 vs 13% in G2), and no recurrence of bleeding was observed in either group.
Conclusion: Upper GI bleeding under DOAC therapy is mainly observed in elderly person with several comorbidities. However, according to our study the DOAC therapy does not appear to increase the severity of GI bleeding or the risk of recurrent bleeding, contrary to what has been described in the literature. Further prospective studies are needed to better investigate this association.
Our study has certain limitations, its retrospective nature and sample size limiting subgroup analyses.
Disclosure: Nothing to disclose.

Introduction: Peptic ulcer bleeding (PUB) is a common cause of non-variceal upper gastrointestinal bleeding (NVUGIB). In cases with high-risk stigmata (HRS) endoscopic therapy is recommended.
Aims & Methods: Our aim was to analyze the course of patients with adherent clots found on index endoscopy.Patients undergoing emergency endoscopy for upper GI bleeding at the Department of Emergency Medicine at Semmelweis University between January 1, 2022 and December 31, 2023 were included in a retrospective cohort analysis. In case of a peptic ulcer with adherent clot, its removal was encouraged according to our in-house protocol. If needed endoscopic treatment was applied as defined by ESGE based on the Forrest classification.
Results: There were 92 patients (56 males, 36 females, mean age 74) with PUB and HRS. In 33 patients (35.8%) an adherent clot (Forrest IIb) was detected during index endoscopy, 13 cases in the stomach and 20 cases in the duodenum. The frequency of further HRS was as follow: Forrest Ia: 8.7% (n=8/92), Forrest Ib: 34.4% (n=31/92), Forrest IIa: 22.8% (n=21/92). Rebleeding rate was 10.8% (n=10/92), 30-day mortality was 21.7% (n=20/92). Of the 33 cases with adherent clot, in 25 cases (75.8%) there was an attempt to remove the clot. In eight cases (24.2%) the clot could

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

not be removed. In the 17 cases (51.5%), where the clot was removed successfully, the underlying ulcer got upgraded in four cases (23.5%) to Forrest Ib; and downgraded in 13 cases (76.5%): to Forrest IIc in five cases (29.4%), Forrest III in eight cases (47.1%). During post-endoscopy course six out of the 33 patients (18.1%) experienced rebleeding. In four patients, where clot removal led to active bleeding (Forrest Ib), after initial hemostasis at index endoscopy, one patient required additional treatment during second look endoscopy. In those 13 patients, who got downgraded, three (21.4%) needed repeated endoscopic treatment; whereas in the eight patients, where clot removal was not endeavoured, two needed endoscopic re-treatment.

Overall, in five cases endoscopic hemostasis was achieved and one patient required surgery. During a 30-day follow-up 12 patients (36.3%) died in this cohort, but only one patient (3%) related to bleeding and one patient due to complications of surgery.

Conclusion: Based on our finding in a small cohort of patients with PUB and an adherent clot, endoscopic removal can be attempted and accomplished. Irrespective of the subsequent finding on the ulcer base, successful endoscopic hemostasis can be achieved on index endoscopy. However, the risk of rebleeding and mortality is higher than patients with other HRS. Further prospective studies on larger patient cohorts are encouraged.

Introduction: Proton pump inhibitors (PPIs) are commonly prescribed for acid-related disorders, yet concerns about overuse and long-term adverse effects persist. Physicians, due to their medical knowledge and unrestricted access to medications, may demonstrate unique self-medication behaviors. This study aimed to assess the prevalence, indications, self-prescribing habits, and awareness of PPI-related risks among physicians.

Aims & Methods: A cross-sectional online survey was administered to 442 physicians across different healthcare levels. The anonymous questionnaire collected data on demographics, frequency and indications for PPI use, self-medication practices, knowledge of adverse effects, and deprescribing behavior. Descriptive and comparative statistical analyses were conducted.

Results: Of the respondents, 60.8% reported occasional PPI use, and 52.0% admitted to self-medicating without prior medical consultation. The most common indications were gastroesophageal reflux disease (GERD) and dyspepsia. Preventive use (e.g., before fatty meals or alcohol) was rare, reported by only 6.1%. Although awareness of potential side effects was high, just 2.0% had discontinued or reduced PPI use due to adverse effects.

Conclusion: Self-medication and occasional PPI use are prevalent among physicians, despite a high level of awareness regarding potential harms. These findings underscore the need for targeted educational efforts and clearer deprescribing guidelines to promote more rational PPI use in the medical community.

Disclosure: The authors declare no conflicts of interest related to this study.

AUDIT ON ENDOSCOPIC FOLLOW-UP OF GASTRIC ULCER: COMPLIANCE WITH THE UK, NICE GUIDELINES

G. Saengkrajang[1,2], S. Hoque[3]
[1]Queen Mary, University of London, Medical School, London, United Kingdom, [2]Medical School, Queen Mary University of London, London, United Kingdom, [3]Barts Health NHS Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: G.Saengkrajang@smd20.qmul.ac.uk

Introduction: Peptic ulcers are a common gastrointestinal condition with potential risks for recurrence and complications. Timely follow-up, particularly repeat endoscopy, is critical for confirming ulcer healing and minimizing unnecessary interventions or missing gastric cancer. The National Institute for Health and Care Excellence (NICE) recommends repeat esophagogastroduodenoscopy (OGD) 6–8 weeks following gastric ulcer diagnosis to confirm healing.

Aims & Methods: Aim: To evaluate compliance with NICE guidelines for repeat endoscopy following a gastric ulcer diagnosis within a large UK hospital trust.

Methods: A retrospective audit was conducted on patients diagnosed with gastric ulcers from October 2022 to September 2024 at Barts Health NHS Trust. Patient records, endoscopy reports, and laboratory results were reviewed to assess whether follow-up endoscopy occurred and its timing relative to NICE recommendations.

Results: A total of 62 cases were identified and their follow up were recorded. Out of 62 patients (mean age 58 years), 53 (85%) underwent follow-up, while 9 (15%) did not. Only 12% received follow-up within the 6–8-weeks guideline window, while 50% had follow-up within 9 weeks. Most follow-ups (70%) occurred within 24 weeks. A Kaplan-Meier survival analysis (figure 1) was performed to visualise time-to-follow-up, showing a gradual increase in follow-up rates over time, with a plateau reached by 24 weeks. This analysis highlighted delays in achieving the recommended 6–8-week benchmark and demonstrated that only a minority of patients received follow-up in a timely manner.

Follow-up timing influenced diagnostic outcomes. Patients reviewed before 6 weeks had a higher rate of ongoing ulcers (44%), often prompting further investigations (figure 2). Those seen between 6–8 weeks had complete ulcer healing. Among patients reviewed at 8–12 weeks and beyond 12 weeks, 27% still had ongoing ulcers, though the majority had healed. Notably, patients with follow-up beyond 12 weeks often underwent repeated endoscopy for continued management.

Non-compliance was primarily due to failure to request follow-up (56%), patient non-attendance (33%), and medical inappropriateness (11%).

Conclusion: Although most patients received follow-up endoscopy, adherence to NICE-recommended timing was suboptimal. Our study shows that while most patients were eventually followed up, only a small pro-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

portion were reviewed within the ideal 6–8-week window. Patients who had early follow-up (<6 weeks) often still had ongoing ulcers, necessitating unnecessary investigations due to insufficient healing time. Conversely, patients with follow-up after 12 weeks typically required repeated endoscopy for ongoing management. To optimise care, systems should be improved to ensure timely and targeted follow up. Further research should explore only targeted cases merit follow ups and patient-level factors contributing to delayed follow-up adherence.

Figure 1: Kaplan-Meier Survival Curve for Follow-Up Endoscopy After Peptic Ulcer Diagnosis.

The curve illustrates the cumulative proportion of patients without follow-up endoscopy over time since initial peptic ulcer diagnosis. A steep initial decline indicates that most follow-ups occurred within the first 24 weeks. However, only a small proportion of patients received follow-up within the NICE-recommended 6–8 week timeframe. The plateau after 24 weeks reflects the reduced likelihood of follow-up beyond this point.

Figure 2: Outcomes of Follow-Up Endoscopy After Peptic Ulcer Diagnosis by Timing Interval

AVOIDANT/RESTRICTIVE FOOD INTAKE DISORDER IN FUNCTIONAL DYSPEPSIA REFLECTS INCREASED PSYCHOSOCIAL DISTRESS AND BURDEN, NOT WORSE DYSPEPSIA SYMPTOMS

H. Burton Murray[1], B. Peterson[2], M. Atkins[1], R. Karlson[2], K. Staller[1], C. Vélez[1], B. Surjanhata[1], K. Becker[1], R. Sclocco[1], L. Shabazian[2], L. Van Oudenhove[3], L. Keefer[4], B. Ljótsson[5], E. Lawson[1], J. Thomas[1], B. Kuo[1]

Introduction: Avoidant/restrictive eating is common in people with neurogastroenterology disorders including functional dyspepsia (FD). There is debate on whether avoidant/restrictive food intake disorder (ARFID) is an expected response to severe symptoms or simply a common comorbid disorder. To address this, among adults with FD, we aimed to contrast those with and without ARFID on FD symptoms, quality of life, psychosocial factors, nutrient tolerance, and gut transit.

Aims & Methods: Adults with Rome-IV confirmed FD and healthy controls (HC) from an ongoing study participated. ARFID diagnosis was assigned based on a semi-structured *DSM-5* diagnostic interview. Surveys: Patient Assessment of GI Disorders Symptom Severity Index (PAGI-SYM), Short Form Nepean Dyspepsia Inventory (SF-NDI), Nine-Item ARFID Screen (NIAS), Fear of Food Questionnaire (FFQ), Visceral Sensitivity Index (VSI), and Hospital Anxiety/Depression Scale (HADS). Nutrient Drink Test (NDT) measured gastric tolerance—liquid nutrient ingestion at 30mL/minute until subject reported unbearable fullness. Wireless Motility Capsule (WMC) measured gut transit. Height/weight was measured for body mass index (BMI).

Results: Sample (80% female, M_{age}=37.1±14.4y) included 37 FD+ARFID, 14 FD only, and 18 HC. Groups did not significantly differ in sex or age. Adjusted pairwise comparisons showed small (*r*=.1-.2) non-significant differences between FD and FD+ARFID on FD symptoms by PAGI-SYM and SF-NDI (Table 1). However, FD+ARFID had significantly worse scores compared to FD with medium effects (*r*=.3-.4) on: FD-related quality of life by SF-NDI, Fear of Food by NIAS-Fear and FFQ, GI-anxiety by VSI, and anxiety by HADS. FD+ARFID vs FD also had small differences (*r*s=.2) on: feeling more bothered by FD symptoms on SF-NDI, worse depression by HADS, lower BMI, and less NDT consumption. Compared to HC, FD and FD+ARFID had significantly worse survey scores with large effects for FD+ARFID (*r*=.6-.8) and medium effects for FD vs HC (*r*=.3-4). For the NDT, FD+ARFID consumed significantly less than HC with large effect (*r*=.6) but with a trend medium effect for FD consuming less than HC (*r*=.3). Groups did not significantly differ in WMC transit times.

Small Bowel	5.2±1.9	4.1±1.4	5.2±1.4			
Colonic	45.3±30.6	28.0±12.8	25.4±17.1			

[1]Kruskal-Wallis H Tests among groups were all significant except for WMC transit times. Corrected post-hoc p-values displayed in the table. Effect sizes reported in abstract body.
[2]Total scores presented, but results were similar for all subscales.

Table 1: Differences between groups.

Conclusion: Our findings suggest ARFID, when present in FD, does *not* reflect a response to more severe FD symptoms. Thus, ARFID is a legitimate secondary condition in FD. ARFID may reflect more profoundly altered distress around symptoms (e.g., fear of symptoms, anxiety sensitivity) and greater negative impacts (e.g., FD-related quality of life, lower liquid nutrient tolerance).

Contact E-Mail Address: bert.broeders@kuleuven.be

Introduction: Functional dyspepsia (FD) is one of the most frequent disorders of the gut-brain interaction with a worldwide prevalence of around 7%.[1]

Our group showed that a diet excluding fermentable oligo-, di-, monosaccharides, and polyols (FODMAPs) improved symptoms in the majority of FD patients.[2]

FODMAPs have been studied in irritable bowel syndrome, where poor intestinal absorption may lead to osmotic effects and fermentation, contributing to symptoms.

However, this has not been studied in FD to date. In this study, we assessed pathophysiological parameters after ingestion of mannitol and a control meal in FD patients and healthy volunteers (HV).

Aims & Methods: FD patients (N=11) that responded to the low FODMAP diet and showed symptom triggers by mannitol during reintroduction were recruited. Also, 11 HV participated in this trial. FD and HV had a similar age (47 (24-55) vs. 25 (21-46), p=0.14) and BMI (22 (21-31) vs. 23 (21-25), p=0.85), but FD cohort included more females (100% vs 55%, p=0.04).

After an overnight fast, abdominal magnetic resonance imaging (MRI) was performed in patients and HV. MRI images, gastrointestinal (GI) symptoms and blood samples were collected at baseline and at six separate time points after a challenge meal (0, 15, 30, 45, 60, 120, 240 min). The meal was an oat porridge breakfast containing either mannitol or glucose, as a control, in a randomized, double blind cross-over fashion.

MRI images were analyzed for gastric emptying $T_{1/2}$ (GE $T_{1/2}$), duodenal volume, small bowel water content (SBWC) and colonic gas volume. Blood samples were analyzed for glucose like peptide-1 (GLP-1), peptide YY (PYY), and GIP.

Results: FD patients exhibited more FD symptoms compared to HV after consuming both the glucose-rich meal (54 ± 10 vs 24 ± 7, p=0.02) and the mannitol-rich meal (64±13 vs 23±7, p=0.01). No differences were found for GE $T_{1/2}$ in FD and HV, as indicated in Table 1.

Colonic gas volume was significantly increased in patients compared to HV. Duodenal volumes tended to increase more after intake of mannitol compared to glucose in both groups, but reached significance only in HV. SBWC was increased after mannitol in both HV (p=0.01) and FD (p=0.01).

After intake of mannitol, postprandial GLP-1 levels were significantly lower in FD compared to HV, after 15 (p=0.02) and 30 min (p=0.001). Also, the AUC of GLP-1 was significantly lower in FD versus HV after mannitol (p=0.04), as well as after glucose-rich (p=0.04) meal. In FD, AUC of GIP levels was significantly lower after mannitol versus glucose (p=0.002). GI symptom scores did not correlate with PYY, GLP-1, and GIP levels. GLP-1 and GIP values did not correlate with GE $T_{1/2}$.

Conclusion: In this pilot study no difference in symptom triggering in FD was observed between mannitol and glucose (control) supplemented meals, but compared to HV the meals were associated with higher symptom burden, lower release of GLP-1 and GIP, and larger colonic gas volumes. The mechanisms underlying decreased peptide hormone release and their relevance to symptom generation deserve further studies.

	FD mannitol	FD glucose	HV mannitol	HV glucose
Gastric emptying $T_{1/2}$	46 (36-58)	54 (45-65)	48 (44-58)	53 (48-62)
Δ Colonic gas (mL)	15.45 ±4.18*	-0.35 ±4.38*	7.27 ±7.91	10.53 ±4.12
Δ duodenum volume (AUC mL*min)	1272 ± 520	469 ±271	1167 ±366*	643 ±221*
Δ small bowel water content (AUC mL*min)	154 ±16*	103 ±8*	167 ±16¶	119 ±4¶
AUC GLP-1 (pmol/L *min)	358±35*	344±34¶	504±52*	458±34¶
AUC GIP (pmol/L *min)	81,875±9,631*	109,554±9,362*	189,929±86,981	205,771±65,071
AUC PYY (pmol/L *min)	20,910±2680	19,651±2445	23,501±3656	23,170±3427

GE $T_{1/2}$: Gastric emptying half time, FD: Functional dyspepsia, HV healthy volunteers. * or ¶ indicating pairs of values that are significantly (p<0.05) different after correction for multiple testing. Volumes were compared using a two-way ANOVA. AUC values (4 hours postprandially) were compared using multiple T-tests. GE $T_{1/2}$ was compared using multiple Mann Whitney U test.

THE CORRELATION BETWEEN STRESS AND AUTONOMIC NERVOUS SYSTEM RESPONSE IN GASTROINTESTINAL PATIENTS

A. Furgala[1], M. Przybylska-Felus[2,3], I. Kovalchuk[1], K. Gil[1], M. Zwolińska - Wcisło[2,3]
[1]Jagiellonian University, Medical College, Department of Pathophysiology, Cracow, Poland, [2]Jagiellonian University, Medical College, Department of Gastroenterology and Hepatology, Cracow, Poland, [3]Jagiellonian University, Medical College, Institute of Clinical Dietetics, Department of Gastroenterology and Hepatology, Cracow, Poland

Contact E-Mail Address: a.furgala@uj.edu.pl

Introduction: The brain-gut axis plays a crucial role in the regulation of gastrointestinal (GI) function, with the activity of the autonomic nervous system (ANS) being significantly important. Increased stress, correlated with socioeconomic, behavioral, dietary, and environmental factors, may lead to an overactive sympathetic nervous system response.

The aim of this study was to evaluate the correlation between stress and autonomic nervous system responses in gastrointestinal patients.

Aims & Methods: The study comprised 136 GI patients, divided into three groups: the Dyspepsia Group (DG) with 39 patients, a mean age of 37.8 ±11.2 years; the IBS Group (IBS) with 41 patients, a mean age of 45±15 years; and the Celiac Group (CG) with 53 patients, a mean age of 38.2±14 years. ANS activity was assessed using parameters from Heart Rate Vari-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ability (HRV) analysis, including time domain, frequency domain, and nonlinear analysis. The severity of stress was assessed using stress indices calculated based on hemodynamic parameters and indicators from linear and nonlinear HRV analysis with the HRV Kubios Premium software.
Results: Patients in the IBS Group exhibited the highest stress indicators and sympathetic ANS activity parameters compared to those in the DG and CG groups (SNS index [stress] p=0.038, SNS index AVG p=0.038). Furthermore, the IBS Group had higher stress indices compared to the DG Group (Stress Index 14.0 vs 9.0; p=0.024). Positive correlations were found between the Stress Index, SNS index (stress), and average heart rate (R=0.525; p=0.0001), as well as with sympathetic ANS activity indices. Negative correlations were observed with indicators of parasympathetic nervous system activity across all investigated groups (R=0.433; p=0.001). A high level of stress, indicated by a Stress Index value above 12, was found in 18% of patients with CD, 38% with IBS, and 28% with DG.
Conclusion: Approximately 27% of GI patients experienced significant levels of stress. The stress indicators positively correlated with sympathetic ANS activation and/either impaired function of the parasympathetic system. Assessing the severity of stress will enable targeted therapy to improve the dysfunctions of the brain-gut axis.
Disclosure: Nothing to disclose.

THE MULTIDISCIPLINARY GASTROPARESIS PATHWAY: IS IT BEING FOLLOWED AND DOES IT CHANGE PATIENT OUTCOMES?

A. Roy[1], R. Perry[2], M. Lockett[3], S. Meade[3], B. Watson[4]
[1]North Bristol NHS Trust, Medicine Department, Bristol, United Kingdom, [2]University Hospitals Lincolnshire NHS Trust, Gastroenterology Department, Lincoln, United Kingdom, [3]North Bristol NHS Trust, Gastroenterology Department, Bristol, United Kingdom, [4]North Bristol NHS Trust, Dietetic Department, Bristol, United Kingdom

Contact E-Mail Address: anisha.roy@nbt.nhs.uk
Introduction: Idiopathic gastroparesis (IG) is delayed gastric emptying in the absence of mechanical obstruction. (1) Patients with IG are often high service users and are frequently extensively investigated and can frequently become reliant upon long-term enteral feeding support. (2) Data collected from 18 patients with IG at North Bristol NHS Trust between 2018-2019 identified a significant burden of psychiatric comorbidities (69%) and high service use (44 hospital attendances with a cumulative length of stay of 303 days). We therefore designed a holistic, multi-disciplinary team (MDT)-led pathway for patients with IG, which involved more routine consideration of dietary, psychological and pain team assessment. Discussion at the MDT was made mandatory prior to consideration of tube feeding, with a list of prerequisite criteria, including engagement with psychology and psychiatry services. Further data collection was required to assess the effectiveness of the pathway on the number of emergency and elective admissions, the number of investigations and the need for enteral feeding.
Aims & Methods: We performed a retrospective review. Data collected included patient demographics, past medical and psychiatric history, gastrointestinal investigations before and after diagnosis, the number of referrals to the MDT and the number of local emergency and elective admissions for poorly-controlled IG symptoms, as well as the cumulative length of stay during these admissions.
Results: Table 1 shows the comparison of data before and after the introduction of the pathway. Data from 13 patients were included in the second round of data collection: 12 (92%) were female, the mean age at diagnosis was 33 years(compared to baseline data with 17(94%) females, and mean age at diagnosis being 27 years), and 6 (46%) had known psychiatric comorbidities. 100% of patients were reviewed for MDT, with a significant proportion referred to psychology. Comparison of patient outcomes before (2018-2019) and after (2022-2023) intervention demonstrated a significant reduction in patients receiving enteral tube feeding (13/18 [72%] vs 3/13 [15%], p<0.001) and therefore significantly fewer patients underwent endoscopic tube insertion (11/18 [61%] vs 1/13 [8%], p=0.001). There was a reduction in the overall frequency of radiological investigations performed during the study period. The frequency of elective and emergency admissions was significantly reduced (44 [mean attendances per patient 2.4] vs 11 [mean attendances per patient 0.8]) (p<0.05). There was a significant reduction in the cumulative length of stay, 303 (mean per patient 16.8) days vs 13 (mean per patient 1.0) days (p<0.05).

Variable	Baseline data(n=18)	Follow-up data(n=13)
Psychiatric Comorbidity	15 (69)	6 (46)
Dietetic referral/Psychology referral	16 (89)/2 (11)	13(100)/9 (69)
MDT review	0/18 (0)	13/13 (100)
Number of radiological investigations during study period (total n, mean)	27 (1.5)	0 (0)
Number of patients receiving enteral feeding tube insertions(n,%)	13 (72)	3 (15)
Number of patients receiving endoscopic tube placements/ replacements(NG/NJ or PEG)(n,%)	11 (61)	1 (8)
IR tube interventions (total n, mean total cohort/mean amongst tube fed) Before diagnosis After diagnosis During the study period	 23 (1.3/1.8) 67 (3.7/5.2) 23 (1.3/1.8)	 0 (0/0) 10 (0.8/3.3) 6 (0.5/2.0)
Number of admissions (Total n, mean per patient) Elective Emergency	 26 (1.4) 18 (1.0)	 4 (0.3) 7 (0.5)
Cumulative Average Length of stay (days/mean per patient) Elective admission Emergency admission	 40 (2.2) 263 (14.6)	 3 (0.2) 10 (0.7)

Conclusion: Introduction of a holistic, MDT-led pathway improved outcomes in patients with a diagnosis of IG. Early access to the MDT was associated with a reduction in rates of admission, length of stay, radiation exposure and invasive tube-related procedures. Tube feeding can be used in gastroparesis where patients are unable to meet their nutritional needs but is associated with iatrogenic harm and may not necessarily be required.

LOW PREVALENCE OF HIGH-RISK OLGA STAGES DESPITE HIGH HELICOBACTER PYLORI INFECTION: A 5-YEAR CROSS-SECTIONAL STUDY IN COLOMBIA

J. Frias-Ordoñez[1,2], H. Marulanda[2,3], J.A. Rodríguez Criollo[2], L. Otero-Parra[3,2], S.F. Niño Ramirez[4], E. Otero[3], A. Villareal[5], L. Peña[3], W. Otero[2,3]

Introduction: Atrophic gastritis (AG) is a well-established precursor of gastric cancer, and its most frequent aetiological agent is Helicobacter pylori (H. pylori). Accurate risk stratification is essential to optimise endoscopic surveillance and resource allocation. The Operative Link on Gastritis Assessment (OLGA) system offers a histological staging tool to quantify the severity of gastric atrophy and associated cancer risk. Despite high H. pylori endemicity in Colombia, local data on the prevalence of advanced OLGA stages remains scarce. This study aimed to elucidate the distribution of OLGA stages and their correlation with age and H. pylori status in a large dyspeptic cohort.

Aims & Methods: We conducted a cross-sectional, observational study of adult patients undergoing upper gastrointestinal endoscopy for dyspepsia between January 2019 and December 2023 at a high-volume reference centre in Bogotá, Colombia. All cases followed the updated Sydney biopsy protocol, with five mapped gastric samples analysed by experienced gastrointestinal pathologists. The OLGA system was applied to stage gastric atrophy (0–IV). H. pylori detection was based on histology using Giemsa and H&E stains. Demographic variables, H. pylori status, OLGA stage, and histological features were recorded. Data were processed using SPSS v26, and statistical significance was set at $p<0.05$.

Results: Out of 6,746 patients (mean age: 59 years; 73.4% female), 99% exhibited low-risk OLGA stages (0–II). Only 3 patients (0.04%) presented with advanced OLGA stages (III–IV). A positive correlation was noted between increasing age and the frequency of gastric atrophy, although this did not correspond to an increase in advanced stages. H. pylori infection was confirmed in 82% of the cohort, showing an upward trend over the study period. Interestingly, no cases of H. pylori infection were observed among patients with OLGA III–IV. The majority of infections were restricted to the antrum. Gastric dysplasia and cancer were rare events, both observed in <1% of patients. The association between H. pylori and gastric cancer did not reach statistical significance (OR 0.49; 95% CI 0.23–1.04; p=0.07).

Conclusion: Despite the high prevalence of H. pylori, the frequency of advanced OLGA stages remains remarkably low in Colombian dyspeptic patients. These findings reinforce the utility of the OLGA system, coupled with Sydney protocol biopsies, as a valuable approach to risk stratification. Only 1% of patients would benefit from endoscopic surveillance under international guidelines, suggesting that widespread follow-up may be unnecessary and potentially wasteful.

PP0243
IS THERE AN ASSOCIATION BETWEEN CELIAC DISEASE AND HELICOBACTER PYLORI?

A. Chams[1,2], I. Douhri[1], O. Elmqaddem[1], H. Koulali[1], Z. Abdelkrim[1], Z. Ismaili[1], G. Kharrasse[1]

Contact E-Mail Address: azouzoutc@gmail.com

Introduction: Celiac disease (CD) is an immune-mediated enteropathy triggered by gluten ingestion in genetically predisposed individuals, characterized by small intestinal inflammation and villous atrophy. Microbial agents such as Helicobacter pylori (H. pylori) may influence autoimmune disorders, including CD, through immune modulation.
However, the relationship remains controversial.This study aimed to assess the association between CD and H. pylori infection by comparing the prevalence of H. pylori in patients with and without CD.

Aims & Methods: We conducted a retrospective study from January 2019 to December 2024. Two groups were analyzed: patients with biopsy-confirmed CD and controls without CD who underwent upper endoscopy for dyspeptic or non-specific gastrointestinal symptoms. Exclusion criteria included prior H. pylori eradication, recent use of PPIs, antibiotics, or bismuth compounds, other autoimmune disorders, and incomplete data.

Results: A total of 231 patients were included: 103 with CD (19.4% male, mean age 28.8 ± 12.6 years) and 128 controls (28.1% male, mean age 33.9 ± 11.9 years).
No significant differences were observed in age ($p = 0.73$) or sex distribution ($p = 0.167$) between groups.
H. pylori was detected in 67% of CD patients and 50% of controls, with a significantly higher prevalence in the CD group ($p = 0.014$).

Conclusion: Contrary to some previous reports suggesting a protective effect, this study found a significantly higher prevalence of H. pylori in patients with CD compared to controls.
These findings highlight the need for further investigations into the potential impact of H. pylori on the clinical presentation and management of celiac disease.

Disclosure: Nothing to disclose.

RELATIONSHIP BETWEEN THE PRESENCE OF ANTIBODIES TO CAGA VIRULENCE FACTOR OF *H.PYLORI* AND THE STAGE OF CHRONIC GASTRITIS ACCORDING TO THE OLGA SYSTEM IN MOSCOW POPULATION

D. Bordin[1,2], K. Nikolskaya[1,3], S. Khomeriki[1], A. Dorofeev[1], E. Kuznetsova[1], M. Chebotareva[1,3], A. Spasenov[1], N. Neyasova[1], I. Voynovan[1], I. Khatkov[2,1]
[1]A.S. Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation, [2]Russian University of Medicine, Moscow, Russian Federation, [3]Research Institute of Health Organization and Medical Management, Moscow, Russian Federation

Contact E-Mail Address: dmitrybordin@gmail.com

Introduction: *H.pylori* infection is widespread in the world and affects about 41% of the world's population. *H. pylori* causes chronic gastritis. However, the development of atrophic gastritis is associated both with the duration of the disease and, possibly, with the presence of virulence factors of *H.pylori*. CagA is one of the most significant virulence factors of *H.pylori.*

Aims & Methods: The aim of the study is to determine the influence of the presence antibodies to CagA virulence factor of *H. pylori* on the development of atrophic gastritis according to the OLGA system.

Methods: 221 *H. pylori*-positive patients (69 men and 152 women) were examined in A.S. Loginov Moscow Clinical Scientific Center as part of the study on the prevalence of *H. pylori* in Moscow (Grant of the Moscow Center for Innovative Technologies in Healthcare, 0903-1/22). The mean age of the patients was 49.80 ± 13.66 years (from 20 to 73 years). The presence of *H.pylori* infection was confirmed by a ^{13}C-urea breath test. All patients underwent endoscopy with morphological examination by the OLGA system and serological determination of total antibodies to CagA antigen («Vector-Best», Russia, the normal level is < 0.41 conventional unit (c.u.)). All patients were divided into 5 groups based on the OLGA system gastritis stage (from stage 0 to IV stage). The mean age of patients in the groups was 43.33, 46.52, 53.87, 56.76, and 56.86 years respectively.

Results: Results are presented in Table 1. Total antibodies to CagA virulence factor were detected in 57.47% of patients (127 of 221 patients). The proportion of CagA-positive patients was higher in groups with atrophic gastritis and was rising with increasing stage of atrophy (maximum at stage IV - 85.7%) [Kendall's correlation coefficient (K.c.c.) is 0.247 (p<0.01)]. The trend is noted that the mean age of patients increases in groups from 0 to IV stage of atrophy according to OLGA system, the K.c.c. is 0.282 (p<0.01). Groups with II, III and IV stages of atrophy were comparable in age, but proportion of CagA-positive patients reached a maximum at stage IV of atrophy - 85.7%.

Atrophy stage by OLGA system	Number of patients	Mean age, years	Proportion of CagA-positive patients, %	Mean level of CagA antibodies at CagA-positive patients, c.u.
0	52	43.33 ± 12.94	30.77	2.029 ± 0.808
I	62	46.52 ± 13.40	56.45	1.925 ± 0.846
II	71	53.87 ± 13.47	76.05	2.01 ± 0.827
III	29	56.76 ± 9.78	55.17	1.65 ± 0.664
IV	7	56.86 ± 8.27	85.7	1.355 ± 0.549

Table 1: Frequency of detection CagA-positive patients and mean age of patients in groups with different stage of atrophic gastritis according to the OLGA system

Conclusion: We found positive relationship between the presence of antibodies to CagA antigen and the atrophy stage of the OLGA system in *H. pylori* gastritis patients.

Disclosure: This study is part of the study on the prevalence of *H. pylori* in Moscow (Grant of the Moscow Center for Innovative Technologies in Healthcare, 0903-1/22).

THE DEMONSTRATED EPIDEMIOLOGICAL LINK BETWEEN HELICOBACTER PYLORI COLONIZATION AND ESOPHAGITIS: A CROSS-SECTIONAL STUDY IN AN IRANIAN POPULATION

V. Bozorgi[1], J. Vafaeimanesh[1], M.M. Shams[2], F. Sarfarazi[1], M.S. Eftekhar[2], E. Vesali Monfared[3], M. Khavari Estahbanati[2]
[1]Center of Gastroenterology, Shahid Beheshti Hospital of Medical Science, Gastroenterology, Qom, Iran, [2]Research Center of Gastroenterology and Hepatology, Shahid Beheshti Hospital of Medical Science, Gastroenterology, Qom, Iran, [3]Shahid Beheshti Hospital, Qom University of Medical Science, Gastroenterology and Hematology Disease Research Center, Qom, Iran

Contact E-Mail Address: jvafaeemanesh@yahoo.com

Introduction: Helicobacter pylori (H. pylori) infection and esophagitis are common gastrointestinal disorders, yet their relationship remains controversial. Some studies suggest that H. pylori may have a protective effect against gastroesophageal reflux disease (GERD).
This study aimed to examine the relationship between H. pylori infection and esophagitis in a group of patients undergoing endoscopic assessment.

Aims & Methods: This hospital-based study examined patients who had upper endoscopy (EGD) at Shahid Beheshti Hospital in Qom, Iran, from 2013 to 2018. Inclusion criteria required availability of esophageal biopsies and gastric samples for H. pylori assessment. Demographic data, H. pylori infection status, and esophagitis diagnoses were retrieved from medical records. Different statistical tests, including Chi-square, t-tests, and regression analyses have been used, with p-values below 0.05 considered statistically significant.

Results: The investigation enrolled 244 participants (mean age 58±19.8 years, male predominance 63%). Esophagitis was detected in half the cohort, whereas H. pylori was observed in 23%. Initial analysis revealed a robust association between H. pylori presence and esophageal inflammation (p<0.001), whereas neither age (p=0.245) nor sex (p=0.691) demonstrated significant relationships. In adjusted models, H. pylori-positive individuals experienced tripled esophagitis likelihood (adjusted odds ratio [AOR] 3.1; 95% confidence interval 1.6-5.9; p=0.001).

Variables		Total n (%)	With esophagitis n (%)	Without esophagitis n (%)	p-value
Mean Age ± SD (year)		58.0 ± 19.8	56.5	59.5	0.245
Gender	Female	91 (37.3)	44 (48.4)	47 (51.6)	0.691
	Male	153 (62.7)	78 (51.0)	75 (49.0)	
H. Pylori Positive	Yes	56 (23.0)	40 (71.4)	16 (28.6)	<0.001
	No	188 (77.0)	82 (43.6)	106 (56.4)	

Table 1: distribution of demographic variables in patients.

Conclusion: The data reveal a clinically significant relationship, indicating that H. pylori-positive patients have a threefold increased likelihood of concurrent esophagitis compared to uninfected individuals. This finding challenges the hypothesis that H. pylori exerts a protective role in GERD pathogenesis. Further prospective and mechanistic studies are warranted to elucidate the pathways underlying this relationship.

Disclosure: The authors declare no potential conflicts of interest related to this study.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. PP0246

ORAL UREASE RAPID TEST SERVE AS AN EFFECTIVE COMPLEMENT TO THE DETECTION OF HELICOBACTER PYLORI INFECTION THROUGH UREA BREATH TEST

Y. He[1], C. Wang[1], Y. Wan[2], J. Zhao[1]
[1]Jiangmen Central Hospital, Jiangmen, China, [2]Panyu District Central Hospital, Guangzhou, China

Contact E-Mail Address: 305864956@qq.com

Introduction: The urea breath test (UBT) is the clinic's most popular and accurate non-invasive diagnostic method for H. pylori infection. Yet, it is time-consuming and unavailable to some individuals. The oral rapid urease test (RUT) is an emerging non-invasive convenience method but lacks clinical data support.

Aims & Methods: A double-center, double-blind, methodological comparative design experiment is invited to evaluate the consistency of the oral RUT with UBT. 247 participants were enrolled. Their Dental plaque and tongue coating samples were collected, blind and tested with RUT.

Results: The significant association between the RUT and UBT was analyzed.A total of 247 participants were included in the study. The oral RUT showed a high level of agreement with the UBT. The sensitivity of the test reagent was 98.63% (95% CI: 92.64%, 99.76%), and the specificity was 96.34% (95% CI: 92.25%, 98.31%). The overall conformity rate was 97.05% (95% CI: 94.03%, 98.56%). The positive predictive value was 92.31%, and the negative predictive value was 99.37%. The positive likelihood ratio was 26.96, and the negative likelihood ratio was 0.01. The Kappa value was 0.97.

Conclusion: The efficacy of oral RUT for Helicobacter pylori infection diagnosis is extremely consistent with the UBT.

Disclosure: Nothing to disclose.

PP0247

UNCOVERING THE DIAGNOSTIC TRUTH BEHIND STOOL ANTIGEN TESTING IN *HELICOBACTER PYLORI*: PRE- AND POST-TREATMENT ACCURACY AND CLINICAL PREDICTORS FROM A TUNISIAN PROSPECTIVE STUDY

A. Gnaba[1], M.H. Loghmari[1], I. Jemni[1], A. Sabbek[1], M. Ben Abdelwahed[1], B. Raoua[1], M. Zakhama[1], A. Guediche[1], L. Safer[1]
[1]Fattouma Bourguiba University Hospital of Monastir, Department of Hepato-Gastroenterology, Monastir, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: Early *Helicobacter pylori (HP)* infection diagnosis is crucial to prevent associated complications. Therefore, reliable and accessible noninvasive methods are necessary. Among these, the detection of HP antigen in stool (HpSA) has demonstrated effectiveness, though its performance varies across studies.

Aims & Methods: To evaluate the reliability of the HpSA test for diagnosing HP infection before and after eradication treatment, and to identify factors influencing its performance.

A prospective, single-center, quasi-experimental study was conducted in the gastroenterology department of Fattouma Bourguiba University Hospital in Monastir over 13 months (February 2019–February 2020).

109 patients aged 18 to 65 years, with clinical indications for endoscopy, were included. All underwent endoscopy with biopsies for formal histological diagnosis of HP.

For patients who were on proton pump inhibitors (PPIs), treatment was discontinued at least two weeks prior to both the diagnostic EGD and the HpSA testing, in accordance with standard guidelines.

Patients who tested positive for HP histologically were randomized into two groups to receive either concomitant quadruple therapy (CQT) or triple therapy (TT). HpSA tests were performed before and after treatment and compared to gold standard results: pre-treatment biopsies and post-treatment urea breath tests (UBT).

Results: Out of 109 patients, 100 were histologically positive for HP.

Before treatment, HpSA sensitivity was 49%, specificity 88%, positive predictive value (PPV) 98%, and negative predictive value (NPV) 13.5%.

After treatment, HpSA sensitivity was 31.8%, specificity 100%, PPV 100%, and NPV 82.4%. Agreement with gold standards was low pre-treatment (kappa=0.107) and moderate post-treatment (kappa=0.415).

Multivariate analysis: identified diarrhea, prior PPI use, constipation (odds ratios: 9.43, 4.29, and 4.17 respectively), and dyspepsia (OR=0.31) as independent factors affecting test performance. Post-treatment analysis highlighted prior PPI use and performing HpSA more than 52 days after treatment as significant factors (ORs: 4.94 and 0.29 respectively).

Conclusion: While the HpSA test is a useful non-invasive tool, its practical application requires cautious interpretation due to various factors influencing its reliability.

Disclosure: Nothing to disclose.

IMPACT OF PERSISTENT H. PYLORI INFECTION ON PEPTIC ULCER BLEEDING AND CARDIOVASCULAR OUTCOMES IN LONG-TERM LOW-DOSE ASPIRIN USERS: A PROSPECTIVE OBSERVATIONAL STUDY

A. Semeya[1]
[1]Benha Teaching Hospital, Hepatogastroenterology, Tanta Gharbia, Egypt

Contact E-Mail Address: Semeyaatteyat@gmail.com

Introduction: Long-Term Low-Dose aspirin (LDA) use is associated with an increased risk of peptic ulcer bleeding (PUB). Helicobacter pylori (H. pylori) infection is a well-known risk factor for peptic ulcer disease (PUD). This study aimed to evaluate the prevalence of H. pylori infection in long-term LDA users, assess the impact of eradication on PUB risk, and explore its association with cardiovascular outcomes.

Aims & Methods: A prospective observational study was conducted at Banha Teaching Hospital from January 2023 to January 2024. Four hundred adults (≥18 years) on daily LDA for at least one year were enrolled. H. pylori was diagnosed via a stool antigen test, urea breath test, and histopathology. Infected patients received levofloxacin-based triple therapy for 14 days. Eradication was assessed at six weeks, and participants were followed for six months to evaluate PUB incidence and cardiovascular outcomes.

Results: The prevalence of H. pylori infection was 65.5% (262/400). H. pylori-positive patients exhibited significantly lower albumin levels (3.5±0.4 g/dL vs. 3.9±0.6 g/dL, p< 0.001) and higher levels of urea (29.3±6.4 mg/dL vs. 23.5±4.6 mg/dL, p< 0.001), sodium (137.8±2.9 mmol/L vs. 135.3 ±3.5 mmol/L, p< 0.001), potassium (4.1±0.9 mmol/L vs. 3.8±0.6 mmol/L, p =0.014), and cholesterol (191.0±29.7 mg/dL vs. 177.0±35.9 mg/dL, p= 0.004). PUB was significantly more prevalent in H. pylori-positive patients with gastric erosions (12.2% vs. 0.0%, p< 0.001), peptic ulcers (23.7% vs. 0.0%, p< 0.001), and gastric ulcers (10.7% vs. 0.0%, p< 0.001). After eradication therapy, 51.9% (136/262) of patients tested negative for H. pylori, while 48.1% (126/262) remained positive. All cases of PUB occurred in patients with persistent H. pylori infection, highlighting the importance

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of successful eradication in reducing PUB risk. Additionally, H. pylori-positive patients had a higher prevalence of ischemic heart disease (54.3% vs. 33.3%, p< 0.001), suggesting a potential interaction between H. pylori infection and cardiovascular risk.

Conclusion: Persistent H. pylori infection significantly increases peptic ulcer bleeding and cardiovascular risk in long-term low-dose aspirin users. Successful eradication reduces these complications, underscoring the need for routine screening and treatment in high-risk populations.

EVALUATION OF THE EFFICACY AND SAFETY OF DIFFERENT REGIMENS FOR HELICOBACTER PYLORI ERADICATION THERAPY DURING THE COVID-19 PANDEMIC AND POST-PANDEMIC PERIOD IN UKRAINE: A RETROSPECTIVE OBSERVATIONAL STUDY

V. Cherniavskyi[1], A. Baylo[1]
[1]Bogomolets National Medical University, Internal Medicine 1, Kyiv, Ukraine

Contact E-Mail Address: alinabajlo@gmail.com

Introduction: COVID-19 pandemic has negatively affected treatment of H. pylori and has long-term consequences, in particular, bacterial susceptibility decreased to broad-spectrum antibiotics used in typical H. pylori eradication regimens. Currently, there is limited scientific data on the effectiveness and safety of standard eradication regimens in the post-COVID period.

The aim of the study is to investigate the effectiveness and safety of 10- and 14-day H. pylori eradication regimens used during 2022-2025 and to compare their effectiveness and safety with 10-day regimens used during 2019-2021 in Ukraine, as well as to identify the relationship between unsuccessful treatment cases and anamnestic data.

Aims & Methods: We conducted retrospective multicenter observational study during 2019-2025 years. A comparative analysis of the effectiveness and safety of various eradication regimens for group I (n=82) treated during 2019-2021 years and group II patients (n=74) treated during 2022-2025 years was performed. We determined frequency, intensity, and spectrum of side effects in both groups. A multivariate regression analysis of relationship between unsuccessful treatment cases and anamnestic data was performed.

Results: Comparative analysis revealed no statistical difference in the eradication rates between groups I and II (p≥0.05). The lowest eradication rate among patients in group II was detected on three-component regimens esomeprazole + clarithromycin +amoxicillin (67%) and pantoprazole + clarithromycin/metronidazole/tinidazole (70%). The highest eradication rate was on quadruple regimen esomeprazole + levofloxacin +amoxicillin + furazolidone (100%).

In group II, the frequency of side effects, their intensity, and spectrum significantly increased after 14-day treatment (p<0.001) in comparison with group I.

Regression analysis revealed that male gender, history of COVID-19 infection, and first treatment attempts were significantly more frequently associated with unsuccessful treatment (p<0.05).

Conclusion: Standard 14-day three-component H. pylori eradication regimens esomeprazole + clarithromycin +amoxicillin, pantoprazole + clarithromycin/metronidazole/tinidazole, pantoprazole + amoxicillin + metronidazole/tinidazole have inappropriate eradication rates (≤70%).

The 14-day quadruple esomeprazole + levofloxacin +amoxicillin + furazolidone regimen demonstrates a high eradication rate (>90%), but is accompanied by frequent and diverse side effects, reduced adherence to treatment.

Treatment failure is significantly associated with male gender, previous COVID-19 infection, and first treatment attempts.

DUAL THERAPIES CONTAINING AN ANTIBIOTIC PLUS A PROTON PUMP INHIBITOR OR VONOPRAZAN FOR *HELICOBACTER PYLORI* INFECTION: A SYSTEMATIC REVIEW

C.-A. Shih[1], P.-I Hsu[2]
[1]Antai Medical Care Corporation, Antai Tian-Sheng Memorial Hospital, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Pingtung County, Taiwan, [2]An Nan Hospital, China Medical University, Division of Gastroenterology, Department of Internal Medicine, Tainan City, Taiwan

Introduction: Due to the increasing prevalence of antimicrobial resistance, the efficacy of standard triple therapy for *Helicobacter pylori* (*H. pylori*) infection has declined, with eradication rates now falling below 80% in most countries. Although bismuth quadruple therapy and concomitant therapy are advised in regions with high clarithromycin resistance, these treatments commonly cause frequent adverse events and require the use of two or three antibiotics.

Aims & Methods: Aim: To evaluates the effectiveness of 14-day mono-antibiotic therapies for the first-line treatment of *H. pylori* infection.

Methods: Randomized controlled trials published in English that reported the efficacies of 14-day high-dose amoxicillin/PPI dual, 14-day high-dose amoxicillin/vonoprazan dual, and 14-day tetracycline/vonoprazan dual therapies for the first-line treatment of *H. pylori* infection in adults were included in our literature search. Medical literature searches were conducted using PubMed, Embase, and Cochrane Library electronic databases from October 1, 2014, to October 1, 2024.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The pooled eradication rates for 14-day high-dose amoxicillin/proton-pump inhibitor (PPI) dual therapies were 86.1% (3335/3875; 95% confidence interval [CI]: 85.1% - 87.2%) by intention-to-treat (ITT) analysis and 87.3% (3232/3702; 95% CI: 86.2% - 88.4%) by per-protocol (PP) analysis. For 14-day high-dose amoxicillin/vonoprazan dual therapies, the rates were 87.4% (1085/1241; 95% CI: 85.5% - 89.2%) by ITT and 93.0% (1044/1124; 95% CI: 91.5% - 94.5%) by PP. In the penicillin-allergic population, 14-day tetracycline/vonoprazan dual therapy showed eradication rates of 92.0% (138/150) by ITT and 95.1% (135/142) by PP.
Conclusion: 14-day tetracycline/vonoprazan dual therapy presents an effective option for eradicating *H. pylori* in patients allergic to penicillin. For those without a penicillin allergy, first-line treatments can include 14-day mono-antibiotic regimens such as high-dose amoxicillin/PPI dual, high-dose amoxicillin/vonoprazan dual, and tetracycline/vonoprazan dual therapies.

THE EFFECT OF SUPPLEMENTING WITH SACCHAROMYCES BOULARDII ON VONOPRAZAN-AMOXICILLIN DUAL THERAPY FOR NAIVE HELICOBACTER PYLORI INFECTION: A RANDOMIZED CONTROLLED TRIAL

X. Wang[1], Z. Ji[1]
[1]The Affiliated Changzhou No. 2 People's Hospital of Nanjing Medical University, Gastroenterology, Changzhou, China

Contact E-Mail Address: wxy20009@126.com
Introduction: It remains uncertain if the addition of Saccharomyces boulardii (S. boulardii) to Vonoprazan-amoxicillin dual therapy as a first-line treatment can enhance the Helicobacter pylori (H. pylori) eradication rate and decrease the incidence of adverse events. Therefore, we conducted the randomized controlled trials (RCTs) to address this issue.
Aims & Methods: This is a single-center, prospective randomized controlled study. A total of 150 eligible patients, recruited from December 2023 to November 2024, were randomly assigned to the VA (vonoprazan 20 mg twice daily, amoxicillin 750 mg 3 times daily for 10 days) and VAS groups (vonoprazan 20 mg twice daily, amoxicillin 750 mg 3 times daily, and S. boulardii 250 mg twice daily for 10 days). The eradication rates, adverse events, safety, and compliance were compared between the two groups. Factors associated with eradication rate were explored.
Results: The eradication rates of VA and VAS were 89.3% and 93.3%, respectively, by intention-to-treat analysis (P = 0.384); 93.1%, and 94.6%, respectively, by per-protocol analysis (P=0.966). The incidence of adverse events significantly lower in the VAS group (5.4%) than in the VA group (22.2%; P=0.003).
There was no significant difference in compliance between the VA (96%) and VAS groups (98.7%, P = 0.612). Body surface area (BSA) was found to be a influencing factor for eradication rate in both VA and VAS groups. Serum chemistry tests revealed no significant differences in liver and kidney function before and after treatment in both groups.
Conclusion: Although the addition of S. boulardii to VA dual therapy could not increase the eradication rate, it could decrease the incidence of adverse events. Low-BSA patients are more suitable candidates for this regimen.
Disclosure: Nothing to disclose.

Introduction: Data about the effectiveness and safety of vonoprazan (VPZ) as an adjuvant for treating *H. pylori* are lacking in Brazil. Previous studies suggest that greater acid suppression might improve effectiveness, with an acceptable eradication rate around 90%.

Aims & Methods: To evaluate VPZ in eradication therapy in Brazil, as part of the Hp-BrazilReg, WorldHpReg's partner, a multicenter and prospective real-life registry was performed, assessing outcomes of *H. pylori* management by Brazilian gastroenterologists. Data were registered at e-CRF AEG-REDCap from March 2022 to October 2024. The effectiveness was assessed by modified intention-to-treat (mITT) analysis. Data were subject to quality review.

Results: 2,132 Brazilian patients, with a mean age of 52 years, 61% of whom were women, were included in the mITT analysis. The main treatment indications were: 63% dyspepsia, 10% gastroduodenal ulcers, and 5% premalignant gastric lesions. Endoscopy was performed in 95% of the cases, using histology (90%) and/or the rapid urease test (15%) for diagnosing the infection. No pre-treatment bacterial resistance test was performed.

First-line treatments were administered to 73% (n=1,560) of cases, second-line to 18% (n=386), and rescue to 9% (n=186), with 94% of patients receiving 14-day prescriptions. Low-dose (between 4.5 and 27mg of omeprazole equivalent BID), standard-dose (between 32 and 40mg of omeprazole equivalent BID), and high-dose (between 54 and 128mg of omeprazole BID) of proton pump inhibitor (PPIs) as well as 20mg BID of vonoprazan (VPZ) were used in 39%, 38%, 23%, and 15% of treatment cases, respectively.

Probiotics were used as adjuvant in 15% of patients. Compliance (>90% drug intake) was reported in 99% of the patients.

Eradication was mostly confirmed by endoscopy in 88% (histology [74%] and/or rapid urease test [14%]). The ^{14}C-urea breath test was used in 8% of the cases. At least one adverse event was reported by 25% of patients, mainly nausea (13%), dysgeusia (8%) and diarrhea (7%).

The regimens reaching 90% eradication were: dual-VPZ+amoxicillin for first-line and rescue treatments (96% and 100%, respectively), quadruple VPZ+bismuth+tetracycline+metronidazole for second- and third-line treatments (92% and 90% respectively), and quadruple PPI+bismuth+levofloxacin+amoxicillin (100%) for second-line treatment.

Prescribing VPZ (vs PPI) was an independent factor associated with higher effectiveness both in first-line (OR 2.95; IC 95%: 1.71-5.09) and in second-line and rescue treatments (OR 2.87; IC 95%: 1.69-5.13). There was no difference in adverse effects between VPZ and PPI-based regimens (p<0.01).

Conclusion: VPZ, when prescribed as an adjuvant for treating *H. pylori* infection, shows highly effective results as part of dual therapy with amoxicillin for first-line and rescue treatments, as well as in quadruple therapy with bismuth+metronidazole+ tetracycline or bismuth+amoxycillin and rifabutin for rescue treatments.

UNMASKING PERSISTENT SYMPTOMS AFTER *HELICOBACTER PYLORI* ERADICATION: A PROSPECTIVE ANALYSIS OF CLINICAL PREDICTORS IN REAL-WORLD PRACTICE

A. Gnaba[1], I. Jemni[1], A. Guediche[1], M. Zakhama[1], M.H. Loghmari[1], L. Safer[1]

[1]Fattouma Bourguiba University Hospital of Monastir, Department of Hepato-Gastroenterology, Monastir, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: *Helicobacter pylori* (H. pylori) infection is often asymptomatic, but it can lead to significant gastric pathologies, including chronic gastritis and peptic ulcer disease. Despite effective antimicrobial eradication therapies, a subset of patients continues to experience upper gastrointestinal symptoms. This raises questions regarding the underlying factors contributing to persistent symptomatology following successful treatment.

Aims & Methods: We conducted a prospective, single-center study in the Department of Gastroenterology at Fattouma Bourguiba University Hospital in Monastir, Tunisia.

Patients with histologically confirmed H. pylori infection were randomized to receive either concomitant quadruple therapy (CQT) or standard triple therapy (TT).

All patients underwent esophagogastroduodenoscopy (EGD) with gastric biopsies at baseline for diagnostic confirmation. A urea breath test (UBT) was performed to assess eradication status, followed by a clinical follow-up visit to evaluate symptom resolution.

For patients using proton pump inhibitors (PPIs), therapy was discontinued at least two weeks before the diagnostic EGD and HpSA testing to avoid diagnostic interference.

Results: A total of 109 patients with clinical indications for upper endoscopy were enrolled. H. pylori infection was confirmed histologically in 100 patients, resulting in a prevalence rate of 91.74% in the studied population. The mean age was 41.28 years (SD ±13), and the female-to-male ratio was 3.18.

The most common indication for EGD was chronic epigastric pain (64 patients, 69.6%), followed by iron-deficiency anemia (9.8%) and refractory gastroesophageal reflux disease (7.6%).

Therapeutic adherence, defined as ingestion of ≥90% of prescribed medications, was achieved in 92 patients (92%). Among them, eradication failure was observed in 22 cases (23.9%).

Univariate analysis identified several factors significantly associated with persistent post-treatment symptoms ($p < 0.05$), including:

- Overweight status ($p = 0.014$)
- Presence of epigastric pain at baseline ($p = 0.028$)
- Constipation at baseline ($p = 0.05$)
- Eradication failure ($p = 0.05$)

No significant association was found with diabetes, smoking, initial symptom severity, bacterial load, gastritis severity, or mucosal abnormalities such as ulcers or erosions.

Multivariate logistic regression confirmed the following independent predictors of persistent symptoms:

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

• Epigastric pain (p = 0.009; OR = 8.3; 95% CI: 1.7–40.2)
• Overweight status (p = 0.012; OR = 3.6; 95% CI: 1.3–9.7)
• Constipation (p = 0.02; OR = 4.0; 95% CI: 1.2–13.3)
• Eradication failure (p = 0.04; OR = 3.2; 95% CI: 1.0–10.1)

Conclusion: This study highlights the necessity of a multidimensional approach in the post-treatment follow-up of *H. pylori*-infected patients. Persistent symptoms may not solely be explained by endoscopic or histological findings, but are also influenced by clinical factors such as baseline symptom profiles, functional bowel disorders, and eradication outcomes. Identifying these predictors is essential for optimizing management strategies and improving patient quality of life.

Disclosure: Nothing to disclose.

Introduction: The infection by *H. pylori* can be successfully treated and eradicated if the recommendations from consensus guidelines are correctly followed. It is essential to continuously assess the applicability of these recommendations to ensure their alignment with clinical practice.

Aims & Methods: Multicentre, prospective registry evaluating the decisions and outcomes of *Helicobacter pylori* management by European gastroenterologists (Hp-EuReg, Hp-WorldReg's partner). Data were registered at AEG-REDCap e-CRF until December 2024. Modified intention-to-treat (mITT) and time trend analyses were performed.

Results: Overall, 64,084 (84%) first-line empirical prescriptions were analysed. The total number of different therapeutic regimens prescribed exceeded 100. Triple therapy prescriptions decreased from 58% during 2013/15 to 34% in 2022/24; likewise, non-bismuth concomitant therapy use decreased from 23% in 2013/15 to 14% in 2022/24; while three-in-one single-capsule increased from 0.3% in 2013/2015 to 20% in 2022/24. An increase in the average duration of treatments, from 9.9 to 12.7 days in 2013-2024 was identified, as well as in the use of standard/high-dose of PPIs —defined as a 14-day course with standard or high-dose PPIs at >40mg omeprazole equivalent twice daily —, increasing from 36% to 61% in 2013-2024. Over 12 years of evolution, an overall improvement of ≈10% in first-line effectiveness was observed, increasing from 86% to 93%, both globally and across geographic regions (Table).

Conclusion: European gastroenterological practice is continuously adapting to the latest published evidence and recommendations—reducing the use of triple therapies while increasing both treatment duration and PPI dosage—leading to a progressive improvement in overall effectiveness. These changes have remained consistent in recent years.

Introduction: The use of the three-in-one single-capsule formulation of bismuth quadruple therapy (PPI, bismuth, tetracycline, and metronidazole), introduced several years ago, has become increasingly widespread in Europe. However, the experience with this regimen should be analysed in depth.

Aims & Methods: To evaluate the effectiveness and safety of the three-in-one single-capsule in the European Registry on *Helicobacter pylori* Management (Hp-EuReg).

International, multicenter, prospective, non-interventional registry aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists (Hp-EuReg, Hp-WorldReg's partner). All infected adult patients treated with 10-day single-capsule according to data sheet (3 capsules/6 h) or alternative three times a day (4 capsules/8 h) prescriptions were systematically registered at AEG-REDCap e-CRF until December 2024. Variables included: Patient's demographics, previous eradication attempts, prescribed treatment, adverse events, compliance and effectiveness. Modified intention-to-treat (mITT) and per-protocol (PP) analyses were performed, and data were subject to quality review.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Results: Of the 76,042 empirical patients included in the Hp-EuReg, 12,519 (16%) received single-capsule bismuth quadruple therapy. The majority of these patients were naïve (80%), with an average age of 51 years, 63% female and 11% with peptic ulcer. In both the mITT and PP analyses, the single-capsule regimen achieved an eradication rate of 92%. In first-line treatment, effectiveness (mITT) reached 93%, decreasing to 87% in second-line and to 83% in subsequent lines (3rd to 6th) (Table 1).

In rescue therapy, even when the regimen was optimised with standard or high-dose PPIs, optimal (≥90%) effectiveness was never achieved. Compliance with treatment (>90% of drug intake) was reported in 97% of cases, and was the factor most closely associated with the effectiveness of treatment (OR: 7.7, 95% CI: 5.8-10.4). Adverse events (21%) were generally mild and transient; with 0.1% of patients reporting serious adverse events, leading to the discontinuation of treatment in 1.7% of patients.

	Use, N (%)	mITT, N (%)	95% CI	PP, N (%)	95% CI	Compliance, N (%)	95% CI	AEs, N (%)	95% CI
Overall	12,519 (16*)	11,833 (92)	(91-92)	11,627 (92)	(92-93)	12,198 (97%)	(97-97)	12,213 (21%)	(20-22)
1st line (naïve)	9,958 (80)	9,449 (93)	(93-94)	9,299 (94)	(93-94)	9,707 (97%)	(97-98)	9,719 (20%)	(19-21)
2nd line	1,850 (15)	1,721 (87)	(85-89)	1,684 (88)	(86-89)	1,799 (96%)	(95-97)	1,803 (22%)	(20-24)
3rd to 6th line	710 (5.7)	662 (83)	(80-86)	643 (84)	(81-87)	692 (95%)	(93-96)	691 (29%)	(25-32)

*Of the total of treatments included in the Hp-EuReg up to January 2025 (i.e., N= 77,954); mITT: modified intention-to-treat; PP: per-protocol; N: total number of patients analysed; CI: confidence interval; AEs: adverse events.

Table 1. Three-in-one single-capsule effectiveness, compliance and safety in first-line and rescue treatment lines.

Conclusion: The 10-day treatment with single-capsule bismuth quadruple therapy achieves *H. pylori* eradication in approximately 90% of patients by mITT in real-world clinical practice, both as a first-line and rescue treatment, with a favourable safety profile.

Introduction: Minocycline is considered the most potent semi-synthetic tetracycline, demonstrates promising pharmacokinetic and antimicrobial properties against Helicobacter pylori (H. pylori). While previous studies suggested the efficacy of minocycline-containing bismuth quadruple therapy for H. pylori eradication, real-world evidence remains limited.

Aims & Methods: his study aimed to evaluate the clinical efficacy, safety, and cost-effectiveness of minocycline-containing bismuth quadruple therapy in routine clinical practice.This multicenter, real-world observational study was conducted at 25 hospitals in Fujian China between January and March 2025. Patients diagnosed with H. pylori infection received one of three 14-day bismuth-containing quadruple regimens with b.i.d. esomeprazole 20 mg and bismuth 220 mg, plus amoxicillin 1000 mg b.i.d. and clarithromycin 250 mg b.i.d. (PBAC), or minocycline 100 mg b.i.d. and clarithromycin 250 mg b.i.d. (PBMC), or minocycline 100 mg twice b.i.d. and levofloxacin 500mg q.d. (PBML).

The primary outcome was the H. pylori eradication rate, secondary outcomes included the frequency of adverse events, patient compliance, and cost-effectiveness.

Results: A total of 347 patients were enrolled, with 110 patients completing treatment in each group. In the intention-to-treat (ITT) analysis, eradication rates were 77.4% (PBAC), 85.5% (PBMC), and 84.3% (PBML). In the per-protocol (PP) analysis, eradication rates were 80.9%, 90.9%, and 88.2%, respectively. Although the differences among the three regimens were not statistically significant, minocycline-based regimens achieved numerically higher eradication rates.

Adverse event incidence was 32.73%, 20.91%, and 23.64% in the three groups, respectively. Compliance rates exceeded 94% across all groups. Cost-effectiveness analysis showed PBML had the lowest cost-effectiveness ratio (5.38 CNY per 1% eradication), followed by PBAC (5.41 CNY) and PBMC (6.06 CNY).

Analysis	PBAC group	PBMC group	PBML group	χ2	P
ITT	77.4%(89/115)	85.5%(100/117)	84.3%(97/115)	3.053	0.217
95% CI	69.7%-85.0%	79.1%-91.9%	77.7%-91.0%		
PP	80.9%(89/110)	90.9%(100/110)	88.2%(97/110)	5.087	0.0786
95% CI	73.6%-88.2%	85.5%-96.3%	82.1%-94.25%		

Conclusion: H. pylori eradication, with favorable patient compliance and pharmacoeconomic profiles. These regimens present a viable alternative to traditional amoxicillin-or tetracycline-based therapies. Further large-scale randomized controlled trials are warranted to confirm these findings.

Disclosure: Nothing to disclose.

Introduction: *H. pylori* infection represents a significant global health challenge. Despite international efforts to standardise eradication protocols, treatment success varies substantially across regions due to differences in antibiotic resistance patterns and healthcare practices and accessibility.

Aims & Methods: This study aimed to assess the effectiveness of empirical first-line therapies for *H. pylori* infection outside Europe.
The WorldHpReg, an international, multicenter, prospective registry, was created to evaluate the management and clinical outcomes of *H. pylori* infection by gastroenterologists world-wide. Data were collected via the AEG-REDCap e-CRF from March 2022 to April 2025. Modified intention-to-treat (mITT) and per-protocol (PP) analyses were performed to assess therapy effectiveness. A regimen was considered optimally effective if the mITT cure rate was ≥90%. The data were stratified by country and by specific first-line therapeutic regimen.

Results: A total of 9,973 cases were collected, with 7,738 (78%) first-line empirical prescriptions analysed across several non-European countries including: Latin America (LATAM), Brazil, Africa, Australia, Canada, Egypt, India, Jordan, Pakistan, and Saudi Arabia. Overall, 90 different first-line

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

therapeutic regimens were prescribed, achieving an overall mITT and PP effectiveness of 84% and 85%, respectively. Optimal (≥90%) mITT cure rates were achieved, overall, in Australia (95%), India (99%), Jordan (96%) and Saudi Arabia (91%). Optimal treatment effectiveness was observed in LATAM with following therapies: non-bismuth quadruple therapy containing amoxicillin-clarithromycin-metronidazole (91%) or with various combinations of bismuth-containing quadruple therapies, such as amoxicillin-metronidazole (94%), metronidazole-doxycycline (90%), and amoxicillin-doxycycline (97%). Additionally, high effectiveness was achieved also in LATAM with the single-capsule formulation (94%) and with the combination of metronidazole-tetracycline in the classical format (91%), this latter also obtaining optimal results in Brazil (97%). Standard triple therapy with amoxicillin-clarithromycin achieved over 90% mITT cure rates in Africa (92%), Australia (95%), Egypt (100%), India (100%), and Jordan (100%), although the number of patients was still very low. The remaining regimens provided suboptimal results. Complete results by treatment scheme and country are detailed in Table 1.

Country	LATAM	Brazil	Africa	Australia	Canada	Egypt	India	Jordan	Pakistan	Saudi Arabia
Treatment[a]	N (% mITT)									
Triple-C+A	1,041 (75%)	1,826 (80%)	25 (92%)	19 (95%)	NA	4 (100%)	61 (100%)	14 (100%)	53 (59%)	7 (86%)

Overall	3,774 (85%)									

[a]Treatments were categorised in 11 categories encompassing over 90% of first-line prescriptions world-wide. LATAM: Latin America; ASEAN: Association of South-East Asian Nations; A: amoxicillin; B: bismuth salts; C: clarithromycin; D: doxycycline; L: levofloxacin; M: metronidazole; T: tinidazole; Tc: tetracycline; *Three-in-one single-capsule containing metronidazole, tetracycline and bismuth; N: total number of patients analysed; %: total number of patients with H. pylori eradicated; mITT: modified intention-to-treat.

Table 1. Modified intention-to-treat effectiveness of most frequent first-line empirical treatments world-wide.

Conclusion: In this large, real-world cohort from several non-European countries, first-line *H. pylori* empirical eradication therapies yielded unsatisfactory overall results. However, optimal (≥90%) eradication rates were consistently observed in Australia, India, Jordan, Egypt and Saudi Arabia. In LATAM and Brazil, the highest cure rates were predominantly obtained with bismuth and non-bismuth quadruple therapies. Triple therapy with amoxicillin-clarithromycin remained highly effective in selected regions. These findings reinforce the importance of tailoring first-line empirical therapy to regional performance in order to optimise *H. pylori* eradication success.

Introduction: A 10-14 day non-bismuth quadruple "concomitant" therapy is currently the preferred first-line regimen for Helicobacter pylori (HP) eradication in Greece [1,2]. In this country, bismuth salts have recently become commercially available; however, lack of tetracycline still precludes use of bismuth quadruple therapy. Adding bismuth to the current concomitant therapy (ie; a quintuple regimen) could be an alternative; however, it has never been explored previously.

Aims & Methods: The present study aimed to assess a quintuple 10-day bismuth-enhanced concomitant regimen as first-line treatment for HP eradication in Greece. Prospective, open-label, multicenter pilot study including treatment-naïve patients diagnosed with HP infection via histology and/or rapid urease test. Exclusion criteria included recent use of PPIs, antibiotics, NSAIDs, bismuth, serious comorbidities, prior gastrectomy, pregnancy or lactation, allergy to any study drug, and refusal to participate. All patients received a 10-day regimen consisting of esomeprazole 40 mg BID, amoxicillin 1000 mg BID, clarithromycin 500 mg BID, metronidazole 500 mg BID, and bismuth subcitrate 240 mg BID.

A specific probiotic supplement containing Lactobacillus acidophilus, Lactiplantibacillus plantarum, Bifidobacterium lactis, and Saccharomyces boulardii was also administered in all patients. Efficacy was evaluated by intention-to-treat (ITT), per-protocol (PP), and modified ITT (mITT) analyses. Successful eradication was defined as a negative histology or urea breath test at least 8 weeks post-treatment.

Results: A total of 52 patients were analyzed (mean age 48.6 ± 18.7 years, 50% male, peptic ulcer disease: 7/52, non-ulcer dyspepsia: 29/52).

Eradication rates were:

i) ITT: 47/52 (90.4%, 95% CI: 79.4–95.8),

ii) PP: 46/49 (93.9%, 95% CI: 83.5–97.9),

iii) mITT: 47/51 (92.2%, 95% CI: 81.5–96.9).

Adverse events were reported by 29.4% (15/51) of patients, with taste disturbances being the most frequent (39.1%); no serious adverse events occurred. Compliance was excellent with 49/51 (96.1%) patients taking >90% of the prescribed therapy.

Conclusion: A quintuple 10-day bismuth-enhanced concomitant regimen appears to be an effective (93.9% PP), safe and well tolerated treatment option for first-line HP eradication in a country with high clarithromycin and metronidazole resistance, without negatively affecting patient compliance.

PP0259

HIGH CUMULATIVE HELICOBACTER PYLORI ERADICATION THERAPY IN OBESE PATIENTS UNDERGOING GASTRIC BY-PASS SURGERY

R. Cerqueira[1], M. Correia[1], M. Sousa[1], I. Pita[1], I. Ribeiro[1], S. Costa[1], M. Manso[2]
[1]ULS Entre Douro e Vouga, Gastroenterology, Porto, Portugal, [2]RISE-Health, Faculty of Health Sciences, Fernando Pessoa University, Biostastistics, Porto, Portugal

Introduction: The Maastricht V/ Florence Consensus has updated guidelines for the management of *Helicobacter Pylori* (HP) infection with special emphasis in high clarithromycin resistance settings as it is the case in our country. In line with the recommendations of the European Guidelines on surgery of severe obesity [1] and the recommendations of the American Society of Gastrointestinal Endoscopy on endoscopy of the bariatric patient [2) a policy of systematic HP screening and overtime updated eradication was implemented in obese patients undergoing Roux-en Y gastric bypass (RYGB) surgery.

Aims & Methods: Five year period (2020-2024) single center study. The aim was, in obese patients undergoing RYGB surgery, to assess the cumulative HP eradication rate by adopting, at first line, a 10 days bismuth quadruple therapy (BQT) - proton pump inhibitor (PPI) bid and three-in-one single capsule containing bismuth, metronidazole, and tetracycline qid - and, at second line, a 14 days levofloxacin based therapy (LBT) – PPI bid, amoxicillin 1000 mg bid and levofloxacin 500mg bid. HP infection status was assessed, at baseline, by histology or urea breath test and post treatment, by urea breath test 4-6 weeks after the end of the therapy.

Results: One thousand four hundred and forty-nine consecutive HP-positive patients completed BQT treatment: 1160 (80.1%) female, age 43.5 (±10.5) years, median age of 44 years), age range of 18-69 years. HP was eradicated in 1220 patients – 84.2% (95%CI: 82.2%-86.0%). In the remaining 229 patients, 87 patients withdrew and HP was eradicated in 118 patients out of 145 with LBT. The intention to treat (ITT) and per protocol (PP) cumulative eradication rates were, respectively, 92.3% (95%CI: 90.9%-93.6%). and 98.0% (95%CI: 97.1%-98.6%). Eradication rates were not significantly different by gender and age.

Conclusion: By adopting the Maastricht V/ Florence Consensus BQT first line therapy and second line LBT therapy, high ITT and PP cumulative HP eradication rates are achieved leaving only a residual number of obese patients undergoing RYGB in need of the culture and susceptibility testing prior to third line treatment.

PP0260

EFFICACY OF TRIPLE VS. SEQUENTIAL THERAPY IN *HELICOBACTER PYLORI* ERADICATION: ADDRESSING ANTIBIOTIC RESISTANCE IN A RESOURCE-LIMITED SETTING

A. Samad[1]
[1]Hamdard University Hospital, Department of Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: samaddhedhi@gmail.com

Introduction: Helicobacter pylori is a common cause of peptic ulcers and gastritis. Standard triple therapy includes a PPI with amoxicillin and either clarithromycin or levofloxacin. Rising antibiotic resistance has reduced its effectiveness. Sequential therapy offers a phased alternative with better outcomes in resistant cases.

Aims & Methods: To evaluate and compare the efficacy of clarithromycin and levofloxacin-based triple and sequential therapies for *Helicobacter pylori* (H. pylori) eradication in a resource-limited setting, in the context of emerging antibiotic resistance.

A prospective, randomized study was conducted at a tertiary care center from January 1, 2022, to January 1, 2025. A total of 300 treatment-naïve patients aged 18–60 years, diagnosed with *H. pylori* infection through stool antigen, urea breath test, or histology, were included. Patients with prior eradication therapy or recent antibiotic use were excluded. Participants were randomized into four equal groups (n=75 each):

- Clarithromycin-based triple therapy (amoxicillin, clarithromycin, PPI)
- Levofloxacin-based triple therapy (amoxicillin, levofloxacin, PPI)
- Clarithromycin-based sequential therapy (amoxicillin + PPI for 5 days, followed by clarithromycin + tinidazole + PPI for 5 days)
- Levofloxacin-based sequential therapy (amoxicillin + PPI for 5 days, followed by levofloxacin + tinidazole + PPI for 5 days) Therapeutic response was assessed post-treatment for eradication.

Results: Out of 300 patients (180 males, 120 females), eradication was achieved in:

- 48/75 (64%) in clarithromycin-based triple therapy
- 53/75 (70.7%) in levofloxacin-based triple therapy
- 51/75 (68%) in clarithromycin-based sequential therapy
- 61/75 (81.3%) in levofloxacin-based sequential therapy

All patients completed therapy without notable adverse events or compliance issues. Lower eradication rates in clarithromycin-based regimens suggest rising resistance.

Conclusion: Levofloxacin-based sequential therapy demonstrated the highest eradication rate, highlighting its potential as a preferred regimen in settings with rising clarithromycin resistance. Clarithromycin-based treatments showed suboptimal outcomes, emphasizing the need for region-specific antibiotic stewardship and resistance surveillance.

PP0261

BISMUTH-BASED VERSUS CONCOMITANT QUADRUPLE THERAPY: PREDICTIVE FACTORS OF HELICOBACTER PYLORI ERADICATION FAILURE

A. Oueslati[1], G. Mohamed[1], B. Sonia[1], K. Boughoula[1], D.B. Sondes[1], R. Bouali[1], H. Ben Abdallah[1]
[1]Military Hospital of Tunis, Tunis, Tunisia

Contact E-Mail Address: oueslatialaa1996@gmail.com

Introduction: Nowadays, bismuth-based quadruple therapy (BQT) and concomitant quadruple therapy (CQT) are both recommended as first-line treatments for Helicobacter pylori (HP) eradication. However, several clinical trials report treatment failure rates ranging from 5% to 20%.

Aims & Methods: The aim of this study was to identify predictive factors for eradication failure in both treatments.

We conducted a prospective, randomized, open-label clinical trial. Eligible patients were randomized to receive one of the two regimens:

(A) BQT: a combination of potassium bismuth subcitrate 140 mg, metronidazole 125 mg, and tetracycline hydrochloride 125 mg, administered as 3 capsules 4 times/day, plus omeprazole 20 mg twice/day for 10 days.

(B) CQT: amoxicillin 1 g twice/day, clarithromycin 500 mg twice/day, and metronidazole 500 mg twice/day, plus esomeprazole 40 mg twice/day for 14 days.

The primary endpoint was HP eradication, defined by a negative urea breath test 4 to 6 weeks after completing treatment.

Results: A total of 200 patients were included (median age = 40.8 years; sex ratio = 1.04).

In the intention-to-treat analysis, eradication rates were 82% in the CQT group versus 87% in the BQT group (p = 0.29).

In the per-protocol analysis, HP eradication was achieved in 84.53% of patients in the CQT group versus 89.58% in the BQT group (p = 0.39).

In the concomitant therapy group, female gender and poor treatment adherence were significantly associated with treatment failure (p = 0.003 and 0.005, respectively).

In the bismuth-based therapy group, a body mass index (BMI) greater than 25 kg/m^2 and poor adherence were associated with treatment failure (p = 0.002 and 0.007, respectively).

Conclusion: Poor treatment adherence was a predictor of treatment failure in both groups. A BMI over 25 kg/m^2 and female gender were associated with therapeutic failure in the BQT and CQT groups, respectively.

Disclosure: No conflict of interest.

PP0262

LONG-TERM EFFECT OF *HELICOBACTER PYLORI* ERADICATION ON RISK FACTORS FOR CARDIOVASCULAR DISEASE – IS THERE A CONNECTION?

K. Tepeš[1], S. Aygen[2], G. Avguštin[3], R. Orel[4], D. Štubljar[5], B. Tepes[1]
[1]Diagnostic Center Rogaška, Gastroenterology, Rogaska Slatina, Slovenia, [2]INFAI GmbH, Dr., Köln, Germany, [3]University of Ljubljana, Biotechnical Faculty, Microbiology, Ljubljana, Slovenia, [4]University Childrens Hospital, Paediatric Gastroenterology, Haepatology and Nutrition, Ljubljana, Slovenia, [5]In-Medico, Research & Development, Metlika, Slovenia

Contact E-Mail Address: tepes.katja@gmail.com

Introduction: Cardiovascular disease (CVD) remains the leading cause of mortality worldwide and although traditional risk factors for atherosclerosis are well established, accumulating evidence suggests that inflammatory parameters may also play a pivotal role in its pathogenesis. Recently, *Helicobacter pylori* infection has gained increasing attention as a potential contributor to CVD risk. Thus, our aim was to investigate the long-term effects of successful *H. pylori* eradication on several CVD risk factors.

Aims & Methods: A total of 72 patients meeting the inclusion and exclusion criteria were enrolled (July 2020 to November 2022). Participants were randomly assigned to two treatment groups (group 1: 14-day regimen with esomeprazole, amoxicillin, and clarithromycin; group 2: 14-day regimen with esomeprazole, amoxicillin, metronidazole and colloidal bismuth subcitrate).

We evaluated changes in insulin resistance (HOMA-IR score), lipid profiles and subtypes (nuclear magnetic resonance spectroscopy) and trimethylamine N-oxide (TMAO; Cardio Test INFAI) at baseline, two months, and one year following successful *H. pylori* eradication.

Results: Of the 72 patients included, 13.9% (10/72) did not complete the study protocol. At baseline, no statistically significant differences were observed in CVD risk factors between the two groups. Following successful *H. pylori* eradication (Table 1), both groups demonstrated significant reductions in total cholesterol (p = 0.004), low-density lipoproteins (p = 0.011), small dense lipoprotein particles (p = 0.029), and TMAO levels (p = 0.05). No statistically significant changes were observed in body mass index (BMI, p=0.910), waist circumference (p = 0.325) or insulin resistance (p = 0.342).

	T1 (n=62)	T2 (n=62)	T3 (n=62)	p-value between times
Body mass index	27.0 ± 4.4	27.0 ± 4.3	26.8 ± 5.2	0.910
Waist circumference	92.8 ± 11.8	92.6 ± 12.0	93.7 ± 11.8	0.325
Insulin resistance (HOMA-IR)	2.3 ± 2.1	2.2 ± 1.4	2.0 ± 1.1	0.342
Cholesterol (mg/dl)	212.1 ± 39.5	200.3 ± 40.4	197.3 ± 41.9	0.004
LDL (mg/dl)	131.9 ± 34.0	124.1 ± 37.0	120.2 ± 35.4	0.011
HDL (mg/dl)	56.1 ± 15.5	54.0 ± 14.7	55.2 ± 15.3	0.159
Triglycerides (mg/dl)	141.3 ± 74.7	136.8 ± 63.1	135.8 ± 76.6	0.686
SLDL-p (nmol/l)	604.7 ± 334.0	552.0 ± 351.4	542.7 ± 351.9	0.029
TMAO (mg/l)	38.3 ± 29.9	29.2 ± 18.8	31.5 ± 30.4	0.050

T1 – at baseline, T2 – 2 months post-eradication, T3 – 1-year post-eradication
LDL – low density lipoproteins, HDL – high density lipoproteins, SLDL-p – small low density lipoprotein particles, TMAO – trimethylamine N-oxide

Table 1. Changes in various parameters over time in the entire cohort.

Conclusion: Successful eradication of chronic *H. pylori* infection was associated with a significant reduction in total cholesterol, low-density lipoproteins, small dense lipoprotein particles and TMAO in both treatment groups. These findings suggest that chronic *H. pylori* infection may influence lipoprotein levels and potentially increase the risk for CVD, possibly through increased systemic inflammation.

PP0263

THE IMPACT OF *HELICOBACTER PYLORI* ERADICATION ON LONG-TERM GHRELIN LEVELS AND BODY WEIGHT

K. Tepeš[1], M. Lunder[2], U. Pečar Fonović[2], G. Avguštin[3], R. Orel[4], D. Štubljar[5], B. Tepes[1]
[1]Diagnostic Center Rogaška, Gastroenterology, Rogaska Slatina, Slovenia, [2]University of Ljubljana, Faculty of Pharmacy, Department of Pharmaceutical Biology, Ljubljana, Slovenia, [3]University of Ljubljana, Biotechnical Faculty, Department of Microbiology, Ljubljana, Slovenia, [4]University Childrens Hospital, Department of Paediatric Gastroenterology, Haepatology and Nutrition, Ljubljana, Slovenia, [5]In-Medico, Department of Research & Development, Metlika, Slovenia

Contact E-Mail Address: tepes.katja@gmail.com

Introduction: The association between chronic *Helicobacter pylori* infection and hormone levels affecting food intake and obesity remains controversial. Thus, our aim was to investigate the long-term effect of *H. pylori* eradication on changes in ghrelin and leptin levels.

Aims & Methods: A total of 72 patients meeting the inclusion and exclusion criteria were enrolled (July 2020 to November 2022). Participants were randomly assigned to two treatment groups (group 1: 14-day regimen with esomeprazole, amoxicillin, and clarithromycin; group 2: 14-day regimen with esomeprazole, amoxicillin, metronidazole and colloidal bismuth subcitrate). We evaluated changes in insulin resistance (HOMA-IR score), body mass index (BMI) and serum levels of ghrelin and leptin (ELISA test) at baseline, two months, and one year following successful *H. pylori* eradication.

Results: Of the 72 patients included, 13.9% (10/72) did not complete the study protocol. Both treatment groups were similar at enrolment and showed no statistically significant differences (p = 0.332 for OLGIM stages; p = 0.583 and p= 0.696 for antrum and corpus atrophy respectively, p = 0.177 and p = 0.296 for antrum and corpus intestinal metaplasia respectively).

No statistically significant changes were present in BMI (p = 0.910) and insulin resistance (p = 0.342) after *H. pylori* eradication. A statistically significant decrease in ghrelin serum levels was observed in both treatment groups (p < 0.001), but not in leptin serum levels (p = 0.309), as shown in Table 1.

	T1	T2	T3	p-value
Leptin (pg/ml)	8128.0 ± 8171.2	9207.1 ± 8255.7	9469.4 ± 7761.5	0.257
Ghrelin (pg/ml)	3963.9 ± 2270.8	3076.7 ± 1767.2	3160.5 ± 1875.2	< 0.001
Body mass index	27.0 ± 4.4	27.0 ± 4.3	26.8 ± 5.2	0.910
Waist circumference (cm)	92.8 ± 11.8	92.6 ± 12.0	93.7 ± 11.8	0.325
HOMA-IR	2.3 ± 2.1	2.2 ± 1.4	2.0 ± 1.1	0.342

Table 1. Changes in various parameters over time in the entire cohort.
T1 – at baseline, T2 – 2 months post-eradication, T3 – 1-year post-eradication

Conclusion: Successful eradication of chronic *H. pylori* gastritis decreased serum ghrelin levels regardless of the presence of gastric mucosal atrophy.

Furthermore, no changes in BMI or waist circumference were detected after one year of follow-up, proving that *H. pylori* eradication is not related to weight gain through hormonal changes as previously hypothesized. These results reduce the fear that massive *H. pylori* eradication from the population could be associated with obesity.

PP0264

THE EFFICACY AND SAFETY OF HIGH-DOSE DUAL THERAPY FOR *HELICOBACTER PYLORI* ERADICATION IN THE NORTH-WESTERN REGION OF RUSSIA

N. Bakulina[1], V. Ponomarenko[1], I. Savilova[1]
[1]North-Western State Medical University n. a. I. I. Mechnikov, St. Petersburg, Russian Federation

Contact E-Mail Address: nv_bakulina@mail.ru

Introduction: The *Helicobacter pylori (H. pylori)* infection is a common problem (prevalence of 32.7% in 2023) in the North-Western Federal District, comprising one-tenth of Russia, where primary resistance rates of clarithromycin and levofloxacin are >15%.[1]

The eradication rates remain low and do not reach the threshold value of 95% (eradication rate of 86.8% in 2023).[2] There is limited information regarding the best approach for *H. pylori* infection management.

Aims & Methods: The study was conducted in the North-Western Federal District during 2023-2025. Individuals (n=145) who underwent ^{13}C-UBT (^{13}C-urea breath test) was conducted in the prospective randomized clinical trial. Patients were randomly allocated to two eradication groups: high-dose dual therapy for 14 days (esomeprazole 40 mg and amoxicillin 1000 mg three times daily) and optimized high-dose dual therapy for 14 days (esomeprazole 40 mg, amoxicillin 1000 mg, rebamipide 100 mg three times daily).

The modified intention-to-treat (mITT) effectiveness, safety, and adherence were analyzed for the regimens. The secondary endpoints were adverse effects and patient compliance. Eradication was confirmed by a ^{13}C-UBT 4-6 weeks after therapy.

Results: Among all included individuals (mean age 46.27±14.21; 67.6% of whom were female), there were 91.7% (n=133) of primary "naïve" patients (who had had no history of prior eradication therapy). The proportion of treated patients was 8.3% (n=12). The high-dose dual therapy PPI-amoxicillin did not provided encouraging mITT results - 87.5%, 21/24, 95%CI 69.0-95.7; the inclusion of patients in this group was stopped due to unacceptable cure rates.

Whereas the higher was reported with optimized eradication regimen with rebamipide (96.3%, 105/109, 95%CI 90.9-98.6 for treatment-naïve and 91.7%, 11/12, 95%CI 64.9-98.5 for treated patients). The adverse event rates were 37.5% in the PPI-amoxicillin group and 19.8% in the PPI-amoxicillin-rebamipide group (p=0.211). The most common were a diarrhea (25% and 12.4% respectively), bloating (25% and 3.5% respectively), ab-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. dominal pain (20.8% and 10.7% respectively). Good adherence, defined as > 90% of drug intake, were similar between the two groups (100% of cases).

Conclusion: In the North-Western region of Russia, the fourteen-day optimized high-dose dual therapy with PPI-amoxicillin-rebamipide provided encouraging results (over 90% cure rates) and had the lower incidence rate of side effects (19.8%) suggesting as an alternative for *H. pylori* rescue treatment in the local region.

Introduction: Both the effectiveness and tolerability of Helicobacter pylori (H.p.) eradication therapy regimens are important in the management of H.p. infection, since the presence of side effects significantly reduces compliance between the doctor and the patient and sometimes can lead to treatment interruption. Our study aimed to compare the efficacy and tolerability of eradication therapy depending on the addition of Saccharomyces boulardii or a synbiotic complex.

Aims & Methods: The study included 78 patients (54 women and 24 men) with confirmed H.p. infection using validated tests, without previous eradication in the anamnesis. All patients underwent a course of eradication therapy, which included proton pump inhibitor (PPI) + amoxicillin (A) + clarithromycin (C) + bismuth subcitrate (B). Patients were divided into 2 groups: in group A (37 patients, 25 women, 12 men, mean age 44±3.2 years) S. boulardii CNCM I-745 was added to the mentioned regimen. In group B (41 patients, 29 women, 12 men, mean age 47±2.8 years), a synbiotic complex containing strains of probiotic bacteria Lactobacillus acidophilus, Lactobacillus plantarum, Lactobacillus delbrueckii subsp. bulgaricus, Lactobacillus fermentum, Lactobacillus rhamnosus, Lactobacillus casei subsp. casei, Streptococcus thermophilus, Bifidobacterium bifidum, Bifidobacterium longum, Bifidobacterium adolescentis, Propionibacterium freudenreichii subsp. Shermanii, prebiotics inulin and lactulose were added to the indicated regimen. The duration of eradication therapy was 10 days. The duration of taking the probiotic and synbiotic complex – 15 days.

Results: In group A, the effectiveness of the PPI+A+C+B regimen with the addition of S. boulardii was 75.7%. In group B (with the addition of a synbiotic) - 87.8%. We compared the tolerability of the indicated regimens. In no case (in both groups) was the treatment interrupted due to the presence of serious side effects. In total, 20 (54.1%) patients from group A and 17 patients (41.5%) from group B reported non-serious adverse events, including nausea (group A – 8 patients (21.6%), group B – 6 (14.6%), bitter taste in the mouth (group A – 16 patients (43.2%), group B – 15 (36.6%), and diarrhoea (group A – 6 patients (16.2%), group B – 0 (0%). No other adverse events were documented. Comparing gastrointestinal symptoms using the Gastrointestinal Symptom Rating Scale (GSRS) showed that in group A, mean values of the total score before treatment were 35.9±3.14 points, vs 26.2±1.64 points 20 days after the eradication course ($p<0.05$). In group B 34.1±2.44 points before treatment, vs 21.7±1.98 points 20 days after the eradication course ($p<0.05$). Comparing the total score of the GSRS questionnaire after treatment between groups A and B also showed a significant difference: 26.2±1.64 points in group A vs 21.7±1.98 points in group B ($p<0.05$).

Conclusion: Our study revealed better efficacy (87.8%) of the eradication regimen PPI+A+C+B with the addition of a synbiotic compared to the similar regimen with the addition of Saccharomyces boulardii (75.7%) in patients from Vinnytsia region, Ukraine. In addition, it was found that when the synbiotic complex was added, side effects of eradication therapy were noted in a smaller percentage of patients and significantly ($p<0.05$) lower values of the total score of the GSRS questionnaire were noted 20 days after treatment, in contrast to the regimen with the addition of Saccharomyces boulardii.

Introduction: *Helicobacter pylori* (*H. pylori*) infection is a well-established risk factor for gastric cancer. While high-incidence countries promote population-based test-and-treat strategies, Germany—classified as an intermediate-risk country—follows a more targeted approach. According to the latest German S3 guidelines, *H.pylori* eradication is strongly rec-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ommend in specific high-risk groups, including first-degree relatives of gastric cancer patients and individuals who have undergone surgical or endoscopic resection of gastric cancer. However, real-world data on how these recommendations are implemented in clinical practice remain limited. Additionally, data on the use and effectiveness of different first-line eradication regimens in Germany are sparse.

Aims & Methods: We conducted a retrospective analysis of patients who received first-line empirical *H. pylori* eradication therapy across five German university-based centers participating in the European Registry on *H. pylori* Management (Hp-EuReg). Three centers contributed the majority of cases. Demographic and clinical data were extracted from databases. Data were collected in AEG-REDCap from June 2013 to January 2025. Indications were categorized by symptom profile, endoscopic findings, and cancer risk. A descriptive analysis was performed. Eradication rates were compared between treatment regimens and durations using the χ^2 test. A particular focus was placed on evaluating how the recommendations of the German S3 guidelines regarding gastric cancer prevention were implemented in clinical practice.

Results: Of the 448 patients (53% male, median age 55) ncluded, the most common indications were non-investigated dyspepsia (33%) and dyspepsia with normal endoscopy (30%). Peptic ulcer disease was reported in 18%: duodenal ulcer (5%) and gastric ulcer (13%). Five percent underwent eradication for gastric cancer prevention; these included patients with preneoplastic lesions (0.4%), prior gastric cancer resection (0.9%), first-degree relatives of gastric cancer patients (2.0%), and individuals undergoing screening (1.3%). Other indications included unexplained iron deficiency anemia (4.0%), vitamin B12 deficiency (0.7%), and MALT lymphoma (0.2%). The most frequent first-line therapies were triple therapy with amoxicillin and clarithromycin (54%) and a three-in-one single-capsule containing metronidazole, tetracycline, and bismuth (41%). Therapy commonly lasted 7 (19%) or 10 days (72%). No difference in eradication rates between the two regimens was observed when given for 10 days (97.8% vs. 97.0%, respectively).

Conclusion: In this multicenter German cohort from dedicated *H. pylori* centers, most eradication therapies were prescribed for dyspeptic symptoms. Notably, a significant proportion of treatments aimed at gastric cancer prevention, aligning with the approach outlined in the current German S3 guidelines. Both recommended first-line therapies—triple therapy with amoxicillin and clarithromycin, and the three-in-one single-capsule bismuth-based quadruple therapy—were widely used and achieved similarly high eradication rates when administered for 10 days. These findings underline the importance of implementing guideline-based indications in intermediate-risk countries like Germany, where targeted eradication in high-risk individuals remains a cornerstone of gastric cancer prevention.

Introduction: Both proton pump inhibitors (PPIs) and *Helicobacter pylori* (HP) infection are risk factors for osteoporotic fracture. However, the interaction between PPI use and HP infection status post-eradication therapy in HP-infected individuals on fracture risk remains unclear.

Aims & Methods: We aimed to investigate the effect of HP treatment outcome on PPI-associated fracture risk in HP-infected patients. We conducted a retrospective cohort study using a population-based healthcare database. Adults (≥18 years) prescribed clarithromycin-containing triple therapy for 7-14 days (first-line HP eradication therapy during the study period) between 2003 and 2012 were included. The cohort was stratified into: (1) successful HP eradication (HP-) and (2) failure of HP eradication (HP+). Failure of HP eradication was identified by the need of subsequent prescriptions of HP therapy including repeated course of eradication therapy. Exclusion criteria included epilepsy, Paget's disease, bone tumor, gastrectomy, gastric cancer, fracture due to motor vehicle traffic accidents, and ever use of PPIs before index date. The exposure of interest was PPI use following HP eradication therapy. PPI exposure was modelled as a time-vary variable (≥14 days per 3-month interval). Histamine 2 receptor antagonists (H2RAs) served as a negative control. The primary outcome was a composite outcome of major osteoporotic fractures (hip, vertebra, humerus, forearm, wrist). Covariates included demographics, smoking status, alcohol use disease, prior fractures/falls, osteoporosis/osteomalacia, metabolic factors, cardiovascular diseases, chronic renal failure, cirrhosis and concomitant medications (such as aspirin, H2RAs, anti-osteoporotic agents, hormonal therapy, steroids, calcium and vitamin D supplements). The index date was defined as the first date of HP eradication. Patients were followed till occurrence of outcome, death or study end (31 December, 2019). Multivariable Cox regression was used to estimate adjusted hazard ratios (aHRs). Stratified analysis was conducted by combined HP/PPI status to examine the interaction between HP infection status post-eradication therapy on fracture risk.

Results: There was a total of 59,380 eligible subjects (median age: 55.2 [interquartile range: 45.8-64.8] years; male: 44.0%) in this study, including 52,033 (87.6%) with successful HP eradication (HP-) and 9,713 (16.4%) PPI users. Over a median follow-up of 11.8 (interquartile range: 9.2-14.3) years, 2,736 (4.6%) experienced fracture. In the whole cohort, PPI use was associated with higher fracture risk (aHR: 1.31, 95% CI:1.20-1.50), whereas H2RA use was not (aHR: 0.98, 95% CI: 0.89-1.08); when compared with failure of HP eradication, successful HP eradication was associated with lower fracture risk (aHR: 0.78, 95% CI: 0.70-0.86). In stratified analysis, the highest fracture risk was observed in the failure of HP eradication and PPI use (HP+/PPI+) group (aHR: 1.77, 95% CI: 1.46-2.14), compared with reference group (successful HP eradication and no PPI use [HP-/PPI-]; Table 1).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: PPIs are still associated with higher fracture risk irrespective of HP eradication status, although subjects with successful eradication have lower risk than subjects with failure of eradication. Testing and treating HP infection may be advisable to reduce fracture risk in long-term PPI users.

Disclosure: Nothing to disclose.

INCIDENCE OF HELICOBACTER PYLORI AND PRECANCEROUS LESIONS IN A TERTIARY CENTRE IN TRANSYLVANIA REGION

S. Bataga[1]
[1]University of Medicine, Pharmacy, Science and Technology, GE Palade, Emmergency Hospital, Gastroenterology Clinic, Targu-Mures, Romania

Contact E-Mail Address: simonabataga@yahoo.com

Introduction: Helicobacter pylori (HP) has been designated as a Grade I Carcinogen by the WHO and remains an important factor in the pathogenesis of intestinal-type gastric cancer. Gastric cancer was the fifth most common malignant disease in the world in 2022 (Globocan) with 968,784 new cases(1), after lung, breast, colorectal and prostate cancers. The incidence of gastric cancer has changed significantly since the first estimates in 1975, when stomach cancer was the leading cancer, and one of the most important factors has been the eradication of HP.(2)

Aims & Methods: The purpose of this study was to determinate the trends in the incidence of HP in our region, and also of the precancerous lesions. There have been included in the study a group of 12541 patients from the years 2014-2018 and a group of 7138 patients from more recently years 2020-2024.

All the patients had dyspeptic syndrome and in all the patients upper digestive endoscopy has been performed in the Gastroenterology Clinic from Târgu Mureş, Emergency Clinical Hospital. Patients with haemorrhage were excluded from the study. In all the patients gastric biopsies and histopathological exam were made, OLGA classification was used.

Results: From the first group, in 2131 patients (52,9% males and 47,1% females) were found gastric changes. Histopathological, 32,7% of the patients had atrophic gastritis, 43,1% intestinal metaplasia (23,7% complete metaplasia and 19,4% incomplete metaplasia) and 0,7% dysplasia. Active gastritis/pangastritis with HP was identified in 59,3% of the patients. In 4,8% of cases there were revealed polyps (hyperplastic, adenomatous) and were removed.

In the second group from 2560 patients (54,4% males and 45,6 females) that underwent upper gastrointestinal with biopsy sampling, HP was present in 442 patients (17,26%.) Histopathological, 14,50% of the patients had atrophic gastritis, 23,8% intestinal metaplasia and 2,58% dysplasia.

Conclusion: HP incidence is decreasing, as it has been treated by the gastroenterologist and also by the general practitioner. The decreasing in incidence of HP is corelating with the decreasing of the precancerous lesions and gastric cancer, so it is worth to treat it.

Introduction: Helicobacter pylori (H. pylori) is a well-recognized gastric carcinogen. However, whether this infection is related to colorectal polyps and colorectal cancer remains debatable. Data from some recent studies have indicated a significant association between H. pylori infection and the development of colorectal polyps or cancer. Potential effects of H. pylori on the colorectal mucosa include the induction of inflammatory responses, alteration of gut flora, and the release of toxins.

The aim was to investigate the association between H.pylori infection and colorectal polyps.

Aims & Methods: We retrospectively included patients diagnosed with colorectal polyps who underwent H. pylori testing between September 2024 and March 2025. Patients with incomplete colonoscopies were excluded. Demographic, clinical, and endoscopic data were subsequently collected. Polyp subtypes and dysplasia grades were extracted from histopathology reports. Screening for H. pylori infection was performed on gastric biopsies.

Patients were divided into two groups: Group 1 (H. pylori-negative) and Group 2 (H. pylori-positive). The number, size, location, and pathological type of colorectal polyps were compared between the two groups.

Results: One hundred thirty patients were included, with a male-to-female sex ratio of 3.2. The mean age was 56.3 ± 11.23 years. The main comorbidities were diabetes (33.1%), dyslipidemia (26.9%), and hypertension (25.4%). The locations of colorectal polyps varied: 18.5% in the rectum, 17.7% in the sigmoid colon, 8.5% in the left colon, 7.7% in the transverse colon, 16.9% in the right colon, and 30.8% of patients had polyps in multiple locations. A total of 219 polyps were identified, with a mean of 2.16 polyps per patient and a mean size of 5.9 mm (range: 2–30 mm).

Histopathological examination revealed predominantly hyperplastic polyps (36.9%), low-grade dysplastic adenomas (48.5%), high-grade dysplastic adenomas (7.7%), and adenocarcinomas (6.9%). The prevalence of H. pylori infection was 31.5%.

Statistical analyses showed that the H. pylori-positive group had a significantly higher proportion of colorectal polyps with sizes ≥10 mm (55.6% vs. 44.4%, $p = 0.027$) and multiple polyps (≥5) (56.3% vs. 43.8%, $p = 0.04$) compared to the H. pylori-negative group. However, neither dysplasia grading nor polyp localization was significantly associated with H. pylori infection.

Conclusion: In our study, H. pylori infection was associated with an increased risk of large and multiple colorectal polyps. Further studies are needed to confirm these findings and to better understand the impact of H. pylori eradication on the occurrence of colorectal polyps, as well as its tumorigenic effects on the colorectal mucosa.

Introduction: Idiopathic Sclerosing Mesenteritis (SM) is a rare fibroinflammatory disease of unknown etiology. The clinical course is generally benign, as has been demonstrated in retrospective studies and large case series.

Aims & Methods: To more accurately determine the natural history of patients with symptomatic SM and describe the clinical features of those with idiopathic SM, we performed a prospective cohort study. Inclusion criteria were adult patients with typical SM symptoms, after ruling out other causes of abdominal pain, who met the Coulier criteria in computed tomography scans for establishing SM diagnosis. We identified 58 patients with symptomatic SM. During the follow-up period, 3 patients were lost and excluded from the analysis. Most patients (95.7%) underwent upper and lower endoscopy and chest imaging to rule out co-existing cancer disease. Secondary SM cases were also excluded (n=5 had a co-existing cancer diagnosis within 6 months of SM diagnosis and n=4 had a pre-existing diagnosis of SM-related autoimmune disease at SM diagnosis). The final cohort of symptomatic idiopathic SM cases consisted of 46 patients. Data were collected prospectively at each site visit from January 2014 to January 2024. Descriptive statistics were used to summarize the results.

Results: In total, 46 patients with idiopathic SM were included, of whom 56.5% were females and 43.5% were males with a mean age at diagnosis of 62 years. Overweight or obese were 62.8%, and 37.2% had normal weight. SM was histologically confirmed in 13%. Features of IgG4-related disease were present in 21.7% with other organ involvement (13% pancreas, 10.9% bile ducts, 2.2% orbit, and 2.2% lymph nodes). Multiple organ involvement was observed in 6.5%. All patients who presented with an abdominal mass (8.7%) developed features similar to IgG4-related disease. Elevated serum IgG4 levels at diagnosis were found in 7 of 36 patients (19.4%). All patients presented with abdominal pain, followed by bloating (84.8%), nausea (43.5%), anorexia (39.1%), weight loss (37%), vomiting (30.4%), dyspepsia (19.6%), diarrhea (19.6%), constipation (13%), fever (8.7%), icterus (4.3%), early satiety (4.3%), sarcopenia (4.3%), and peripheral edema (2.2%). Hospitalization was required in 37%, and severe complications were observed in 30.4% [ileus (15.2%), acute pancreatitis (8.7%), acute cholangitis (8.7%), abdominal mass (8.7%), chronic pancreatitis (4.3%), mesenteric thrombosis (2.2%), and obstructive lymphadenopathy (2.2%)]. Surgical intervention was performed in 13%. During the disease course, most patients (84.8%) were treated with colchicine in combination or not with corticosteroids (54.3%), antiplatelets (50%), and low-molecular heparin (28.3%).

Conclusion: In this prospective cohort study, we observed an aggressive clinical course with severe intra-abdominal complications in a substantial proportion of patients with idiopathic SM (30.4%). Almost one in four patients (21.7%) manifested other organ involvement, identical to IgG4-related disease, indicating that some idiopathic SM cases could be part of the IgG4 disease spectrum. These observations suggest that idiopathic SM requires clinical vigilance similar to that applied to IgG4-related disease.

Disclosure: No potential conflicts of interest.

Introduction: Dyslipidemia is a major contributor to cardiovascular disease and requires comprehensive treatment strategies. Emerging evidence supports the role of gut microbiota in lipid metabolism regulation, suggesting that targeted microbiome correction could be an effective adjunct to lipid-lowering therapy.

Aims & Methods: The aim was to evaluate the effectiveness of combined therapy—including probiotics, dietary recommendations, and lifestyle modifications—in correcting dyslipidemia and restoring gut microbial balance. A total of 168 patients with dyslipidemia were divided into two groups based on SCORE cardiovascular risk. All participants received a 12-week course of probiotics (Lactobacillus acidophilus LA-5 and Bifidobacterium lactis BB-12), lifestyle advice, and a cholesterol-lowering diet. Patients in the moderate-risk group additionally received simvastatin. Lipid profiles and gut microbiota composition (by qRT-PCR targeting 16S rRNA) were assessed before and after therapy.

Results: Both groups demonstrated significant reductions in total cholesterol, LDL-C, and triglycerides, and increased HDL-C levels ($p<0.05$). Analysis of gut microbiota revealed an increase in Bacteroidetes and a reduction in Firmicutes and Actinobacteria, alongside improvement in the Firmicutes/Bacteroidetes index. Notably, the percentage changes in lipid profile parameters were not significantly different between the probiotic-only and probiotic-plus-statin groups ($p>0.05$), suggesting a potential lipid-modulating effect of probiotics alone.

Conclusion: Combined therapy with probiotics, lifestyle modification, and diet effectively improves lipid metabolism and gut microbial composition in patients with dyslipidemia. Probiotic treatment may reduce the need for pharmacologic therapy in some patients and should be considered in personalized dyslipidemia management strategies.

Disclosure: Nothing to disclose.

NON-COELIAC GLUTEN/WHEAT SENSITIVITY IN THE POST-PANDEMIC ERA: AN EXCLUSIVE PRIMARY CARE PROBLEM?

F. Manza[1,2], S. Raju[3,2], C. Cotton[2], L. Lungaro[1], I. Aziz[4,2], G. Caio[1], D.S. Sanders[5,3]
[1]University of Ferrara, Translational Medicine, Ferrara, Italy, [2]Sheffield Teaching Hospitals, Academic Unit of Gastroenterology, Sheffield, United Kingdom, [3]University of Sheffield Medical School, Faculty of Medicine and Population Health, Division of Clinical Medicine, Sheffield, United Kingdom, [4]University of Sheffield, Academic Department of Gastroenterology, Sheffield, United Kingdom, [5]Sheffield Teaching Hospitals, Sheffield, United Kingdom

Contact E-Mail Address: mnzfnc@unife.it

Introduction: Non-coeliac gluten/wheat sensitivity (NCGWS) is characterized by gastrointestinal and extra-intestinal symptoms triggered by gluten/wheat ingestion in patients without coeliac disease (CD) or wheat allergy. There are controversies on the mechanism leading to this phenomenon, including media influence and the presence of a nocebo effect. Moreover, after the COVID-19 pandemic, a decrease in the rates of NCGWS diagnosis has been noted. The only treatment available for the management of NCGWS is a gluten/wheat-free diet (GFD), yet long-term outcomes are poorly understood.

This study aimed to evaluate post-pandemic trends in NCGWS and the long-term GFD adherence in patients with NCGWS. The secondary goals are the assessment of the perceived efficacy of GFD and the need of further medical support.

Aims & Methods: We retrieved data from gluten-free products vendors up to September 2024 (top 6 retailer in the UK) and gluten free products customers up to July 2021, using a questionnaire. Subsequently, patients with self-reported NCGWS referred to a tertiary center clinic from 2006 to 2018 completed a questionnaire regarding their dietary habits and further need of medical advice for symptoms related to their diagnosis. The Biagi score was used to assess their adherence to a GFD. We compared the dietary adherence scores to age and sex matched controls cohort of patients with CD to validate the results.

Results: The marked data analysis showed a persistent rise in the sales of gluten free products, from £200B in 2014 vs £600B in 2024. Moreover, NCGWS patients account for 9.7% of the total number of buyers and for 26% of the spent for GF products.

In our cohort, out of 186 patients with NCGWS, 111 answered the questionnaire (response rate 59.7%, female 82.0%, average age 54 ± 13 years). Of these 111, 58 are not currently following a GFD. Out of the 53/111 patients following a GFD, only 27/53 (50,9%) are adhering strictly (Biagi score 3-4), 2/53 had a Biagi score of 2 (3,8%) indicating poor adherence to a gluten free diet, and 24/53 (45,2%) voluntarily ate gluten (Biagi 1-0). Only two patients report that gluten/wheat is not causing them any symptoms if eaten. The average time patients remained on a gluten free diet was 141±58 months.

Compared to patients with CD those with NCGWS on a GFD showed a significantly lower adherence to a GFD (Biagi score of 0-1 NCGS: 73.9% vs CD: 8.1%, p<0.05; Biagi score 3-4, NCGWS: 24.3% vs CD: 90.1%, p<0.05). After being discharged, 40 patients (36.0%) sought medical advice again, but no significant correlation was found between the adherence to a GFD and need for further medical intervention.

Conclusion: Self-reported NCGWS is still consistently present among general population. Unlike CD, the vast majority of patients with self-reported NCGWS do not continue a GFD or significantly reduce their level of adherence. Still, NCGWS patients account for a vast part of the expenses in the gluten-free market. However, over a third of NCGWS sought further medical advice to manage their symptoms. These findings underline the need of a better understanding of this condition and the challenges in the management of these patients.

Introduction: Small intestinal bacterial overgrowth (SIBO) is characterized by the presence of excessive gram-negative aerobic and anaerobic colonic bacteria in the small intestine[1,2], leading to increased carbohydrate fermentation and gas production.

Symptomatology frequently overlaps with other gastrointestinal disorders[3].

This study aimed to identify factors associated with test positivity and improve patient selection for diagnostic evaluation.

Aims & Methods: Retrospective, unicentric study. A cohort of 34 patients underwent glucose hydrogen and methane breath testing for SIBO. Demographic, clinical, laboratory data and test results were analyzed.

Results: The cohort included 21 females (61.8%) and 13 males (38.2%), with a mean age of 46.5 ± 15.9 years. Chronic diarrhea was the leading indication for testing (82.4%), followed by abdominal pain (8.8%). Tests results were positive in 4 cases (11.8%).

Positive patients had a higher mean age (56.0 ± 10.8 vs. 46.1 ± 15.8 years, $p = 0.236$) and a comparable gender distribution. Among positive patients, diarrhea was reported in 100% of cases, followed by abdominal distension (75%) and abdominal pain (50%). Folic acid levels were higher in the positive group (11.65 vs. 6.54 ng/mL, $p = 0.074$), while fecal calprotectin levels were significantly elevated (480 vs. 44.26 µg/g, $p = 0.027$).

Altered small intestine anatomy due to prior surgical interventions was strongly associated with test positivity ($p = 0.012$), while systemic disorders affecting gastrointestinal motility showed a non-significant trend ($p=0.136$). Proton pump inhibitor use was not associated with test positivity ($p = 1.0$). Rifaximin treatment led to symptom improvement in all positive cases, but with no significant difference compared to negative patients ($p = 0.444$).

Conclusion: Elevated serum folate and fecal calprotectin levels may serve as indicators of underlying SIBO in the appropriate setting. Altered small intestine anatomy was strongly associated with test positivity, and could

Introduction: Fecal microbiota transplantation (FMT) is becoming an increasingly used procedure in the treatment of gastrointestinal diseases. In this summary, we present our experience of FMT in hematological indications and patients.

Aims & Methods: From January 2023 to January 2024, 15 FMT procedures in 7 patients were performed. The transplant was prepared by standard technique from a healthy donor at the Department of Microbiology. Hematology team was responsible for selecting patients with adequate FMT indication.

Procedure was performed with standard gastroscope in 6 patients by transplantation into the distal duodenum, and in one patient by a colonoscope in the large bowel.

Results: Patient 1: acute GVHD and recurrent CD colitis after alogenic bone marrow transplantation (BMT) due to acute T-lymphoblastic leukemia. Application of FMT was done from caecum to rectum in a dose of 200 ml with complete symptom resolution and CD negativization Patient 2: alogenic BMT for MDS with development of severe small intestine GVHD refractory to standard immunosuppression. Two FMT performed with transplantation into the distal duodenum (200 ml in three weeks apart). Although relatively good clinical recovery was observed after 6-8 weeks, patient died 4 months later due to respiratory insufficiency and sepsis.

Patient 3 and 4. patients with AML in preparation for BMT. Due to repeated stool isolate of Pseudomonas aeruginosa, FMT was performed with the application of 200 ml of transplant (2 weeks apart) to the duodenum for the purpose of intestinal decolonization. Two weeks after FMT, the stool cultures showed a physiological flora and a planned BMT was performed.

Patient 5 and 6: patients with alloBMT due to primary myelofibrosis who developed intestinal GVHD and CD colitis. 200 ml of transplant was applied (3 weeks aparat) to the duodenum. The condition improved quickly and in further follow-up CD toxin was negative with partial improvement of GVHD symptoms (one patient required additonal photopheresis).

Patient 7: patient with AML in whom multidrug-resistant Enterococcus faecium has been isolated in coprocultures on several occasions during chemotherapy. Prior to the planned BMT, FMT was performed with the aim of intestinal decontamination with the application of 200 ml (2 weeks apart) of transplant to the distal duodenum. Stool analysis 2 weeks after FMT indicated physiological flora and a planned BMT was performed

Conclusion: Our experience indicates that FMT is a useful method in the treatment of GI pathology (GVHD, decontamination of the intestine before BMT and treatment of CD colitis) in hematological patients.

Disclosure: Nothing to disclose.

PRIMARY MACROPHAGE-DERIVED SIGNALS DRIVE FIBROGENESIS IN A GASTROINTESTINAL *IN VITRO* SCAR-IN-A-JAR MODEL

T. Tsapanou Katranara[1,2], M. Pehrsson[2], M. Sorokina Alexdóttir[2], A.-C. Bay-Jensen[2], M.A. Karsdal[2], J. Kjeldsen[3], M.A. Ainsworth[3], J.H. Mortensen[2]

Introduction: Inflammatory bowel disease (IBD) is characterized by chronic inflammation, where tissue remodeling and fibrosis are involved. Cytokine-driven activity originating from different inflammatory cell types could be responsible for fibrosis, by promoting fibroblast activation and excessive deposition of ECM. Specifically, inflammatory monocytes have recently been shown to be prominent in patients with higher disease severity in IBD. Although anti-inflammatory therapies are available, their impact on fibrogenesis remains limited, highlighting the need for *in vitro* models that can assess inflammation-driven fibrosis. Simultaneously, the 10 WFA-like domain from type VI collagen enables activated fibroblasts to bind and activate platelets, linking wound healing to fibrogenesis. Thus, we aimed to evaluate the pro-fibrotic effects of macrophages in a gastrointestinal scar-in-a-jar model, by quantifying a biomarker of type VI collagen formation.

Aims & Methods: Monocytes were isolated from buffy coats of healthy donors and differentiated to M0 macrophages for 6 days using 20 ng/ml MCSF. Upon differentiation, on day 0 the macrophages were polarized to M1 using 10 ng/ml LPS. The conditioned media was collected after 1 and 6 days. Human primary small intestine fibroblasts (Innoprot) were stimulated on day 0, 4 and 8 with: conditioned media from naive macrophages (M0) and activated macrophages (M1) in 3 dilutions (100%, 30%, 10%), 50 pM TGF-β, 3.3 ng/ml LPS and media control (MCSF). Unstimulated fibroblasts (w/o) were included as negative control. The experiment was concluded on day 12 and PRO-C6 (quantification of type VI collagen formation) was measured for all days. Cell viability was assessed using Live/Dead staining on day 12. To compare the changes for the biomarker levels (% change and ng/ml) two-way ANOVA and one-way ANOVA (with Tukey correction) were applied.

Results: On day 4, PRO-C6 levels were significantly elevated upon stimulation with TGF-β and M1-Day1 conditioned media, compared to unstimulated fibroblasts (Table 1, $p<0.001$ & $p<0.05$). On day 8, TGF-β and conditioned media from M0-Day6, M1-Day1 and M1-Day6 significantly increased PRO-C6 ($p<0.001$, $p<0.001$, $p<0.0001$ & $p<0.0001$). No significant increase was observed for TGF-β on day 12, whereas all conditioned media (M0-Day1, M0-Day6, M1-Day1 & M1-Day6) induced a significant increase of PRO-C6 ($p<0.0001$, $p<0.001$, $p<0.01$ & $p<0.0001$). On days 8 and 12, a significant decrease was observed for PRO-C6, when comparing the 100% M1-Day1 and M1-Day6-conditioned media to both 30% and 10% (all: $p<0.0001$).

8	M1-Day1 (MCSF) 100% vs. 30% (ng/ml)	1.78	[1.39, 2.17]	<0.0001	12	M1-Day1 (MCSF) 100% vs. 30% (ng/ml)	1.66	[1.03, 2.30]	<0.0001
8	M1-Day1 (MCSF) 100% vs. 10% (ng/ml)	1.68	[1.29, 2.07]	<0.0001	12	M1-Day1 (MCSF) 100% vs. 10% (ng/ml)	1.17	[0.54, 1.81]	<0.0001
8	M1-Day1 (MCSF) 100% vs. 30% (ng/ml)	2.37	[1.79, 2.96]	<0.0001	12	M1-Day6 (MCSF) 100% vs. 30% (ng/ml)	3.12	[2.30, 3.94]	<0.0001
8	M1-Day1 (MCSF) 100% vs. 10% (ng/ml)	1.66	[1.07, 2.24]	<0.0001	12	M1-Day6 (MCSF) 100% vs. 10% (ng/ml)	2.72	[1.90, 3.54]	<0.0001

Table 1.

Conclusion: Conditioned media from M0 and particularly from M1 macrophages, induced type VI collagen formation over time, whereas the effect of TGF-β stimulation depleted by day 12, suggesting a more sustained pro-fibrotic potential of inflammatory macrophage-derived cytokines. When fibroblasts were stimulated with 100% M1-conditioned media on day 8, and 12, the highest type VI collagen formation was exhibited and a significant reduction was noted in the 30% and 10% dilutions, suggesting a dose-sensitive response.

GUT HEALTH AND LIPID METABOLISM: THE ROLE OF SIBO THERAPY

K. Kvit[1], N. Kharchenko[2], M. Aksentiychuk[1]
[1]Danylo Halytsky Lviv National Medical University, Therapy No1 and Medical Diagnostics, Lviv, Ukraine, [2]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: Small intestinal bacterial overgrowth (SIBO) is a frequent condition characterized by an abnormal increase in the bacterial population in the small intestine. It is associated with digestive disorders, metabolic disturbances, and an elevated cardiovascular risk in patients with dyslipidemia. Emerging evidence suggests that SIBO may aggravate lipid metabolism abnormalities by disrupting the gut microbiota.

Aims & Methods: The aim of the study was to determine the prevalence of SIBO among patients with dyslipidemia and evaluate the impact of SIBO-targeted therapy on lipid metabolism correction. The study included 342 patients with dyslipidemia. SIBO was diagnosed via hydrogen breath testing. Patients received a combined therapy with rifaximin (400 mg TID for 14 days) followed by *Saccharomyces boulardii* CNCM I-745 (250 mg BID for 14 days). Clinical symptoms, lipid profiles (total cholesterol, triglycerides, LDL-C, HDL-C), apolipoprotein levels (ApoA1, ApoB), and homocysteine were assessed before and after treatment.

Results: SIBO was detected in 45.3% of patients with dyslipidemia. Combined therapy significantly reduced the prevalence of SIBO to 18% and alleviated clinical symptoms such as abdominal pain, bloating, meteorism, and stool disturbances.

Notably, therapy led to significant improvements in lipid profiles: reductions in total cholesterol, LDL-C, triglycerides, ApoB, and homocysteine levels, alongside increases in HDL-C and ApoA1. These improvements were comparable between patients receiving statin therapy and those not receiving it.

Conclusion: SIBO is highly prevalent in patients with dyslipidemia and may contribute to lipid metabolism disorders and cardiovascular risk. Targeted therapy with rifaximin and *S. boulardii* effectively reduces SIBO prevalence, improves gut symptoms, and enhances lipid parameters. Integrating SIBO treatment into dyslipidemia management strategies offers promising new therapeutic opportunities for cardiovascular risk reduction.

NON-SURGICAL MANAGEMENT OF CANCER-RELATED SMALL BOWEL OBSTRUCTION VIA DSA-GUIDED SMALL BOWEL DECOMPRESSION TUBE PLACEMENT: A NOVEL THERAPEUTIC

C. Zheng[1,2], S. Lin[2], B. Xu[2], Z. Huang[2]
[1]Fujian Medical University, Fuzhou, China, [2]Fujian Medical University Union Hospital, Fuzhou, China

Contact E-Mail Address: 351289617@qq.com

Introduction: Cancer-related small bowel obstruction (SBO) is a common and debilitating complication in patients with advanced cancer. It often requires surgical intervention, but in patients with multiple comorbidities or poor surgical prognosis, non-surgical alternatives can provide significant symptom relief.

This study presents a series of three cases where digital subtraction angiography (DSA)-guided small bowel decompression tube placement was successfully utilized as a non-invasive approach to manage cancer-related SBO.

Aims & Methods: We report three cases of advanced cancer patients who presented with SBO. The patients were diagnosed with mechanical obstructions due to rectal cancer and metastatic breast cancer. After comprehensive pre-operative evaluation, DSA-guided small bowel decompression tube placement was performed as a non-surgical treatment. The procedure involved introducing a multifaceted catheter through DSA-guided access, with real-time contrast-enhanced fluoroscopy used to position the tube in the distal small bowel. Post-procedural clinical outcomes, including symptomatic relief, bowel function restoration, and complication rates, were recorded and analyzed.

Results: The DSA-guided small bowel decompression tube placement led to immediate symptom improvement in all patients with cancer-related small bowel obstruction (SBO). In one patient with rectal cancer and post-surgical recurrence, the procedure resulted in significant relief from abdominal distension and pain. In another patient with metastatic breast cancer and multi-organ involvement, the DSA-guided intervention significantly reduced nausea and vomiting, improved gastrointestinal motility, and allowed for an uneventful recovery. A third patient, post-rectal cancer resection, experienced recurrent SBO, and after the DSA-guided procedure, the obstruction was alleviated, enabling the patient to resume

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. enteral feeding and spontaneous bowel movements without the need for surgery. Across all cases, patients demonstrated substantial symptom relief, restored bowel function, and experienced minimal complications, with no procedure-related mortality or major adverse events, underscoring the safety and effectiveness of this technique as a non-surgical alternative for managing cancer-related SBO.

Conclusion: DSA-guided small bowel decompression tube placement is a safe and effective non-surgical alternative for managing cancer-related SBO. This approach provides symptomatic relief, preserves the patient's quality of life, and may reduce the need for invasive surgical interventions, particularly in patients with advanced cancer and poor surgical candidacy. Further studies with larger sample sizes are necessary to validate the long-term benefits and outcomes of this technique in clinical practice.

Introduction: Chronic idiopathic intestinal pseudo-obstruction (CIIPO) is a rare disease, characterized by symptoms and signs mimicking mechanical obstruction of the gut in the absence of organic obstacles to intestinal transit (1). It is the most severe clinical expression of intestinal dysmotility that markedly affects quality of life, precipitates relevant personal and social costs and may lead to death affected individuals. Not all patients present with the same clinical picture. Although the typical manifestation of CIIPO is characterized by recurrent subocclusive episodes (RSE) that are separated by periods with digestive symptoms of variable severity, some patients present with a chronic subocclusive condition (CSC) with unremitting clinical and radiological features of intestinal mechanical obstruction.

Aims & Methods: To compare clinical and small bowel manometric features of RSE and CSC CIIPO patients seen in a single referral center.
Family history, onset of digestive symptoms, surgical procedures, digestive symptoms, subocclusive episodes (if applicable), body mass index, and feeding habits were recorded at the time of diagnosis (DIA) and at follow up (FU) by a structured questionnaire. Small bowel manometry was performed by perfusion techniques and abnormal motor patterns were visually identified.

Results: Between 1985 and 2023 we evaluated 125 CIPO patients without underlying systemic, metabolic diseases or mitochondrial cytopathies (CIIPO). Of these, 15 were lost after diagnosis. Of the remaining 110 patients (84 F; age at DIA: 33.06±13.4yrs; m±SD) 97 had RSE (76 F; 37.9±13.0 yrs) and 13 CSC (11 F; 12%; 34.6±16.1 yrs). Duration of FU was 10.5±9.2 yrs, range 1-36 yrs. At FU 90 still had RSE (82 F: 48.5±15.3 yrs) and 20 CSS (18%; 18 F:43.9±15.1 yrs). Clinical features of RSE at DIA and FU are summarized in the table.

	RSE at DIA	RSE at FU	CSC at DIA	CSC at FU
Body mass index	18.17 ± 4.6	19.27±3.5	16.99±2.3	18.28±4.2
Parenteral nutrition (%)	15 (15.5%)	26 (28.9%)	4 (23.1%)	15 (75.0%) ° *
Abdominal surgeries / yr	0.39 ±0.5	0.08±0.1^	0.61±0.5 °°	0.19 ±0.3 °
Restorsternal burning	15 (15.5%)	21 (23.3%)	2 (11.8%)	9 (45.0%) *
Epigastric pain	30 (30.9%)	32 (35.4%)	2 (15.4%)	12 (60.0%) ° *
Nausea	59 (60.8%)	33 (36.7%) ^	7 (53.9%)	15 (75.0%) *
Constipation	62 (63.95)	47 (52.2%)	11 (84.6%)	10 (50%) °

*P<0.05 °CSC FU vs CSC DIA; * CSC FU vs RSE FU; °° CSC DIA vs RSE DIA; ^ RSE FU vs RSE DIA*

The following manometric patterns were detected in 88 diagnostic tracings obtained: abnormal activity fronts 53 (52.5%); minor activity fronts abnormalities 60 (59.4%); hypocontractility 8 (7.9%); inability to convert fasting vs feeding patterns 7 (6.9%), discrete clustered contractions 23 (23%). Not significant differences were detected between the two CIIPO subgroup. 23 patients dead during the FU: 8 (34.8%) in the CSC group and 15 (16%) in the RSE group (P< 0.05). Main causes of death were: sepsis / cachexia (63.9%), transplant failure (19.4%), others (17%).

Conclusion:
CIIPO remains an often unrecognized disease, characterized by disabling and potentially life-threatning complications over time. Two subgroups exists among CIIPO patients. The continuos subocclusive condition (CSC) is more severe and may represent a dangerous evoultion of the episodic subtype (RSE).

Contact E-Mail Address: astrid.verbiest@kuleuven.be

Introduction: Citrulline is frequently used as surrogate marker for enterocyte mass in short bowel syndrome (SBS), but also to assess response with analogs of glucagon-like peptide 2 (GLP-2) in intestinal failure (IF). However, in SBS with colon-in-continuity (CiC), citrulline might not be the best marker given the short lengths of preserved small intestine. Therefore, we aimed to identify more informative biomarkers for SBS-IF-CiC in relation to GLP-2 analog therapy.

Aims & Methods: STARS Nutrition was a 52-week multicenter, open-label, phase 2 study in adult patients with SBS-IF-CiC (n=9) receiving weekly subcutaneous injections with the novel, long-acting GLP-2 analog apraglutide. A fasting blood sample was collected at baseline and at 4, 24 and

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 48 weeks of treatment. Apolipoprotein B-48 (ApoB-48), intestinal fatty-acid binding protein (iFABP) and lipopolysaccharide-binding protein (LBP) concentrations were measured (ELISA).

Results: At baseline, ApoB-48 levels correlated positively to the preserved small intestinal length (r=0.7983). With apraglutide, the ApoB-48 levels increased significantly at all timepoints (Table 1). While iFABP concentrations remained stable at 4 weeks, a significant increase was observed at 24 weeks. At 48 weeks, iFABP levels continued to be elevated but failed to reach statistical significance. LBP concentrations were not significantly affected by apraglutide.

	Baseline	4 weeks	24 weeks	48 weeks
ApoB-48 (ng/mL)	1,001 (165.8 – 22,400)	1,549 (909.5 – 31,830) p=0.0273	1,616 (899.4 – 65,390) p=0.0078	1,978 (767.2 – 101,900) p=0.0039
iFABP (pg/mL)	102.0 (17.77 – 4,409)	101.5 (45.66 – 4,468) p=0.25	149.3 (83.26 – 4,467) p=0.0078	135.1 (30.69 – 4,507) p=0.0742
LBP (ng/mL)	19,730 (11,830 – 47,860)	19,350 (11,950 – 32,340) p=0.82	23,030 (11,340 – 27,020) p=0.91	18,870 (10,910 – 23,070) p=0.20

Table 1 Systemic plasma levels of ApoB-48, iFABP and LBP.
Data are presented as median (min – max). Nominal p-values were calculated using Wilcoxon matched-pairs signed rank tests (significance ≤0.05). ApoB-48: apolipoprotein-B48; iFABP: intestinal fatty-acid binding protein; LBP: lipopolysaccharide binding protein. p≤0.05

Conclusion: Apraglutide treatment resulted in distinct increases of ApoB-48, a protein synthesized by the enterocytes and involved in fat absorption. Our results suggest that ApoB-48 could be a suitable candidate as biomarker for treatment response as not only it reflects the number of enterocytes but also their ability to absorb and transport nutrients, especially lipids.

RIFAXIMIN FOR SMALL INTESTINAL BACTERIAL OVERGROWTH. CAN WE PREDICT THE RESPONSE?

R. Mortensen[1], Z. Soh[2], P.J. Toong[2], J. de la Revilla Negro[3]
[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]Cambridge University Hospitals NHS Foundation Trust, Gastroenterology, Cambridge, United Kingdom

Contact E-Mail Address: rebecca.mortensen@nhs.net

Introduction: Small intestinal bacterial overgrowth (SIBO) and intestinal methanogen overgrowth (IMO) are increasingly recognised as common causes of non-specific gastrointestinal symptoms. Diagnosis and treatment remain challenging in clinical practice. Rifaximin can be an expensive medication in certain healthcare settings.

This retrospective audit evaluated the efficacy and safety of rifaximin for the treatment of SIBO and IMO at Cambridge University Hospitals. Also, the diagnostic value of the glucose hydrogen breath test (GHBT) vs clinical judgement and potential predictors of response to rifaximin were explored.

Aims & Methods: 124 patients treated with rifaximin for suspected bacterial overgrowth over one year were reviewed. Data collected included rifaximin dosing, presenting symptoms, risk factors for bacterial overgrowth, GHBT results (if available), concurrent use of neomycin, treatment response and reported side effects. Predictive factors for response were analysed using two-tailed t-tests and Fisher's exact test.

Results: Rifaximin improved symptoms in 68.3% of patients, with only 8.9% reporting side effects, of which none were severe.

Among the 124 patients, 69 had a positive GHBT, 8 had a negative GHBT result and 47 were not tested. There was no significant difference in response rate to rifaximin treatment between these groups (68.3%, 50%, 68.3% respectively, p=0.077).

Among patients with a positive GHBT, 72% had SIBO, 25% IMO and 3% had SIBO and IMO. Response rate was significantly higher in patients diagnosed with SIBO by GHBT (80%) compared to patients diagnosed with IMO (18%) (p<0.0001). 9 out of 17 patients with IMO received combination therapy with both rifaximin and neomycin.

The number of risk factors for bacterial overgrowth was significantly associated with higher response rates, with responders having an average of 1 risk factor compared to non-responders having an average of 0.65 risk factors (p=0.003).

Type and number of presenting symptoms, as well as dosing of rifaximin did not show a consistently significant association with response.

Conclusion: This audit supports the effectiveness and safety of rifaximin as a first line treatment for SIBO. Patients with IMO did not benefit from any regimen including rifaximin. GHBT result did not affect the response rate to rifaximin overall. The presence of risk factors for bacterial overgrowth was associated with significantly higher response rates, suggesting the potential utility of this observation as a predictive factor of response. Based on these findings, and considering the costs of rifaximin, we propose a clinical algorithm that prioritises rifaximin as first line treatment in a group of patients with higher chances to respond.

PP0281

SOCIAL DETERMINANTS OF ABDOMINAL TUBERCULOSIS VISITING LARGE TERTIARY CARE HOSPITAL OF COUNTRY JPMC KARACHI

O. Idris[1], A.S. Bhatti[1], N. Butt[1]
[1]Jinnah Post Graduate Medical Center, Gastroenterology, Karachi, Pakistan

Contact E-Mail Address: dr.omaridris@gmail.com

Introduction: Abdominal tuberculosis is a major concern in developing countries due to socioeconomic factors, influencing disease severity. This study at Jinnah Postgraduate Medical Centre (JPMC), Karachi, aims to explore the link between social determinants like socioeconomic status, residence, co-morbidities, addiction patterns, and abdominal tuberculosis severity in patients.

Aims & Methods: This study aimed to analyze prevalent social determinants in high TB-prevalent countries. Anticipated insights will aid in developing strategic interventions for TB. By highlighting social factors affecting TB, the study can guide targeted policies and interventions. The generated knowledge can enhance public health planning in high prevalence settings.

An ongoing descriptive cross sectional study conducted at the Department of Gastroenterology, JPMC, Karachi, from 2024 till date. A total of 120 patients diagnosed with abdominal tuberculosis were included. Data on social determinants such as socioeconomic status, residence, addiction, HIV status, diabetes, and malnutrition were collected.

Disease severity was assessed based on ADA levels and categorized as mild, moderate, or severe. Associations between social determinants and abdominal tuberculosis severity were analyzed using Chi-square tests with a significance level of $p \leq 0.05$.

Results: Total 120 patients were observed,The average patient age was 47.18 ± 20.56 years, with 51.7% males and 48.3% females. Low and middle socioeconomic groups accounted for most patients.

Malnutrition affected 32.5% of cases, with 19.2% HIV positive. Tobacco chewing (27.5%), smoking (15.0%), and alcohol consumption (14.2%) were common addictions. Urban areas housed 57.5% of cases, with most from Karachi (36.7%).

No social determinant showed significant association with abdominal tuberculosis severity ($p > 0.05$), but malnutrition ($p = 0.082$) and diabetes ($p = 0.298$) hinted at greater severity. Smoking and tobacco use were prevalent in moderate-to-severe cases ($p = 0.261$).

Conclusion: This study at JPMC, Karachi, found potential links between social factors like malnutrition, diabetes, and addiction, and intestinal tuberculosis severity. Though no significant associations were observed ($p > 0.05$), trends suggest these factors may influence disease progression.

Patients from low socioeconomic backgrounds and urban areas were more affected, emphasizing the need for targeted interventions such as nutritional support, diabetes management, and tobacco cessation to enhance outcomes.

Larger studies are necessary to confirm these connections and devise effective public health initiatives for at-risk populations

Introduction: Pancreatic exocrine insufficiency (PEI) is seen in primary pancreatic disease, but has also been seen in extrapancreatic conditions including celiac disease (CeD). The symptoms of PEI and CeD often overlap, which makes differential diagnosis challenging.

Aims & Methods: We aimed to investigate the prevalence of PEI in CeD in a systematic review and meta-analysis.

We searched five databases: PubMed, Embase, Cochrane, Web of Science Core Collection, and Google Scholar, up until October 21, 2024. The pooled prevalence of PEI in biopsy-confirmed CeD was estimated. The quality of studies was appraised, and results were reported according to the PRISMA guidelines.

Results: We identified and screened the titles and abstracts of 1432 publications, of which 60 were reviewed in full text and 12 were included in the analyses. The overall pooled weighted prevalence of PEI in CeD was 13.5% (95% CI 7.2–21.0). The prevalence was similar among children (14.2%; 95% CI 2.0–32.8) and adults (12.8%; 95% CI 7.8–18.7) with CeD.

The prevalence in studies that used secretory testing to define PEI was 13.1% (95% CI 6.4–21.3) and in those requiring digestive tests 17.1% (95% CI 5.8–32.1). The weighted prevalence of PEI was however significantly higher among untreated CeD patients (21.7%) than patients on a gluten-free diet (6.9%) ($p=0.03$), in both adults and children.

Conclusion: One in eight individuals with CeD may suffer from PEI. The prevalence was particularly high in children with untreated CeD. PEI should be considered in patients who do not respond to a gluten-free diet.

Contact E-Mail Address: ayari.myriam@hotmail.fr
Introduction: Fibromyalgia and coeliac disease share chronic symptoms that have a significant impact on patients' quality of life. While coeliac disease is widely recognized and well-documented, fibromyalgia remains frequently underestimated. Although coeliac disease is widely recognized, fibromyalgia is often underestimated and the association between these two pathologies has been little studied, leaving gaps in understanding their possible connections and implications for patient care.
Aims & Methods: The aim of the study was to determine the frequency of fibromyalgia positive screening in patients with coeliac disease and to investigate the associated factors. A cross-sectional study was conducted including patients with coeliac disease during September 2024. Participants were asked to complete the Fibromyalgia Rapid Screening Tool (FiRST) questionnaire, a validated screening tool for fibromyalgia, which assesses the presence and intensity of associated symptoms.
The questionnaire included 6 items: body pain, fatigue, sleep quality, cognitive impairment, mood disorders and impact on daily life. Positive screening for fibromyalgia was based on a FiRST score ≥ to 5 items.
Results: A total of 60 patients participated to the study, with a mean age of 45.35 years. The M/F sex ratio was of 0.22. According to the FiRST questionnaire, fibromyalgia was detected in 43.3% of patients (n=26). The mean score on the questionnaire was 3.58. The positive screening of fibromyalgia in patients with coeliac disease was significantly associated with the presence of associated auto-immune diseases (p=0.029), Helicobacter pylori gastritis (p=0.045), anemia (0.012), hypoferritinemia (p=0.047), hypocholesterolemia(p=0.026) and hypovitaminosis D (p=0.031).
However, no significant association was found between positive fibromyalgia screening and age (p=0.68), gender (p=0. 43), physical activity (p=0.53), type of occupation (p=0.66), gluten-free diet compliance (p=0.31), body mass index (p=0.107), intestinal villous atrophy (p=0.88) and anti-transglutaminase antibodies positivity (p=0.60).
Conclusion: Our study showed a notable frequency of fibromyalgia positive screening in patients with coeliac disease. This suggests a link between the autoimmune inflammatory process associated with gluten and the development of central nervous system sensitivity responsible for fibromyalgia symptoms. Early recognition of this comorbidity and associated factors is important to improve management and quality of life in patients with both conditions.
Disclosure: Nothing to disclose.

PP0284

MICROBIOTA IN PATIENTS WITH CELIAC DISEASE: FROM DIAGNOSIS TO FOLLOW-UP

M. Palo[1], E. Agostini[1], A. Pretto[2], C. Caranfil[3], S. Facchin[3], E.V. Savarino[4], F. Zingone[3]
[1]University Of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy, [2]University of Padua, Padua, Italy, [3]University of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy, [4]University of Padua, Division of Gastroenterology, Department Of Surgery, Oncology And Gastroenterology, Padua, Italy

Contact E-Mail Address: michela.palo@unipd.it
Introduction: The intestinal microbiota is defined as the community of microorganisms inhabiting the gastrointestinal tract, which confer benefits to the organism and play a role in immune system regulation. It has been suggested that the microbiota may play a role in the pathogenesis of gut diseases, including Celiac Disease (CeD), and the response to a gluten free diet (GFD). (1)
Intestinal dysbiosis may be a contributing factor to the inflammatory state, thereby hindering resolution of symptoms and complete mucosal healing, particularly in patients who show a lack of clinical and histological improvement despite following a GFD. (2,3)
Aims & Methods: We aimed to provide a preliminary evaluation of the gut microbiota profile from diagnosis to follow-up, classifying patients who respond and do not respond to diet in order to establish a first baseline of the microbial composition and its relationship to the dietary response.
We collected fecal samples from patients enrolled at the Gastroenterology Unit of Azienda Ospedale- Università of Padova, from March to November 2024. All patients needed to be off antibiotics, probiotics and proton-pump inhibitors for at least one month before enrolment. Stool samples were collected and transferred in a buffer solution, and stored at -20°C.
Fecal samples were analyzed by BMR Genomic s.r.l. (Padua, Italy) that sequenced the V3-V4 hypervariable 16S ribosomal RNA region using the Illumina MiSeq. The results were compared to an internal population of healthy subjects (provided by BMR genomics) using Qiime2 tools. Statistical analysis was conducted using STATA 18 software. Categorical variables were compared using the Chi-square test, while non-parametric continuous variables were analysed using the Mann-Whitney test.
Results: We enrolled 71 CeD patients with mean age at diagnosis of 35.76 ± 16.29 years old (50 out of 71 were female). Of the 71 patients, 9 were newly diagnosed with CeD, while 62 were in follow-up. Among follow-up groups, 44 of 62 patients (71%) were classified as responders to diet and 18 (29%) were classified as non- responders, exhibiting classical symptoms, positive serology and histology. We compared the relative abundance of the main bacterial phyla in each sample: a significant decrease in beneficial phyla such as Actinobacteria (p = 0.04) and a decrease close to the significant threshold in Firmicutes (p = 0.06) was observed after the follow-up. This factor could be ascribed to a long-term dietary regime rather than to the disease itself. (4)
Proteobacteria were more abundant in follow-up, especially in non-responders. This phylum includes many potentially pathogenic microorganisms belonging to Escherichia, Klebsiella and Shigella genera. Comparing

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

diagnosis and follow-up patients, Clostridium perfringens was significantly more present in patients during follow-up (p=0.02), while Escherichia coli showed greater presence in patients at diagnosis (p=0.035) and in non-responders, consistently with his role in the inflammatory phase of the disease. (5)

Conclusion: Our preliminary data suggest that a long-term GFD does not always restore completely the intestinal dysbiosis present at the diagnosis and could be associated with specific alterations in beneficial bacteria. The presence of abundant Proteobacteria at diagnosis and in non-responder patients may be considered as biomarkers of active state of CeD. Future studies on various biological samples, as well as a more extensive investigation into the impact of long-term GFD, are required to highlight microbiota-immunity relationships involved in development of CeD.

Introduction: Irritable bowel syndrome (IBS) and coeliac disease are common disorders that share overlapping symptoms. In this systematic review and meta-analysis, we aimed to provide up-to-date and comprehensive estimates of the prevalence of coeliac disease in patients with IBS.

Aims & Methods: We searched several databases through January 2025 for studies reporting the prevalence of coeliac disease in patients with IBS. Eligible studies used Rome III or Rome IV criteria for IBS diagnosis and used serological screening with tissue transglutaminase, endomysial antibodies, or deamidated gliadin peptide, and/or confirmatory duodenal biopsies for coeliac disease diagnosis. We used random-effects meta-analysis to estimate the pooled prevalence of seropositive and biopsy-proven coeliac disease with 95% confidence intervals (CI). We calculated pooled odds ratios (ORs) to compare the likelihood of coeliac disease between patients with IBS and controls.

Results: A total of 29 studies comprising 7,209 patients with IBS were included. The pooled seroprevalence of coeliac disease in patients with IBS was 6% (95% CI, 5% - 8%), and the pooled prevalence of biopsy-proven coeliac disease was 2% (95% CI, 2% - 3%). A significant proportion of seropositive patients (15%; 95% CI, 6% - 24%) did not undergo endoscopy and biopsy. Patients with IBS had significantly higher odds of a positive serology than controls (OR 4.42; 95% CI, 2.82 – 6.92). The odds of coeliac disease were similar across genders and IBS subtypes.

Conclusion: Coeliac disease is highly prevalent in patients with IBS, according to the Rome III and Rome IV criteria. A positive diagnosis of IBS should not be made without excluding coeliac disease.

COELIAC DISEASE IN BONE FRACTURE PATIENTS: A 1000 PATIENT PILOT SCREENING STUDY

F. Fan[1,2], A. Calder[1], S. Fox[1], P. Raymode[1], R. Harris[3], S. Shyamsundar[4], A. Verma[1]

[1]Kettering General Hospital, Department of Digestive Diseases, Kettering, United Kingdom, [2]University of Leicester, Leicester, United Kingdom, [3]Kettering General Hospital, Kettering, United Kingdom, [4]Kettering General Hospital, Department of Trauma and Orthopaedics, Kettering, United Kingdom

Contact E-Mail Address: francis.fan3@nhs.net

Introduction: Coeliac disease (CD) affects 1% of the population in the United Kingdom (U.K.) but is often underdiagnosed[1]. Complications of CD include detrimental effects on bone health and increased fracture risk[2]. Currently, evidence supporting routine serological testing for CD in adults with fractures is limited.

Aims & Methods: The aims of this study were to:

1. Determine whether the prevalence of CD among adult fracture patients exceeds the expected 1% in the general population.

2. Characterise demographic and fracture-site patterns to identify high-risk subgroups.

This cross-sectional observational study was conducted at a single U.K. fracture clinic with 1000 adults (≥16 years) with a fracture recruited between April 2023 and April 2025. Patients under 16 or unable to provide consent were excluded. Patients with known CD were included. Demographic data (age, gender, ethnicity) and fracture sites were recorded.

Anti-tissue transglutaminase antibody (tTG-IgA) tests were performed unless known to have CD. Equivocal tTG-IgA results were reviewed by a gastroenterologist, and repeat testing was conducted if needed. Seropositive participants were invited for duodenal biopsy. Laboratory processing issues were treated as negative results. Statistical analyses included descriptive demographic analyses and prevalence calculations.

Results: Baseline characteristics are summarised in Table 1. Of 1000 participants, 978 participants underwent tTG-IgA testing, of which 5 participants tested positive, yielding a seroprevalence of 5/1000 (0.5%). Duodenal biopsy confirmed CD in 2 participants 2/1000 (0.2%), while 1 seropositive participant did not attend biopsy, 1 is awaiting biopsy, and 1 had a negative biopsy. 28 participants were classified as having negative results. This group included untested samples (n=15), equivocal results (n=6), and known CD (n=7).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The overall prevalence of CD in our study population was 9/1000 (0.9%): 7 known and 2 newly confirmed CD. The CD population were predominantly white, and upper limb fractures were most common, aligning with prior studies[3,4].

Variable	Categories	Frequency (%)	Known coeliac disease (n=7) (%)	New seropositive patients (n=5) (%)
Age in years (mean ± SD, median, range)	-	54.2 ± 17.7, 56, 18–89	55.4 ± 26.0, 64, 24–85	47.8 ± 18.6, 40, 30–74
Gender	Male	371 (37.1)	2 (28.6)	2 (40)
	Female	628 (62.8)	5 (71.4)	3 (60)
	Non-binary	1 (0.1)	0	0
Ethnicity	White	951 (95.1)	6 (85.7)	5 (100)
	Other*	49 (4.9)	1 (14.3)	0
Fracture site	Upper limb	628 (62.8)	5 (71.4)	4 (80.0)
	Lower limb	364 (36.4)	2 (28.6)	1 (20.0)
	Spinal/ Other	3 (0.3)/ 5 (0.5)	0	0

Table 1.

** Asian or Asian British, Mixed or multiple, Black, Black British, Caribbean, or African, and Other ethnic group.*

Conclusion: This represents one of the largest evaluations of CD prevalence in fracture patients. The observed prevalence of CD 9/1000 (0.9%) closely aligns to the expected UK prevalence for CD. However, given only 5/1000 (0.5%) tested positive serologically and 2/1000 (0.2%) confirmed through biopsy, these findings suggest that routine screening in fracture clinics is unlikely to be efficient. Instead, we should explore targeted screening in fracture clinics, reserving testing for patients with iron-deficiency anaemia, chronic GI symptoms, or a first-degree family history of coeliac disease.

OSTEOPROTEGERIN AS A MARKER OF BONE HEALTH AND NUTRITIONAL STATUS IN PEDIATRIC CELIAC DISEASE: A COMPARATIVE STUDY OF NEWLY AND LONG-TERM DIAGNOSED PATIENTS BEFORE AND AFTER GLUTEN-FREE DIET

Y. Dyankova[1], R. Pancheva[2], M. Dzhogova[3], K. Koleva[1], M. Georgieva[4]

[1]St. Marina University Hospital, Pediatrics, Varna, Bulgaria, [2]Medical University Varna, Nutrition and Hygiene, Varna, Bulgaria, [3]Medical University Varna, Varna, Bulgaria, [4]St Marina University Hospital, Pediatrics, Varna, Bulgaria

Contact E-Mail Address: doktordqnkova@gmail.com

Introduction: Osteoprotegerin (OPG), a regulator of bone turnover, may serve as a marker of skeletal and nutritional status in pediatric celiac disease (CD). This study evaluates the relationship of OPG with growth, bone age, and biochemical parameters before and after gluten-free diet (GFD) intervention.

Aims & Methods: The study included two cohorts of CD patients treated at the Department of Pediatrics, St. Marina University Hospital, Varna, Bulgaria (2018–2021): newly diagnosed patients (Group A, n = 25) and long-term diagnosed patients (Group B, n = 54). Parameters included weight, height, calcium, magnesium, phosphorus, alkaline phosphatase (ALP), ferritin, hemoglobin, PTH, bone age, osteocalcin and OPG. Data were analyzed at baseline and after six months of GFD using Pearson and Spearman correlation coefficients.

Results: Group A (7.28±4.56 years, male n = 14 [56%]) and Group B (8.15±3.76 years, male n = 16 [29.6%], p = 0.376) were analyzed for growth and bone turnover. In Group A, OPG negatively correlated with bone age before (r = -0.325, p = 0.017) and after diet (r = -0.335, p = 0.013), and positively with hemoglobin and iron post-diet (r = 0.301, p = 0.029). In Group B, similar correlations appeared after diet: bone age (r = -0.325, p = 0.017) and iron (r = 0.297, p = 0.029). OPG did not correlate significantly with vitamin D in either group (p > 0.15).

Conclusion: OPG shows consistent negative correlation with bone age and positive association with iron status after GFD, supporting its role as a marker of skeletal and nutritional recovery in pediatric CD.

DETERMINATION OF ANTI-TISSUE TRANSGLUTAMINASE ANTIBODIES IN THE LONG-TERM FOLLOW-UP OF ADULT CELIAC DISEASE

F.J. Pardilla[1], J. Gisbert[1], M. Jiménez[1]

[1]Hospital Universitario de La Princesa, Instituto de Investigación Sanitaria Princesa and CIBEREHD, Gastroenterology Unit, Madrid, Spain

Contact E-Mail Address: fjpm95@gmail.com

Introduction: Anti-tissue transglutaminase IgA antibodies (tTG) are used in the follow-up of celiac disease (CD) to assess adherence to a gluten-free diet (GFD). Persistent positivity may indicate the need for histological reassessment. There is limited information about the rate of complete normalization of tTG and associated factors. Our objective was to evaluate the percentage, kinetics, and factors related to tTG normalization.

Aims & Methods: This was a retrospective observational study including patients with tTG testing at diagnosis and follow-up monitoring of these antibodies from 1991 to 2023 in a specialized unit dedicated to patients with CD. Inclusion criteria were: patients over 16 years of age at diagno-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sis, initially elevated tTG titres, and at least one serological follow-up after starting a GFD. Time to tTG normalization was estimated using the Kaplan-Meier method. Comparisons between groups were performed using the log-rank test. The association between demographic and clinicopathological characteristics at diagnosis and time to tTG normalization was assessed using Cox regression analysis.

Results: A total of 179 patients were included (75% female, mean age 40 ± 16 years). Duodenal atrophy was present in 81%, and 79% had symptoms. 83% strictly adhered to a GFD. Median follow-up was 3 years. The incidence rate of tTG normalization was 35% per patient-year. The cumulative tTG normalization rate was 38% (95% CI: 30-45) at 1 year, 61% (53-69) at 2 years, 70% (63-77) at 3 years, 80% (73-87) at 4 years, 81% (74-89) at 5 years, and 95% (88-100) at 10 years. The median time to tTG normalization was 24 months (95% CI: 20–28). *Table 1* shows Kaplan–Meier estimates expressed as percentages of tTG normalization by adherece to GFD and baseline tTG. In the multivariable analysis, two factors were found to be significantly associated with the normalization of tTG: lower baseline tTG and good adherence to a GFD. Regarding baseline tTG level, patients with titres ≤ 286 U/ml (median) had 2.46 times higher likelihood of antibody normalization compared to those with higher titres (HR: 2.46; 95% CI: 1.69–3.56; p < 0.001). Regarding adherence to a GFD, patients who followed a strict GFD had 5.38 times higher likelihood of tTG normalization (HR: 5.38; 95% CI: 2.79–10.36; p < 0.001).

Months		12	24	36	48	60
GFD	Yes	43 (35-51)	69 (60-76)	79 (70-85)	89 (83-94)	91 (84-95)
	No	11 (0.2-22)	26 (10-42)	31 (13-49)	37 (15-59)	-
Baseline tTG titres	≤ 286*	56 (45-66)	80 (71-89)	83 (75-92)	85 (77-94)	-
	> 286*	19 (11-27)	42 (31-53)	56 (44-68)	75 (63-86)	77 (66-88)

Table 1. Kaplan–Meier estimates expressed as percentages of normalization (with 95% CIs) after CD diagnosis, by adherece to GFD and baseline tGA titres.

*CD: celiac disease; GFD: gluten-free diet; tTG: anti-tissue transglutaminase IgA antibodies; CI: confidence interval; *median*

Conclusion:

1. The incidence rate of tTG normalization in CD patients after initiating a GFD was 35% per patient-year of follow-up.
2. In the long-term (10 years), 95% of CD patients achieved tTG normalization.
3. Lower tTG titres at diagnosis and good adherence to the GFD were predictive factors for tTG normalization.
4. Understanding the kinetics of tTG normalization according to various factors is essential before considering histological reassessment for suspected poor disease progression.

Contact E-Mail Address: gerasimatos.ger@gmail.com

Introduction: Celiac disease, a chronic autoimmune enteropathy caused by exposure to gluten in genetically predisposed individuals, is characterized by a broad clinical spectrum often with multisystem involvement. Symptoms related to the reproductive system include delayed menarche, early menopause, fertility disorders, miscarriages, and prematurity.

Aims & Methods: To study the impact of celiac disease on fertility in a female Greek population. A retrospective review of all patient records from the celiac disease outpatient clinic at our hospital.

Results: Medical histories of 231 female patients were reviewed (69% of the total patient population) with a mean age of 44.3 years and a mean age at diagnosis of 35.3 years. The mean age of menarche was 12.7 years. Menstrual irregularities were reported in 27% (20% instability, 7% dysmenorrhea). A total of 28% (65/231) were in menopause, with an average age of menopause onset at 50.7 years.

A history of miscarriages was recorded in 15% of all women (35/231), but in 29% of women in menopause (19/65). 82% (53/65) of women in menopause had children, with 98% (52/53) having been pregnant before the diagnosis of the disease.

Among all women who gave birth, only 12/113 (11%) had been diagnosed before pregnancy. 56% (63/113) and 44% (50/113) had a vaginal delivery and cesarean section, respectively. Pregnancy complications were recorded in 24 women (18 preterm births, 15 low birth weight infants, 1 intrauterine death).

Conclusion: Women with celiac disease tend to have relatively late menarche and an increased rate of miscarriages. However, the disease does not seem to significantly affect fertility.

Contact E-Mail Address: mara@nordicbio.com

Introduction: Celiac disease (CeD) is characterized by intestinal inflammation and epithelial damage upon exposure to immunogenic gluten peptides, directly disrupting tissue architecture and by extension the extracellular matrix (ECM). The intestinal tissue is rich in ECM proteins such as collagens, which, during inflammation, undergo enzymatic remodeling due to increased proteolytic activity. IMU-856 is an orally available and systemically acting small-molecule modulator of sirtuin 6 (SIRT6), a histone/non-histone protein deacetylase and transcriptional regulator that aims to restore intestinal barrier function and regenerate bowel epithelium.

Aims & Methods: We investigated biomarkers of ECM remodeling as potential indicators of disease activity and pharmacodynamic response to IMU-856 in patients with CeD. A total of 39 patients with CeD were included from a sub-study (Part C) of a double-blind, randomized, placebo-controlled phase 1/1b clinical trial of IMU-856.

Plasma was drawn at baseline before dosing and at day 14. Biomarkers of MMP-degraded type III, IV, and VI collagen (C3M, C4M, C6M), and type VII collagen formation (PRO-C7) were measured. Spearman's rank correlation was applied at baseline. Group differences were evaluated using the Mann-Whitney U-test. Mean change from baseline to day 14 was computed.

Results: At baseline, C3M, C4M, and PRO-C7 showed significant inverse correlation with villus height (ρ=-0.32, ρ=-0.34, ρ=-0.33, all $p<0.05$). C4M and PRO-C7 significantly correlated to histological inflammation and mucosal damage (Q-Marsh) at baseline (ρ=0.31, ρ=0.33, both $p<0.05$). PRO-C7 also significantly correlated with the villus height/crypt depth ratio (ρ=-0.32, $p<0.05$) (*Table 1*).

At day 14, C3M and PRO-C7 levels numerically decreased in IMU-856 treated patients by 5.8% and 8.3% while increasing in placebo treated patients by 10.8% and 7.0% respectively. C6M levels decreased numerically by 4% in IMU-856 treated patients with a 0.7% increase in placebo treated patients. Plasma citrulline levels, a biomarker of enterocyte mass and function, increased by 16% in patients treated with IMU-856.

	Q-Marsh	Villus height	Crypt depth	Villus height/crypt depth	Citrulline
C3M	0.28 (0.079)	-0.32 (0.045)	0.10 (0.535)	-0.25 (0.108)	-0.25 (0.114)
C4M	0.31 (0.048)	-0.34 (0.029)	0.11 (0.506)	-0.27 (0.082)	-0.19 (0.241)
C6M	0.07 (0.685)	-0.06 (0.725)	0.17 (0.285)	-0.12 (0.443)	-0.11 (0.512)
PRO-C7	0.33 (0.033)	-0.33 (0.037)	0.24 (0.137)	-0.32 (0.041)	-0.17 (0.292)

Table 1. Correlations between biomarkers and clinical parameters at baseline. Data is presented as Spearman's rho with p-value in brackets.

Conclusion: Biomarkers of ECM remodeling reflect histological inflammation and mucosal architecture parameters such as Q-Marsh score and villus height, offering a direct insight into intestinal barrier integrity. Furthermore, these biomarkers potentially reflect treatment-induced improvement in intestinal tissue remodeling upon treatment with IMU-856.

PP0291

IS IT USEFUL TO MEASURE QUALITY OF LIFE IN THE FOLLOW-UP OF PATIENTS WITH CELIAC DISEASE? A SINGLE-CENTER EXPERIENCE

M.d.M. Díaz Alcázar[1], L. Marta[1], E. Redondo-Cerezo[1]
[1]Hospital Universitario Virgen de las Nieves, UGC Aparato Digestivo, Granada, Spain

Contact E-Mail Address: mmardiazalcazar@gmail.com

Introduction: Celiac disease is a chronic disease that requires lifelong treatment with a strict diet, which has an impact on the health-related quality of life of the patients.

Aims & Methods: To analyse the quality of life in patients with celiac disease that are followed in our centre.

A single-center, prospective, observational study based in the Spanish version of Celiac Disease Quality of Life Survey (CD-QOL), a validated questionnaire.

Results: 53 patients agreed to complete the questionnaire. Mean age of the patients at the moment of the consultation was 39.15 years, while mean age at diagnosis of the patients who agreed to participate was 33.20 years. Of them, 35.8% had university degree, 28.3% completed professional training and 35.8% only had compulsory basic education.

Of these patients, 69.2% didn't have any relative diagnosed with celiac disease, and only the 13.2% used to live with another celiac patient. Just 9.4% of the patients who filled in the questionnaire were members of a celiac patient society.

75.5% of the patients claimed that celiac disease affects their social life, 84.9% declared that they comply properly with the gluten-free diet, although for the 32.7% the adherence to the dietary treatment is difficult.

Of the patients who participated, 33.9% declared that they feel quite / a lot limited by the disease, 27.4% feel quite / much stigmatized because of the illness, 22.7% have quite / a lot of problems in their social life, 32.2% have quite / a lot difficulties travelling, and 22.7% of patients declared that they have quite / a lot the impression to not have a normal life.

Conclusion:

1. Celiac disease may be quite burdensome even in asymptomatic patients who are not supposed to have small bowel damage in their follow-up. According to our series, up to 75.5% of patients have problems in their social life.
2. Health education during the follow-up providing greater knowledge of the disease, support from specialized nurses, and the recommendation to join patients support groups (patient societies) could be tools that may empower celiac patients to help manage their disease and enjoy a normal life.

CELIAC DISEASE AND SILENT FATTY LIVER: WHAT CHANGES WITH GLUTEN-FREE DIET?

I. Qarch[1], F.-Z. Chabib[1], M. Borahma[1], F.Z. Ajana[1], M. Kadiri[1], N. Lagdali[1]
[1]Ibn Sina University Hospital Center, Faculty of Medicine and Pharmacy, Mohammed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ismail.qarch@gmail.com
Introduction: Hepatic manifestations are increasingly recognized in celiac disease (CD), with metabolic steatopathies emerging as a significant extraintestinal feature.
Aims & Methods: We aimed to assess the prevalence of hepatic steatosis in CD patients and to evaluate its evolution under a strict gluten-free diet (GFD).
We conducted a 30-year retrospective study including 344 patients diagnosed with CD based on clinical, serological, and histological criteria. All patients underwent abdominal ultrasonography. Only those with hepatic steatosis and no other identifiable causes of liver fat accumulation were included for further analysis. Evolution under GFD was assessed through clinical, biological, and imaging follow-up.
Results: Among 344 celiac patients, 64 (21.3%) had hepatic steatosis. The mean age was 30.5 years (17–61), with a female predominance (F/M = 4.3). Common symptoms included fatigue and weight loss (100%), abdominal pain (56%), and malabsorptive diarrhea (41%). Liver function tests were abnormal in 60%, with isolated cytolysis being the most frequent pattern. Liver biopsy (n=18) revealed steatohepatitis in 12 patients, mostly grade 1 or 3.
Under a well-followed GFD, 25% showed normalization of liver ultrasound. Among patients with abnormal liver function tests, 36.9% experienced biochemical improvement. Histological improvement was documented in two cases: one patient initially diagnosed with severe grade 3 steatohepatitis showed complete resolution of hepatic steatosis after one year of strict dietary adherence. Another patient with grade 3 steatohepatitis showed partial improvement, regressing to grade 1 on follow-up biopsy.
Conclusion: Metabolic steatopathies affect over one in five CD patients. A gluten-free diet not only improves gastrointestinal symptoms but can also reverse hepatic steatosis. These findings support routine hepatic monitoring in celiac patients and reinforce the systemic benefits of dietary adherence.
Disclosure: Nothing to disclose.

PP0293

CLINICAL, ENDOSCOPIC AND HISTOLOGICAL PROFILE OF SERONEGATIVE CELIAC DISEASE: A MOROCCAN UNIVERSITY SERIES

I. Qarch[1], F.-Z. Chabib[1], M. Borahma[1], F.Z. Ajana[1], M. Kadiri[1], N. Lagdali[1]
[1]Ibn Sina University Hospital Center, Faculty of Medicine and Pharmacy, Mohammed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ismail.qarch@gmail.com
Introduction: Celiac disease (CD) is a chronic autoimmune enteropathy triggered by gluten ingestion in genetically predisposed individuals. Diagnosis is based on clinical, biological, serological, and especially histological criteria, including villous atrophy and intraepithelial lymphocytic infiltration (>30%).
Aims & Methods: The aim of this study is to highlight the importance of clinical presentation, biological markers, and histology in the diagnosis of seronegative CD, particularly since serological testing often guides biopsy decisions.
We conducted a retrospective descriptive study over a 30-year period, from January 1995 to March 2025, including all patients with histologically confirmed CD based on jejunal biopsy and clinical response to a gluten-free diet (GFD), but with negative anti-transglutaminase IgA and/or anti-endomysial antibodies. All seropositive patients were excluded.
Results: Out of 344 patients diagnosed with CD in our department, 74 (21.3%) were seronegative. The mean age was 65 years (range: 20–65), with a female-to-male ratio of 3.1.
From a clinical standpoint, nutritional deficiency syndromes were present in 95.9% (n=71), malabsorptive chronic diarrhea in 77% (n=57), diffuse abdominal pain in 71.6% (n=53), weight loss in 54% (n=40), and chronic evacuation constipation in 6.7% (n=5). Clinical examination showed anemia in 70.3% (n=52) and neurological signs in 25.6% (n=19).
Endoscopic findings were suggestive of CD in 43.2% of cases, including duodenal fold reduction in 37.8% (n=28), and a ‚scalloping' appearance in 5.4% (n=4). Duodenal mucosa and folds appeared normal in 44.6% (n=33). Histological analysis of jejunal biopsies in all patients revealed intraepithelial lymphocytosis >30%. Severe villous atrophy (Marsh stage IIIc) was found in 71.5% (n=53), and partial atrophy (Marsh IIIa) in 10.8% (n=8).
Conclusion: In our study, seronegative CD represented 21.3% of all celiac patients. These patients had more severe clinical presentations and more advanced villous atrophy (Marsh stage III), despite negative serology. This underlines the importance of histology and clinical judgment in diagnosing CD in seronegative individuals.

Introduction: During the COVID-19 pandemic the British Society of Gastroenterology (BSG) introduced interim guidelines supporting a non-biopsy pathway for the diagnosis of coeliac disease. These guidelines reflect the current recommendations of the American Gastroenterological As-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sociation (AGA). According to these guidelines, symptomatic or high risk adults with anti-Tissue transglutaminase (TTG) IgA titres ≥10× the upper limit of normal (ULN) and a positive endomysial antibody (EMA) on a repeat sample can be diagnosed without endoscopy and referred directly to a specialist coeliac clinic. Patients who do not meet these criteria should be referred for a gastroscopy (OGD) with biopsy for the confirmation of coeliac, prior to starting a gluten free diet.

Aims & Methods: To assess whether general practitioners (GPs) in the community appropriately referred patients with suspected coeliac disease in line with the AGA and BSG interim non-biopsy diagnostic criteria.

A retrospective review was conducted of all new patients referred to the Coeliac clinic in Galway university hospital between January 2023 and December 2024. Data regarding TTG level at diagnosis, EMA result, and compliance with the diagnostic pathway outlined above was collected for each new referral. This data was collected via Evolve - the hospital's electronic based patient record system.

Results:

- There were 119 "new" referrals to our Coeliac Service between January 2023 and December 2024. Of these, 44 cases were known coeliac who were referred by primary care for re-engagement with the clinic, 18 were referred from secondary or tertiary care including GI surgery, Dermatology, Paediatrics, etc. 4 coincidental diagnoses (i.e. OGD performed for indications other than coeliac disease), and 5 outliers (i.e. with incomplete data or incorrectly referred to coeliac clinic) leaving 48 new coeliac cases referred from primary care.
- 18 of these referrals met the non-biopsy criteria for diagnosis (TTG ≥100 + positive EMA)
  - Within this cohort 66% (n=12) were incorrectly referred directly for an OGD which may have delayed the diagnosis of coeliac disease while the remaining 33% (n=6) were correctly referred for direct review at the coeliac clinic.
- The remaining 29 patients all had TTG values less that 10x ULN. 48% (n=14) of these patients were incorrectly referred to clinic prior to endoscopy and of greater concern, 45% (n=13) were recommended by their primary care physician to start a gluten free diet prior to any review or endoscopic procedure.
- Overall, only 44% (n=21) of referrals were compliant with the AGA/BSG guidance.

Conclusion: There is a notable gap in adherence to AGA and BSG non-biopsy coeliac diagnostic guidance in community settings. Half of patients eligible for a non-biopsy diagnosis underwent unnecessary endoscopy, and the majority of ineligible patients were commenced on a gluten free diet prior to, or without, referral for endoscopy. Further GP education is warranted to align referral practices with evidence-based pathways. Dedicated streamlined referral pathways for coeliac disease should ensure a timely diagnosis without mandatory endoscopy in those fulfilling the criteria for a non-biopsy diagnosis and facilitate a timely endoscopy prior to gluten elimination in those who require histological diagnosis.

Introduction: Basic anatomical and functional unit of the epithelial barrier of the small intestine is enterocyte, which plays a key role in assimilation processes nutrients. Therefore, understanding the processes of structure regeneration mucous membrane of the small intestine in celiac disease is of paramount importance meaning.

Aims & Methods: To study the effect of permeability markers (I-FABP of blood serum and fecal zonulin) in patients with celiac disease with atrophy of the mucous membrane of the small intestine.

151 patients with celiac disease was examined: the median (Me) age of those examined was 42 years (Q25-Q75: 30–56 years) (25 (16.6%) men; women - 126 (83.4%). Depending on adherence to AGD, patients were divided into 3 groups: Group I-newly diagnosed patients without AGD (n=58); Group II- patients who do not strictly adhere to AGD (n=38); Group III- patients carefully observing AGD for periods from 6 months to 15 years (n=55). Also serum Fatty-Acid-Binding Protein-I - 1-FABP and zonulin in feces were studied. The reference values for zonulin in feces were 83.15 ng/ml. Reference values for I-FABP determined in the control group are 845 pg/ml.

Results: A significant increase in the level of I-FABP (Me 2045 pg/ml (1690–2350)) in group I compared to the control group ($p < 0.01$). High rates were observed in patients of group I, and averaged 111.6 ng/ml (103.1–124), which was significantly higher than in the control group ($p < 0.01$). The highest levels of I-FABP were observed in patients with the most severe degree of atrophy (Marsh III (A-C)).

The level of I-FABP was significantly different from the control depending on the degree of villous atrophy: with atrophy corresponding to Marsh IIIA - median: 1310 pg/ml, (1212-1461 pg/ml), with atrophy corresponding to Marsh IIIB - median: 2090 pg/ml ml, (1812-2322 pg/ml), and for atrophy corresponding to Marsh IIIC - median: 2058 pg/ml, (1858-2678 pg/ml). The highest levels of fecal zonulin were found in patients with the most severe atrophy (Marsh III (A-C)).

As follows from the presented data, the level of zonulin was significantly different from the control depending on the degree of villous atrophy: with partial atrophy (Marsh IIIA) - median: 97.5 ng/ml, (90-105 ng/ml), with subtotal atrophy (Marsh IIIB)) - median: 107 ng/ml, (96.5-117 ng/ml), and with total (Marsh IIIC) - median: 113.7 ng/ml, (104-128.8 ng/ml).

Conclusion: The average values of I-FABP and zonulin correlated with the degree of mucosa atrophy ($p<0.01$). Each of the studied non-invasive markers of intestinal permeability (serum I-FABP and fecal zonulin) reflects its own level and degree of damage to the STC in patients with celiac disease and can be used in clinical practice to assess ongoing structural changes in STC during a gluten-free diet.

ANALYTICAL PERFORMANCE OF A NOVEL, FULLY AUTOMATED MULTIPLEXED MICROARRAY IMMUNOASSAY FOR THE DETECTION OF CELIAC DISEASE AUTOANTIBODIES

J. Sillitoe[1], C. Wilson[1], G. Gomez[2], J. Santiago[3], E. Garyga[3], R. Pasion-Galvan[3], H. Laird[4], M. Hooper[4], S. Seaton[4], A. Yau[4], C. Fischer[2], J. Tyson[1]
[1]The Newcastle upon Tyne Hospitals NHS Foundation Trust, North East Innovation Lab, Newcastle, United Kingdom, [2]AliveDx, Scientific and Medical Affairs, Eysins, Switzerland, [3]AliveDx, Clinical Affairs, Eysins, Switzerland, [4]AliveDx, Research and Development, Edinburgh, United Kingdom

Contact E-Mail Address: gerber.gomez@alivedx.com

Introduction: Autoantibody detection is a cornerstone in the evaluation of Celiac Disease (CD); however, there is a limited offer of multiplexed testing devices.

Aims & Methods: We assessed the analytical performance of a novel, single-use, multiplexed microarray immunoassay (MosaiQ AiPlex® CD microarray. AliveDx, Switzerland), used with its fully automated high-throughput proprietary system, for the qualitative detection of total IgA and semiquantitative detection of autoantibodies (IgA and IgG isotypes) against tissue transglutaminase (tTG) and deamidated gliadin peptide (DGP), compared with selected devices.

The study was conducted at two sites.

Site 1: North East Innovation Lab (The Newcastle upon Tyne Hospitals NHS Foundation Trust, UK),

Site 2: AliveDx (Eysins, Switzerland).

Included human serum samples were banked, de-identified and tested using the investigational device after characterization as reactive or non-reactive to the respective measurand by Phadia AB assays: tTG IgA (EliA Celikey tTG IgA), tTG IgG (EliA Celikey tTG IgG), DGP IgA (EliA Gliadin^{DP} IgA) and DGP IgG (EliA Gliadin^{DP} IgG). Comparator for total IgA was Tina-quant IgA Gen.2 (Roche Diagnostics Gmbh). Positive percent agreement (PPA) and negative percent agreement (NPA) were calculated. Double-sided 95% Confidence Interval (CI) were calculated using Clopper-Pearson Exact Method.

Results: Compared with the respective devices (equivocal results excluded), the investigational microarray showed PPA ranging from 95.7% to 100% and NPA ranging from 87.5 to 98.7%. Table 1 shows the performance of the individual measurands.

	PPA			NPA		
Measurand / Parameter	PPA value (%)	n/N	95% CI	NPA value (%)	n/N	95% CI
tTG IgA	100	61/61	94.1, 100	98.7	456/462	97.2, 99.5
DGP IGA	95.8	69/72	88.3, 99.1	96.5	439/455	94.4, 98
tTG IgG	100	25/25	86.3, 100	97.1	471/485	95.2, 98.4
DGP IgG	95.7	45/47	85.5, 99.5	95.3	448/470	93, 97
Total IgA	100	158/158	97.7, 100	87.5	35/40	73.2, 95.8

tTG: tissue transglutaminase. PPA: positive percent agreement. NPA: negative percent agreement. CI: confidence Interval.

Table 1. Agreement of the investigational microarray immunoassay with comparators.

Conclusion: The investigational microarray immunoassay showed high level of agreement with the compared singleplex devices, providing laboratorians and clinicians with unified results coming from one multiplexed device. This platform has the potential to assist in the simplification of CD evaluation by simultaneously and automatically analyzing key serological markers.

A SYSTEMATIC REVIEW AND META-ANALYSIS ON GLUTEN TOLERANCE IN PATIENTS WITH COELIAC DISEASE: WHEN OCCASIONAL GLUTEN CONSUMPTION DOES NOT RESULT IN DUODENAL ATROPHY

N. Nandi[1], G. Aldinio[2], M.G. Shiha[3], L. Scaramella[4], M. Vecchi[4,2], L. Elli[2,4]
[1]Sheffield Teaching Hospitals NHS Foundation Trust, Academic Unit of Gastroenterology and Hepatology, Sheffield, United Kingdom, [2]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy, [3]University Hospitals of Leicester, Gastroenterology Department, Leicester, United Kingdom, [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Contact E-Mail Address: nico.nandi@hotmail.it

Introduction: Coeliac disease (CD) is the most common atrophic enteropathy. Currently, the only treatment is a life-long gluten free diet (GFD). However, the reported adherence of strict GFD among adults has been reported to vary between 42% to 91%[1], with patients reporting occasional gluten ingestion without a documented CD activity suggesting a gluten tolerance[2,3]. Data on the outcomes on these patients are scarce and conflicting.

Aims & Methods: In this systematic review and meta-analysis, we aimed to evaluate the proportion of non-adherent CD patients with no signs of atrophy (Marsh>3) at duodenal histology as a scenario indicating a potential tolerance.We searched Medline, PubMed, Web of Science, Cochrane Library and EMBASE to identify studies assessing GFD adherence and duodenal histology at follow-up.

No limits were placed on the year of publication, studies published through March 2025 were included. A random-effect meta-analysis was performed, and the results were reported as pooled proportions with 95% CIs.

Results: Thirteen studies comprising 457 patients with CD occasionally ingesting gluten were included in the final analysis. The pooled prevalence of "gluten tolerant" patients, showing no atrophy (Marsh 0-2) despite non strict GFD compliance, was 42% (95% CI 29% to 55%). Histology reassessment in all studies was performed at least 1 year from CD diagnosis, with follow-up periods within individual studies ranging from 12 months to 20 years. Sub-analysis based on method of GFD adherence (gluten immunogenic peptides vs questionnaires/self-reported) were not statistically different.

Conclusion: This systematic review and meta-analysis suggests the existence of a subgroup of patients capable of developing some degree of gluten tolerance. Although further studies are needed, these findings suggest that a relevant number of patients could be tolerant to a certain quantity of gluten ingestion and thus a personalization (on demand or low gluten content) of the GFD could be a future approach to coeliac patients.

Contact E-Mail Address: fabiana.zingone@unipd.it

Introduction: We evaluated celiac disease (CeD)-related symptoms and comorbidities in two US healthcare databases after CeD diagnosis according to the presence/absence of CeD-related symptoms or comorbidities before diagnosis.

Aims & Methods: This matched case–control study used data from two US healthcare databases:

1. MarketScan® Commercial and Medicare Supplemental database (collection period: 2002–2023);

2. Optum Clinformatics® Data Mart (Optum CDM; collection period: 2007–2023).

Patients with CeD had ≥ 1 inpatient or ≥ 2 outpatient International Classification of Diseases (ICD)-9 or -10 codes (579.0 and K90.0, respectively) at any time during the collection period. Patients were matched in a 1:5 ratio with controls without CeD (no CeD ICD-9/-10 codes at any time during data collection) for age at diagnosis, sex, region, and diagnosis year. All individuals had continuous medical and pharmacy enrollment for 2 years pre/post CeD diagnosis. Odds ratios (ORs) and 95% confidence intervals (CIs) for symptoms/comorbidities after CeD diagnosis were estimated by generalized multivariate logistic regression comparing cases vs matched controls stratified by those with (persistent) or without (new-onset) the relevant symptom/comorbidity pre-diagnosis. Symptoms assessed included abdominal pain, bloating, diarrhea, headache, nausea/vomiting, and tiredness. Comorbidities assessed included depression/anxiety, irritable bowel syndrome (IBS), and iron deficiency anemia (IDA).

Results: The numbers of CeD cases and controls were 39,814 and 198,961 in MarketScan, and 18,357 and 91,754 in Optum CDM, respectively. In both databases, CeD diagnosis was significantly positively associated with having CeD-related symptoms/comorbidities 2 years after CeD diagnosis regardless of pre-diagnosis status; and the strengths of associations were greater among patients with new-onset than with persistent symptoms/comorbidities after CeD diagnosis.

In MarketScan, the ORs (95% CI) in patients with new-onset symptoms were highest for bloating (7.98 [7.32–8.71]), diarrhea (6.83 [6.48–7.19]), and nausea/vomiting (3.75 [3.49–4.04]), and in those with new-onset comorbidities for IBS (8.30 [7.65–9.00]), IDA (6.35 [5.94–6.79]), and depression/anxiety (2.12 [2.04–2.20]). The ORs (95% CI) in patients with persistent symptoms were 2.47 (1.86–3.27) for bloating, 2.47 (2.21–2.76) for diarrhea, and 2.46 (2.05–2.96) for nausea/vomiting, and in those with persistent comorbidities were 1.38 (1.16–1.64) for IBS, 1.93 (1.70–2.18) for IDA, and 1.42 (1.34–1.51) for depression/anxiety.

In Optum CDM, the ORs (95% CI) in patients with new-onset symptoms were highest for bloating (6.15 [5.56–6.80]), diarrhea (5.85 [5.48–6.24]), and nausea/vomiting (3.38 [3.08–3.70]), and in those with new-onset comorbidities for IBS (6.17 [5.56–6.85]), IDA (5.31 [4.89–5.77]), and depression/anxiety (2.10 [1.99–2.21]). The ORs (95% CI) in patients with persistent symptoms were 2.25 (1.70–2.97) for bloating, 2.51 (2.22–2.84) for diarrhea, and 2.77 (2.23–3.43) for nausea/vomiting, and in those with persistent comorbidities were 1.40 (1.15–1.71) for IBS, 2.54 (2.17–2.97) for IDA, and 1.50 (1.38–1.62) for depression/anxiety.

Conclusion: CeD diagnosis was significantly associated with having CeD-related symptoms/comorbidities 2 years after CeD diagnosis, with greater associations among patients with new-onset symptoms/comorbidities than those with persistent symptoms/comorbidities. These results emphasize the clinical burden of CeD and the need for improved treatment options.

PREVALENCE OF DIAGNOSED CELIAC DISEASE IN THE UNITED STATES (2013–2022): A HEALTH CLAIMS DATABASE STUDY

M. Arvizu[1], S. Manne[1], N. Cheinquer[1], K. Ghelani[1], D.A. Leffler[1,2]
[1]Takeda Development Center Americas, Inc., Cambridge, United States of America, [2]Harvard Medical School, Celiac Center, Beth Israel Deaconess Medical Center, Boston, United States of America

Contact E-Mail Address: mariel.arvizu-boy@takeda.com

Introduction: The estimated global prevalence of biopsy-confirmed celiac disease (CeD) is 0.7% and sero-positive prevalence is 1.4%. Differences in definitions of CeD cases and at-risk populations, as well as underdiagnosis, may affect accurate estimation of the size of the diagnosed CeD population. In this study, we calculated the 10-year prevalence of diagnosed CeD in the USA using different CeD case definitions and at-risk populations.

Aims & Methods: A prevalence analysis of CeD cases was conducted using data collected from the Optum Clinformatics® Data Mart, a US claims database. Prevalence calculations were based on two different definitions of CeD cases.

Case definition 1 included any of the following:

1) International Classification of Diseases (ICD)-9/-10 diagnostic codes for CeD (≥ 1 inpatient or ≥ 2 outpatient codes),

2) tissue transglutaminase immunoglobulin A (tTG-IgA) positive serology or;

3) biopsy-confirmed CeD (defined as esophagogastroduodenoscopy [EGD] followed by an ICD diagnostic code for CeD used as proxy).

Case definition 2 was defined as the first ever positive tTG-IgA test followed by biopsy-confirmed CeD.

The prevalence of diagnosed CeD was estimated for each study year from 2013 to 2022. Prevalence estimations were age- and sex-standardized using 2022 US Census data.

Results: The total population (denominator) comprised ~81 million individuals; of whom, 110,140 had ≥ 1 inpatient or ≥ 2 outpatient diagnostic codes for CeD, 41,184 had ≥ 1 positive tTG-IgA test and 44,641 had biopsy-confirmed CeD. Among all individuals that were tested for tTG2-IgA, 0.85% (95% confidence interval [CI]: 0.82, 0.89) were positive for CeD. The age- and sex-standardized prevalence of diagnosed CeD according

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

to case definition 1 modestly increased from 0.27% (95% CI: 0.27, 0.27) in 2013 to 0.35% (0.34, 0.35) in 2022. Over the same time period, the age- and sex-standardized prevalence of diagnosed CeD according to case definition 2 increased from 0.01% (0.01, 0.01) to 0.03% (0.03, 0.03), respectively.

Conclusion: The overall prevalence of diagnosed CeD in the USA modestly increased from 2013 to 2022. During this same time period, the proportion of patients who underwent an EGD after a positive tTG-IgA test steadily rose. Validation of the CeD case definitions used in this study will be important to enable these results to be replicated or refuted.

Furthermore, a standardized and validated CeD case definition will support comparisons between studies and inform better clinical care/disease management.

UTILIZATION OF VIDEO CAPSULE ENDOSCOPY AMONG PATIENTS WITH CELIAC DISEASE IN A US HEALTH CLAIMS DATABASE

M. Arvizu[1], S. Lewis[2], N. Cheinquer[1], V. Gandhi[1], D.A. Leffler[1], S. Manne[1], R. Saad[1], S. Topic[1], D.S. Mishkin[3]
[1]Takeda Development Center Americas, Inc., Cambridge, United States of America, [2]Columbia University Irving Medical Center, Division of Gastroenterology, Department of Medicine, New York, United States of America, [3]Atrius Health, Division of Gastroenterology, Weymouth, United States of America

Contact E-Mail Address: mariel.arvizu-boy@takeda.com

Introduction: The real-world utilization of video capsule endoscopy (VCE) still remains poorly understood, particularly among patients with celiac disease (CeD). Current guidelines recommend utilizing VCE as a management tool for patients with CeD, such as for the follow-up and monitoring of the disease, rather than for diagnostic purposes. This study aimed to obtain an improved understanding of the patterns of VCE utilization in a US healthcare database.

Aims & Methods: This retrospective observational study was conducted using data collected from the US MarketScan® Commercial and Medicare Supplemental claims database from 2002 to 2023. Patients were grouped into two cohorts: all patients with ≥ 1 VCE procedure code (cohort 1) and those with ≥ 1 VCE procedure code who were subsequently diagnosed with CeD (cohort 2).

CeD diagnosis and indications for VCE were identified by ≥ 1 inpatient or ≥ 2 outpatient International Classification of Diseases (ICD)-9/-10 medical diagnostic codes. Demographic and clinical characteristics, patterns and indications for VCE utilization, and provider type were summarized using descriptive statistics.

Results: Of the 229,941 patients who had ≥ 1 procedure code for VCE (cohort 1), 4,996 were diagnosed with CeD (cohort 2) from 2002 to 2023. During this period, the frequency of VCE use peaked between 2008 and 2014, and was similar between patients from cohort 1 and cohort 2, with proportions ranging from 7.3% to 9.1% in cohort 1, and from 8.1% to 9.7% in cohort 2.

The mean age (standard deviation) at first VCE procedure date was 55.0 (17.7) years in cohort 1 and 47.9 (17.3) years in cohort 2, and there were more females than males in both cohorts (59.1% vs 40.9% in cohort 1 and 69.7% vs 30.3% in cohort 2, respectively).

VCE use was notably greater in those aged 18–49 years with CeD than in those of the same age in the overall population. Most VCE procedures were performed by gastroenterologists in both cohorts of patients (72.7% in cohort 1 and 73.9% in cohort 2). The most common indication for VCE use in cohort 1 was unspecified anemia, reported in over half of the patients. Abdominal pain with unspecified location and fatigue/other malaise were the most common indications for VCE use among patients in cohort 2 and were reported in over half of these patients.

Among the VCE indications reported in both cohorts, the most common were abdominal pain with unspecified location (51.5% in cohort 1 and 62.0% in cohort 2), followed by fatigue/other malaise (47.2% in cohort 1 and 52.7% in cohort 2).

Conclusion: Findings from this study suggest that VCE may have a role among patients with CeD beyond the current clinical guideline recommendations, although use has decreased in recent years in both patients with CeD and the general population.

Disclosure: MA, NC, VG, DAL, SM, RS, and ST are employees of Takeda Development Center Americas, Inc. and receive stock or stock options. SL and DSM have nothing to disclose.

ANALYTICAL COMPARISON OF A NOVEL, FULLY AUTOMATED MULTIPLEXED MICROARRAY IMMUNOASSAY AND ROUTINE METHODS FOR THE DETECTION OF CELIAC DISEASE ANTIBODIES IN A LABORATORY IN ENGLAND

F. Sims[1], G. Gomez[2], C. Fischer[2]
[1]Peterborough City Hospital, North West Anglia NHS Foundation Trust, Clinical Biochemistry and Immunology Department, Peterborough, United Kingdom, [2]AliveDx, Scientific and Medical Affairs, Eysins, Switzerland

Contact E-Mail Address: gerber.gomez@alivedx.com

Introduction: Detection of autoantibodies directed to tissue transglutaminase (tTG) and deamidated gliadin peptide (DGP) is important in the assessment of individuals under clinical suspicion of celiac disease (CD).

Aims & Methods: In this study, we compared the analytical performance for the detection of autoantibodies to tTG (IgA isotype), of the MosaiQ AiPlex® CD microarray (AiPlex CD. AliveDx, Switzerland), a CE-marked, novel, single-use, fully automated, multiplexed microarray immunoassay and routine methods. De-identified serum samples, characterized as reactive or non-reactive for tTG IgA as per the routine practice method of the evaluation site (EliA™ Celikey® IgA, Phadia AB, Sweden), were tested with the evaluated device.

Although AiPlex CD features the semi-quantitative measurement of both tTG IgA and IgG and anti-deamidated gliadin peptide (DGP) IgA and IgG antibodies, and qualitative measurement of total IgA in serum; this comparison was limited to tTG IgA as no samples characterized for other CD autoantibodies were available. Positive percent agreement (PPA) and negative percent agreement (NPA) were calculated. Double-sided 95% Confidence Intervals (CI) were calculated using Clopper-Pearson Exact Method.

Results: 77 samples characterized as reactive for tTG IgA by the routine method and 90 samples characterized as non-reactive for this marker were included in the analysis. The evaluated device identified 73 out of 77 samples characterized as reactive by the routine method, for a PPA of 95% (95% CI: 87.2, 98.5). Out of the four discordant samples, one also yielded a non-reactive result for tTG IgG and reactive results for both DGP IgA and IgG in the evaluated device and negative anti-endomysial antibodies (EMA) by immunofluorescence; two samples were reactive to DGP IgA or DGP IgG by the evaluated device and one sample was non-reactive to all four markers and was negative to EMA. Regarding the samples characterized as non-reactive by the routine method, the evaluated device identi-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. fied 86 out of 90, for an NPA of 96% (95% CI: 89.0, 98.7). For the four samples with discordant results, the evaluated device also yielded reactive results for at least one additional CD antibody (tTG IgG, DGP IgA, DGP IgG).

Parameter / Measurand	tTG IgA
Reactive results (n)	77
PPA	95%
95% CI	87.2, 98.5
Non-reactive results	90
NPA	96%
95% CI	89.0, 98.7

tTG: tissue transglutaminase. PPA: positive percent agreement; NPA: negative percent agreement. CI: Confidence interval.

Table 1. Agreement of the investigational microarray immunoassay with the comparator method.

Conclusion: In this study, the evaluated microarray immunoassay showed high concordance with the compared routine method for the serological assessment of tTG IgA, a key marker in the evaluation of CD.
Disclosure: This study was funded by AliveDx Suisse SA, Eysins, Switzerland. Gerber Gomez and Christian Fischer are AliveDx employees.

ANALYTICAL COMPARISON OF A NOVEL, FULLY AUTOMATED MULTIPLEXED MICROARRAY IMMUNOASSAY AND ROUTINE METHODS FOR THE DETECTION OF CELIAC DISEASE AUTOANTIBODIES IN A REFERENCE LABORATORY IN WALES

P. Griffiths[1], G. Gomez[2], C. Fischer[2], T. El-Shanawany[1]
[1]Swansea Bay University Health Board, Immunology Department, Laboratory Medicine, Swansea, United Kingdom, [2]AliveDx, Scientific and Medical Affairs, Eysins, Switzerland

Contact E-Mail Address: gerber.gomez@alivedx.com
Introduction: Serology plays a key role in the evaluation of celiac disease (CD).
Aims & Methods: We assessed the analytical performance for the detection of CD autoantibodies, compared with routine laboratory methods, of MosaiQ AiPlex® CD microarray (AiPlex CD. AliveDx, Switzerland) a CE-marked, novel, single-use, multiplexed microarray immunoassay, used with its fully automated proprietary system. The valuated device features the simultaneous, semi-quantitative measurement of both IgA and IgG anti-tissue transglutaminase (tTG) and IgA and IgG anti-deamidated gliadin peptide (DGP) antibodies, as well as a qualitative measurement of total IgA in human serum; however, for this study, the comparison was limited to tTG IgA and tTG IgG as no samples characterized for DGP IgA nor for DGP IgG were available. Banked, de-identified serum samples characterized as reactive or non-reactive for tTG IgA and tTG IgG as per routine methods were tested with the evaluated device. Routine methods included EliA™ Celikey® IgA (Phadia AB, Sweden), EliA™ Celikey® IgG (Phadia AB, Sweden), QUANTA® Flash h-tTG IgA (Inova Diagnostics, USA), QUANTA® Flash h-tTG IgG (Inova Diagnostics, USA), Anti-Tissue-Transglutaminase IgA (ORGENTEC Diagnostika GmbH, Germany), Anti-Tissue-Transglutaminase IgG (ORGENTEC Diagnostika GmbH, Germany) and QUANTA Lite® R h-tTG IgA ELISA (Inova Diagnostics, USA). Positive percent agreement (PPA), negative percent agreement (NPA) for individual analytes were calculated as were overall positive and percent agreements.
Results: The evaluated device identified 43 out of 45 samples characterized as reactive for tTG IgA per routine methods and 79 out of 81 samples characterized as non-reactive, for a PPA of 96% (95% CI: 84.8, 99.4) and an NPA of 98% (95% CI: 91.3, 99.7). Likewise, it identified 14 out of 18 samples characterized as reactive for tTG IgG per routine methods and 79 out of 85 samples characterized as non-reactive, for a PPA of 78% (95% CI: 52.3, 93.5) and an NPA of 93% (95% CI: 85.2, 97.3). Overall positive and negative percent agreement were 90% (95% CI: 80.4, 96.4) and 95% (95% CI: 90.7, 97.9), respectively (Table 1).

Parameter / Measurand	tTG IgA	tTG IgG	Overall
Reactive results (n)	45	18	63
PPA	96%	78%	90%
95% CI	84.8, 99.4	52.3, 93.5	80.4, 96.4
Non-reactive results	81	85	166
NPA	98%	93%	95%
95% CI	91.3, 99.7	85.2, 97.3	90.7, 97.9

PPA: positive percent agreement. NPA: negative percent agreement. CI: confidence interval.

Table 1. Agreement of the investigational microarray immunoassay with routine laboratory methods.

Conclusion: In the present study, the evaluated multiplexed microarray immunoassay showed high concordance with routine methods for the detection of tTG IgA and tTG IgG. This device may be considered a suitable alternative method for the serological assessment of patients under clinical suspicion of CD and has the potential to help simplifying the laboratory evaluation of this condition by simultaneously and automatically analyzing IgA and IgG isotypes of key CD markers.
Disclosure: This study was funded by AliveDx Suisse SA, Eysins, Switzerland. Gerber Gomez and Christian Fischer are AliveDx employees.

THROMBOEMBOLIC COMPLICATIONS IN CELIAC DISEASE

E. Ikram[1], F.-Z. Chabib[2], M. Borahma[3], F.-Z. Ajana[1], M. Kadiri[4], N. Lagdali[1]
[1]Mohammed V University of Rabat, Hepato-gastroenterology, Rabat, Morocco, [2]Ibn Sina university Hospital, Rabat,Morocco, Medical Unit C, Seclin, France, [3]Mohammed the Vth University, Ibn Sina Hospital, Department Of Gastroenterology C, Rabat, Morocco, [4]Ibn Sina Hospital, Rabat, Rabat, Morocco

Contact E-Mail Address: ikramelbasri18@gmail.com
Introduction: Celiac disease (CD) is an autoimmune enteropathy induced by the ingestion of gluten in genetically predisposed individuals. Although its clinical expression is most often digestive, extra-digestive manifestations can occur, among which thromboembolic complications, although rare, deserve particular attention.
The aim of this study is to describe the profiles of coeliac patients with thromboembolic complications, analyze their clinical, paraclinical and etiological characteristics, and discuss the underlying pathophysiological mechanisms.
Aims & Methods: This is a retrospective, descriptive, monocentric study conducted in the hepato-gastroenterology department of Ibn Sina Hospital in Rabat over a 30-year period, from 1995 to 2025. The records of 344 patients followed for celiac disease were reviewed. Patients with one or more documented thromboembolic complications during follow-up were included in the study. Clinical, biological, endoscopic and histological data were collected and analyzed.
Results: Of a total of 344 patients followed for celiac disease in the department, 5.5% (n=19) developed a thromboembolic complication during follow-up. The population concerned was predominantly female, with 89.5% women (n=17) versus only 10.5% men (n=2). The mean age at the time of complication was 39.6 years, with a median of 35.5 years, and extremes ranging from 18 to 62 years.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Endoscopic exploration (oesogastro duodenal fibroscopy) in these patients showed lesions suggestive of celiac disease in 68.4% (n=12), while it was non-specific in 31.6% (n=6), and normal in 5.3% (n=1). Histologically, villous atrophy was found in all patients, with 78.9% (n=15) showing total atrophy (Marsh IIIc) and 21.1% (n=4) subtotal atrophy (Marsh IIIb).

As regards thromboembolic manifestations, portal vein thrombosis was the most frequent complication, observed in 57.9% of cases (n=11). It was followed by deep vein thrombosis of the lower limbs, reported in 15.8% of cases (n=3), and ischemic stroke in 10.5% (n=2). Isolated cases of thrombosis of the inferior vena cava, axillary vein and femoral vein were recorded, each accounting for 5.3% of cases (n=1).

The etiological study revealed hyperhomocysteinemia in 36.8% of patients (n=7) and protein C and/or S deficiency in 21.1% (n=4). In the remaining 42.1% of patients (n=8), the thrombophilia work-up was normal, suggesting that celiac disease itself was the cause of the thrombotic event. Therapeutically, all patients were treated with oral anticoagulation. One patient required a vena cava filter because of the risk of bleeding on anticoagulation, and another underwent surgical treatment for axillary thrombosis. The outcome was favorable in all cases, with no recurrence or major complication during follow-up.

Conclusion: Thromboembolic complications in celiac disease are rare but potentially serious. This study highlights the predominance of women, the diversity of thrombotic localizations, and the possible involvement of hyperhomocysteinemia and C/S protein deficiencies. In almost half the cases, no thrombophilic cause has been identified, suggesting a role for celiac disease in the genesis of these events. Clinical vigilance is essential, particularly in cases of late diagnosis or poor compliance with the gluten-free diet.

Introduction: Celiac disease (CD) is a chronic autoimmune enteropathy triggered by gluten ingestion in genetically predisposed individuals. While isolated hypertransaminasemia is the most frequent hepatic manifestation of CD, its association with portal hypertension (PHT) remains rare and poorly understood.

Aims & Methods: This study aims to describe this association and evaluate the impact of a gluten-free diet (GFD) on the progression of PHT-related complications.

We conducted a 30-year retrospective study including 20 patients with both histologically and serologically confirmed CD and PHT, among a total cohort of 344 CD patients. Clinical, biological, endoscopic, imaging, and histological data were analyzed.

Results: Among the 20 patients (75% female, F/M ratio 3; mean age 34.2 years), the most frequent symptoms were abdominal pain and weight loss (45% each), followed by ascites (35%), malabsorptive diarrhea (30%), atypical diarrhea (20%), and vomiting (15%). One patient presented with upper gastrointestinal bleeding. Splenomegaly was observed in 70%, and collateral venous circulation in 30%. Liver was clinically normal in 80%, cirrhotic in 20%. Imaging showed a regular liver in 65%, nodular in 35%, with 25% having portal cavernoma and one patient with focal IVC thrombosis.

Liver biopsy findings included porto-sinusoidal vascular disease (40%), celiac cirrhosis (20%), granulomatous hepatitis (15%), and normal histology (25%). Upper endoscopy revealed esophageal varices in 55%. PHT led to the diagnosis of CD in 4 patients. In non-adherent patients, progression of varices and cirrhosis occurred in 20% over 5 years.

Conclusion: The CD–PHT association is rare (5.8% in our series) but clinically significant. Various mechanisms may underlie this link, highlighting the importance of screening for CD in unexplained PHT. GFD adherence appears to slow hepatic deterioration and variceal progression, reinforcing its therapeutic value.

Disclosure: Nothing to disclose.

CELIAC DISEASE AND ANTI-PHOSPHOLIPID ANTIBODIES: PREVALENCE AND CLINICAL IMPLICATIONS IN A MOROCCAN COHORT

I. Qarch[1], F.-Z. Chabib[1], M. Borahma[1], F.Z. Ajana[1], M. Kadiri[1], N. Lagdali[1]

[1]Ibn Sina University Hospital Center, Faculty of Medicine and Pharmacy, Mohammed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ismail.qarch@gmail.com

Introduction: Celiac disease (CD) is an autoimmune enteropathy triggered by gluten in genetically predisposed individuals. Both hereditary and acquired factors may increase thrombotic risk in CD. Anti-phospholipid antibodies (aPL), including anti-cardiolipin (aCL) and anti-β2 glycoprotein I (β2GPI), are known markers of thrombophilia.

Aims & Methods: This study aimed to evaluate the frequency of these antibodies in CD patients and investigate any correlation with gluten-free diet (GFD) adherence.

This prospective, descriptive study was conducted over four years and included 42 patients diagnosed with CD based on clinical, serological, and histological criteria. Anti-cardiolipin IgG (aCL) and anti-β2GPI IgG antibodies were tested by ELISA, and lupus anticoagulant (LA) was assessed via coagulation assay.

Results: Among 42 CD patients, aPL results were available for 9 (22%). The mean age was 35.5 years (range 18–58), with a female-to-male ratio of 2. All patients were prescribed a GFD with regular follow-up.

aCL IgG antibodies were positive in 3/9 patients (15.2%), β2GPI IgG antibodies were positive in 1/9 (5%), and LA was negative in all patients. No correlation was found between the presence of aPL and disease activity or adherence to GFD. Additionally, aPL presence was not associated with disease duration or thrombotic events.

Conclusion: In our cohort, we did not observe a high prevalence of anti-phospholipid antibodies among CD patients. aCL IgG was the most frequently detected antibody (15.2%) under strict GFD. The clinical significance and pathogenic role of these antibodies in CD remain unclear and warrant further large-scale prospective studies.

Disclosure: Nothing to disclose.

Introduction: Capsule endoscopy (CE) is a valuable, non-invasive diagnostic tool for the evaluation of small bowel disorders, particularly in patients with suspected inflammatory bowel disease (IBD), known Crohn's disease, or non-responsive celiac disease (NRCD) (1). Its role in identifying mucosal lesions and guiding clinical decision-making continues to expand, especially in the context of complex or unclear gastrointestinal symptoms.

Aims & Methods: This observational, single-centre retrospective study included all CE procedures performed at the Department of Gastroenterology of the Azienda Ospedaliera–Università di Padova between January 1, 2018, and December 31, 2024. Indications for CE included suspected IBD (e.g., diarrhea, abdominal pain, elevated fecal calprotectin), follow-up of known ileal Crohn's disease, and evaluation of NRCD. Demographic and clinical data were collected in a dedicated database. CE was considered positive if at least one of the following findings was present: evidence of recent bleeding, ulcers, or villous atrophy. Multivariate analyses were used to assess risk factors associated with ulcers and villous atrophy. Statistical analyses were conducted using STATA 18.

Results: A total of 351 CE procedures were included: 210 for suspected IBD, 108 for IBD follow-up, and 37 for NRCD. The mean age of the cohort was 45.7 ± 16.0 years, with 47% male patients. The diagnostic yield was 39.3% for suspected IBD, 44.4% for IBD follow-up, and 56.7% for NRCD. The prevalence of recent bleeding was similar across groups (31.1% vs. 27.4% vs. 31.6%, p=0.895), as was the presence of ulcers (65.3% vs. 62.1% vs. 40%, p=0.105).

However, villous atrophy was significantly more frequent in NRCD patients (0% in suspected IBD, 2.3% in IBD, and 66.7% in NRCD; p<0.001). No association was found between lesions and age, sex, hemoglobin levels, or comorbidities. CE findings led to therapeutic changes in 37% of IBD cases and in 16% of NRCD cases.

Conclusion: This single-centre cohort study confirms the high diagnostic yield of capsule endoscopy in patients with small bowel disorders and highlights its impact on their clinical management.

Introduction: A considerable proportion of patients with disorders of gut-brain interaction suffer from carbohydrate intolerances. The European Guideline[1] recommends a diagnostic evaluation that combines malabsorption testing using hydrogen breath tests with symptom assessment using the validated aCPQ[2]. This study evaluates 1) the relationship between the severity of abdominal symptoms (pain, nausea, bloating, flatulence, diarrhea) in patients' histories and the results of malabsorption and intolerance testing, and 2) the response to a diet in patients diagnosed with carbohydrate intolerance (positive aCPQ) with or without malabsorption (pos. or neg. breath test).

Aims & Methods: This is a retrospective analysis of 1,139 tests performed between February 2017 and June 2024in 708 patients (62% female; mean age 42 ± 16 years) referred for evaluation of suspected carbohydrate intolerance at the Medical Universities of Graz and Vienna. Malabsorption was evaluated by breath tests (H_2 maximum rise above baseline and area under the curve), and intolerance by the aCPQ after ingestion of 50 g lactose (n=588), 25 g fructose (n=550) or 25 g trehalose (n=1). Symptom intensities over the preceding six months for diarrhea, bloating, nausea, flatulence, and abdominal pain were assessed using the Bowel Disease Questionnaire (BDQ; VAS scale 0–100 mm). 63 patients with intolerance completed a 4- to 12-week diet. Symptoms after the diet were evaluated using identical VAS scales, with symptom intensity assessed within the previous 10 days. The difference between the VAS scores of each symptom (deltaVAS) before and after diet was determined.

Results: 625 tests revealed intolerance (pos aCPQ), 373 malabsorption (pos. breath test), 273 tests a combination of intolerance and malabsorption and 414 tests were negative in both tests. In patients with intolerance weak positive correlations were found between each of the five symptoms in the preceding six months and maximum symptom intensity of the respective symptom on the aCPQ (r ranging from 0.17 to 0.31; p<0.001); the strongest correlation was observed for bloating and the weakest for diarrhea. This applied for the lactose and fructose groups. These correlations were present whether or not malabsorption was detected in the breath test. No significant correlation was observed between BDQ symptom severity and breath test results. The table shows symptom severity by VAS scoring before and after diet in patients with aCPQ-diagnosed intolerance: dietary intervention led to a significant improvement in all symptom severities (p>0.001). For all of the five symptoms strong correlations were observed between baseline symptom severity in the preceding 6 months (BDQ) and the extent of symptom improvement after the diet (delta VAS; *p<0.001). Malabsorption detected by breath test did not predict dietary response. Weak positive correlations were noted between aCPQ symptom severity and deltaVAS for nausea (r=0.32; p=0.012) and bloating (r=0.37; p=0.003).

	Pain	Bloating	Flatulence	Diarrhea	Nausea (median, range
VAS (mm) before diet, mean+SD	40+24	52+28	48+28	36+29	24 (0-75)
VAS (mm) after diet, mean+SD	11+18*	19+20*	26+30*	10+17*	0 (0-65)*
Correlation BDQ vs delta VAS	r =0.76*	r=0.79*	r=0.54*	r=0.84*	r=0.83*

Asterisks denote p<0.001 for comparison of VAS before vs. during diet and for correlation.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Diagnosis of intolerance using the aCPQ identifies patients who benefit from dietary intervention. Patients who have the most severe baseline symptom history respond the best. Symptom history is a weak predictor of carbohydrate intolerance, and breath tests are not useful for explaining baseline symptom history or guiding treatment.

Introduction: Owing to their deep location, small-bowel tumors have long eluded definitive endoscopic diagnosis with conventional instruments. The advent of balloon-assisted enteroscopy has expanded diagnostic and therapeutic options.

Aims & Methods: Aim: We aimed to evaluate the diagnostic performance of single-balloon enteroscopy (SBE) for malignant small-bowel tumors at a tertiary center.

Methods: We reviewed 1,031 consecutive SBEs performed between September 2005 and June 2024. Among 84 patients in whom a small-bowel tumor was visualised, 63 had histologically malignant lesions and were analysed. Primary outcomes were lesion-access rate, definitive histology rate by target biopsy, pre-operative tattoo-marking rate, and avoidance of diagnostic laparotomy.

Results: Malignancy accounted for 63 / 84 tumors (75 %). Histology comprised malignant lymphoma (ML; 26, 41 %), adenocarcinoma (16, 25 %), gastrointestinal stromal tumor (GIST; 12, 19 %), metastatic carcinoma (8, 13 %), and neuroendocrine tumor (NET; 1, 2 %). Index presentations were obscure gastrointestinal bleeding (27, 43 %), abnormal imaging (18, 28 %), intestinal obstruction (14, 22 %), and other causes (4, 7 %). SBE reached the lesion in 59 / 63 cases (93.7 %). Tattoo marking before surgery was feasible in 37 / 41 surgical patients (90.2 %). Target biopsy yielded definitive histology in 43 / 47 accessible cases of adenocarcinoma, metastatic carcinoma, or ML (91.5 %). Endoscopic appearance suggested GIST in 12 patients, 11 of which were pathologically confirmed. Diagnostic laparotomy was avoided in 55 / 63 patients overall (87.3 %), including 21 / 26 with ML (80.8 %).

Conclusion: SBE achieved a high rate of deep-bowel intubation, lesion-targeted biopsy, and intra-operative localisation. It provided histologic confirmation in >90 % of accessible malignant lesions and obviated diagnostic surgery in most cases, supporting its routine use in the work-up of small-bowel malignancies.

Disclosure: Nothing to disclose.

Introduction: Gastroenteropancreatic neuroendocrine neoplasms (GEP-NENs) are a heterogeneous group of tumors with rising incidence. Despite several available treatments, including somatostatin analogues (SSAs), targeted therapies (everolimus, sunitinib), and chemotherapy (capecitabine-temozolomide, CAPTEM), predicting therapeutic response and disease progression remains difficult. Tumor-related features (e.g., grading, metastatic burden) influence outcomes but whether some patient-related variables (e.g., lifestyle, comorbidities) play a role is poorly explored.

Aims & Methods: This study aimed to identify tumor and patient-related factors associated with progression and survival outcomes in GEP-NENs treated with SSAs, CAPTEM, or targeted therapies. This is a multicenter, retrospective observational cohort study including patients with well-differentiated GEP-NENs treated with SSAs, CAPTEM, or EVE/SUN.

Inclusion criteria were age ≥18 years, histologically confirmed GEP-NEN, and at least 6 months of treatment. Exclusion criteria included poorly differentiated tumors, prior radioligand therapy, and MiNENs. Clinical, pathological, therapeutic, and exposome-related variables were collected.

The primary endpoint was progression-free survival (PFS); overall survival (OS) was also evaluated. A target sample size of 400 was estimated for adequate power in subgroup analyses. Univariate analyses were conducted using t-tests or chi-square tests as appropriate. Associations with PFS and OS were further assessed through Cox proportional hazards models.

Results: A total of 301 patients (52.2% pancreatic) from four Italian referral centers for neuroendocrine tumors (Itanet centers) were included: 258 (85.7%) received SSAs, 32 (10.6%) CAPTEM, and 17 (5.6%) EVE/SUN. Median age at diagnosis was 59 years; 51.9% were female. Most patients (73.7%) presented with metastatic disease at diagnosis, and the majority were G2 (58%) or G3 (2.3%).

In univariate analysis, patient-related variables were not significantly associated with PFS, except for lower age at diagnosis and shorter duration of metformin use (both p = 0.05). Conversely, tumor-related variables (grading, Ki67 and presence of bone or liver metastases) were significantly associated with PFS.

In multivariable Cox analysis, only liver metastases (HR 2.0), bone metastases (HR 2.15), and G3 tumors (HR 3.35) were associated with shorter PFS. For OS, univariate analysis showed worse survival in male patients (p = 0.017), those with a history of alcohol use (p = 0.027), liver disease (p = 0.013), higher tumor grading/Ki67 (p < 0.001), absence of primary tumor

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

resection (p < 0.001), and presence of bone (p = 0.004) or liver metastases (p < 0.001). Cox multivariable analysis confirmed association of OS with male sex (HR 2.73), alcohol use (HR 6.46), G3 tumors (HR 8.26), liver metastases (HR 6.45), and absence of primary tumor resection (HR 6.45). A subgroup analysis restricted to SSA-treated patients and pancreatic NENs patients revealed similar trends.

Conclusion: In this multicenter real-world study, progression and survival outcomes in GEP-NENs were primarily driven by tumor-related variables such as grading and metastatic spread, while patient-related factors played a limited role. However, results are currently underpowered, having reached approximately 75% of the planned sample size. Future efforts will aim to expand the EVE/SUN and CAPTEM groups to enhance subgroup analyses and improve robustness of findings.

Disclosure: Nothing to disclose.

Introduction: Capsule Endoscopy (CE) offers a minimally invasive method for comprehensive visualization of the gastrointestinal (GI) tract. Protruding lesions are relatively common findings in CE, with variable incidence and diverse pathological significance. Accurate detection of these lesions is crucial but remains challenging due to the time-consuming nature of CE interpretation and susceptibility to human error. While artificial intelligence (AI) presents a promising solution, real-world evidence evaluating its clinical performance is still scarce. To assess the diagnostic performance of a deep learning convolutional neural network (CNN) for the detection of protruding lesions in complete CE videos under real-world clinical conditions.

Aims & Methods: Our group conducted a prospective, multicenter validation study comparing AI-assisted CE reading to standard, conventional interpretation. A total of 211 CE videos, obtained using three different CE systems across seven centers in Portugal, Spain, Brazil, and the United States, were analyzed. Following initial standard readings, an independent expert conducted AI-assisted readings using a CNN specifically trained to detect small bowel protruding lesions. Discrepancies between conventional and AI-assisted reports were adjudicated by a third-party expert from an independent center to establish the reference standard. Diagnostic performance was assessed using sensitivity, specificity, accuracy, and the area under the receiver operating characteristic curve (AUC-ROC).

Results: AI-assisted reading detected 106 confirmed protruding lesions, compared to 42 identified through conventional reading. Sensitivity was significantly higher with AI-assisted reading (95.9% vs. 64.6%), although specificity was lower (78.7% vs. 96.1%). Overall accuracy was relatively lower with AI-assisted reading (81.2% vs. 91.5%). The AUC-ROC was 0.86 for AI-assisted and 0.80 for standard reading. Additionally, AI-assisted reading reduced the mean examination time to 316 seconds per video.

Conclusion: AI-assisted interpretation of complete CE videos significantly enhances the detection of protruding lesions compared to conventional reading, although at the expense of slightly reduced specificity. The inclusion of videos from multiple CE systems addresses interoperability challenges, while the participation of centers from four countries across two continents supports the model's generalizability and real-world clinical applicability.

Contact E-Mail Address: karypton@hotmail.com

Introduction: Intestinal perforation is an infrequent complication of single balloon enteroscopy (SBE) and usually requires surgery. Factors associated with increased risk of perforation remain unclear.

Aims & Methods: The objective of this study was to identify risk factors associated with intestinal perforation during SBE. Data from patients who underwent SBE at three tertiary care hospitals in China between January 2016 and September 2024 were retrospectively collected and analyzed. Single factor analysis was conducted to evaluate the possible risk factors for intestinal perforation. Binary Logistic Regression was further conducted to evaluate the factors associated with the occurrence of intestinal perforation.

Results: A total of 2861 SBE procedures were performed in 1840 patients (1187 male and 653 female; mean age 51 ±18 years). Intestinal perforation occurred in 7 patients during SBE (0.4%, 7/1840), and all cases were successfully managed with surgical repair. Among these 7 patients, 1 had duodenal stenosis of unknown cause, the other 5 presented with abdominal pain, and 1 with obscure gastrointestinal bleeding had a history of prior abdominal surgery. Binary logistic regression showed that previously abdominal surgery was an increased risk factor for intestinal perforation (odds ratio, 19.52; 95% CI, 2.32 to 164.05; P=0.006).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Previously abdominal surgery was identified as an increased risk factor for intestinal perforation during SBE. These findings underscores the importance of careful patient selection and procedural planning for reducing the incidence of intestinal perforation, and the subsequent need for surgical intervention.
Disclosure: Nothing to disclose.

CLINICAL OUTCOMES OF COMPLETE VERSUS INCOMPLETE SMALL BOWEL EXAMINATION BY SINGLE-BALLOON ENTEROSCOPY IN OBSCURE GASTROINTESTINAL BLEEDING: A PROSPECTIVE MULTICENTER STUDY

S. Ullah[1], N. Wareesawetsuwan[2], Y. Bai[3], L. Cui[4], Y. Danzhu[5], K. Wang[1], X. He[1], X. Cao[1], F. Zhang[1]
[1]The First Affiliated Hospital of Zhengzhou University, Gastroenterology and Hepatology, Zhengzhou, China, [2]Division of Hematology-Oncology, Beth Israel Deaconess Medical Center, Department of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States of America, [3]Henan Provincial People's Hospital, People's Hospital of Henan University, People's Hospital of Zhengzhou University, Gastroenterology, Zhengzhou, China, [4]Zhengzhou University, School of Public Health, Zhengzhou, China, [5]Qinghai Provincial People's Hospital, Gastroenterology, Qinghai, China

Contact E-Mail Address: karypton@hotmail.com
Introduction: Obscure gastrointestinal bleeding (OGIB), which accounts for about 5% of all gastrointestinal bleeding cases, often originates in the small intestine [1, 2]. Single-balloon enteroscopy (SBE) has recently been introduced as a simplified diagnostic and therapeutic tool for OGIB; however, it has significant limitations, including a low rate of complete small bowel examination at 22% [3, 4]. It remains unclear whether complete enteroscopy with SBE leads to better clinical outcomes.
Aims & Methods: This study aimed to compare the rebleeding rate between patients with OGIB who underwent complete versus incomplete SBE.
This multicenter retrospective analysis of prospectively collected data identified adult patients with OGIB from January 2016 to December 2024 in three tertiary care institutions: The First Affiliated Hospital of Zhengzhou University, Henan Provincial People's Hospital, and Qinghai Provincial People's Hospital. Demographic data, initial SBE findings, and rebleeding events during follow-up were collected and analyzed. The study was approved by the Institutional Review Board of all participating hospitals (Ethics Approval No. 2022 KY 1136 002) and registered at the ISRCTN Registry under the reference number ISRCTN17191331.
Results: A total of 431 patients were enrolled, with 43 patients in the complete SBE group and 388 patients in the incomplete SBE group. The mean age was 51 ± 17 years, 68.4% were male, and the mean follow-up duration was 44 ± 23 months. Initial SBE findings revealed no significant difference between the two groups, with diverticular bleeding being the most common abnormal finding in the complete SBE group (25.6%) and angioectasia the most common in the incomplete SBE group (25.8%). During the follow-up period, the rebleeding rate was similar between the complete and incomplete SBE groups (27.9% vs. 26.5%, P = 0.848). Similarly, when stratified by initial SBE findings, no difference in rebleeding rates was observed between the two groups. Although most rebleeding patients were managed conservatively, 45 out of 115 underwent reevaluation with either SBE or surgery. Among the 5 rebleeding cases in the complete SBE group that underwent reevaluation, an 80% (4/5) change in findings from initial SBE was observed, with reevaluation revealing angioectasia (n = 2), no abnormal finding (n = 2), and ulcers/erosions (n = 1). Conversely, among the 40 rebleeding cases in the incomplete SBE group, subsequent SBE findings changed in 92.5% (37/40) of patients, and notably, 27.5% (11/40) of patients were found to have malignant lesions (adenocarcinoma and GIST) that were initially misdiagnosed as benign.
Conclusion: No significant difference in rebleeding outcomes was observed between patients with OGIB who underwent complete versus incomplete SBE during follow-up. These findings indicate that, despite the low rate of complete enteroscopy, SBE remains a valuable diagnostic and therapeutic tool in the management of OGIB. However, caution is advised in cases of incomplete SBE, as clinically significant lesions, including malignancies, may be missed during the initial evaluation.

REAL-LIFE EVALUATION OF THE BEST BOWEL PREPARATION METHOD FOR CAPSULE ENDOSCOPY IDENTIFIED IN THE PREPRICE STUDY

C. Costa[1], P.F. Da Silva Mesquita[1], P. Teixeira[1], R. Ferreira[1], R.T. Pinho[1], M.M. Estevinho[1], A. Ponte[1], M.A. Rodrigues[1], T.J. Marques Ferreira Freitas[1]
[1]Unidade Local de Saúde Gaia e Espinho, Gastroenterology, Vila Nova de Gaia, Portugal

Contact E-Mail Address: catarina.icosta97@gmail.com
Introduction: Bowel preparation is recommended for small-bowel capsule endoscopy (SBCE) by current guidelines, although the ideal regimen remains unclear. The PrepRICE clinical trial is a multicenter randomized trial that compared different timings of intestinal preparation administration, showing that administration after the capsule reached the duodenum improved mucosal visualization and diagnostic yield.
This study was limited to patients with suspected mid-gastrointestinal bleeding who met strict inclusion criteria. Real-life results are generally inferior to those of clinical trials.
Aims & Methods: This work aims to report real-life results (including patients with all indications, comorbidities, and undergoing different types of bowel preparation) after the implementation of the new protocol and to compare them with those of PrepRICE.
A prospective analysis was performed on all consecutive patients who underwent capsule enteroscopy between December of 2024 and March of 2025. The quality of small bowel visualization (QSBV), gastric transit time (GTT), small bowel transit time (SBTT), adequate visualization rate, and complete examination rate were assessed. QSBV was evaluated according to the Brotz quantitative scale, both globally and by tertiles.
Results: A total of 59 patients were included, 55.9% of whom were male, with a median age of 61.0 years (IQR 31). The examination was complete in 100% of cases. The median Brotz scale scores were 9 (IQR 1), 8 (IQR 2), 8 (IQR 3), and 8 (IQR 2) in the first, second, third tertile, and overall, respec-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tively (compared to 9, 9, 9, 9 in the PrepRICE trial, p<0.001). The visualization rate was adequate in 83,1% of exams (vs. 92%). QSBV was statistically inferior to that observed in the group with the best bowel preparation regimen identified by the clinical trial (yet non-inferior to the pre-procedure preparation groups), as well as the SBTT. In the remaining outcomes, no significant differences were found.

Conclusion: Real-life results were similar to those of the original study, with a high rate of complete examination and adequate visualization, with only slightly lower QSBV compared to that reported in the peri-procedural group in the PrepRICE study, yet still non-inferior to the pre-procedural groups.

Introduction: Small bowel bleeding remains challenging to diagnose due to limited access with conventional endoscopy. Capsule endoscopy (CE) is increasingly used both in emergency settings following overt bleeding and in the evaluation of chronic, unexplained anemia (1-2). Better risk stratification for small bowel lesions may refine the need for CE.

Aims & Methods: Our primary aim was to assess the diagnostic yield of CE in suspected small bowel bleeding, while secondarily identifying predictive factors for angiodysplasia, recent bleeding, and ulcers. This observational single-centre retrospective study included all CE procedures performed at the Department of Gastroenterology of the Azienda Ospedaliera–Università di Padova between January 1, 2018, and December 31, 2024, for indications of overt or occult gastrointestinal bleeding. Demographic and clinical data were collected in a dedicated database. CE was considered positive if at least one of the following lesions was identified: angiodysplasia, signs of recent bleeding, polyps, ulcers, red spots, or villous atrophy. Multivariate analyses were conducted to assess the risk factors associated with angiodysplasia, recent bleeding, and ulcers. Statistical analyses were performed using STATA 18.

Results: A total of 1,057 CE procedures were performed for the indication of gastrointestinal bleeding, including 310 for overt bleeding and 747 for occult bleeding. The mean age of the cohort was 71 ± 13 years, and 55.6% were male, with no significant differences in age or sex between the two groups. The overall diagnostic yield was comparable between patients with overt and occult bleeding (77.1% vs. 75.2%, p=0.520). The prevalence of angiodysplasia was similar in both groups (80.4% vs. 78.1%, p=0.501), as was the detection of recent bleeding (57.1% vs. 50.2%, p=0.150). However, small bowel ulcers were significantly more frequent in patients with overt bleeding (45.9% vs. 34.2%, p=0.023).

In the multivariate analysis, the risk of detecting angiodysplasia was lower in patients receiving antiplatelet (OR 0.60; 95% CI: 0.66–0.99) or anticoagulant therapy (OR 0.40; 95% CI: 0.26–0.66), but significantly higher in older age groups compared to those aged 18–45 years: 46–60 years (OR 6.02; 95% CI: 2.2–16.7), 61–80 years (OR 8.80; 95% CI: 3.4–22.7), and >80 years (OR 13.62; 95% CI: 4.9–37.3). Increased risk was also associated with lower hemoglobin levels: 7–10 g/dL (OR 2.90; 95% CI: 1.5–5.5) and <7 g/dL (OR 2.17; 95% CI: 1.2–3.9). Similar predictors were found for recent bleeding. Conversely, the risk of ulcers was lower in patients with occult bleeding (OR 0.60; 95% CI: 0.4–0.9), and higher in those who received blood transfusions (OR 1.70; 95% CI: 1.0–2.7) and those with hemoglobin <10 g/dL (OR 2.40; 95% CI: 1.2–5.0 for Hb 7–10 g/dL and OR 2.60; 95% CI: 1.3–5.2 for Hb <7 g/dL).

Conclusion: This large single-centre cohort study confirms the high diagnostic yield of capsule endoscopy in patients with both overt and occult gastrointestinal bleeding. Older age and severe anemia are strong predictors for angiodysplasia and signs of recent bleeding, while overt bleeding and low hemoglobin levels are significantly associated with the presence of small bowel ulcers.

FATIGUE AND IMPAIRED QUALITY-OF-LIFE IN PATIENTS WITH SMALL BOWEL ANGIODYSPLASIA: RESULTS FROM A PROSPECTIVE COMPARISON COHORT STUDY

R. Grainger[1], C. Costigan[1], D. Kripakaran[2], D. McNamara[1]

[1]Tallaght University Hospital, Gastroenterology, Dublin, Ireland, [2]Trinity College Dublin, TAGG, Dublin, Ireland

Contact E-Mail Address: richardgrainger1@hotmail.com

Introduction: Patients with angiodysplasia, and chronic anaemia often experience a complex symptom burden, including reduced quality of life (QoL) and fatigue. While cross-sectional studies suggest impaired QoL in this population, longitudinal data assessing how these symptoms evolve over time are limited (1).

Both general QoL tools, such as the RAND-SF36 and measures, like the Fatigue Severity Scale (FSS), may offer insight (2, 3).

Argon Plasma Coagulation (APC) (4) is commonly employed for vascular lesions, but its impact on long-term symptom burden remains unclear. This study aimed to evaluate changes in QoL and fatigue over time in patients with small bowel angiodysplasia compared to anaemia controls without small bowel pathology.

Aims & Methods: Following ethical approval, patients with angiodysplasia and controls (those with anaemia and negative bidirectional and capsule endoscopy), were invited to complete an initial and subsequent (minimum of six months) RAND-SF36 and FSS. Baseline QoL and fatigue

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

assessment was performed on the day of small bowerl capsule endoscopy (SBCE) or enteroscopy. Repeat RAND-SF-36 and FSS were obtained from participants via telephone interview. Basic demographics and procedural related data, QoL and fatigue data were recorded. An FSS >36 was defined as clinically significant fatigue. Paired t-tests were used to assess within-group changes from baseline to follow-up. In the angiodysplasia group, a subgroup analysis compared changes in fatigue and QoL between patients who received APC and those who did not, using independent t-tests.

Results: A total of 28 patients in the angiodysplasia group (mean age 67.5 years; 35.7% female) and 38 anaemia controls (mean age 64.8 years; 42.1% female) were included, with no significant demographic differences. In the angiodysplasia group, the proportion of patients with clinically significant fatigue (FSS > 36) increased from 82.1% at baseline to 92.9% at follow-up (p = 0.046) suggesting overall worsening of fatigue over time. Anaemia controls showed no change in FSS scores (44.7% at both time points, p = 1.000). Despite this, in the angiodysplasia group several SF-36 domains, including Energy/Fatigue, Social Functioning, and Emotional Wellbeing, demonstrated statistically significant improvements (p < 0.05), suggesting, in our cohort, there is a significant improvement in QoL over time. 19 patients (67.9%) in the group underwent Argon Plasma Coagulation (APC). The proportion of patients with clinically significant fatigue (FSS >36) decreased from 57.9% to 31.6% in the APC angiodysplasia subgroup group (p = 0.433) and from 55.6% to 33.3% in angiodysplasia patients who did not receive APC (p = 0.570). Both groups received the same standard of care, transfusions and iron replacement as required. Data on medical therapy was unavailable.

Domain	Vascular Group (N=48)	Control (N=57)	p-value
FSS >36 (% patients)	69%	62%	0.523
Physical Functioning	48.3	54.6	0.290
Role Limitations (Physical)	25.8	45.	0.013
Energy/ Fatigue	38.5	48.0	0.048
Social Functioning	56.2	67.8	0.04
General Health	49.1	52.4	0.435

Conclusion: Patients with small bowel angiodysplasia experience greater fatigue and impaired quality of life compared to those with unexplained anaemia and normal SBCE. These results build on our previous findings and reinforce the clinical burden associated with angiodysplasia. Early recognition and targeted management may improve outcomes in this under-recognised group.

NON-OCCLUSIVE MESENTERIC ISCHEMIA AND PORTAL VENOUS THROMBOSIS CAUSING SMALL BOWEL OBSTRUCTION: TWO CASES AND MANAGEMENT REVIEW

C. Zheng[1,2], X. Lin[2], Z. Huang[2]
[1]Fujian Medical University, Fuzhou, China, [2]Fujian Medical University Union Hospital, Fuzhou, China

Contact E-Mail Address: 351289617@qq.com

Introduction: Non-occlusive mesenteric ischemia (NOMI) is a rare but critical condition resulting from insufficient mesenteric blood flow without arterial occlusion. When complicated by portal venous thrombosis and small bowel obstruction, NOMI presents significant diagnostic and therapeutic challenges, requiring early recognition and multidisciplinary management to improve outcomes.

Aims & Methods: This study retrospectively analyzed two patients with NOMI complicated by portal venous thrombosis and small bowel obstruction. Clinical history, imaging findings, treatment strategies, and outcomes were reviewed. The effectiveness of catheter-directed thrombolysis combined with systemic anticoagulation and the role of surgical intervention in recurrent ischemia were assessed. Statistical data include recurrence rates and treatment outcomes.

Results: Patient 1, a 62-year-old male, presented with acute abdominal pain, bloating, and vomiting. Imaging revealed portal venous thrombosis, partial small bowel obstruction, and signs of ischemia. He underwent catheter-directed mesenteric thrombolysis followed by systemic anticoagulation, resulting in symptom resolution and no recurrence at the 6-month follow-up. Patient 2, a 60-year-old male with atrial fibrillation, presented with prolonged abdominal pain and bloating. Imaging showed mesenteric and portal venous thrombosis causing small bowel obstruction. He underwent catheter-directed thrombolysis with initial improvement. However, symptoms recurred one month later, necessitating small bowel resection due to chronic ischemia. Postoperatively, the patient recovered well with no further recurrence.

Conclusion: This study highlights the importance of early identification and multidisciplinary management of NOMI with portal venous thrombosis. Catheter-directed thrombolysis combined with anticoagulation is an effective strategy for restoring mesenteric blood flow and relieving symptoms. Surgical intervention is critical in recurrent or chronic cases. These findings support individualized, evidence-based approaches to optimize outcomes in this complex condition.

IS OCTREOTIDE A SALVAGE THERAPY FOR PREVENTING RECURRENT BLEEDING FROM GASTROINTESTINAL ANGIOECTASIAS?

I. Marques[1,2,3], C. Macedo[1,2,3], J. Berkeley Cotter[1,2,3]
[1]Unidade Local de Saúde do Alto Ave, Gastroenterology Department, Guimarães, Portugal, [2]Life and Health Sciences Research Institute (ICVS), University of Minho, Braga, Portugal, [3]ICVS/3B's – PT Government Associate Laboratory, Guimarães/Braga, Portugal

Contact E-Mail Address: ines.abreu.marques@gmail.com

Introduction: Gastrointestinal angioectasia is a significant etiology of recurrent gastrointestinal bleeding, often requiring hospital care. Octreotide has been proposed as a therapeutic option in patients in whom endoscopic treatment is insufficient, particularly in cases of small bow-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

el or diffuse angioectasia.[1] This study evaluates the clinical efficacy of long-acting intramuscular octreotide in the recurrency of gastrointestinal bleeding from angioectasia.

Aims & Methods: A sample of 21 patients receiving monthly octreotide, either 10 mg or 20 mg, were retrospectively analyzed. Clinical efficacy was assessed by comparing the frequency of hospitalizations, urgency department visits, red blood cell (RBC) transfusions and intravenous iron infusions during the 6-month and 12-month intervals that preceded and followed the start of treatment. Additional contributing factors, including anticoagulation therapy and underlying diseases, were also examined.

Results: The sample studied has an mean age of 78 years, with 13 males and 8 hypocoagulated patients. The Charlson Comorbidity Index averaged 5.6 points, with 5 patients having cirrhosis and 5 patients Osler-Rendu-Weber Syndrome. Hospitalizations significantly decreased after octreotide initiation at both 6 and 12 months of treatment ($p < 0.001$; $p = 0.019$). Urgent care visits and RBC transfusions were significantly lower in the first 6 months of treatment ($p < 0.001$; $p = 0.007$), though this effect was not sustained at 12 months. Intravenous iron requirements did not differ statistically between pre- and post-treatment periods. Patients receiving 10 mg of octreotide had significantly fewer urgent care visits and iron infusions at 6 months of treatment compared to the 20 mg group ($p = 0.031$; $p = 0.026$).

Conclusion: In recurrent bleeding from angioectasias, when endoscopic treatment is ineffective, a 12-mounth course of octreotide therapy significantly reduces hospitalizations. Additionally, treatment in the first 6 months proves to be effective in reducing the number of urgency department visits and red blood cell transfusions.

UNRAVELING THE VICIOUS CYCLE: SUPERIOR MESENTERIC ARTERY SYNDROME IN ANOREXIA NERVOSA: A TUNISIAN RETROSPECTIVE COMPARATIVE STUDY

A. Gnaba[1], M. Zakhama[1], A. Guediche[1], I. Jemni[1], A. Sabbek[1], M.H. Loghmari[1], L. Safer[1]
[1]Fattouma Bourguiba University Hospital of Monastir, Department of Hepato-Gastroenterology, Monastir, Tunisia

Contact E-Mail Address: azergnaba84@gmail.com

Introduction: Superior Mesenteric Artery Syndrome (SMAS) is a rare condition characterized by compression of the third portion of the duodenum between the aorta and the superior mesenteric artery, leading to duodenal obstruction. While anorexia nervosa is a recognized risk factor due to rapid weight loss and loss of mesenteric fat, distinguishing whether SMAS is a cause or consequence of anorexia remains challenging.

Aims & Methods: The study aims to evaluate the clinical characteristics, management strategies, and outcomes of SMAS in patients with and without anorexia nervosa.

A retrospective comparative study was conducted in a hepatogastroenterology department from 2018 onwards, including 20 patients diagnosed with SMAS based on CT imaging criteria (aortomesenteric angle ≤25° and/or aortomesenteric distance ≤8 mm). Patients were divided into two groups: Group 1 (G1) comprised 9 patients with anorexia nervosa, and Group 2 (G2) included 11 patients without anorexia. All patients received enteral nutrition and psychiatric evaluation. Symptom severity was assessed using a subjective score considering symptom frequency, intensity, and weight loss, with scores >12 indicating severe symptoms.

Results: The mean age in G1 was 20.6 ± 2 years, with 77.4% being secondary school students. The average delay between diagnosis and treatment initiation was 147.3 ± 116.5 days for both groups.

Initial anthropometric measurements for G1 showed a mean weight of 45.7 ± 4.5 kg and a mean BMI of 17.5 [13.6–19.5]. The average weight loss at diagnosis was 4.9 ± 1.5 kg over 6 months, with 77.7% experiencing ≥10% weight loss. G2 had comparable anthropometric data.

The initial mean severity score was higher in G1 (14 ± 3.0 [9–17]) compared to G2 (12.1 [11–17], p=0.05). G1 had a longer mean hospital stay (37.6 ± 20.9 days), significantly associated with anorexia nervosa and higher initial severity scores.

Treatment failure occurred in one G1 patient (11.1%) versus none in G2 (p=0.04). Recurrence of symptoms was observed in 44.4% of G1 compared to 16.7% in G2 (p=0.02).

Psychiatric intervention, including antidepressant therapy, was administered to 78% of G1 patients. Post-treatment, G1 showed better tolerance (77.8%, p=0.01) and a lower mean severity score (3.1, p=0.002). The average weight gain was 3.3 kg [1–11], with 29.4% achieving adequate weight restoration. Hospitalization duration was reduced, with trends approaching statistical significance.

Conclusion: Anorexia nervosa, even when initially subclinical, can lead to severe malnutrition and SMAS, posing significant risks to young patients. Clinicians should be vigilant for the coexistence of these conditions and implement comprehensive management strategies that address both nutritional and psychological aspects.

LONGITUDINAL ASSESSMENT OF FATIGUE AND QUALITY OF LIFE IN PATIENTS WITH SMALL BOWEL ANGIODYSPLASIA: INSIGHTS FROM RAND SF-36 AND FATIGUE SEVERITY SCALE

R. Grainger[1], C. Costigan[1], D. Kripakaran[2], D. McNamara[1]
[1]Tallaght University Hospital, Gastroenterology, Dublin, Ireland,
[2]Trinity College Dublin, TAGG, Dublin, Ireland

Contact E-Mail Address: richardgrainger1@hotmail.com

Introduction: Patients with small bowel angiodysplasia, and chronic anaemia often experience a complex symptom burden, including reduced quality of life (QoL) and fatigue. While cross-sectional studies suggest impaired QoL in this population, longitudinal data assessing how these symptoms evolve over time are limited (1).

Both general QoL tools, such as the RAND SF-36 and measures, like the Fatigue Severity Scale (FSS), may offer insight (2, 3).

Argon Plasma Coagulation (APC) (4) is commonly employed for vascular lesions, but its impact on long-term symptom burden remains unclear. This study aimed to evaluate changes in QoL and fatigue over time in patients with small bowel angiodysplasia compared to anaemia controls without small bowel pathology.

Aims & Methods: Following ethical approval, patients with small bowel angiodysplasia and controls, those with anaemia and negative bidirectional and capsule endoscopy, were invited to complete an initial and subsequent (minimum of six months) RAND SF-36 and FSS. Baseline QoL and fatigue assessment was performed on the day of SBCE or enteroscopy. Repeat RAND SF-36 and FSS were obtained from participants via telephone interview. Basic demographics and procedural related data, QoL and fatigue data were recorded. An FSS >36 was defined as clinically

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. significant fatigue. Paired t-tests were used to assess within-group changes from baseline to follow-up. In the angiodysplasia group, a subgroup analysis compared changes in fatigue between patients who received APC and those who did not, using independent t-tests.

Results: A total of 28 patients in the angiodysplasia group (mean age 67.5 years; 35.7% female) and 38 anaemia controls (mean age 64.8 years; 42.1% female) were included, with no significant demographic differences. In the angiodysplasia group, the proportion of patients with clinically significant fatigue (FSS > 36) increased from 82.1% at baseline to 92.9% at follow-up ($p = 0.046$) suggesting overall significant worsening of fatigue over time. Anaemia controls showed no change in FSS scores (44.7% at both time points, $p = 1.000$). Despite this, in the angiodysplasia group, several SF-36 domains, including Energy/Fatigue, Social Functioning, and Emotional Wellbeing, demonstrated statistically significant improvements ($p < 0.05$). This suggests that in our cohort there was a significant improvement in QoL over time. 19 patients (67.9%) in the angiodysplasia group underwent Argon Plasma Coagulation (APC). The proportion of patients with clinically significant fatigue (FSS >36) decreased from 57.9% to 31.6% in the APC angiodysplasia subgroup ($p = 0.433$) and from 55.6% to 33.3% in angiodysplasia patients who did not receive APC ($p = 0.570$). Both groups received the same standard of care, transfusions and iron replacement as required. Data on medical therapy was unavailable.

Domain	Vascular Group Baseline	Vascular Group Follow-up	Change (p-value)	Control Baseline	Control Follow-up	Change (p-value)
FSS > 36 (%)	82.1%	92.9%	+10.8% (p=0.046)	44.7%	44.7%	+0.0% (p=1.00)
Energy/ fatigue	37.5	50.7	+13.2% (p=0.014)	40.2	40.7	+0.5 (p=0.841)
Social Functioning	58.5	84.8	+26.3 (p = 0.001)	65.0	66.2	+1.2 (p = 0.762)
Emotional Wellbeing	65.4	78.2	+12.8 (p = 0.013)	68.7	69.1	+0.4 (p = 0.891)
Role Limitations (Physical)	27.3	49.1	+21.8 (p = 0.028)	30.5	31.0	+0.5 (p = 0.812)

Conclusion: Despite improvements in several general QoL domains measured by RAND SF-36, patients with angiodysplasia experienced a significant worsening of fatigue over time, as captured by the FSS. These findings highlight the limitations of generic QoL tools in detecting persistent, clinically meaningful fatigue. APC alone appears not to have an impact on fatigue. This underlines the importance of assessing patient-reported fatigue as a treatment outcome.

Introduction: Obesity and metabolic dysfunction-associated steatotic liver disease (MASLD) have been linked to gut dysbiosis.

Aims & Methods: This study aimed to investigate the relationship between gut microbiota composition, hepatic fat content and stiffness, and body mass index (BMI) status. This cross-sectional study enrolled adolescents aged 12 to 18. Transient elastography with controlled attenuation parameter (CAP) was employed to diagnose hepatic fibrosis and steatosis. Fecal samples were analyzed by 16S rRNA sequencing. Relative abundance, as well as alpha- and beta-diversity of the microbiota, were compared across participants with different nutrition statuses and the presence of hepatic steatosis and fibrosis.

Results: A total of 76 participants (51 males) were recruited for this study, including 43 with normal weight, 19 overweight, and 14 obese. The clinical characteristics of the participants are presented in Table 1. Hepatic steatosis was present in 8 out of 14 obese participants (57.2%) and 2 out of 19 overweight (10.5%) participants. Hepatic fibrosis was detected in 4 out of 14 obese participants (28.6%) but none in the normal weight or overweight groups. There were no significant differences in alpha- or beta-diversity between the normal weight, overweight, and obese groups. The Firmicutes to Bacteroidetes (F/B) ratio was 1.2 across all three groups. Several genera, including *Eubacterium_halli_group* and *Ruminococcus_gauvreauii_group* were present in higher abundances in the gut microbiome of the obese group compared to the normal-weight group, with *p* values of 0.025 and 0.036, respectively. In contrast, *Bifidobacterium* was more abundant in the normal-weight participants (p=0.012). Obese individuals with hepatic fibrosis exhibited a significantly higher F/B ratio compared to those without hepatic fibrosis (p=0.04). There were significant differences in the relative abundance of specific genera between the fibrosis and non-fibrosis groups: *Phascolarctobacterium* (p=0.020), *Dorea* (p=0.040), and *Ruminococcus_gauvreauii_group* (p=0.045) were present in higher abundances in the fibrosis group, whereas *Senegalimassilia* was more abundant in the non-fibrosis group (p=0.037).

	Normal (n=43)	Overweight and obesity (n=33)	P value
Age (year)	14.4 (14.1-17.2)	15.2 (13.6-16.5)	0.71
CAP (decibels/meter)	186 (154-207)	203 (191-237.5)	<0.001*
Presence of hepatic steatosis	0 (0.0%)	10 (30.4%)	<0.001*
Liver stiffness (kilopascals)	3.9 (3.2-4.4)	4.9 (3.9-7.2)	0.025*
Presence of hepatic fibrosis	0 (0.0%)	4 (12.0%)	0.032*

BMI Body mass index, CAP Controlled attenuation parameter
Data expressed as number (percentage) or median (interquartile range); *P<0.05

Conclusion: Hepatic steatosis and fibrosis are common among obese adolescents. The gut microbiota abundance in obese individuals with hepatic fibrosis differ from those without it. Further studies are crucial to explore the role of gut microbiota modification in the progression of hepatic steatosis and fibrosis.

A NOVEL GASTRIC PERORAL ENDOSCOPIC MYO-NEUROTOMY TECHNIQUE FOR BARIATRIC INTERVENTION: EFFICACY AND SAFETY IN A PORCINE MODEL

Y. Yamasaki[1], J. Toyosawa[1], K. Hamada[1], A. Takaki[1], M. Otsuka[1]
[1]Okayama University Hospital, Department of Gastroenterology, Okayama, Japan

Contact E-Mail Address: yasshifive@yahoo.co.jp

Introduction: Endoscopic sleeve gastroplasty (ESG) is a minimally invasive and effective treatment for obesity. However, concerns remain regarding gastric mucosal folding and the resulting reduced visibility of the gastric lining. To address these limitations, we developed a novel peroral endoscopic myo-neurotomy (POEM-N) technique (1), adapted from peroral endoscopic myotomy (POEM), as a weight-loss procedure. Although promising, the original POEM-N was time-consuming.

This study aims to evaluate the safety and efficacy of a revised POEM-N (R-POEM-N) technique using a submucosal approach as a less invasive bariatric option in a porcine model.

Aims & Methods: Twelve pigs were assigned to either the R-POEM-N group (n = 8) or a sham endoscopic control group (n = 4). Myo-neurotomy was performed at four gastric sites in the R-POEM-N group: two on the greater curvature of the gastric body and two in the antrum. All pigs were fed a hypercaloric diet (twice the standard weight-based intake) and monitored for eight weeks post-procedure.

The primary outcome was the proportional change in body weight at 8 weeks, calculated as the ratio of weight change to baseline weight. Secondary outcomes included food intake, changes in serum glucolipid levels, and assessments of safety and procedural duration.

Results: R-POEM-N was successfully completed in all pigs without major adverse events. The mean procedure time was 171.3 ± 3.0 minutes. At 8 weeks, the proportional change in body weight was significantly lower in the R-POEM-N group compared to controls (P = 0.017). Food intake was also significantly reduced in the R-POEM-N group (P < 0.05). No significant differences were observed in serum glucolipid levels between groups.

Conclusion: R-POEM-N effectively limited weight gain in a porcine model and demonstrated a favorable safety profile. These findings suggest that R-POEM-N may serve as a promising, minimally invasive bariatric intervention.

SAFETY AND OUTCOMES OF ENDOSCOPIC SLEEVE GASTROPLASTY FOR MANAGEMENT OF OBESITY AT THE FIRST NHS ENDOBARIATRICS CENTRE IN NORTH OF ENGLAND

W. Rasool[1], S. Cameron[1], A. Newbery[1], L. Sut[1], A. Samier[2], A. Dhar[1]
[1]Darlington Memorial Hospital, Department of Gastroenterology, Darlington, United Kingdom, [2]Co Durham & Darlington NHS Foundation Trust, General Surgery, Darlington, United Kingdom

Contact E-Mail Address: wasif.rasool@nhs.net

Introduction: The National Institute of Health and Care Excellence (NICE) recently endorsed Endoscopic Sleeve Gastroplasty (ESG) in combination with lifestyle modifications as a therapeutic modality to bariatric surgery in patients with body mass index > 30. Darlington Memorial Hospital was the first NHS Endobariatric Centre offering ESG to patients since 2022.

Aims & Methods: This is a retrospective analysis of the clinical outcomes and safety of ESG for the management of obesity in patients with BMI >30 between 2022-2024 at a single centre. A total of 21 procedures have been performed at this centre in the last 24 months, 2 procedures were performed in 2022, 4 procedures in 2023, and 15 procedures were carried out in 2024. We analysed procedural safety and total body weight loss (TBWL) at 6, 12 and 24 months.

Results: All patients were discussed in a multi-disciplinary team prior to being enlisted for ESG. Appropriate lifestyle modifications were initiated with Specialist Dietitian support. The average age of patients was 50.75 years (range 25 – 72), average BMI was 44.317 (range 35.37 - 57.4) and 75% of patients were women. None of the patients were receiving medications for weight loss (GLP-1 agonists). 3 patients were diabetic, 11 were hypertensive, 3 dyslipidemic and 4 had fatty liver. Other obesity related morbid conditions included Obstructive sleep apnoea in 5 patients and Osteoarthritis in one.

A total of 13 patients have at least 6 months follow up since the time of their procedure. Average total body weight loss in 6, 12 and 24 months was 17.78%, 36% and 26.7% respectively. Patient satisfaction scores have been consistently high.

The average time to completion of ESG was 88.26 minutes. The average length of stay in hospital was 2.24 days (range 1-11). All sutures were made in a U shape. The average number of sutures was 4.24 (range 1- 7). There were only 3 minor complications in this period: 1 post operative upper gastrointestinal bleed, 1 subphrenic collection and 1 minor pharangeal perforation.

All of these complications occurred in the early phase of the service, and were managed conservatively, with full recovery.

Conclusion: Our initial 24 month experience with ESG shows excellent TBWL, similar to the MERIT Study.

Procedural time is less than conventional bariatric procedures, with no major complications. These outcomes are similar to other international publications from larger centres.

ENDOSCOPIC GASTRIC MUCOSAL ABLATION FOR WEIGHT LOSS: 8 YEARS FOLLOW-UP

B. Liu[1], D. Liu[1], M.R. Ahmed[1]
[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Contact E-Mail Address: drjiyuzhang@163.com

Introduction: Obesity, currently regarded as a pandemic, is a life-threatening medical condition that impacts health and quality of life. Bariatric surgery is the most effective and sustained weight loss method for treating obesity, resulting in significant improvement in obesity-related multimorbidity and lower mortality rates. Endoscopic gastric mucosal ablation (EGMA) is a restrictive procedure that combines endoscopic submucosal dissection (ESD) and endoscopic mucosal resection (EMR), removing 80% of the gastric mucosa, which leads to stomach shrinkage and decreased gastric volume.

Aims & Methods: This study aimed to evaluate the effects of EGMA on weight loss and metabolic parameters. This study included 18 patients who underwent EGMA between July 2015 and June 2023. We collected basic anthropometric measurements, such as weight (kg) and height (m), at baseline before the procedure and at routine outpatient follow-up visits conducted annually following EGMA. Patients who failed to be present in person for their scheduled follow-up visits were contacted by phone or online. Additional anthropometric measurements, including WC (cm) and HC (cm), were collected at the baseline and 1 year, 2 years, 4 years, and 6 years post-EGMA procedure to evaluate abdominal obesity.

The primary outcome was weight loss, which was assessed by analyzing the changes in body mass index (BMI) (in kg/m^2), total body weight loss (TBWL) (in %), excess weight loss (EWL) (in %), and abdominal adiposity, as indicated by waist-to-hip ratio (WHR). Secondary outcomes included the impact of EGMA on metabolic indicators, including diabetes, blood pressure, dyslipidemia, and hyperuricemia.

Results: A total of 18 patients (12 women, 6 men; mean age of 35.6 ± 12.6 years) with a mean initial weight of 105.8 ± 16.4 kg underwent the EGMA procedure. Following EGMA, 18 patients had completed a year of follow-up at the time of analysis, followed by 17 in three years, 16 in four years, 9 in six years, 3 in seven years, and 2 in eight years. The changes in BMI, TBWL, %TBWL, %EWL, and WHR are shown in table 1.

The majority of patients presented with one or more comorbidities associated with obesity. At 2 years of post-EGMA, 4/7 (57.1%) patients achieved complete remission of diabetes, 3/7 (42.9%) of hypertension, 7/7 (100%) of hyperlipidemia, and 4/8 (37.5%) of hyperuricemia. There were no major adverse events interprocedurally or during the 8 years of follow-up. The mean post-EGMA hospital stay was 8.4 ± 2.8 days.

Conclusion: EGMA could suggest a new, less invasive, and restrictive endoscopic weight reduction method. The procedure appears to be effective and safe, with minimal technical complexity and no surgical complications.

Disclosure: Nothing to disclose.

PP0324

A NOVEL ENDOSCOPIC MUCOSAL RADIOFREQUENCY ABLATION INDUCES GASTRIC VOLUME REDUCTION: AN ANIMAL EXPERIMENT

D. Liu[1], J. Zhang[1], Z. Kan[1], B. Liu[1]
[1]The First Affilaited Hospital of Zhengzhou University, Zhengzhou, China

Contact E-Mail Address: wilmawell@163.com

Introduction: Obesity is a major global health problem and financial burden. Main treatments of obesity include lifestyle changes, medication, and bariatric surgery. However, lifestyle and drug therapies often fail for moderate to severe obesity. Bariatric surgery is an effective and conventional choice, though it is proven to be invasive with high risk of complication. Recently, endoscopic bariatric treatments including intragastric balloon deployment and sleeve gastroplasty have the advantages of being minimally invasive. However, they also carry the limitations of postoperative weight regain and uncertain long-term outcome.

Aims & Methods: In this study, we introduce a novel approach for mucosal ablation with radiofrequency, to guarantee enough tissue injury as well as achieve gastric volume reduction and potential weight loss. We conducted the first animal experiment of endoscopic radiofrequency ablation to induce gastric volume reduction and weight loss and evaluated its safety and feasibility. Eight pigs were enrolled in this study and observed over a three-month period. Five pigs comprised the experimental group and received endoscopic radiofrequency ablation, while three served as controls. Body weight, abdominal circumference, body length, total food intake, and gastric volume were measured and analyzed, along with follow-up endoscopic examinations.

Results: In experimental group, five pigs successfully underwent endoscopic gastric mucosal radiofrequency ablation. The average weight gain for the experimental group at 1st, 2nd, and 3rd months post-procedure was (5.0±1.5) kg, (17.7±5.6) kg, and (34.3±2.1) kg, respectively. In contrast, the control group showed average weight gains of (9.7±5.2) kg, (31.0±7.8) kg, and (50.8±6.9) kg at the same time point. There was no statistically significant difference in weight gain between the experimental and control groups at 1-month postoperatively (P=0.256); however, pigs in experimental group exhibited significantly less weight gain at 2 and 3 months comparing with controls (P=0.029, 0.048). No significant differences in total food intake were observed between both groups at within 2 months (P=0.214), but the experimental pigs consumed less food than the controls on 3-month follow-up(P=0.029).

Additionally, the growth rates of body length and abdominal circumference were significantly lower in the experimental group comparing with controls at 1, 2, and 3 months (P=0.001, 0.007, 0.013). The average the procedure time in experimental group was 3.2±0.8 hours, with no significant intra-procedural and post-procedural complications occurred in the experimental group, such as bleeding, perforation, or procedure-related death.

Conclusion: Endoscopic gastric mucosal radiofrequency ablation to induce volume reduction is an effective and safe method as a novel bariatric treatment, suggesting it may be a promising application potential.

Disclosure: Nothing to disclose.

PP0325

RESIDUALS TO REMAINS: GASTRIC RESIDUAL VOLUME AS A PREDICTOR OF MORTALITY IN CRITICALLY III. A SINGLE-CENTER RETROSPECTIVE COHORT STUDY

J.D. Clutario[1], G. Pedregosa[1], M. Esculto-Khan[2], S.L. Cham[3], A. Mamaradlo[3], N. Mapa[4]
[1]Makati Medical Center, Internal Medicine - Gastroenterology, Makati, Philippines, [2]Makati Medical Center, IM-Nutrition, Makati, Philippines, [3]Makati Medical Center, IM-Gastroenterology, Makati, Philippines, [4]Makati Medical Center, Makati City, Philippines

Contact E-Mail Address: johnderekclutario@gmail.com

Introduction: Gastric residual volume (GRV) serves as a surrogate marker for gastrointestinal dysfunction during enteral feeding in critically ill patients. It helps detect delayed gastric emptying early, potentially guiding interventions to prevent complications such as aspiration and feeding intolerance. The American Society for Parenteral and Enteral Nutrition (ASPEN) defines GRV as the liquid drained from the stomach post-enteral feeding, composed of nutritional formula, water, and GI secretions, measured via aspiration or gravity drainage. While monitoring GRV is commonly used to assess feeding tolerance, its clinical relevance in predicting mortality remains unclear. A study by Hsu et al. linked higher GRV with increased disease severity and higher SOFA scores in ICU patients. However, the latest ESPEN guidelines highlight inconsistencies in GRV monitoring, suggesting that enteral feeding should be delayed when GRV exceeds 500 mL/6h, though no definitive cut-off for intervention or its role in mortality prediction has been established.

Aims & Methods: The aim of this study is to determine the impact of gastric residual volume in predicting incidence of mortality in critically ill patients admitted at a tertiary hospital in the Philippines (PH). This single-center, three-year retrospective analytical cohort study was conducted via chart review of critically ill patients admitted in a tertiary hospital in the PH. Patients aged ≥19 years, on enteral nutrition via nasogastric or gastrostomy tube, and admitted for >3 days were included. Exclusions were pediatric, pregnant, and lactating patients, as well as those with gastric outlet obstruction, bowel obstruction, or recent abdominal surgery.

The primary outcome assessed the impact of gastric residual volume (GRV) on ICU mortality. Secondary outcomes included the association between GRV and clinical parameters such as SOFA score, mortality risk stratification based on GRV >500mL versus <500mL, and time intervals related to feeding and GRV trends. Data were collected from electronic and paper medical records and analyzed using Mann-Whitney U test and multivariable logistic regression. Prognostic accuracy was assessed using sensitivity, specificity, and predictive values.

Results: A total of 150 ICU patients were analyzed (median age 68.5 years, 57.3% male). Survivors had a significantly younger median age than non-survivors (62 vs. 72 years, p<0.001). Key comorbidities included hypertension (63.3%), kidney disease (72.0%), and diabetes (42.7%). The SOFA score, PF ratio, MAP, bilirubin levels, platelet count, and GCS differed significantly between survivors and non-survivors (p<0.001). Among patients with GRV >500mL (n=24), mortality was significantly higher (87.5%) compared to those with GRV <500mL (63.5%, p=0.029). Sensitivity for predicting mortality with GRV >500mL was 93.9% (CI: 83.1%-98.7%), though specificity was low at 25.9% (CI: 16.8%-36.9%). The positive predictive value was 43.4%, while the negative predictive value was 87.5%, with an overall diagnostic accuracy of 44.7%. These findings suggest that elevated GRV is associated with increased mortality risk in critically ill patients, though its predictive specificity is limited.

Conclusion: This study highlights the association between increased gastric residual volume (GRV) and higher mortality risk in critically ill patients, with GRV >500mL linked to a fourfold increase in mortality. GRV may serve

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. as a clinical tool to guide management decisions, balancing diagnostic and therapeutic interventions with palliative care when appropriate. In resource-limited settings like the Philippines, this could help reduce healthcare costs and optimize hospital resources. As no prior studies have explored GRV's role in mortality prediction, this research provides a foundation for future investigations.

Introduction: The term "cold" describes a range of respiratory illnesses primarily triggered by viral infections. Colds are the most common infectious diseases in the world, affecting daily life and increasing healthcare costs and lost productivity. Cold symptoms typically emerge 2-3 days after viral exposure. Children and those with a compromised immune system may experience more severe complications. The gut microbiota is directly involved in immune function, and probiotics can restore gut balance and enhance immunity. Specific probiotic strains, including *L. plantarum PBS077, L. acidophilus PBS066, and B. lactis BL050*, have demonstrated antimicrobial and anti-inflammatory properties.

Aims & Methods: This study aims to evaluate the effects of a dietary supplement containing *L. plantarum PBS077, L. acidophilus PBS066, and B. lactis BL050* probiotics on relieving cold symptoms in healthy individuals, focusing on its potential to enhance immune response and improve quality of life (QoL). This randomized, double-blind, placebo-controlled clinical trial was conducted in Italy in winter from 2022 to 2024, involving 65 healthy volunteers aged 18-44. Participants were assigned to two groups: 40 received a probiotic treatment with specific strains (*L. plantarum PBS077, L. acidophilus PBS066, B. lactis BL050*), B6 and B12 vitamins, folic acid, and bulking agents (Probiotic), while 25 received a placebo, consisting of bulking agents, B6 and B12 vitamins and folic acid, without probiotics (Placebo).

Participants took one capsule daily for 12 weeks, with assessments conducted at baseline (T0), after treatment (T1), and 6 weeks post-treatment (T2). Cold symptoms and quality of life (QoL) were assessed using a validated questionnaire (WURSS-21), and systemic inflammation was evaluated through serum cytokine levels (IFN-γ and IL-10) at each time point. The total observation period lasted 18 weeks.

Results: Probiotics were associated with a shorter average duration of cold symptoms (4.5 *vs.* 6.7 days for the Placebo), with a 32.7% reduction in symptom duration, $p<0.05$. At T1, fever occurred in 8 out of 40 participants in the Probiotic group (20%) and in 7 out of 25 participants in the Placebo group (28%), $p<0.05$. Additionally, at T1, muscle pain was reported by 20% of the Probiotic group (8 out of 40) *vs.* 44% of the Placebo group (11 out of 25). By T2, muscle pain occurred in 17.5% of the Probiotic group (7 out of 40) and 20% of the Placebo group (5 out of 25), $p<0.05$. At T1, the pro-inflammatory cytokine IFN-γ levels decreased in the Probiotic group compared to T0 (17,946±2,857 vs. 28,962±4,143 pg/ml, $p < 0.05$) and increased in the Placebo group compared to T0 (22,279±3,538 vs. 19,432±3,143 pg/ml, $p < 0.05$). Though not statistically significant, at T1 the Probiotic group had higher levels of IL-10 compared to T0 (266,98±78,432 vs. 240,967± 70,238, $p>0.05$).

Conclusion: The probiotic mix alleviated symptoms in patients with colds and reduced levels of the pro-inflammatory cytokine IFN-γ, demonstrating anti-inflammatory properties.

ASSESSING DIET QUALITY INDICES FOR AN INFLAMMATORY BOWEL DISEASE POPULATION – WHICH IS BEST?

L. Portmann[1,2], J. Fitzpatrick[3,4], E. Halmos[3,4], R. Bryant[1,2], A. Day[1,2]

Introduction: Assessing the role of diet in the pathogenesis of inflammatory bowel disease (IBD) has moved away from analyses of individual nutrients and towards dietary patterns, helping to account for the complexity of food and nutrient interactions. Dietary patterns such as ultra-processed foods or the Mediterranean diet (MED), which have been implicated in IBD onset and course indicate need for diet quality assessment. However, an IBD-specific diet quality index (DQI) does not exist. It is unknown which DQI is most suitable to use in therapeutic IBD diet trials. This review aimed to identify current DQIs and assess their suitability for use on an IBD population.

Aims & Methods: MEDLINE and EmCare electronic databases were systematically searched for *a-priori*, food-based DQI reflecting national dietary guidelines and/or latest nutrition science for adults published 2013 to 2023 in English language. Posteriori or non-IBD disease-specific (e.g., diabetes) DQI were excluded. Data extracted were adapted from optimal DQI criteria described by Burggraf et al.,[1] which include quality measures of adequacy, moderation, variety and balance for food and nutrient components and DQI evaluation, as well as its use, if any, for IBD health outcomes.

Results: Twenty-four articles describing 24 DQI were included in final analysis. Dietary guidelines were used to develop 18/24 (75%) DQI. The other six were developed from dietary patterns (e.g., EAT-Lancet Diet). The majority were developed in Australia (7/24), North America (5/24), Europe (5/24) and Asia (4/24). One was developed from an international cohort. All DQI assessed whole food groups, but assessment of individual foods varied. Ultra-processed foods were assessed in 16/24 (67%) DQI. No DQI included all optimal DQI criteria[1]. The Dietary Guideline Index 2013 (DGI-2013) most closely met DQI criteria, followed by the Healthy Eating Index for Australian Adults-2013 (HEIFA-2013), Dutch Healthy Diet Index-2015 (DHD Index-2015) and Planetary Health Diet Index (PHDI) (Table 1). Most DQI assessed adequacy (22/24, 92%) and moderation (21/24, 88%), half assessed balance (12/24, 50%) while few assessed variety (9/24, 38%).

Index	Dimensions				Diet Assessment Method	Normative*, age & gender-based score criteria	Unequal Weight+	Applied to IBD cohort
	Adequacy	Moderation	Variety	Balance				
DGI-2013	Y	Y	P	Y	FFQ	Y	N	Y
DHD Index-2015	Y	Y	N	P	FFQ, 24hr Recall	Y	N	Y
HEIFA-2013	Y	Y	P	P	FFQ, Weighed Food Record	Y	Y	N
PHDI	Y	Y	N	P	FFQ	Y	Y	N

Footnotes. Green highlight (Y), DQI met adapted optimal DQI criteria;[1] Yellow highlight (P), criteria partially met; Red highlight (N), criteria not met; *evidence-derived e.g., recommended nutrient intakes or guideline serving quantities, +accounts for contributions of foods/nutrients to established health outcomes where one food/nutrient may have a greater health impact than another.

Table 1. Highest rated Diet Quality Indices (DQI) meeting a selection of adapted optimal construction criteria for an Inflammatory Bowel Disease-specific DQI

Outlined in *Table 1*, application of other recommended DQI criteria varied. Food frequency questionnaires (FFQ) (13/24) and 24-hour diet recall (12/24) were the most common dietary assessment methods used. Seventeen of 24 (71%) DQI were validated, however, few were evaluated for reliability (6/24) or reproducibility (2/24). No DQI was validated to assess IBD-specific health outcomes, however, the DGI-2013 and DHD Index-2015 have been applied to FFQ from IBD participants.

Conclusion: No existing DQI meets all recommended optimal criteria for an IBD-specific DQI. The DGI-2013 met the most criteria, followed by the HEIFA-2013, DHD Index-2015 and PHDI. These DQI, depending on country and diet assessment method, may be most appropriate for an IBD population. An IBD-specific DQI is lacking and needed.

Introduction: Inflammatory bowel disease (IBD) significantly impacts patients' nutritional status and quality of life. Nutritional deficiencies are common in IBD and can worsen disease progression.

Aims & Methods: The aim of this study is to assess the nutritional status of patients with IBD and explore its relationship with quality of life in this cohort. A cross-sectional study conducted at a specialized center assessed nutritional status using the MUST and MIRT tools. For pediatric patients, the "Strong Kids" screening tool was used.

A multidisciplinary nutritional intervention was provided, followed by quality of life evaluation using the EQ-5D and IBDQ-32 instruments. Statistical analyses were performed to examine the association between nutritional status and quality of life.

Results: Among 90 IBD patients, 26.6% required hospitalization due to disease flare-ups, primarily adults and females. The median age was 36.7 years (range: 4–81, SD: 32.6), with 58.3% diagnosed with Crohn's disease and 83.3% requiring biologic therapy (Table 1). The odds ratios (OR) for malnutrition in hospitalized patients were 8.33 (95% CI: 1.16–27) for ulcerative colitis and 25 (95% CI: 11.6–45.2) for Crohn's disease. All hospitalized adults exhibited poor biochemical control and moderate-to-severe hypoalbuminemia; 25% had sarcopenia. Nutritional support was provided to 49% of patients within the past year. All severely ill hospitalized patients were malnourished.

Pediatric patients, all of whom received nutritional support, demonstrated a higher degree of nutritional compromise. Among these, 25% required parenteral nutrition, while 87.5% received enteral nutrition, primarily with high-calorie, high-protein formulas. During hospitalization, 87.5% gained weight and improved nutritionally, with 75% achieving normal nutritional status at three-month follow-up, although one patient died.

Following the nutritional intervention, over 80% of adults did not experience further nutritional deterioration. In the outpatient cohort, 20 patients were evaluated, of whom 30% were identified as high risk for malnutrition according to MUST, and 25% had nutritional risk (MIRT score ≥3). Patients

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with poorer initial nutritional status had significantly worse quality of life, with notable impairments in mobility (P = 0.2778; 95% CI: 2.03–64.1), self-care (P = 0.003; 95% CI: 9.45–90.5), daily activities (P = 0.1457; 95% CI: 1.14–58.2), pain/discomfort (P = 0.197; 95% CI: 0.53–53.3), and visual analog scale scores (P = 0.012; 95% CI: 22.9–88.4). Poor nutritional status was also associated with lower quality of life scores on the IBDQ-32 (P = 0.04; 95% CI: 10.3–60.7).

Conclusion: Nutritional status is a key component of IBD management, as malnutrition is linked to poorer quality of life. Screening tools such as MUST and MIRT in adults, and "Strong Kids" in children, are essential for early identification of at-risk patients. Pediatric patients tend to have more severe nutritional compromise than adults, and nutritional support during hospitalization contributes significantly to recovery.

LAURIC ACID AND GUT HEALTH: A FRIEND OR FOE IN FIBROSIS MODULATION?

Introduction: Nutritional factors are increasingly recognized as key modulators of intestinal inflammation and fibrosis, offering new therapeutic angles in IBD management. Among dietary components, medium-chain fatty acids (MCFAs) have drawn attention for their bioactive properties. Lauric acid (LA), MCFA with anti-inflammatory properties, has an unclear role in IBD, particularly within a fibrotic context. LA interacts with G protein-coupled receptor 84 (GPR84), which is notably elevated in UC[1]

Aims & Methods: This study evaluated the effects of lauric acid (0, 50, 100, and 250 μM) on human intestinal fibroblasts (HSIF) and colonic epithelial cells (CoEpi) under basal and pro-fibrotic conditions induced by TGFβ1 (10 ng/mL). Fibrotic gene expression was assessed by PCR—HSIF: COL1A1, COL3A1, COL4A1, ACTA2, FN1, TGFβ, GPR84; CoEpi: SNAI1/2, CDH1, COL1A1, FNDC4, VIM, GPR84. Protein levels of GPR84, FNDC5, COL1A1, αSMA, and FGFR2 in HSIF were measured via Western blot. Data were expressed as fold change (mean ± SEM) relative to 0 μM LA and analyzed using ANOVA or Kruskal-Wallis tests, depending on normality (*P < 0.05 vs. 0 μM LA; **P < 0.01 vs. 0 μM LA; #P < 0.05 vs. 0 μM LA + TGFβ1; ##P < 0.01 vs. 0 μM LA + TGFβ1).

Results: Under basal conditions, lauric acid (LA) significantly decreased the mRNA expression of fibrosis-related genes in HSIF, including COL1A1 (250 μM: 0.2 ± 0.07**) and COL3A1 (50 μM: 0.4 ± 0.1**), as well as ACTA2 (100 μM: 0.1 ± 0.1**).

These anti-fibrotic effects were maintained or enhanced under TGFβ1 stimulation, particularly at lower LA doses—e.g., COL1A1 (50 μM: 1.1 ± 0.15##), COL3A1 (50 μM: 0.24 ± 0.1#), COL4A1 (250 μM: 0.6 ± 0.1#), and ACTA2 (100 μM: 0.7 ± 0.4#). Under fibrotic conditions, LA also significantly reduced the protein expression of COL1A1 (250 μM: 0.4 ± 0.17##) and αSMA (250 μM: 0.9 ± 0.14#). LA increased GPR84 mRNA expression in HSIF under both basal (250 μM: 1167 ± 646*) and fibrotic (250 μM: 1048 ± 505##) conditions, without affecting fibronectin or TGFβ levels.

In CoEpi cells, LA promoted epithelial-mesenchymal transition (EMT) markers in both basal and TGFβ1-stimulated states. This included upregulation of VIMENTIN (250 μM: 3.9 ± 0.6*; with TGFβ1: 6.4 ± 1.5#), SNAI2 (250 μM: 3.4 ± 0.5*; with TGFβ1: 3.9 ± 0.5##), and FIBRONECTIN (250 μM: 2.6 ± 0.5*; with TGFβ1: 4.4 ± 0.8##), alongside a decrease in E-CADHERIN (250 μM: 0.5 ± 0.08*; with TGFβ1: 0.35 ± 0.07#). GPR84 mRNA expression also increased significantly in CoEpi cells under both conditions (basal: 6.9 ± 1.5**; pro-fibrotic: 5.1 ± 1.0##). No changes were observed in COL1A1 or SNAI1 expression.

Conclusion: Lauric acid plays a dual, context-dependent role in intestinal fibrosis. It reduces fibrotic markers in fibroblasts, suggesting therapeutic potential, but promotes EMT in epithelial cells, which may contribute to fibrosis progression. These opposing effects, possibly mediated by GPR84, highlight lauric acid as both a friend and foe in gut health—supporting the need for further investigation before considering it as a dietary intervention in IBD.

VITAMIN D STATUS AND BONE MINERAL DENSITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: ASSOCIATIONS WITH BODY COMPOSITION

B.G. Costa[1], A. Spiller[1], R.N.Y. Yoshihara[1], N. Salvador Castelhano[1], D. Salate Biagioni Vulcano[1], F.F. Gondo[1], S.A.R. Paiva[1], L. Yukie Sassaki[1]

[1]Medical School, São Paulo State University (Unesp), Internal Medicine, Botucatu, Brazil

Contact E-Mail Address: bg.costa@unesp.br

Introduction: Patients with inflammatory bowel disease (IBD) are at increased risk of reduced bone mineral density (BMD), often linked to chronic inflammation, corticosteroid use, biologics, and vitamin D deficiency. 25-hydroxyvitamin D (25(OH)D) is a fat-soluble vitamin essential for calcium and phosphorus homeostasis, and its deficiency is common in IBD due to malabsorption, dietary, altered metabolism, or impaired VDR signaling.

Aims & Methods: This cross-sectional study aimed to evaluate the relationship between serum 25(OH)D levels, BMD, and body composition in IBD patients. A total of 73 outpatients with IBD (38 ulcerative colitis, 35

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Crohn's disease) were assessed. Body composition was evaluated using BMI and bioelectrical impedance analysis (BIA). BMD was measured using whole-body dual-energy X-ray absorptiometry (DEXA), and vitamin D status was assessed by serum 25(OH)D concentration. Statistical analysis included descriptive and comparative tests (Chi-square and t-test).

Results: Participants had a mean age of 45.27±11.37 years, with 67.1% being female and a mean disease duration of 10.22±7.54 years. Most patients (93.15%) were in clinical and endoscopic remission. The average BMI was 26.85±4.51 kg/m^2, with 39.7% classified as overweight. DEXA revealed a high prevalence of osteopenia (39.7%) and osteoporosis (19.0%). Mean BMD Z-scores were whole body -1.32±1.13, spine -0.92±1.19, and femoral neck -0.34±1.02. Mean serum 25(OH)D level was 31.20±8.78 ng/mL; 52.1% had insufficient levels and 47.9% were sufficient. Vitamin D insufficiency was significantly associated with osteopenia/osteoporosis (p=0.0144) and with overweight/obesity (p=0.0265).

No significant associations were observed between vitamin D levels and age (p=0.6476), sex (p=0.4565), lean mass (p=0.2941), fat mass (p=0.1218), phase angle (p=0.3154), or regional BMD (total body p=0.5001; spine p=0.3067; femoral neck p=0.2364).

Conclusion: IBD patients are vulnerable to low serum vitamin D levels and present a high prevalence of low BMD. Vitamin D insufficiency was associated with altered BMI and increased risk of osteopenia/osteoporosis, though not with other body composition metrics. Further studies are needed with larger and more clinically heterogeneous samples to confirm these associations and guide screening and supplementation strategies.

THE DEVELOPMENT OF FUNCTIONAL GASTROINTESTINAL DISORDERS IN SCHOOL-AGE CHILDREN: THE INFLUENCE OF MALNUTRITION AND EATING DISORDERS

O. Bielousova[1]

[1]Vilnius University, Faculty of Medicine, Institute of Clinical Medicine, Department of Paediatrics, Vilnius, Lithuania

Contact E-Mail Address: olga.yu.belousova@gmail.com

Introduction: Nutrition is one of the important risk factors for the occurrence of functional gastrointestinal disorders in children. These disorders, including functional dyspepsia (FD) and irritable bowel syndrome (IBS), are increasingly prevalent in the pediatric population. Understanding dietary patterns in affected children is crucial for developing preventive and therapeutic strategies.

Aims & Methods: The aim is to study eating behavior disorders in children with functional gastrointestinal disorders and to analyze the diet of children with combined functional gastrointestinal pathology.

Materials and methods: 110 children aged 6 to 18 with functional gastrointestinal disorders were examined. Patients were divided into two groups: 44 with a combination of symptoms of functional dyspepsia and irritable bowel syndrome and 66 with functional dyspepsia. The control group consisted of 30 practically healthy children. The diagnosis of functional dyspepsia and irritable bowel syndrome was established on the basis of clinical symptoms according to the Rome IV criteria (2016). In order to detect a violation of the nutritional regime, children were interviewed according to a questionnaire developed by us. They also studied the food preferences of schoolchildren using the Youth Adolescent Food Frequency Questionnaire, adapted to the model of children's nutrition in Ukraine.

Indicator	Combined FD and IBS, n = 44, N 14	% ± m	Functional Dyspepsia n = 66, N 8	% ± m	Control Group n = 30, N 3	% ± m
Eating less than 3 times a day		**31.8 ± 7.3***		**12.2 ± 4.4**		**10 ± 5.5**
Skip breakfast	17	38.6 ± 7.3*	5	7.6 ± 3.9	4	13.3 ± 6.2***
Eat sandwiches for breakfast	14	31.8 ± 6.7	27	40.9 ± 7.4**	4	13.3 ± 6.2
Eat hot meals for breakfast	13	29.7 ± 6.6*	34	51.6 ± 7.5	22	73.3 ± 8.1***
Do not eat lunch at school	2	4.54 ± 1.51	5	7.57 ± 3.98	0	-
Eat lunch in school cafeteria	19	43.2 ± 7.5	42	63.2 ± 7.3	20	66.7 ± 8.6
Buy food in school snack bar	21	47.7 ± 7.53*	15	22.7 ± 6.3**	2	6.7 ± 4.5*
Bring food from home	2	4.5 ± 1.5	4	6.1 ± 3.7**	8	26.6 ± 8.1*
Have an afternoon snack	23	52.3 ± 7.6*	55	83.0 ± 5.6	27	90.0 ± 5.5*
Eat dinner	43	92.7 ± 3.9	61	92.4 ± 3.9	30	100

Legend:

** – statistically significant difference (p < 0.05) between groups I and II;*

*** – statistically significant difference (p < 0.05) between group II and the control group;*

**** – statistically significant difference (p < 0.05) between group I and the control group.*

Results: The frequency of eating disorders (absence of breakfast or full lunch at school, reduced number of meals) in children with functional disorders is higher than in healthy children. In children with overlap syndrome, these disorders were detected statistically significantly more often than in children with isolated functional dyspepsia.

In children with functional disorders, the frequency of consumption of vegetables, cereals and cereal products is lower than in healthy children, and the consumption of meat, sausages and confectionery, fast food, chips, nuts, seeds, energy and sweet carbonated drinks, and fruit juices is

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. higher. In children with a combination of functional dyspepsia and irritable bowel syndrome, the frequency of consumption of vegetables, cereals, and grain products is lower, and the consumption of confectionery, fast food, energy and sweet carbonated drinks is higher than in children with functional dyspepsia.

We conducted an analysis of nutrition in children with a combined pathology of functional dyspepsia (FD) and irritable bowel syndrome (IBS) (see table below).

Conclusion: Violation of the regime and quality of nutrition is a risk factor for the formation of functional gastrointestinal disorders in children, which must be taken into account in treatment.

CLINICIAN KNOWLEDGE AND CONFIDENCE IN ADVISING ON FIBRE INTAKE: A CROSS-SECTIONAL SURVEY STUDY

E. Sultana[1], A. Chirapurath[1], E.V. Carrington[1,2]
[1]Translational Colorectal Research Laboratory, Department of Surgery and Cancer, London, United Kingdom, [2]Imperial College Healthcare NHS Trust, Department of Colorectal Surgery, London, United Kingdom

Contact E-Mail Address: emiko.sultana.8@gmail.com

Introduction: A well-established association exists between dietary fibre intake and overall health, with fibre recognised as a therapeutic intervention for a number of gastrointestinal disorders, including irritable bowel syndrome and chronic constipation.[1,2]

A diet rich in dietary fibre is endorsed by guidance from United European Gastroenterology and the European Society of Clinical Nutrition and Metabolism, however only 9% of the UK population consumes the recommended amount of 30g/day of fibre.[3-5]

Providing patients with clear and specific dietary recommendations is likely to enhance compliance, leading to improved health outcomes.[6] While doctors often provide generalised advice to patients to increase their fibre intake, little is known about their specific or detailed knowledge of fibre-rich foods and the methods they use to counsel patients on dietary modifications.

Aims & Methods: This study aimed to assess how well doctors identified food as high fibre sources, their confidence in providing fibre-related advice, and how frequently they engage in such discussions.

A cross-sectional survey targeting hospital doctors in the UK was conducted via a questionnaire in April 2025 using the Qualtrics platform. The survey captured demographic data, clinical practices, knowledge, and confidence levels in fibre-related counselling. All responses were anonymous. Participants were asked to rate the amount of dietary fibre in a representative selection of 8 foods from different food categories. Food was classified as high fibre (≥6g/100g), medium fibre (3-5g/100g), and low/no fibre food (<3g/100g). All nutritional information was obtained from the British Nutrition Foundation.[7]

Results: Seventy-one responses were collected, 1 was incomplete, leaving 70 for analysis. Most doctors worked in either gastrointestinal surgery (46%) or internal medical (41%) specialties. The largest group of respondents stated that they were required to provide dietary advice to patients at least each week (49%).

Many respondents could not identify that high fibre food sources such as bran flakes (49%) and wholemeal toast (56%) had more than 6g/100g of fibre. Some respondents also wrongly classified low/no fibre food to be high fibre sources (apple [30%], banana [29%], and salads [40%]). No respondent was able to correctly identify the correct fibre category for all 8 foods.

Sixty percent of respondents stated a lack of confidence in providing dietary advice regarding fibre intake to patients and 61% did not feel confident in altering a patient's daily fibre intake based on their clinical condition.

Conclusion: Many doctors cannot accurately categorise food which are high, medium and low/no fibre food sources. Most doctors do not feel confident in providing fibre advice to patients. This is likely to impact patient understanding and successful adherence to fibre rich diets. Easily accessible resources and dedicated teaching on fibre intake should be provided to doctors in allied specialties as this has the potential to improve patient care.

Introduction: Several metabolomic profiling studies have reported elevated endogenous erythritol and xylitol production in patients with conditions such as cardiovascular disease; however, the underlying cause of this upregulation remains unknown. In addition to their endogenous production in the human body, erythritol and xylitol are commonly used as sweeteners. A recently published pilot trial suggested that acute intake of these sweeteners may directly influence platelet aggregation and increase platelet responsiveness in short term (30 minutes post-administration). It is important to note that platelet responsiveness fluctuates under physiological conditions and may be influenced by external factors such as physical activity and nutrition.

Aims & Methods: We conducted a randomized, double-blind, placebo-controlled crossover trial to evaluate the effects of acute oral erythritol, xylitol, and water intake on platelet and endothelial activation as well as plasma erythritol and xylitol concentrations.

Eleven healthy, lean participates (mean ± SD; age: 26.4 ± 5.7 years, BMI: 21.5 ± 1.9 kg/m^2) were included in the trial. In a randomized crossover design, participants completed 3 different test sessions, receiving one of the following beverages per session: 50 g erythritol or 33.5 g xylitol dissolved in 300 mL water, or 300 mL water as control.

Blood samples were collected for the measurement of:

i. Platelet aggregation in response to TRAP6 10 µM *ex vivo* before and 60 min post-administration,

ii. Platelet (P-selectin) and endothelial (sVCAM-1) activation *in vivo* up to 180 minutes post-administration, and;

iii. Erythritol and xylitol concentrations up to 48 hours post-administration.

Results: The maximum adjusted platelet aggregation shows inter-individual and inter-visit variability. For erythritol, the fasting mean ± SD was 62.28 % ± 29.27 %, vs. 59.02 ± 28.82 % 60 min post-administration. For xylitol, the fasting mean ± SD was 78.17 ± 22.20 %, vs. 72.93 ± 26.20 % 60 min post-administration. For water, the fasting mean ± SD was 58.07 ± 28.2 %, vs. 57.45 ± 29.69 % 60 min post-administration. P-selectin and sVCAM-1 concentrations did not differ significantly between treatment conditions and showed no correlation with changes in platelet aggregation. Plasma erythritol concentrations peaked 60 min post-administration, remained slightly elevated for up to 48 hours, whereas plasma xylitol concentrations reached their peak at 30 min post-administration and returned to baseline within 24 hours.

Conclusion: Our results suggest that acute intake of erythritol or xylitol does not have a direct effect on platelet aggregation, P-selectin, or s-VCAM-1 concentrations.

Disclosure: Nothing to disclose.

AVOIDANT/RESTRICTIVE FOOD INTAKE DISORDER (ARFID) IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: IMPACT ON BODY COMPOSITION AND QUALITY OF LIFE

A. Spiller[1], B.G. Costa[1], R. Nunes Yoshio Yoshihara[1], E. Zucari Nogueira[2], N. Salvador Castelhano[1], G.S. Prates Herreira[1], D. Salate Biagioni Vulcano[1], L. Yukie Sassaki[1]
[1]São Paulo State University (Unesp), Pathophysiology In Clinical Medicine - Medical School, Botucatu, Brazil, [2]São Paulo State University, Institute of Biosciences, Botucatu, Brazil

Contact E-Mail Address: a.spiller@unesp.br

Introduction: Inflammatory bowel disease (IBD) is a significant risk factor for the development of Avoidant/Restrictive Food Intake Disorder (ARFID). ARFID is an eating disorder characterized by restrictive food intake, accompanied by at least one of the following: significant weight loss, nutritional deficiencies, dependence on enteral feeding or supplementation, or marked psychosocial impairment.

Aims & Methods: Objective: To assess the presence of ARFID and its impact on body composition and quality of life in patients with IBD. Methodology: This cross-sectional study included 105 outpatients diagnosed with IBD. The Nine Item ARFID Screen (NIAS) was used to assess ARFID symptoms, and quality of life was measured using the Inflammatory Bowel Disease Questionnaire (IBDQ). Body composition was evaluated through anthropometric measurements, bioelectrical impedance analysis, and handgrip strength testing.

Results: The study included 61 patients with ulcerative colitis and 44 with Crohn's disease, with a mean age of 41.5 ± 15.11 years; 70% were female, and the mean disease duration was 11.19 ± 7.58 years. Regarding disease activity, 27% had clinical activity and 45% had endoscopic activity. Overall, 23% of patients were classified as having ARFID symptoms, and 35% scored ARFID subtype 3, which is associated with gastrointestinal-related food avoidance. The mean BMI was 25.92 ± 5.18 kg/m^2, with 52.38% classified as overweight. The mean body fat percentage by skinfold measurement was 28.47 ± 7.5%, with 8% of individuals below average. Bioimpedance analysis showed that 86.41% had low muscle mass, and the mean handgrip strength was 27.37 ± 8.67 kgf, with 7% of participants having inadequate strength. The mean total IBDQ score was 141.29 ± 47.68 points. ARFID classification was associated with lower quality of life, as reflected by the total IBDQ score ($p = 0.0078$) and its gastrointestinal ($p = 0.0022$), systemic ($p = 0.0138$), and social ($p = 0.0194$) subdomains. It was also correlated with lower BMI ($p = 0.0206$) and lower body fat percentage ($p = 0.0045$). However, no correlation was found with muscle mass ($p = 0.2969$).

Conclusion: ARFID symptoms are common in patients with IBD, likely due to prolonged dietary restrictions during active disease and maintained during remission, potentially impacting both nutritional status and quality of life. Despite this, there is a scarcity of research on this topic, particularly among IBD patients. Further studies are needed to explore how the restriction of various food groups affects nutritional, psychosocial, and quality of life outcomes in this population.

TARGETED ANALYSIS OF VOLATILE METABOLITES FROM THE GUT MICROBIOME IN EXHALED BREATH

W. Arulvasan[1], J. Greenwood[1], M. Tardelli[1], O. Birch[1], S. Coplowe[1], S. Levett[1], H. Davies[1], F.J. van Schooten[2], B. Boyle[1], M. Allsworth[1]
[1]Owlstone Medical, Cambridge, United Kingdom, [2]Maastricht University, Faculty of Health, Medicine and Life Sciences, Pharmacology and Toxicology, Maastricht, Netherlands

Contact E-Mail Address: huw.davies@owlstone.co.uk
Introduction: Breath volatile organic compounds (VOCs) are promising non-invasive biomarkers for clinical purposes. In digestive health, gut microbiome VOCs enter the bloodstream and diffuse into exhaled breath, offering a real-time snapshot of gut activity and metabolism. Translating these biomarkers into clinical practice depends on precise identification and robust validation—challenges that require standardized protocols and data integration. Our previously developed breath collection and GC-MS analysis method identified 148 on-breath VOCs against ambient background that were catalogued into an Atlas using purified chemical standards. Building on this success, further method development was undertaken, with a focus on enhancing the detection of previously underrepresented compound classes.
Aims & Methods: Our aim was to create a high-resolution TD-GC-MS method using a PEG-phase column to detect and confidently identify gut microbial VOCs—fatty acyls, esters, phenols, indoles, and sulfones. By combining enhanced sample preparation and compound enrichment with rigorous spectral and retention-time matching, plus improved quality-control and identity-confirmation protocols, we could reliably assign chemical identities to candidate VOCs in breath samples.
Results: Using three metrics; standard deviation analysis, paired t-test, and ROC-AUC evaluation, we identified 621 VOCs as potential breath biomarkers, 223 of which met all three on-breath criteria. These tools effectively distinguished exhaled VOCs from ambient background, allowing us to select a focused subset for confident chemical identification.
Notably, over 25% of these are metabolites derived from the gut microbiome, and their detection offers mechanistic insights into microbial activity. Butyric acid, for example, serves as a crucial energy source for colonocytes and plays a key role in regulating intestinal inflammation.
Branched-chain fatty acids—including isobutyric acid, isovaleric acid, 2-methylbutyric acid, and 4-methylvaleric acid—are products of protein fermentation and have been associated with inflammatory responses. The phenolic compound p-cresol, linked to dysbiosis, may affect gut barrier integrity, while 2-methylindole, derived from altered tryptophan metabolism, has implications for immune modulation and gut homeostasis. Dimethyl sulfone, involved in sulphur metabolism, may contribute to inflammatory signalling. Alongside previously identified short-chain fatty acids such as acetic and propionic acid, these compounds represent a broad and functionally diverse profile of gut microbial metabolism. Their detection across all on-breath metrics supports their endogenous origin in exhaled breath.
Conclusion: The high-confidence identification of these gut-derived VOCs reinforces their potential as non-invasive biomarkers for monitoring gastrointestinal health. With the updated methodology, our Atlas now includes a total of 186 confirmed on-breath VOCs, paving the way for improved diagnostic breath tests tailored to gut health and disease.
Disclosure: No conflict of interest.

BEYOND THE BMI: A COMPREHENSIVE LOOK AT SARCOPENIA, MYOPENIA, AND MALNUTRITION IN POLISH PATIENTS WITH INFLAMMATORY BOWEL DISEASES

O. Kaczmarczyk[1], M. Olczyk[2], A. Dąbek[3], P. Zagrodzki[4], A. Piątek-Guziewicz[1], M. Zwolińska-Wcisło[1]

Contact E-Mail Address: okaczmarczyk@su.krakow.pl
Introduction: Inadequate nutritional status is a major complication of chronic gastrointestinal diseases such as Inflammatory Bowel Diseases (IBD), including two main types: Crohn's Disease (CD) and Ulcerative Colitis (UC) [1].
Previously, sarcopenia and myopenia were associated only with ageing, but they also affect patients with chronic diseases, including IBD, regardless of age [2].
Both malnutrition and sarcopenia lead to poorer health outcomes in IBD patients, increasing the risk of hospitalization, disease exacerbation, need for surgery and post-operative complications [3, 4].
Aims & Methods: The aim of this study was to assess the prevalence of sarcopenia, myopenia and malnutrition in Polish patients with IBD using clinical tools available in daily practice. A total of 91 IBD patients (48 CD, 43 UC), aged 18-65 years, with both inactive and active disease (30 and 61, respectively), were included in the study. Sarcopenia was assessed using the Strength, Assistance in walking, Rise from a chair, Climb stairs, and Falls (SARC-F) questionnaire and the 5-times sit-to-stand test, while myopenia was evaluated through the Fat-Free Mass Index (FFMI). Nutritional status was determined using BMI, the Nutritional Risk Screening (NRS-2002), biochemical parameters (albumin and ferritin levels), and body composition analysis.
Results: Malnutrition was identified in 22% of patients based on BMI (3 inactive, 17 active IBD) and in 31.9% based on NRS-2002 (1 inactive, 28 active IBD). Based on BMI, 25 patients (27.5%) were classified as excessive body weight, and 44% of these were in the active phase of the disease. Hypoalbuminemia and low ferritin levels were observed in 64% and 38.3% of participants, respectively. Sarcopenia was present in 24.3% of patients (SARC-F) and 17.6% (sit-to-stand test), while myopenia was detected in 36.7%. Sarcopenia and myopenia were more common during active disease phases. A significant association was found between regular physical

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

activity of patients and a reduced incidence of myopenia (OR = 0.24; 95% CI: 0.09 - 0.64) – compared to patients who did not declare such activity. It was observed that patients receiving biological therapy had a significantly lower prevalence of malnutrition according to the NRS - 2002 scale (OR = 0.33; 95% CI: 0.11 - 0.98).

Additionally, in this patient group, a trend toward a lower prevalence of sarcopenia, as assessed by the SARC - F questionnaire, was observed. No significant associations were found between the increased prevalence of either sarcopenia or myopenia and disease type, patient gender, or disease duration.

Conclusion: Our study shows that malnutrition and sarcopenia are prevalent in Polish IBD patients, necessitating comprehensive assessment tools. We demonstrated that reliance on BMI alone is insufficient. While BMI identified malnutrition in a lower percentage of patients, the use of additional parameters, such as the NRS - 2002 scale and biochemical markers, provided a more comprehensive assessment. Higher BMI values can obscure malnutrition by masking muscle loss and nutritional deficiencies, making standard BMI assessments insufficient.

In addition, we observed that biological therapy can have a beneficial effect on the nutritional status of IBD patients. We have shown that all of the methods we have presented for detecting malnutrition and sarcopenia can be successfully used in patients with IBD. However, further research is needed to identify the preferred method.

GLUTEN-INDUCED GASTRIC VISCERAL HYPERSENSITIVITY VIA SP-MEDIATED NEUROIMMUNE MECHANISMS: INSIGHTS FROM CLINICAL AND ANIMAL STUDIES IN FUNCTIONAL DYSPEPSIA

M. Kang[1,2], Y. Zhang[1], J. Jie[3], N. Dai[1]

[1]Sir Run Run Shaw Hospital, School of Medicine, Zhejiang Univeristy, Department of Gastroenterology, Hangzhou, China, [2]The First Affiliated Hospital, School of Medicine, Zhejiang University, Department of Gastroenterology, Hangzhou, China, [3]Wenzhou Central Hospital, Department of Gastroenterology, Wenzhou, China

Introduction: Gastric visceral hypersensitivity (VH) is a key pathophysiological feature of functional dyspepsia (FD), characterized by enhanced perception of gastric distension and postprandial pain. Recent studies suggest that dietary gluten may act as a pro-nociceptive factor in FD, particularly in individuals without celiac disease but with dyspeptic symptoms. However, mechanisms linking gluten to VH remain elusive.

Aims & Methods: In the clinical arm, multiple linear regression assessed associations between gluten intake and symptom frequency/severity (postprandial fullness, epigastric pain, early satiety), adjusting for age, sex, and BMI. In the experimental arm, Sprague-Dawley rats received either a 20% gluten diet or gluten-free diet for 8 weeks; an iodoacetamide-induced FD model served as a positive control. Gastric sensitivity was evaluated by abdominal withdrawal reflex (AWR) and electromyography (EMG) following surgical placement of a gastric balloon and electrodes. Duodenal and fecal samples were collected for 16S rRNA microbiota profiling and RNA-seq. Histological and molecular analyses included H&E staining, intraepithelial lymphocyte (IEL) counts, RT-qPCR of cytokines, and quantification of GFAP, Substance P, and MAPK components by RT-qPCR, Western blot, or immunofluorescence. Aprepitant (10 mg/kg/day) was administered during the final 2 weeks to assess its therapeutic effect.

Results: A total of 74 patients diagnosed with FD based on Rome IV criteria (EPS (epigastric pain syndrome)+PDS (postprandial distress syndrome): 29, EPS: 12, PDS: 33) and 29 healthy controls were included. FD patients, particularly EPS subtypes, exhibited significantly higher gluten intake than healthy controls ($P<0.001$). Multiple linear regression revealed that gluten intake was a significant positive predictor of symptom frequency and severity in FD patients (frequency: $\beta = 0.0407$, 95% CI: 0.0197–0.0617, $P<0.001$; severity: $\beta = 0.0230$, 95% CI: 0.0091–0.0368, $P<0.01$).

In rats, gastric sensitivity in the 20% gluten group was comparable to the iodoacetamide-induced FD model and significantly greater than the gluten-free control group, exhibited by slower weight gain, increased AWR score, higher area under the curve (AUC) of electromyograph and reduced 24-hour food intake. Compared to controls, gluten-fed rats showed reduced fecal abundance of Lactobacillus and Lactococcus, increased Lachnoclostridium, and decreased Lactococcus in duodenal mucosa. Duodenal tissues also exhibited elevated intraepithelial lymphocyte (IEL) counts, increased expression of IL-1β, IL-4, and IL-5, and upregulation of inflammation-related genes Reg1α and Reg3β, indicating low-grade mucosal inflammation. In addition, gluten exposure significantly increased duodenal expression of Substance P (SP), GFAP, and phosphorylated MAPK pathway proteins.

At week 8, rats in the gluten group were treated with either the NK1R antagonist aprepitant or saline. Aprepitant administration significantly attenuated VH, as shown by reduced AWR scores and EMG AUC compared with the gluten+saline group. Aprepitant also suppressed the expression of IL-1β, IL-4, Reg1α, Reg3β, and MAPK-related genes, suggesting a key role of SP-mediated neuroimmune activation in gluten-induced VH.

Conclusion: Long-term high gluten intake induces gastric hypersensitivity, accompanied by gut dysbiosis, mucosal inflammation, and SP-mediated MAPK signaling. Targeting neuroimmune pathways may offer novel therapeutic strategies for gluten-induced epigastric symptom management.

ULTRA-PROCESSED FOOD CONSUMPTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

A. Spiller[1], B.G. Costa[1], R. Nunes Yoshio Yoshihara[1], E. Zucari Nogueira[2], N. Salvador Castelhano[1], G.S. Prates Herreira[1], D. Salate Biagioni Vulcano[1], L. Yukie Sassaki[1]

Contact E-Mail Address: a.spiller@unesp.br

Introduction: Modern lifestyles have increased the demand for convenience and extended shelf life, contributing to the rising consumption of ultra-processed foods (UPFs). This trend has been linked to adverse health outcomes, including obesity and inflammatory bowel disease (IBD). IBD encompasses multifactorial digestive disorders characterized by disrupted intestinal homeostasis, resulting in immune dysregulation, impaired nutrient absorption, systemic inflammation, and a marked reduction in quality of life, often associated with chronic fatigue and decreased physical activity. These factors contribute to the activation of muscle protein catabolism and inhibition of skeletal muscle protein synthesis, increasing the risk of sarcopenia in IBD patients.

Aims & Methods: To evaluate ultra-processed food consumption and body composition in patients with IBD. A cross-sectional study was conducted with 105 patients diagnosed with Crohn's disease or ulcerative colitis at the IBD outpatient clinic of Hospital das Clínicas, Botucatu Medical School (HC-FMB). Assessments included handgrip strength using a dynamometer, bioelectrical impedance analysis, anthropometric measurements, and dietary intake evaluation using a food frequency questionnaire (FFQ).

Results: The sample included 61 patients with ulcerative colitis and 44 with Crohn's disease, with a mean age of 41.5 ± 15.1 years; 70% were female. Mean disease duration was 11.2 ± 7.6 years. The average BMI was 25.9 ± 5.2 kg/m^2, with 52.4% classified as overweight. Mean body fat percentage assessed by skinfold measurements was 28.5 ± 7.5%, with 85% exceeding the reference values.

Additionally, 18.3% were classified as malnourished based on mid-arm muscle circumference. According to bioelectrical impedance, 86.4% had low muscle mass. Mean handgrip strength was 27.4 ± 8.7 kgf, with 7% presenting inadequate values. Dietary data showed that 22% reported weekly fast food consumption, 30.5% consumed sweets, and 13% drank artificial juices daily. Daily intake of fruits and vegetables was reported by 48% of participants, and 36% reported daily meat consumption.

Conclusion: Patients with IBD are at increased risk of sarcopenia due to inflammatory burden and dietary restrictions. This study identified reduced muscle mass and high intake of certain processed and ultra-processed foods. Regular consumption of UPFs may worsen disease outcomes and negatively affect body composition by increasing fat mass and decreasing muscle mass.

Further analyses will explore associations between UPF intake and changes in body composition.

Introduction: To investigate the relationships between hand grip strength (HGS), physical activity levels, body composition and BMI in paediatric patients with cystic fibrosis (CF).

Aims & Methods: This single-centre prospective observational study measured hand grip strength (HGS) using a Jamar hydraulic dynamometer, body composition (using InBody 770) and lung function (FEV1) values. Physical activity was calculated using the Modified Godin Scale Score (GSS). Body weight, height and body mass index (BMI) were analysed as z-scores and HGS as percentiles standardised for age and sex. Linear regression was used to estimate relationships, with R^2 values indicating the strength of associations. Participants on CFTR modulators were compared with modulator-naïve individuals.

Results: The study included 82 children with CF (mean age: 12.4 ± 4.4 years). Out of these, 66 patients were receiving CFTR modulator therapy (39 LUM/IVA, 27 ETI).

No significant differences were found in any of the investigated parameters between those on CFTR modulator therapy and those not receiving it (Table 1). However, the modulator groups showed a trend for higher height, weight and BMI z-scores.

Based on their GSS, 95% of children were classified as active. Neither the HGS nor the GSS showed any correlation with BMI (R^2=0.044; 0.034), fat mass percentile (R^2< 0.001; 0.001) or skeletal muscle mass percentile (R^2=0.001; 0.006).

Similarly, the relationship between FEV1 and SMM was negligible (R^2=0.002). Both HGS and GSS showed weak positive correlations with FEV1 (R^2=0.121; 0.077) and with each other (R^2=0.115).

Contact E-Mail Address: Sahbani.feriel1995@gmail.com
Introduction: Various complications can occur in the course of digestive tuberculosis (DTB), such as intestinal obstruction, perforation, fistula formation, or gastrointestinal bleeding, all of which can significantly compromise patient prognosis.
Aims & Methods: The aim of our study was to identify factors associated with the development of these complications.
We conducted a retrospective analytical study including patients diagnosed with DTB over an eight-year period (2017–2024). Clinical, biological, and complication-related data were collected and analyzed.
Results: Ninety-six patients were included, with a mean age of 50.7 years (range: 19–90 years). The sex ratio (M/F) was 2. The diagnosis was confirmed primarily through histological analysis of peritoneal biopsies obtained via laparoscopy (52.1%), revealing epithelioid and multinucleated giant cell granulomas with caseating necrosis in 80% of cases. Additional diagnostic methods included the detection of *Mycobacterium tuberculosis* bacilli in ascitic fluid by direct microscopy (n=2), and molecular testing on colonic biopsies (n=2) or ascitic fluid (n=4).
Clinical outcomes were favorable in 87.5% of cases. Complications were observed in four patients (4.1%), including intestinal perforation (n=2), bowel obstruction (n=6), and death (n=2). One patient experienced early recurrence, and two others had persistent radiological findings despite adequate treatment (n=4).
Univariate analysis showed that severe malnutrition was significantly associated with the occurrence of complications (p=0.001).
Conclusion: Complications were observed in 4.2% of patients with DTB. Severe malnutrition was significantly linked to the development of these adverse outcomes, highlighting the critical importance of early and adequate nutritional support in the management of digestive tuberculosis.
Disclosure: Nothing to disclose.

DETERMINANTS AND INFLUENCE OF PHASE ANGLE AND ITS VARIATION IN HPN PATIENTS WITH INTESTINAL FAILURE

P. Caroli-Bosc[1], N. Barbier[1], E. Eyraud[1], L. Gilli[1], X. Hebuterne[1], S. Schneider[1]
[1]CHU de Nice - Archet, Gastroenterology and Clinical Nutrition, Nice, France

Contact E-Mail Address: stephane.schneider@univ-cotedazur.fr
Introduction: Phase angle (PA) is a composite measure that combines two raw measurements of bioelectrical impedance analysis (BIA): resistance and reactance. Phase angle is considered an indicator of cellular health, integrity and hydration. Its influence has been demonstrated in several chronic diseases with a threshold of 4°.
The aim of our study was to evaluate the determinants of PA and the consequences of low PA or a negative evolution in patients undergoing HPN for intestinal failure (IF).
Aims & Methods: 41 patients (35 F), aged 63±16 years (M±SD) were included. They had been on HPN for 70±83 months for IF (short bowel 58%, enteropathy 15%, dysmotility 10%, occlusion 10%, fistula 7%). They received 1095±693 kcal and 1229±919 mL of PN/hydration per day and oral intakes were 1205±693 kcal per day. 10% were on GLP-2 analogues. Their BMI was 21.7±4.4 (M±SD) (54% well nourished). Body composition and PA were assessed at baseline and after 4 months (6.9±3.0) by BIA (mBCA 515, seca, Semur-en-Auxois, France) and statistical analysis (Student's t, Pearson's r, ANOVA, χ^2) was performed on R++ (Toulouse, France).
Results: Lean and fat mass indices at inclusion were respectively 14.2±2.3 and 7.6±3.2 kg/m^2 respectively, and 13.7±3.2 and 7.9±3.1 at follow-up. PA was 3.9±0.8 and 3.8±0.7°, respectively at inclusion (PA≥4° in 63%) and at follow-up, with a delta PA of -0.2±0.8°. PA was negatively influenced by age (r=-0.52; p<0.0001) and positively by lean body mass index (r=0.46; p<0.01), with no influence from disease or its treatment. Similarly, a PA≥4 was negatively related to age (55±16 vs. 68±14 years; p<0.05) and positively to lean mass index (15.5±1.9 vs 13.4±2.2 kg/m^2; p<0.01). The evolution (delta) of PA was negatively influenced by the volumes and energy received at D0 (r=-25.3; p<0.0001) and positively by changes in lean body mass (r=0.7; p<0.0001). While no complications were associated with PA or PA<4 at inclusion, delta PA was associated with more central venous catheter-related infections (-1.0+0.6 vs -0.1+0.7; p<0.05) and more hospital days (r=-0.45: p<0.05).
Conclusion: In this IF population, the determinants of PA (age and lean body mass) are similar to those observed in other diseases. PA cannot predict the onset complications, and the link between its evolution and the occurrence of complications may be more a consequence than a cause. Notwithstanding a lack of power related to a small number of patients, monitoring PA in patients on HPN for IF does not appear useful.
Disclosure: Nothing to disclose.

ALIGNING PATIENT EXPECTATIONS AND PHYSICIAN PERSPECTIVES ON NUTRITIONAL TREATMENT IN CROHN'S DISEASE: OVERCOMING CHALLENGES AND ENHANCING OPPORTUNITIES FOR EEN THERAPY

R. Magen-Rimon[1], D. Mamet[2], M. Assaf[3,2], Z. Tal-Lashinsky[3,2], O. Libman[3], M. Waterman[3,2], H. Bar-Yoseph[3,2]

Contact E-Mail Address: haggaiby@gmail.com

Introduction: Exclusive enteral nutrition (EEN) is effective and commonly used to induce remission in pediatric Crohn's disease (CD). Nevertheless, the reasons for its low usage in adult patients are not fully understood. We aimed to identify the barriers to EEN use, evaluate the approaches of patients and physicians, and compare them.

Aims & Methods: An online questionnaire was sent to adult CD patients and gastroenterologists. The questionnaires included demographics, disease characteristics, education, previous EEN exposure, approach to EEN and approach to potential barriers (Likert scale of 1-5). Descriptive analysis was followed by comparative analysis of patients/physicians reluctant to use/provide EEN and those who were not reluctant. Logistic regression was applied to search for variables and potential barriers associated with EEN-reluctance. An association network was generated to visualize how different barriers contribute to reluctance to trying EEN.

Results: Three-hundred and fifteen CD patients and 42 physicians completed the questionnaire. The mean age was 36.7 (SD±16) with a median disease duration of 10 (range 0-60) years. Previous EEN use was reported by 40% (n=101), while EEN-reluctance was reported by 20.3% (n=64). No significant baseline variables were found to be associated with EEN reluctance in univariate and multivariate analyses, except for current advanced treatment (biologic/small molecules) use (OR 2.06 [95%CI 1.05-4.35]). Among physicians, 71% had previously prescribed EEN to a patient, while 81% were willing to prescribe EEN. Knowledge of remission rates in adult patients using EEN varied widely. The indication for EEN use varied from mild-moderate disease (41% of respondents) to complicated disease (38% for penetrating disease, 55.9% for severe disease, 52.9% for structuring and 55.9% for malnourished patients). Previous EEN prescription was associated with willingness for future EEN recommendation (OR 4.66 [95%CI 1.11-19.54]). Top-ranked barriers perceived by patients were lack of food variety (65% with scored 4-5), lack of meal-associated social interaction (59% with scored 4-5) and treatment duration (49% scored 4-5). The respondents were less concerned about potential complications (14.6% scored 4-5), treatment-related diarrhea/pain (25.1% scored 4-5) and the notion that the formula is dairy-sourced (29.2% scored 4-5). For physicians, lack of food-associated social interaction (67.3% scored 4-5) and concern about taste (54.7% scored 4-5) were ranked highest among the perceived patient barriers.

Overall, the physicians' perspectives largely aligned with those of the patients. However, we found that 'lack of food variety' and 'hunger concerns' were barriers scored significantly higher by patients than physicians (p<0.05 for both). Network analysis revealed the top three patient barriers associated with EEN reluctance were 'food variety', 'treatment duration' and 'fear of liquid only diet', which were correlated with each other. Supportive factors that could facilitate EEN use were: direct communication with a staff member (68.6% scored 4-5) full funding of the formula (65% scored 4-5), family support (59.7% scored 4-5) and talking with other patients that are EEN experienced (52% scored 4-5). Overall, 47% of the respondents expressed a desire to hear more about EEN, and 87.6% preferred to receive information about EEN from their physician.

Conclusion: Most patients with CD are open to discussing EEN and wish to discuss it with their physicians. Potential barriers to address are the tactile and social eating experience as well as the length of therapy.

Disclosure: Nothing to disclose.

PP0343

OUTPATIENT PERCUTANEOUS ENDOSCOPIC GASTROSTOMY BY PULL (GAUDERER-PONSKY) AND INTRODUCTION (RUSSELL) METHODS IN HEAD AND NECK CANCER PATIENTS: A RANDOMIZED CLINICAL TRIAL

S. Andreola Borba[1], C.C. Fabris[1], N. Ribeiro Cantudo de Souza[1], H. Coelho Stumpf[1], T. Pontes[1], U. Kaize Barbosa[1], J.G. Magalhães Bertazo Silveira[1], A. Costa Coimbra[1], E. Magalhães Carvalho[1], M. Dodsworth de Barros[1], A. Iachan[1], F. Alves Mota Rebello de Mendonça[1], S. Guaraldi[1], M. Ferreira[2], G.F. De Souza e Mello[1]

Contact E-Mail Address: gastrosophiaborba@gmail.com

Introduction: The comparison of different percutaneous endoscopic gastrostomy (PEG) techniques shows that all are equivalent in terms of safety and success rate. Several authors suggest the method of introduction is associated with lower infection rate than the pull method, because there is no transoral passage of the tube. In the case of patients with head and neck cancer (HNC) it also reduces the risk of metastatic implantation to the puncture site. Despite these considerations, the literature is conflicting when comparing the results. There are only few studies about PEG as an ambulatory procedure in HNC outpatients.

Aims & Methods: The main objective is to compare pull and introduction techniques of PEG in HNC patients on an outpatient basis, regarding success rate, overall complication rate, infection rate and total duration of procedure.

The present study is a randomized clinical trial, with a follow-up period of 6 months. Among the adult HNC patients refered to PEG at Cancer Hospital I, of the Brazilian National Cancer Institute (HC I / INCA), subjects in good clinical condition were selected to outpatient PEG tube placement by pull or introduction techniques. Primary endpoints were success rate, complications rate and total PEG procedure time. Secondary endpoints were mortality, elective tube removal and PEG tube in use rates at the end of the study. All patients received 20Fr PEG tubes. Statistical analysis was performed using the Student t test and the Chi-squared test, when appropriate. P values were considered significant when <0.05.

Results: From May 2013 to April 2015, a total of 60 HNC outpatients (48 men and 12 women) underwent ambulatory PEG by pull or introducer technique (30 on each arm). The success rate was 100% for both techniques. There was no significant difference between the groups in relation to gender distribution, age, comorbidities and associated conditions (previous use of enteral tubes, trismus, previous abdominal surgery), type and tumor localization, staging and treatment. There was no significant difference in the procedure complication rate between the pull and introduction techniques (70% x 76.7%, P=0.771).

Regarding the time of occurrence, the traction technique showed a lower rate of immediate complications (0% x 23.3%, P=0.011), but no difference between early (10% x 6.7%, P=0.999) or late complications (70% x 63.3%, P=0.785).

Regarding the severity, there were no significant differences between pull and introduction techniques to major (3.3% for both, P=0.999) or minor complications (70% x 76.7%, P=0.711). There was no significant difference

in mortality between groups (36.7% vs 43.3%, P=0.792). The average duration of the procedure by pull technique was 17.60 minutes versus 32.13 minutes for the introduction technique (P<0.001).

Conclusion: The comparison between the two techniques showed no significant difference in the rate and type of complications, but the introduction technique had a longer duration of procedure time. The placement of a PEG tube by the two techniques is a safe and viable procedure on an outpatient basis.

DIRECT PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY VERSUS PERCUTANEOUS ENDOSCOPIC GASTROSTOMY WITH JEJUNAL EXTENSION: QUALITY OF LIFE AND COMPLICATIONS

G. van Neerven[1], E. Gilissen[1], R. Gielen[1], A. Baars[1], B. Stelten[2], H. Flink[1], L. Gilissen[1]

[1]Catharina Hospital Eindhoven, Department of Gastroenterology and Hepatology, Eindhoven, Netherlands, [2]Catharina Hospital Eindhoven, Department of Neurology, Eindhoven, Netherlands

Introduction: Jejunal feeding and medication such as levodopa-carbidopa intestinal gel for Parkinson's disease can be administered via percutaneous endoscopic gastrostomy with jejunal extension (PEG-J) and direct percutaneous endoscopic jejunostomy (D-PEJ). PEG-J is currently common practice because technically less difficult to insert, but comparative studies are scarce. Also, data on patient related outcomes are lacking.

Aims & Methods: Our aim was to examine patient experiences and adverse events (AE) in a retrospective study, conducted in a referral hospital. Clinical experience and patient related outcomes were analysed. Ninety-six patients had received either PEG-J or D-PEJ between January 1. 2010 to July 1. 2022. Forty-five patients answered a questionnaire including the EQ-5D-5L and questions regarding their experiences.

Results: No statistical differences were found in Quality of Life. Patients with PEG-J underwent significantly more re-endoscopies per tube-year compared to D-PEJ patients (0.63 (SD 0.72) versus 0.27 (SD; 0.50)). PEG-J patients received at least one re-endoscopy in 76.8% (range 0-3.85 per year), of which 77.4% because of dislocation of the jejunal extension. Tube related adverse events (including dislocation, occlusion, perforation and ulceration) occurred significantly more after PEG-J insertion (76.7% versus 25.9%). However, D-PEJ patients reported significantly more tube related pain (44.4% versus 15.9%).

Conclusion: In conclusion, D-PEJ is an interesting alternative for PEG-J. D-PEJ should at least be considered in patients with frequent problems with the jejunal extension of their PEG-J.

Disclosure: Nothing to disclose.

EVALUATION OF SURVIVAL OUTCOMES IN PATIENTS RECEIVING PALLIATIVE HOME PARENTERAL NUTRITION: RESULTS FROM A UK TERTIARY REFERRAL CENTRE

K. Fan[1,2], P. Patel[1], R. Maddison[1], E. McKenzie[1], N. Wilson[1], D. Massey[1], J. Woodward[1], C. Rutter[1]

Introduction: Intestinal failure in advanced malignancy often results from mechanical bowel obstruction, post-surgical complications, or mucosal diseases. Palliative home parenteral nutrition (HPN) can potentially improve survival and quality of life (QoL). However, there is limited robust data on which factors may predict optimum survival, and its use remains contentious. This study aimed to assess the survival of patients receiving palliative HPN and to examine the impact of patient factors on survival outcomes.

Aims & Methods: This is a single-centre retrospective observational study of 84 patients referred for palliative HPN from the period of 1st January 2020 to 19th November 2024. Demographic, nutritional and medical data were analysed. Survival rates were compared using Kaplan-Meier curves and Cox regression.

Results: A total of 84 patients were referred for palliative HPN during the study period and 77 patients were discharged with HPN eventually [median age was 60 yr, (IQR: 51.3-70.4), female 77%]. Underlying primary malignancies of gynaecological and gastrointestinal origin predominated accounting for 78% of the study cohort. Majority of patients had metastatic disease at 95%. Mechanical bowel obstruction was the main indication for HPN (84%). Performance status (PS) scores were ≤ 2 in 88% of patients and 49% had an estimated prognosis of >3 months. The median serum albumin and C-reactive protein (CRP) was 26g/L and 21 mg/L respectively. Median overall survival was 58 days (IQR 31 – 108) with a 3-month mortality of 69%. There was no statistical difference in overall survival when evaluate by PS, estimated prognosis, underlying malignancy or modified Glasgow prognostic score (mGPS).

Conclusion: The overall survival in our study is modest. PS scores, estimated prognosis, mGPS, or tumour type did not show a significant impact on survival. This highlights the challenges in artificial nutrition and emphasizes the role of a multidisciplinary team in the care of these patients.

COMPLICATIONS OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY AS AN AMBULATORY PROCEDURE IN HEAD AND NECK CANCER OUTPATIENTS - A PROSPECTIVE LONG-TERM FOLLOW-UP STUDY

S. Andreola Borba[1], J.G. Magalhães Bertazo Silveira[1], T. Pontes[1], U. Kaize Barbosa Pimentel[1], A. Coimbra[1], E. Magalhães Carvalho[1], H. Coelho Stumpf[1], N. Ribeiro Cantudo de Souza[1], C.C. Fabris[1], M. Dodsworth de Barros[1], F. Alves Mota Rebello de Mendonça[1], A. Iachan[1], S. Guaraldi[1], M. Ferreira[1], G.F. De Souza e Mello[1]

Introduction: Percutaneous endoscopic gastrostomy (PEG) is a relatively simple and safe therapeutic method of providing enteral access for patients with dysphagia and intact gastrointestinal (GI) tract.
However, it is also associated with several complications, as well as a high morbimortality rate. The use of PEG as an ambulatory procedure in head and neck cancer (HNC) outpatients has not been well established in the literature so far.

Aims & Methods: The main objective of this study was to investigate the short and long-term complications of ambulatory PEG in a selected group of HNC outpatients. We performed a prospective clinical study involving HNC subjects who were in good clinical condition. Patients were included from September 2002 to December 2009 in a close long-term follow-up protocol of outpatient PEG by the pull technique.

Results: A total of 201 patients who underwent ambulatory PEG were included in the present study: 58 (28.9%) pretreatment, 48 (23.9%) during treatment and 95 (47.5%) after treatment for the underlying malignant disease. There was no procedure-related mortality. There were complications in 55.7% of patients in the long-term follow-up (16.9% early and 49.8% late, 6.5% major and 55.2% minor). The complications were: granulation tissue (43.3%), periostomal infection (11.4%), leakage (9%), BBS (6%), local pain (5.5%), persistent gastrocutaneous fistula (3.6%), gastric wall hematoma (3.5%), late tube dislodgement (3%), early tube dislodgement (0.5%), and respiratory failure (2.2%). The clinical-demographic variables (age, sex and timing of PEG) were not associated with significant statistical difference for complication rates (early or late, major or minor).

Conclusion: Ambulatory PEG is a viable and safe procedure in HNC outpatients who are in good clinical condition. Although PEG complication rates may be significant in the long-term follow-up, in most cases these complications are classified as minor. There were no deaths related to the procedure itself, and all complications were treated in an outpatient setting.

PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) IN PEDIATRIC CANCER PATIENTS: EFFICACY AND SAFETY ANALYSIS FROM A RETROSPECTIVE COHORT

S. Andreola Borba[1], T. Pontes[1], U. Kaize Barbosa Pimentel[1], J.G. Magalhães Bertazo Silveira[1], E. Magalhães Carvalho[1], A. Costa Coimbra[1], C.C. Fabris[1], N. Ribeiro Cantudo de Souza[1], H. Introduction: PEG is a procedure designed to provide prolonged nutritional access for patients who present an intact and/or functional gastrointestinal, but with difficulty or inability to swallow. In pediatric oncology services, PEG is most frequently indicated for children with central nervous system (CNS) tumors and head and neck cancers. While it is well established in clinical practice as an effective and safe method for obtaining enteral access, few studies specifically address the performance of PEG in children with cancer.

Aims & Methods: The main objective of this study is to describe demographic aspects, underlying pathologies, complications, and outcomes of patients who underwent PEG due to cancer. The present study consists in a retrospective cohort of PEG procedures performed in children with any neoplastic diseases that justified a PEG insertion, during the period of October 2000 and January 2018 at the Digestive Endoscopy Unit of the Cancer Hospital I of the Brazilian National Cancer Institute (INCA). Data collection included demographic and pathology baseline information, as well as details regarding post-PEG follow-up and complications. Data extraction was conducted with Excel with further descriptive analyses.

Results: During the study period, a total of 97 children who underwent PEG were included in the study. The mean age was 10.1 years (range: 0.5 to 18.9 years), and fifty-six children (57.7%) were male.
The underlying oncological pathologies included 69 cases (71.1%) of neurological tumors, 23 cases (23.7%) of head and neck tumors, 4 cases (4.1%) of hematological malignancies and 1 case of adrenal cortex carcinoma (1%). Fifty-eight patients (59.7%) experienced complications, including granulation tissue formation in 25 cases (25.7%), stoma infection in 6 (8.1%), local pain in 21 (21.6%), bleeding in 3 (3.1%), accidental tube dislodgement in 4 (4.1%), and gastrocolocutaneous fistula in 2 (2.0%). The mean duration of tube placement was 22.1 weeks (range: 0.4 to 483 weeks).
At the end of the study, 62 patients had died from their oncological disease (63.9%), 15 patients continued using the tube (15.4%), and 20 patients had the tube removed after completing treatment (20.6%). No cases were lost to follow-up.

Conclusion: PEG is a safe and effective procedure for providing prolonged enteral nutritional access in children with neoplastic disease. Complications are generally classified as minor, and typically do not require invasive treatments.

RETROSPECTIVE MONOCENTRIC ANALYSIS OF PICC LINES PLACED IN A TERTIARY CARE CENTER TO ESTABLISH A FORMULA FOR DETERMINING IDEAL PICC LINE LENGTH

H.-P. Erasmus[1], K. Stratmann[1], F.A. Michael[1], L. Hofbauer[1], D. Hessz[1], S. Zeuzem[1], M. Friedrich-Rust[1], I. Blumenstein[1]
[1]Goethe University Hospital Frankfurt, Medical Clinic 1, Frankfurt am Main, Germany

Contact E-Mail Address: hansperasmus@gmail.com
Introduction: The peripherally inserted central venous catheter (PICC line) is a highly useful form of vascular access in various areas of clinical patient care. It is particularly indicated in patients requiring long-term antibiotic therapy, medium-term parenteral nutrition, extended intravenous treatment during prolonged hospital stays, or those with poor venous access. PICC lines are typically 60 cm in length and must be individually trimmed to the correct length immediately before insertion. Several approaches exist for estimating the appropriate length on a case-by-case basis.
Aims & Methods: To establish a methodology for accurately estimating the required length of PICC lines.
Between November 2023 and April 2025, various body measurements were collected during PICC line placements. The depth of the selected vein was measured sonographically. Patients' height, weight, and sex were documented. The PICC line length was determined based on clinical expertise. A post-insertion chest X-ray was performed to confirm the central position of the catheter tip. The distance from the catheter tip to the carina was measured to objectively define central placement. Multiple formulas in clinical use were compared for their accuracy. A regression analysis was conducted to develop a formula that is both accurate and simple to apply.
Results: A total of 60 PICC lines were successfully inserted without complications. The median patient height was 168 cm (range: 164.3–175.8 cm), weight 59 kg (range: 50.0–83.8 kg), and age 56.5 years (range: 46–65.8). Thirty-five insertions were performed in female patients. The ideal PICC line length was 42 cm (range: 38–44.5 cm). Of the five tested formulas, the best correlations were found with Formula 5 (puncture site to jugulum + jugulum to 3rd intercostal space) with r = 0.68 (p = 0.0005), and Formula 3 (puncture site to acromion + clavicle length + jugulum to 4th intercostal space) with r = 0.67 (p = 0.0005). In simple linear regression, the distances from puncture site to acromion and to jugulum were significantly correlated (p = 0.0007 and p = 0.0019, respectively). The best-fit model in multiple regression included age, height, weight, arm side, puncture site to jugulum, and puncture site to 4th intercostal space (p = 0.0005).

Model	R^2	Success Rate (±2cm)	Success Rate (±3cm)	Success Rate (±4cm)
Formula 1	0.16	31.25%	50.00%	65.63%
Formula 2	0.56	18.75%	37.50%	53.13%
Formula 3	0.53	18.75%	25.00%	28.13%
Formula 4	0.42	0.00%	0.00%	0.00%
Formula 5	0.61	40.63%	59.38%	68.75%
New Formula	0.83	62.50%	90.63%	96.88%

Table 1: comparison between the various existing formulas and the newly developed one.

Conclusion: An optimal formula for calculating the correct PICC line length has been identified.
Disclosure: Nothing to disclose.

LONG TERM ENDOSCOPIC GASTROSTOMY ENTERAL FEEDING OF NEUROSURGICAL PATIENTS: A REFERENCE CENTER'S EXPERIENCE

C. Palma[1], I. Mendes[1], F. Vara-Luiz[1], G. Nunes[2], I. Mocanu[1], M. Patita[1], T.M. Meira Carvalho[1], P. Pinto Marques[1], J. Fonseca[1]
[1]Hospital Garcia de Orta, Gastroenterology, Almada, Portugal, [2]Hospital Garcia de Orta, Gastroenterology, Lisbon, Portugal

Contact E-Mail Address: franciscovaraluiz@gmail.com
Introduction: Neurosurgical patients often face several difficulties with nutritional support due to severe brain injury, neurological disease, or post-surgical complications. This study aimed to assess the outcomes of long-term enteral nutrition via percutaneous endoscopic gastrostomy (PEG) in this population.
Aims & Methods: Single center, retrospective analysis of patients who were referred for PEG from 2001 to 2023. Patients who presented with severe traumatic brain injury (TBI), hemorrhagic stroke, brain tumor or other conditions that required neurosurgery were selected. Demographic, anthropometric and clinical data were recorded.
Results: 196 patients were included, 57% were younger than 65 years. Stroke (41.8%), TBI (35.2%) and brain tumors (19.9%) were the most frequent conditions. The median time from diagnosis to PEG was 94 days. At the time of PEG procedure, only 38.5% were underweight. 21 patients were lost to follow up. Among the remaining, 75.4% died, 12.6% were alive and PEG-fed, and 12% had the tube removed. Of the surviving patients who remained PEG-fed, the majority (77%) were stroke patients. Median overall survival post-PEG was 11.5 months, with 88% of patients surviving more than one month. Albumin, transferrin, and total cholesterol levels at the time of PEG were associated with longer survival. Albumin ($p<0.001$) and transferrin ($p<0.01$) were significantly associated with lower short-term mortality risk.
Conclusion: PEG is an effective method for long-term enteral nutrition in neurosurgical patients. Although survival is limited, reflecting the severity of the underlying conditions, the majority of patients survived beyond one month, supporting the adequacy of the procedure. Higher serum albumin levels were associated with longer survival, suggesting its potential role as a prognostic biomarker in this population. Careful patient selection, timely intervention, and consideration of nutritional status may help optimize outcomes for neurosurgical patients requiring PEG.
Disclosure: Nothing to disclose.

Introduction: Percutaneous endoscopic gastrostomy (PEG) is the standard method for providing long-term enteral nutrition and medication in patients with insufficient oral intake. However, data on the technical aspects of the procedure, adherence to published guidelines, and the decision-making process of endoscopists remain limited in certain countries.

Aims & Methods: The primary aim of this nationwide study was to assess the current practices among Greek gastroenterologists regarding PEG procedure, covering the entire spectrum of PEG, including initial clinical decision-making, technical aspects, periprocedural management, and long-term patient care. An anonymous web-based survey was distributed to every member of the Hellenic Society of Gastroenterology (HSG), including gastroenterology trainees. Participants electronically completed a 36-item questionnaire divided into five sections:

1. Demographics and professional background,
2. General questions on PEG placement,
3. Specific procedural aspects,
4. Post-procedural management, and
5. Future perspectives.

Data analysis was performed using Stata statistical software, version 17.0 (StataCorp LLC, College Station, TX, USA).

Results: A total of 127 out of 766 members of the HSG responded (response rate: 16.5%). Regarding PEG placement, 66.7% reported involvement in up to two procedures per week. Multidisciplinary team meetings were rarely implemented, with 82.0% stating they "rarely" or "never" participate in such meetings. Neurological disorders were the leading indication for PEG (67.7%), followed by dementia (18.1%) and obstructive head, neck, or esophageal malignancies (11.8%).

The primary indications differed significantly between the public and private sectors (P = 0.007), with neurological disorders being more frequently reported in the private sector (40.5% vs 26.1%), while obstructive tumors were less commonly cited as the main indication for PEG placement (1.6% vs 10.3%). The push-PEG technique in malignancy cases was used by 31.7% of respondents, whereas direct percutaneous endoscopic jejunostomy (D-PEJ) and percutaneous endoscopic gastrojejunostomy (PEG-J) were employed in 11.9% and 37.8%, respectively. Skin antisepsis and use of sterile instruments were consistently reported by 93.7% and 89.0% of the participants, while prophylactic antibiotics and surgical hand washing were routine for 58.3% and 45.7% of them. Regarding the reported incidence of serious adverse events, 17.3% of respondents had encountered at least one case of perforation or peritonitis, 12.6% reported severe bleeding, and 7.9% had experienced a PEG-related death.

No statistically significant association was observed between the occurrence of adverse events and the variables age, years post specialization, trainee status, healthcare sector (public vs private), annual number of PEG procedures, or routine use of prophylactic antibiotics. After discharge, structured follow-up programs were reported by 15.1%, while 31.5% indicated that nutritional guidance was provided by a dedicated nutrition department.

Conclusion: This nationwide survey is the first to explore clinical practices related to PEG placement among gastroenterologists in Greece. The findings highlight areas of alignment with international standards, but also reveal important deviations, particularly in multidisciplinary collaboration, infection prevention measures, and postprocedural care. These results provide a valuable foundation for targeted training agendas and quality improvement initiatives.

Introduction: Exclusive enteral nutrition (EEN) is a well-established first-line treatment for inducing remission in paediatric Crohn's disease, however, its use in adult Crohn's disease treatment remains limited. In adults, 22% of patients require surgery within the first five years after diagnosis[1], with postoperative complication rates reaching around 25%[2].

This study investigates whether preoperative EEN can reduce postoperative complications in adults with Crohn's disease undergoing elective surgery.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: A systematic search was conducted on October 26, 2024, across three databases: PubMed, EMBASE, and the Cochrane Library. Studies were included if they involved at least two weeks of preoperative EEN and reported postoperative outcomes.
The primary outcomes were anastomotic leakage, stoma formation, and abscess formation, while the secondary outcome was the length of hospital stay. The odds ratio (OR) and mean differences (MD) with their 95% confidence interval (CI) were calculated using a random-effect model.
Results: A total of 11 studies, including 2112 patients, were included in the analysis. EEN significantly reduced the odds of anastomotic leakage (OR=0.29, CI: 0.19-0.47), stoma formation (OR=0.39, CI: 0.09-1.73), and abscess formation (OR=0.41, CI: 0.23-0.72). However, there was no significant reduction in the length of hospital stay (MD: 0.88 days, CI: -1.85-0.09).
Conclusion: Preoperative EEN significantly reduces the risk of anastomotic leakage, stoma formation, and abscess formation, leading to improved postoperative outcomes. These findings support adding EEN into preoperative management for adult Crohn's disease patients undergoing elective surgery to enhance recovery and minimize complications.

Introduction: People with cancer commonly suffer from loss of appetite which leads to unintended weight and muscle loss, and reduced quality of life. Effective nutrition therapy therefore requires recipes with reliable calorie and macronutrient values. Manual calculation by professionals is time- and resource-intensive. Thus, Large language models (LLMs) could automate this task if their accuracy is sufficient.
Aims & Methods: To evaluate whether an LLM can automatically estimate calories and macronutrients (carbohydrates, protein, fat, fibre) in recipes, we compared their results with manual calculations by dietitians.
125 recipes from the platform was-essen-bei-krebs.de, were used as reference values per 100 g for calories and macronutrients as they were manually calculated by registered dietitians. ChatGPT o1 was prompted with a purpose-built instruction to estimate macronutrients for each ingredient and aggregate totals. The same prompt was repeated five times per recipe. Absolute error (AE) was defined as |estimate - reference| and normalized per 100 g. In line with EU labelling guidelines for packaged foods, an error ≤ 20 % was predefined as acceptable. The primary endpoint was the number of estimates classified as acceptable across all categories.
Results: The LLM returned well formatted outputs for all 625 prompts covering the 125 cancer-oriented recipes. For calorie estimates, 74.3 % fell within the ± 20 % interval. Protein was acceptable in 64.2 %, carbohydrates in 50.4 %, and fat in 58.1 % of cases. The mean absolute error for calories was 20.5 kcal per 100 g.
Conclusion: Preliminary data indicate that ChatGPT o1 can already deliver high-quality nutrient estimates. LLMs therefore have the potential to automate the nutrient calculations that are still performed manually today.

ACTIVATED NOTCH SIGNALING PATHWAY PROTECTS THE INTESTINAL BARRIER IN DSS-INDUCED COLITIS BY REGULATING TIGHT JUNCTIONS

L. Tingting[1,2], S. Shuailing[2,3], C. Geng[2], C. Wang[2]

Introduction: Emerging evidence implicates Notch signaling in intestinal mucosal barrier preservation, though its mechanistic basis remains undefined.

Aims & Methods: This study investigates the molecular interplay between Notch activation and tight junction (TJ) regulation during inflammatory injury. In vivo experiments, the dextran sulfate sodium (DSS)-induced colitis mice were used and LY411,575, a γ-secretase inhibitor, was orally administered for Notch signaling inhibition. In vitro experiments, we modulated Notch signaling by either activating or inhibiting it through the overexpression of Hes1 or LY411,575, respectively. The tight junction (TJ) and relevant myosin light chain kinase (MLCK) pathway were systematically investigated. To elucidate the mechanism underlying Notch activation, we conducted a comprehensive analysis of ligands and receptors associated with the Notch pathway in Caco-2 cells.

Results: Compared to DSS-colitis mice, inhibition of Notch activation by LY411,575 led to severe exacerbation of colitis, accompanied by TJ deterioration and concurrent activation of MLCK pathway. In vitro experiments confirmed the Notch signaling's regulatory effect on TJ function, with MLCK inhibitor ML-7 effectively mitigating the TJ dysfunction induced by LY411,575. Additionally, TNF-α-treated Caco-2 cells exhibited significantly increased expression of Jag1, Notch1, and Hes1. Silencing Jag1 using siRNA resulted in reduced NICD1 and Hes1 expression.

Conclusion: Activation of Jag1/Notch1/Hes1 signaling pathway protects the intestinal mucosal barrier from inflammatory injury by abrogating MLCK-dependent TJ dysregulation. Therapeutic Notch activation may represent a novel strategy for mucosal protection in IBD pathogenesis.

ROLE OF TUMOR NECROSIS FACTOR ALPHA AND VITAMIN D IN ACTIVITY AND SEVERITY OF INFLAMMATORY BOWEL DISEASE IN EGYPTIAN PATIENTS

M. Abdelmonaem[1], A. Mokhtar[1]
[1]Menoufia University, Faculty of Medicine, Internal Medicine Department, Gastroenterology and Hepatology, Menoufia, Egypt

Contact E-Mail Address: m7md_abdelmonaem@yahoo.com

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are two chronic, gastrointestinal tract disorders that are included in the category of inflammatory bowel diseases (IBD). A combination of imaging results, endoscopic biopsies, inflammatory laboratory markers, and clinical symptoms are required to diagnose IBD. Patients with CD suffer from vitamin D insufficiency than UC patients do, and they often have lower levels than the general population.

Aims & Methods: The goal of this research is to clarify the role of vit. D in activity and severity of IBD in Egyptian people.

Between November 2021 and November 2023, we recruited 31 normal individuals (IBS patients and volunteers) and 92 IBD (UC and CD) naïve patients from the internal medicine department of Menoufia University Hospital, GI endoscopy unit. Every participant underwent a clinical examination, a history taking, and standard laboratory testing. Vit. D serum levels were also tested.

Results: This study revealed a highly significant difference in serum vit. D levels across the groups under investigation, with low vit. D levels in individuals with IBD. There was discernible correlation between the plasma vit. D level and disease activity, also we found a highly significant difference in plasma TNF alpha levels among the 3 groups, with significant difference in disease activity and plasma TNF alpha levels.

Conclusion: From this study we concluded that; TNF alpha plays a role in the pathogenesis of IBD with significant difference with the disease activity. Also decrease of vit. D level may play a role in the pathogenesis of IBD with significant relation with the disease activity and vit. D supplementation may help IBD patients.

Introduction: Ulcerative colitis (UC) treatment aims for mucosal healing as a therapeutic goal. However, in some cases, especially in the rectal mucosa, healing cannot be achieved. Moreover, the reason why the rectum is the predilection site of UC remains unknown. In this study, we hypothesized that differences in intestinal epithelial cells (IECs) in the rectum and ascending colon play an important role in the pathogenesis of UC, which may lead to the different treatment responses in the rectum and colon. Therefore, we focused on the differences in gene expression in IECs between the rectum (as the lesion site) and the ascending colon (as the non-lesion site) in UC patients.

Aims & Methods: Colorectal organoids were established from lesional and non-lesional sections of total colectomy specimens from UC patients and cultured under non-inflammatory conditions. We then performed microarray analysis on these organoids and identified genes potentially associated with UC pathology. The expression of candidate genes was validated by q-PCR in lesional and non-lesional areas of surgical specimens from UC patients. To further investigate the role of the selected gene, we knocked down (KD) PITX2 in organoids derived from the ascending colon of a healthy individual using a lentiviral system. These organoids were exposed to TNF-α (100ng/ml), IL-1β (10ng/ml), Flagellin (100ng/ml) for one week, following a previously established human IBD in vitro model(J Crohns Colitis. 2021,2022). We assessed the inflammatory response by measuring the expression of IL-8 and DUOXA2, downstream genes of NF-κB, using qPCR. In addition, fluorescent immunostaining for NF-kB p65 was performed, and the nuclear-to-cytoplasmic fluorescence intensity ratio of p65 was analyzed using ImageJ software. Cell proliferation was evaluated using the CellTiter-Glo® assay. Stem cell function was assessed by sphere formation assay, and apoptosis was analyzed by Western blot for caspase-3 and caspase-7.

Results: We identified PITX2 as a gene specifically upregulated in both organoids derived from the ascending colon and non-lesional tissue of UC patients. Inflammatory response assessment, based on IL-8 and DUOXA2 expression, showed no significant differences between WT and PITX2-KD organoids. Similarly, fluorescent immunostaining for NF-κB p65 revealed no significant difference in nuclear translocation between WT and PITX2-KD organoids, suggesting that PITX2 does not influence inflammatory signaling pathways. PITX2-KD organoids from the ascending colon exhibited similar cell proliferation to WT under normal conditions. However, under inflammatory stimulation for one week, PITX2-KD organoids showed reduced proliferation compared to WT. The sphere-forming ability of PITX2-KD organoids was comparable to WT under both normal and inflammatory conditions, suggesting that PITX2 plays a role in promoting proliferative cells in an inflammatory environment. Western blot analysis revealed increased expression of cleaved caspase-3 and 7 in PITX2-KD organoids following inflammatory stimulation compared to WT. These findings suggest that PITX2 may regulate apoptosis via effector caspases.

Conclusion: PITX2 was identified as a gene specifically upregulated in the ascending colon and non-lesional tissue of UC patients, playing a role in promoting cell proliferation under inflammatory conditions. These findings suggest that PITX2 may contribute to UC pathology by regulating epithelial cell survival and apoptosis in an inflammatory environment.

DELAYS IN INITIATING ADVANCED THERAPY FOR INFLAMMATORY BOWEL DISEASE: THE IMPACT OF ETHNICITY

M. Colwill[1,2], S. Baillie[1,2], C. Radia[3], S. White[1], R. Pollok[1,2], A. Poullis[1,2]

Introduction: Prompt initiation of advanced therapy (AT) medications, encompassing biologics and small molecule treatments, is crucial for the effective treatment of inflammatory bowel disease (IBD). The time taken from the decision to start the AT to it's first administration, or time to advanced therapy (TAT), can vary significantly between individuals negatively impacting upon their disease course. However, our knowledge of the causes for the variation in TAT is poor.

Aims & Methods: We aimed to investigate the impact that different demographic and disease-related factors have on the TAT. A retrospective analysis of electronic patient records, conducted at a tertiary IBD referral centre in London in March 2024, analysed electronic patient records of all those over the age of 18 currently being treated for IBD with an AT and collected data on the TAT for their index AT, defined as the number of days from the documented decision to start an AT to the date of the first administration.

Data was also collected on multiple variables which including disease type, type of AT, age, sex, ethnicity and socioeconomic status by analysing patients' Index of Multiple Deprivation (IMD). A multiple negative binomial regression was performed entering all variables together to assess their relative effect on TAT.

Results: 1298 patients were identified and 485 were excluded due to either their index AT being started elsewhere, incomplete data, a positive screening test or because they were enrolled in a clinical trial. The multiple binomial regression found that TAT was significantly longer for those of non-white ethnicity (p=0.039) (Table 1).

		IRR	95% CI	p-value
Ethnicity	Asian	1.17	0.96, 1.21	0.039
	Black	1.46	1.09, 1.95	
	Mixed	1.26	0.77, 2.05	
	White	1		
Treatment	Adalimumab	1.37	0.95, 1.96	<0.001
	Filgotinib	1.37	0.87, 2.16	
	Infliximab	0.97	0.68, 1.40	
	Tofacitinib	0.89	0.58, 1.36	
	Ustekinumab	0.91	0.61, 1.35	

Table 1. IRR: Incidence Rate Ratio. IMD: Index of multiple deprivation.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Analysis for patients of black ethnicity found an Incident Rate Ratio (IRR) of 1.46 (95% CI 1.09,1.95), for mixed ethnicity IRR=1.26 (95% CI 0.77,2.05) and for asian ethnicity IRR=1.17 (95% CI 0.96, 1.41) when compared to white patients. Treatment with adalimumab was also associated with a longer TAT (p=<0.001, IRR 1.37, 95% CI 0.95,1.96) but no other factors were statistically significant: IMD p=0.133; age p=0.155; sex p=0.702; disease type p=0.335.

Conclusion: Our study has identified that non-white ethnicity is associated with a longer TAT and this may be a contributing factor to worse outcomes in patients with IBD from an ethnic minority background. Further research into the causes for this are required to help address this health disparity.

GUT MICROBIOME COMPOSITION AND ITS ASSOCIATION WITH DIETARY FACTORS IN CROHN'S DISEASE

M.M. de Castro[1], E. Özkurt[2], D. Baker[2], M.d.L.S. Ayrizono[1], M. Milanski[3], N. Beraza[2], R.F. Leal[1]
[1]University of Campinas (Unicamp), IBD Research Laboratory, Gastrocenter, Colorectal Surgery Unit, Department of Surgery, Campinas, Brazil, [2]Quadram Institute Bioscience, Norwich Research Park, Norwich, United Kingdom, [3]University of Campinas (Unicamp), Laboratory of Metabolic Disorders, School of Applied Sciences, Limeira, Brazil

Contact E-Mail Address: rafranco.unicamp@gmail.com

Introduction: The gut microbiota plays a crucial role in the pathogenesis and progression of Crohn's Disease (CD) by maintaining intestinal homeostasis, supporting metabolic and immune functions, and influencing overall health. An imbalance in the gut microbiota is associated with CD, as disruptions in microbial composition can be further impacted by dietary factors, highlighting the connection between nutrition and gut health.

Aims & Methods: This study aimed to evaluate the gut microbiota composition and its interactions with dietary factors to identify potential opportunities for targeted probiotic interventions in CD management. The study included 53 participants, of whom 20 had CD in remission, 18 had active disease, and 15 were healthy controls. CD activity was evaluated by colonoscopy assessment or by nuclear magnetic resonance scan enterography. All participants aged between 18 and 60 years were assessed using 24-hour dietary recall and gut microbiome profiling through 16S rRNA gene sequencing. Patients had confirmed diagnoses of CD with ileal and/or colonic involvement. The local ethics committee approved this study.

Results: Microbial composition analyses (beta diversity) revealed significant differences between groups. At the Operational Taxonomic Unit (OTU) level, healthy microbiome differed significantly from both remission and active CD patients, with healthy controls showing a more similar microbial composition compared to remission (p = 0.001) and active disease (p = 0.001). In addition, Shannon diversity analyses demonstrated that healthy individuals exhibited significantly higher OTU diversity compared to CD patients, further highlighting the microbial imbalance associated with the disease. Among specific taxa, *Eubacterium hallii*, a key butyrate producer, was significantly reduced in patients with active CD. This microorganism is integral to intestinal metabolic balance, playing essential roles in energy homeostasis, colonic motility, immunomodulation, and inflammation suppression. Furthermore, *E. hallii* plays a critical role in bile acid and cholesterol metabolism, highlighting its importance in gut health. Disease severity was associated with changes in microbial abundance, with specific taxa colonizing the gut at higher levels as disease activity increased, including *Escherichia coli*, *Escherichia-Shigella*, and taxa from the *Enterobacteriaceae*, *Lachnospirales,* and *Bacteroides*. This growth may be linked to inflammatory processes and intestinal dysbiosis, suggesting a potentially pathogenic role. Furthermore, dietary components such as saccharin, an artificial sweetener, were significantly associated with alterations in microbial composition.

Conclusion: These findings underline the potential for probiotics targeting specific taxa, such as *E. hallii*, to restore microbial balance and improve clinical outcomes in CD. The study also highlights the impact of dietary components, such as saccharin, in disrupting the gut microbiome, suggesting that certain dietary factors may contribute to microbial imbalance and inflammation in CD. Future research should focus on integrating dietary patterns with probiotic development to optimize gut health and mitigate inflammation in CD patients.

PHENOTYPING OF HUMAN UC COLONIC TISSUE T CELLS REVEALS INFLAMMATORY PATHWAY GENE EXPRESSION IN PD-1+ CONVENTIONAL AND REGULATORY T CELLS WHICH OVERLAP WITH THOSE REGULATED BY ROSNILIMAB IN A MOUSE MODEL OF COLITIS

B. Linggi[1], C. Haines[1], Y. Ren[1], S. Parmley[1], M. Dahl[1], J. Kwon[1], P. Soroosh[1], P. Lizzul[1], C. Sibley[1]
[1]AnaptysBio, San Diego, United States of America

Contact E-Mail Address: blinggi@anaptysbio.com

Introduction: PD-1 co-inhibitory receptor agonists, such as rosnilimab, are a promising class of therapeutics that leverage immune homeostatic mechanisms to regulate T cell activity for treatment of inflammatory diseases, including ulcerative colitis (UC). In UC lamina propria, multiple T cell subtypes express PD-1, including peripheral helper T cells (Tph) and effector memory T cells, and the reduction of PD-1+ Tph cells is correlated with remission.[1]

Also, PD-1+ Tregs may comprise a subpopulation of pro-inflammatory Tregs in the UC colon. In a mouse model of colitis (induced by transfer of CD4+CD45Rb+ T cells from human PD-1 transgenic mice), rosnilimab treatment of established disease showed reduced body weight loss, reduced inflammation of the colon, and reduced infiltration of CD4 T cells.[2]

Aims & Methods: A secondary analysis of active UC patient-derived colonic tissue characterized PD-1+ T cell subsets via a CD3-sorted single-cell proteomics and transcriptomics dataset.[3]

Pathway activity was estimated using Progeny.[4]

Bulk RNA-sequencing, gene expression analysis, and enrichment of human UC significant Reactome[5] pathways was performed on colonic tissue from mice treated with rosnilimab in the colitis model.

Results: In human UC colonic tissue, PD-1+ CD4 conventional T (Tcon) cells and PD-1+ Tregs had increased JAK-STAT, TNF, and NF-κB estimated pathway activity compared to PD-1(-) cells. PD-1+ Tregs had increased expression of genes associated with a pro-inflammatory phenotype, including *TNF*, *TBX21*(TBET), and *IL12RB2*, and decreased expression of *IL2RA*

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(CD25). RNA-Seq of mouse colitis identified upregulated genes, compared to naive animals, in pathways that were also involved in human UC ("Signaling by interleukins" (e.g., *Il6*) and "Chemokine receptors bind chemokines" (e.g., *Ccl20*)). Expression levels of these genes in rosnilimab treated mice were similar to naive control animals. Additionally, the barrier gene *Muc3* and fibrosis-associated *Mmp9* were dysregulated in colitis but normal in rosnilimab-treated mice.

Conclusion: In UC colonic tissue, PD-1+ CD4 Tcon cells demonstrated increased inflammatory gene expression and PD-1+ Tregs exhibited a pro-inflammatory phenotype, suggesting that targeting both PD-1+ CD4 Tcon and PD-1+ Tregs may contribute to the therapeutic efficacy of rosnilimab in UC.

These additional analyses support preclinical findings and suggest beneficial modulation of gene expression pathways of human UC, including reduction of pro-inflammatory cytokines and fibrosis, and upregulation of barrier function genes. These data demonstrate that PD-1 is upstream of multiple clinically validated drivers of UC and support the scientific rationale for studying rosnilimab in an ongoing Phase 2 study in UC (NCT06127043).

FUNGAL CELL WALL MANNAN ENHANCES PLASMA CELL DIFFERENTIATION AND IGA ANTIBODY RESPONSES IN THE GUT

W. Luo[1], S. Wu[2], R. Said[2], S.E. Vankamamidi[2], C. Cervantes[2], M. Fernandez[2], J. Fu[2], A. Burnham-Marusich[3], G. Zhong[2], E.M. Bunnik[2], H. Yan[2], T.R Kozel[3], D. Kadosh[2], B. Wickes[2], X. Wang[1], Z. Xu[2]

Introduction: Fungal cell wall acts as a major interface with the host immune system. Whether its components have a direct impact on differentiation of B lymphocytes, however, is poorly investigated, in contrast to well documented induction of class switch DNA recombination (CSR) and plasma cell differentiation by TLR ligands derived from or mimick bacterial cell wall components or viral genome replication intermediates. This hinders the understanding on the role of mycobiota in the homeostatic production of protective mucosal IgA and pathogenic IgG induction upon barrier damages-triggered exposure of B cells to microbes.

Aims & Methods: In the presence of Toll-like receptor (TLR) ligands or T cell-derived CD154, class switch recombination (CSR) and plasma cell differentiation were examined under conditions treated with Saccharomyces cerevisiae (S. cerevisiae) mannan, β-1,3-glucan, zymosan, and heat-killed (HK)-Candida albicans (C. albicans). Mannans derived from S. cerevisiae and selected Candida species were also tested under comparable conditions. Pathways related to plasma cell survival were detected. An ovalbumin-cholera toxin (OVA-CT) induced mouse IgA expressing model was utilized to investigate the role of mannan in the gut IgA response.

Results: Here we show that, unlike fungal polysaccharide mannan, HK-*C. albicans* and b-1,3-glucan as well as zymosan all failed to activate B cells. Furthermore, while b-1,3-glucan and zymosan had marginal impact on B cells stimulated by a TLR ligand or T cell-derived CD154, mannan from *Saccharomyces cerevisiae* and selected *Candida* species potentiated TLR4 induction of generation of plasma cells, including those secreted class-switched IgA and IgG. It did so in association with increasing survival threshold of pre-differentiating B cells, enhancing NF-kB activation and upregulating expression of XBP-1 and pro-survival genes. Mannan also enhanced IgA antibody responses in the gut.

Conclusion: Thus, mannan uniquely mediates the fungi and bacteria crosstalk by regulating plasma cell differentiation and antibody response.

Contact E-Mail Address: jesus.cosin@uv.es

Introduction: Inflammatory Bowel Disease (IBD) is a gastrointestinal disorder which comprises Ulcerative Colitis and Crohn's Disease. Intestinal Fibrosis is one of the main processes involved in the complications associated to IBD with no effective treatment. Decanoic acid (DA), a medium-chain fatty acid found in coconut oil, is considered to have beneficial biochemical functions such as antifungal and antimicrobial activity, but its role in IBD remains unclear.

Aims & Methods: We aim to analyze the role of decanoic acid in both acute and chronic murine models of colitis.

Acute model of colitis was induced by 2% of DSS in drinking water during 7 days followed by 3 days of H_2O, whereas chronic model was induced with two cycles of DSS 2% in drinking water during 7 days separated by 10 days of H_2O. Mice were administered orally with vehicle (methylcellulose) or DA (516,78 mg/kg) daily. In both models, body weight was registered daily and colon length was measured at sacrifice. Gene and protein expression were analysed by qPCR and Western Blot, respectively. Embedded paraffin colon samples were stained with hematoxylin-eosin for histological analysis and Sirius Red staining for collagen deposition. CD68 and CD3 positive cells were quantified by immunohistochemistry.

Additionally, human small intestine fibroblasts (HSIFs) were treated with increasing concentrations of decanoic acid (0, 50, 100 and 250mM) and TGFb (10ng/ml) during 24 hours.

In addition, some HSIFs were transiently silenced with a specific siGPR84 and siPPARg. Gene and protein expression of fibrotic markers were analyzed by RT-PCRq and Western blot respectively. Data were analyzed using ANOVA and t-test and expressed as fold induction (mean ± SEM). A P-value <0.05 was considered significant.

Results: In acute model there were no significant differences in survival nor colon length between DSS-vh and DSS-DA. H-E stain showed a preserved epithelium architecture and less inflammatory infiltrate in DSS-DA vs DSS-vh. Moreover, DSS significantly increased the gene expression of IL1β, Cox2, IL10, Col1a1, Col3a1, Col4a1, Snail1, inos, cd206, cd163 and

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

cd68 and reduced Acta2 and Fizz1. Of interest, DA significantly reduced the expression of most of the previous genes vs DSS-vh. IH showed a significant increase of CD68+ and CD3+ cells in DSS-vh, while DA significantly reduced these cells vs DSS-vh.

Chronic model showed an increase in survival and colon length in DSS-DA mice vs DSS-vh (5,94±0.18 vs 4,88±0.16 cm). In addition, DSS increased the gene expression of IL1β, TNFa, Cox2, cd68, inos, ccr7, cd16, arginase, Col1a1, Col4a1, TGFβ, timp1 and snail2 and reduced cd163. DSS-DA significantly reduced the expression of those genes vs DSS-vh mice. Sirius Red staining revealed a reduction in the thickness of collagen layer in DSS-DA mice vs DSS-vh mice.

In vitro, DA significantly decreased mRNA expression of COL1A1 (1.06±0.16 vs 0.35±0.06), COL3A1 (1.25±0.31 vs 0.40±0.08), COL4A1 (1.21±0.09 vs 0.41±0.07), ACTA2 (1.09±0.22 vs 0.13±0.02). The treatment with this metabolite also significantly reduced the protein levels of Col1A1 (100±18.93 vs 28±5.3) and aSMA (92.84±7.07 vs 50.62±3.89). Only the transiently silencing of PPARg significantly reverted those reductions, whereas siGPR84 did not modify the expression of COL1A1 nor COL3A1 nor ACTA2.

Conclusion: Decanoic acid exerts a protective role in both acute and chronic murine models of colitis reducing inflammation and fibrosis markers. These effects seem to be mediated through PPARg, and not GPR84, suggesting that this metabolite could be a promising therapeutic approach for IBD.

Disclosure: Nothing to disclose.

PP0361

DECODING NOTCH PATHWAY'S IMPACT ON EPITHELIAL-MESENCHYMAL TRANSITION AND FIBROSIS IN COMPLICATED CROHN'S DISEASE

J. Patel[1], A. Cejudo[1], A. Jarén[1], D.C. Macías-Ceja[1], M.D. Barrachina[1], S. Calatayud[1], A. López[2], J. Cosin-Roger[1], D. Ortiz-Masia[3]

Contact E-Mail Address: jesus.cosin@uv.es

Introduction: The Notch pathway may selectively mediate fibrogenic processes, such as epithelial-mesenchymal transition. The dysregulation of EMT is linked to numerous pathologies, including fibrotic diseases[1]. Previous studies by our group have demonstrated elevated expression of NOTCH3, NOTCH4 receptors, and the DLL4 ligand in the intestines of patients with complicated Crohn's disease (CD)[2]. This study aims to explore the potential of the Notch pathway as a therapeutic target in intestinal fibrosis associated with CD.

Aims & Methods: We analyzed ileal samples from CD patients with complicated lesions to assess the localization of NOTCH3/4 receptors using immunohistochemistry (IHC) and performed RT-qPCR and Western blot (WB) analysis. In vitro studies utilized DLL4-coated plates (1 µg/ml), with or without the γ-Secretase Inhibitor DAPT (10 µL/ml), to evaluate protein and mRNA expression of HES1 and EMT markers (VIMENTIN, SNAI, and E-CADHERIN) in two primary epithelial cell lines: small intestine (HIEC6) and colon (CoEpi) cells over 48 hours. Data, presented as fold induction (mean ± SEM) relative to water-treated cells or control tissues, were analyzed using parametric or non-parametric ANOVA (Kruskal-Wallis) based on normality testing (*P < 0.05 or **P < 0.01).

Results: RT-qPCR analysis revealed significantly increased mRNA levels of NOTCH3 and NOTCH4 receptors. WB analysis showed elevated levels of NOTCH3 (235±87**, compared to control tissues 100±8) but no significant change in NOTCH4 (87±13 vs. control 100±7). Cellular localization studies showed NOTCH3 in endothelial and smooth muscle cells, lamina propria cells, and lower intensity in the epithelium, whereas NOTCH4 was predominantly found in lamina propria cells. In vitro assays indicated that DLL4 significantly altered mRNA and protein expression of HES1 and EMT markers (VIMENTIN and SNAIL) in both epithelial cell lines. Co-treatment with DAPT significantly reversed some EMT markers induced by DLL4 (VIMENTIN and SNAIL).

Conclusion: NOTCH3 appears to play a role in the fibrogenic processes in CD, with elevated expression in affected tissues. The activation of EMT markers by DLL4 suggests that Notch signaling plays a crucial role in driving fibrosis and tissue remodeling in CD, positioning it as a potential therapeutic target.

ELEVATED INTESTINAL AND LIVER FATTY ACID-BINDING PROTEINS (I-FABP AND L-FABP) AND FIBROBLAST GROWTH FACTOR (FGF-19) CONCENTRATIONS IN SERUM MAY REFLECT IMPAIRED MUCOSAL BARRIER AND ASSOCIATED LIVER DAMAGE IN INFLAMMATORY BOWEL DISEASES IN CHILDREN

A. Wedrychowicz[1], P. Tomasik[2], K. Kowalska-Duplaga[1]

Introduction: Inflammatory bowel disease (IBD) is a group of chronic inflammatory diseases of the gastrointestinal tract and about 50% of patients develop liver function disorders of different severity in their course. There is unknown cause directly leading to the symptoms of liver damage, one of the suggested causes is impaired mucosal barrier and the associated increased intestinal permeability to bacterial and nutritional antigens and toxins.

Aims & Methods: The aim of the study was to assess the effect of the severity and location of inflammatory lesions in the gastrointestinal tract in the course of IBD on intestinal mucosal barrier disorders and the occurrence of symptoms of liver damage. To assess the degree of mucosal barrier impairment, the intestinal and liver fatty acid-binding proteins (I-FABP and L-FABP) concentrations were assessed, which are sensitive markers of mucosal damage and to assess the degree of liver damage, the fibroblast growth factor (FGF-19) concentrations assessment and laboratory and imaging results. For IBD severity evaluation, the clinical activity scoring indexes and serum tumour necrosis factor alpha (TNF-alpha) concentrations were assessed.

There were 20 children with Ulcerative Colitis (UC, 12 boys, 8 girls, mean age: 16.0 yrs, range: 7.5 – 18) and 20 with Crohn's Disease (CD, 10 boys,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

10 girls, mean age: 14.8 yrs, range: 6.3 – 18) and 20 healthy controls enrolled into the study. Serum I-FABP, L-FABP, FGF-19 and TNF-alpha concentrations were assessed at the baseline, before the treatment and after 2 weeks of treatment, using ELISA immunoassays. Statistical analysis was performed with Statistica 13.0 software (TIBCO Software, USA) using Mann-Whitney U test, Wilcoxon signed rank test and Spearman's correlation rank test.

Results: We found significantly elevated serum I-FABP in active UC group when compared to active CD group and controls ($p<0.05$), while in inactive UC group and inactive CD group they were comparable to controls (p=NS). Moreover, serum L-FAPB was significantly increased in active UC group when compared to active CD group and controls ($p<0,05$) and in inactive UC group when compared to inactive CD group and controls ($p<0,05$).

When we assessed serum FGF-19 concentrations, we found them significantly increased both in active UC and active CD when comparable to controls ($p<0,05$) and in inactive UC group when compared to inactive CD group and controls ($p<0.05$). Additionally, serum FGF-19 concentrations were related to the stage of liver impairment in UC patients.

Conclusion: Increased serum concentrations of I-FABP and L-FABP may be associated to impaired mucosal barrier in IBD. Nevertheless, impaired mucosal barrier may be connected to increased penetration of bacterial and nutritional antigens and toxins and secondary may be related to liver damage. Furthermore, increased serum FGF-19 concentration may be associated with liver damage in the course of IBD in children.

Introduction: Crohn's disease (CD) has been increasingly linked to imbalances in the gut microbiota, notably through dysregulation in the gut virome. Particularly, elevated levels of *Caudovirales* have been observed in CD patients. Among these, the *Proteus virus Isfahan* species is abundant in CD, suggesting it might trigger an autoimmune response through molecular mimicry.

Aims & Methods: The aim of this study is to investigate whether *Proteus virus Isfahan* proteins share homology with human proteins, potentially initiating autoimmune mechanisms in CD. Utilizing the IBD Transcriptome and Metatranscriptome Meta-Analysis (TaMMA) framework, we analyzed cell populations from intestinal biopsies of CD patients and healthy controls. Immune and non-immune cells were isolated using flow cytometry and underwent transcriptomic analysis.

Additionally, we examined the homology of viral proteins to human proteins using NCBI BLAST and iPBA. *In vitro* experiments involved coculturing T cells with immune cells overexpressing *Proteus virus Isfahan* protein to explore immune responses.

Results: Our results confirmed increased levels of *Proteus virus Isfahan*, in CD patients, especially in dendritic cells and macrophages. Gene ontology analysis indicated compromised immune responses in dendritic cells and enhanced viral-response pathways in CD macrophages. Notably, the viral protein gp82 showed structural homology with human dCMP deaminase, supporting the molecular mimicry hypothesis. These findings highlight *Proteus virus Isfahan* as a potential activator of autoreactive T cells, exacerbating CD's autoimmunity.

Conclusion: This evidence suggests that *Proteus virus Isfahan* may play a significant role in CD pathogenesis through molecular mimicry, where its protein's similarity to human proteins could trigger immune misrecognition, fostering autoimmunity and perpetuating inflammation in CD. Ongoing experiments aim to further elucidate these interactions, potentially identifying novel therapeutic targets.

EVALUATION OF ENDOPLASMIC RETICULUM STRESS IN THE ILEAL POUCH MUCOSA OF PATIENTS WITH ULCERATIVE COLITIS COMPARED TO THE FAMILIAL ADENOMATOUS POLYPOSIS

L.M.V. de Negreiros[1], L.B. Pascoal[1], L.M. Genaro[1], B.L. Rodrigues[1], M.G. Camargo[1], M.d.L.S. Ayrizono[1], R.F. Leal[1]
[1]University of Campinas (Unicamp), IBD Research Laboratory, Gastrocenter, Colorectal Surgery Unit, Department of Surgery, Campinas, Brazil

Contact E-Mail Address: leandromvn@gmail.com

Introduction: Total retocolectomy with ileal pouch anal anastomosis (IPAA) is the surgical procedure of choice for patients with ulcerative colitis (UC) refractory to clinical treatment and familial adenomatous polyposis (FAP) with many polyps in the rectum. Primary ileitis of the ileal pouch (IP) is one of the most common complications in UC, being rare in FAP. Previous studies have identified an increase in pro-inflammatory cytokines, as well as alterations in the apoptosis and macroautophagy pathways markers in the IP mucosa of UC patients, compared to those with FAP and normal distal ileum (controls).

Since autophagy and apoptosis can be modulated by endoplasmic reticulum (ER) stress, we investigated this pathway in IP of UC compared to PAF and controls.

Aims & Methods: The aim was to evaluate the modulation of ER stress in the IP mucosa of UC and FAP patients who underwent IPAA, compared to controls. Thirty-two patients were included, ten in the UC group, twelve in FAP group and ten in the control group. Patients who had undergone ileostomy closure for less than one year and had clinical, histological, or endoscopic evidence of pouchitis were excluded. The patients underwent routine colonoscopy, and biopsies were performed from the IP.

For the control group, biopsies were taken from the normal distal ileum. The local Ethics Committee approved the study. The biopsies were processed for RNA extraction and subsequent gene expression analysis using the quantitative PCR (qPCR) technique. The following transcripts were investigated: IRE1 (ERN), PERK (EIF2AK3), ATF6, GRP78 (HSPA5), GRP94 (HSP90B1), ATF3, STC2, DDIT3, DNAJC3, and CALR. Nonparametric tests were used for statistical analysis, with a significance level of $p<0.05$.

Results: The pouchitis disease activity index (PDAI) was applied to verify the absence of pouchitis, with all patients scoring lower than 7. There was no increase in the transcriptional level of the main ER stress pathway markers (ERE1, PERK, and ATF6) in the IP without pouchitis.

However, there was a significantly lower expression of DDIT3 in the UC and FAP groups compared to the control ($p\leq0.05$), which may suggest a deficiency in counterbalance the ER stress activation.

On the other hand, concerning the UPR pathway markers, the levels of CALR and HSP90B1 were significantly higher in the IP of UC compared to the respective IP afferent loop ($p\leq0.05$), supporting potential activation of the ER stress in the IP in the UC group.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Additionally, the transcriptional level of ATF3 was significantly higher in the PAF group compared to the control (p≤0.05), which may indicate a counter-regulatory mechanism in response to tissue damage, which was not verified in the UC group.

Conclusion: Our findings demonstrated that markers of the unfolded protein response (UPR) signaling pathway, which is activated in response to ER stress, are modulated in the IP mucosa of UC patients, even in the absence of pouchitis. These results may explain the propensity to IP inflammation in UC patients. They may guide the identification of additional molecular pathways contributing to inflammation of the IP and the search for new therapeutic targets.

Introduction: Modulation of kinase activity is part of the therapeutic armamentarium for inflammatory bowel disease (IBD). However, as with other IBD treatments, not all patients respond to treatment. To improve the precision of therapeutic interventions, a better understanding of the mucosal inflammatory environment is essential.

This study investigates mucosal kinase activity, along with mucosal cytokine and chemokine profiles in IBD and in relation to tofacitinib response.

Aims & Methods: Paired inflamed and non-inflamed colonic biopsies were collected from patients with Crohn's disease (CD, N=16), ulcerative colitis (UC, N=16), and non-IBD controls (N=4) to assess IBD-associated kinase activity and cytokine/chemokine profiles.

Additionally, colonic samples were collected from UC patients before start of tofacitinib treatment (cohort 1, N=12) and both before and after 8 weeks of treatment (cohort 2, N=16), to assess kinase activity profiles in relation to tofacitinib response.

Results: The mucosal kinase activity and cytokine/chemokine profiles exhibited significant differences between inflamed and non-inflamed mucosa, with more pronounced alterations observed in UC compared to CD. The increase in kinase activity was most pronounced in the tyrosine kinase families.

Responders to tofacitinib demonstrated higher baseline mucosal kinase activity, although only two predicted kinases (DCLK1 and ATR) were consistently identified across two cohorts. In responders, mucosal kinase activity significantly decreased after 8 weeks of treatment.

Conclusion: Mucosal kinase activity and cytokine/chemokine profiles are associated with inflammation in IBD, with distinct differences between UC and CD. Baseline kinase activity appears to predict response to tofacitinib, with a marked reduction in kinase activity observed after 8 weeks of treatment in responders. These findings highlight the potential of kinase activity profiling in optimizing therapeutic strategies for IBD.

MICROSCOPIC COLITIS: A COMPARATIVE STUDY OF CLINICAL SYMPTOMS AND HISTOPATHOLOGICAL FEATURES

C. Haddad Hachimi[1], M. Konso[2], C. Hiji[1], H.E. Krami[3], M. Tamzaourte[1]
[1]Mohamed V Military Training Hospital, Gastroenterology Department 1, Rabat, Morocco, [2]Faculty of Medicine and Pharmacy of Rabat, Rabat, Morocco, [3]Private Practice, Rabat, Morocco

Contact E-Mail Address: h.h.chaimae@gmail.com

Introduction: Microscopic colitis is a chronic inflammatory condition defined by a clinical triad: chronic diarrhea, endoscopy without significant abnormalities, and distinct histopathological features characterized by a largely normal appearance of the mucosa but increased numbers of lymphocytes in the epithelium and lamina propria on microscopy.

Aims & Methods: This study aims to explore the relationship between clinical presentation and histopathological features in microscopic colitis, with a focus on identifying prognostic factors linked to therapeutic response and symptom resolution.

This is a retrospective, descriptive study conducted over a 10-year period (September 2015 to May 2025), involving 54 patients diagnosed with microscopic colitis based on histological examination of colonic biopsies. Among them, 19 cases were identified as collagenous colitis and 35 as lymphocytic colitis. Data collected included epidemiological, clinical, endoscopic, histopathological, therapeutic, and follow-up information.

The histological parameters assessed were: characteristics of the lamina propria, intraepithelial lymphocytosis, presence and thickness of the subepithelial collagen band, and surface epithelial damage.

Results:

A total of 54 cases of microscopic colitis were included in the study, among which 51 patients (94.4%) presented with chronic diarrhea, with a median of 7 diarrheic stools [IQR: 4.5–10.5]. One patient with lymphocytic colitis had concomitant celiac disease. Concerning medication use, 2 patients (3.7%) were taking proton pump inhibitors, and 3 (5.6%) were on venotonic agents.

Our analysis revealed several statistically significant correlations:

- A very strong positive correlation between the number of intraepithelial lymphocytes (IELs) and the frequency of diarrheal stools ($r = 0.873$; $p < 0.001$).
- A strong positive correlation between the number of diarrheal stools and the rate of clinical improvement ($r = 0.633$; $p < 0.001$).
- A strong association between subepithelial collagen band thickness and clinical improvement ($r = 0.509$; $p < 0.001$).

In addition, patients with an IEL count <30% experienced a significantly faster clinical response compared to those with ≥30%, with a median time to symptom resolution of 2 weeks versus 4 weeks, respectively ($p < 0.001$). Similarly, patients with subepithelial collagen band thickness <20 µm showed more rapid improvement than those with ≥20 µm (median time to improvement: 2 weeks vs. 6 weeks; $p < 0.002$).

Regarding treatment, 49 patients (90.7%) received budesonide, while 5 (9.3%) were managed with loperamide. A follow-up histological assessment performed 12 months after treatment initiation showed complete normalization of the colonic mucosa in all patients.

Conclusion: Microscopic colitis is a common cause of chronic diarrhea and represents a treatable condition. Accurate diagnosis relies on the recognition of characteristic histopathological features, highlighting the importance of a thorough histological assessment. The integration of clinical context with microscopic findings enables the pathologist to establish a confident diagnosis in most cases and to provide the gastroenterologist with precise and clinically relevant information.

Contact E-Mail Address: farrag@gmx.de

Introduction: Inflammatory bowel disease (IBD), encompassing Crohn's disease (CD) and ulcerative colitis (UC), is characterized by chronic inflammation affecting the gastrointestinal tract and extraintestinal organs. The etiology of IBD is multifactorial, involving genetic, immunological, and environmental factors, with significant genetic predisposition indicated by over 200 identified loci associated with the disease. Despite advancements in understanding the genetic basis of IBD, clinical management remains challenging due to heterogeneity in disease presentation and variable treatment responses.

Current therapies, including 5-aminosalicylates and biologics, are not universally effective, highlighting the urgent need for reliable biomarkers to predict therapeutic responses.

This study investigates the potential role of interferon regulatory factor 5 (IRF5) in IBD pathogenesis, particularly in UC.

Aims & Methods: We conducted a systematic analysis of colon biopsies from adult patients diagnosed with UC and non-IBD controls. Immunostaining was performed to assess IRF5 expression in colonic tissues, and statistical analyses were conducted to evaluate the correlation between IRF5-positive cell counts, disease activity, and inflammatory markers such as calprotectin

Results: Our analysis revealed a significant increase in IRF5-positive macrophage-like cells in the inflamed mucosa of IBD patients compared to healthy controls. The number of IRF5-positive cells correlated positively with disease activity and calprotectin levels, indicating that higher IRF5 expression is associated with increased inflammation.

Conclusion: This study establishes a significant correlation between IRF5 expression and disease activity in UC, suggesting that IRF5 may play a crucial role in the inflammatory processes associated with the disease. The findings propose IRF5 as a novel biomarker for therapeutic intervention in IBD. Further research is warranted to elucidate the exact mechanisms by which IRF5 contributes to IBD pathogenesis and to evaluate the therapeutic potential of targeting this pathway in clinical settings.

SEVERE ACUTE COLITIS: CLINICAL PRESENTATION AND THE CONTRIBUTION OF ENDOSCOPY

S. Harchelkorane[1], A. Benchekroun[1], I. Kenafi[1], F. Amina[1], I. Hafid[1], A. Akjay[1], H. Ouaya[1], H. Meyiz[1], M. Ihssane[1]
[1]Mohammed VI University Hospital Center, Hepato-Gastroenterology Department, Tangier, Morocco

Contact E-Mail Address: harchsahar@gmail.com
Introduction: Acute severe colitis (ASC) is a medical and surgical emergency that can be life-threatening. Diagnosis is based on clinical and biological criteria, with clinical and endoscopic severity scores.
The aim of our study was to determine the clinical and endoscopic profile of patients with ASC.
Aims & Methods: We conducted a retrospective study over a 20-month period, from June 2023 to January 2025, in the Hepato-Gastroenterology Department. Patients included had ASC defined by the Truelove and Witts criteria.
Results: Twenty-five patients met the diagnostic criteria. The mean age was 39 years [16–86].
There was a male predominance (64%) with a sex ratio of 1.7.
Five patients (20%) presented with inaugural ASC. Among the remaining 20 patients, 19 (95%) had known ulcerative colitis (UC).
The extent of UC was pancolitis in 17 patients (85%).
The disease duration ranged from 1 month to 20 years, with a mean of 41.36 months.
Among patients with known IBD, nine (45%) had a history of ASC: four were on biologics (infliximab or adalimumab), four on 5-ASA, and one was not receiving any maintenance therapy.
The delay in consultation ranged from 4 to 60 days, with a mean of 17.4 days.
All patients had severe flare-ups based on the Truelove and Witts criteria, with a mean Lichtiger score of 10.2.
Abdominal X-rays were performed for all patients: normal in 88% (n=22) and showed air-fluid levels in 12% (n=3).
All patients underwent recto-sigmoidoscopy to assess endoscopic severity, except one who was admitted with an acute abdomen and underwent colectomy.
Erythema and congestion were the most frequently observed lesions (91%).
Endoscopic Mayo score was 3 in 20 patients (83%), and UCEIS was ≥5 in 12 cases (52%).
Initial management included intravenous corticosteroids at 0.8 mg/kg/day (mean duration: 5.8 days), antibiotics, prophylactic anticoagulation, and a low-residue diet for all patients.
One patient (4%) required a blood transfusion, and another needed correction of electrolyte imbalance.
Second-line therapy with infliximab was required in 2 patients (8%).
One patient underwent colectomy for infliximab-refractory ASC.
There was a significant correlation between the Mayo and UCEIS scores ($P = 0.01$).
Other parameters showed no significant correlation, but hemoglobin levels had a positive impact on corticosteroid response.
Conclusion: Acute severe colitis is a potentially life-threatening complication, primarily of ulcerative colitis.
Management is based on intravenous corticosteroids and endoscopic assessment. Close monitoring is crucial to consider surgery in case of therapeutic failure or complications.
Disclosure: Nothing to disclose.

PP0369

MICROBIOTA METABOLITE BUTYRATE ALLEVIATES INTESTINAL INFLAMMATION THROUGH AUTOPHAGY ACTIVATION

Q. Mao[1], B. Lin[1], Q. Cao[1], M. Xu[1]
[1]Sir Run Run Shaw Hospital, Hangzhou, China

Contact E-Mail Address: xumengque@zju.edu.cn
Introduction: Butyrate, one of the short chain fatty acids produced by bacteria, is known to be beneficial in attenuating inflammatory response. Previous works have demonstrated that activation of autophagy can help alleviate inflammation. However, the roles of autophagy, microbiota and their metabolites in the pathogenesis of inflammatory bowel disease (IBD) are not known.
Aims & Methods: Male wild-type C57BL/6J mice aged 6-8 weeks old were administered 3% dextran sodium sulfate (DSS) to induce experimental colitis models. Mice were treated with sodium butyrate (SB) through oral gavage. 3-methyladenine (3-MA) was administered intraperitoneally to suppress autophagy in mice.
Results: We confirmed that SB treatment changed the composition of the intestinal microbes, restored intestinal barrier dysfunction and diminished the susceptibility of mice to DSS-induced colitis.
Additionally, autophagy levels in the intestine were significantly increased in SB-treated group with enhanced protein levels of Atg16l1 and LC3II, and reduced level of P62. While the SB-treated group showed increased autophagic flux, 3-MA-treated mice conversely displayed significantly attenuated autophagy activity. Meanwhile, the butyrate-mediated protection against colonic injury was considerably diminished in the 3-MA-treated mice.
Conclusion: These results show that autophagy and intestinal microbiota metabolite butyrate are essential for the maintenance of intestinal homeostasis. Butyrate can alleviate inflammation in DSS-induced colitis by activating autophagic flux. These insights may have vital implications for the development of therapeutic strategies for IBD.
Disclosure: The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Contact E-Mail Address: Sahbani.feriel1995@gmail.com

Introduction: Patients with inflammatory bowel disease (IBD) experiencing severe flares are at increased risk of opportunistic infections, particularly cytomegalovirus (CMV), due to immunosuppressive therapy.

Aims & Methods: This study aimed to assess the prevalence and risk factors associated with CMV infection during severe acute colitis.

We conducted a retrospective analytical study on hospitalized patients with severe acute colitis. CMV infection was confirmed by positive anti-CMV IgM serology, positive colonic biopsy PCR for CMV DNA, or histological evidence of CMV cytopathic effect.

Patients were divided into two groups:

Group 1 (CMV-positive) and Group 2 (CMV-negative). Clinical, biological, and therapeutic data were compared (SPSS, $p<0.05$).

Results: Among 41 patients (mean age 39.8 years, 14 men), 17 (41.5%) had confirmed CMV infection. CMV was diagnosed by PCR (n=13), serology (n=3), or histology (n=1). Most received antiviral therapy (Ganciclovir or Valganciclovir). One patient required emergency colectomy; three experienced relapse, with two receiving Foscarnet and one undergoing colectomy for bleeding. No significant association was found between CMV infection and age, sex, disease duration, corticosteroid or immunosuppressant use, anemia, hypoalbuminemia, or CRP >45 mg/L. However, CMV infection was significantly associated with steroid resistance ($p=0.003$).

Conclusion: CMV infection is frequent during severe IBD flares and is strongly associated with corticosteroid resistance. Early recognition of this risk factor is essential for timely diagnosis and management to avoid complications.

Disclosure: Nothing to disclose.

SRB3 DEMONSTRATES ROBUST *EX VIVO* EFFICACY IN BIO-EXPOSED IBD PATIENTS AND CORRELATES WITH DISEASE ACTIVITY

M. Barreiro de Acosta[1], L. Arosa-Garcia[2], I. Bastón-Rey[1], R. Ferreiro-Iglesias[1], S. Porto[1], L. Nieto[1], J.E. Dominguez-Munoz[1], D. Roca[3], E. Alvarez-Coiradas[3], P. Garrido[3], L. Simón[3], J. Conde-Aranda[2]
[1]University Hospital of Santiago de Compostela, Gastroenterology, Santiago de Compostela, Spain, [2]Health Research Institute of Santiago de Compostela (IDIS), Molecular and Cellular Gastroenterology Group, Santiago de Compostela, Spain, [3]SunRock Biopharma S.L, Santiago de Compostela, Spain

Contact E-Mail Address: manubarreiro@hotmail.com

Introduction: Inflammatory bowel disease (IBD) is a complex disease characterized by the dysregulation of host immunity. A key feature is the intestinal activation of T cells with cytotoxic activity and pro-inflammatory cytokine release. Therefore, targeting these pro-inflammatory T cells is a reasonable therapeutic approach. CCR9 is the main activator of gut tropism in the lymphocytes and a promoter of their migration into the lamina propria.

SBR3 is a best-in-class anti-CCR9 monoclonal antibody that effectively depletes $CD4^+$ $CCR9^+$ T cells in intestinal biopsies and peripheral blood of Crohn's Disease (CD) and Ulcerative Colitis (UC) patients, which leads to a marked reduction in pro-inflammatory cytokines and restoration of immune homeostasis.

The main objective of this study is to evaluate the translational efficacy of SRB3 in depleting $CD4^+CCR9^+$ T cells in intestinal explants from patients with UC and CD, and to assess its correlation with clinical parameters such as fecal calprotectin levels and current treatments.

Aims & Methods: Intestinal biopsies were collected in routine colonoscopies with inflammatory activity (defined as a Mayo Endoscopic Score <1 in ulcerative colitis and presence of ulcers in CD) from a cohort of IBD patients that included both naïve individuals and those previously treated with biologics, including TNF inhibitors (adalimumab, infliximab) and IL-12/23 antagonists (ustekinumab). Gut explants were cultured and treated *ex vivo* with SRB3. The frequency of $CD4^+CCR9^+$ T cells and cytokine levels were measured by flow cytometry and multiplex immunoassays.

Clinical and demographic parameters from the patient cohort, including smoking habits, type of disease, Montreal Classification, and fecal calprotectin levels (µg/g), were reviewed to evaluate correlations with SRB3 response.

Results: SRB3 efficiently depleted $CD4^+$ $CCR9^+$ T cells in both naïve patients and those treated with biologic therapies, including anti-TNF agents and IL-12/23 antagonists, indicating robust activity across diverse treatment backgrounds.

Importantly, higher levels of fecal calprotectin showed a statistically significant correlation ($p = 0.032$) with the extent of $CCR9^+$ cell depletion following SRB3 treatment. Given that elevated calprotectin levels are commonly associated with active disease or acute inflammatory flares, this finding suggests that SRB3 is particularly effective in patients with moderate-severe inflammatory activity.

Conclusion: These findings support the broad therapeutic potential of SRB3 in IBD patients, demonstrating efficacy not only in bio-exposed patients but also in those with active disease, where higher calprotectin levels correlate with stronger depletion levels.

Disclosure: Dr. Barreiro and Dr. Conde are both collaborators in a project funded by SunRock Biopharma.

PP0372

AN EXPLORATORY STUDY OF THE ASSOCIATION BETWEEN ENDOCYTOSCOPIC AND HISTOPATHOLOGICAL FINDINGS AND MUCOSAL CYTOKINE EXPRESSION PROFILES IN ULCERATIVE COLITIS

R. Ogihara[1], H. Kurumi[1], H. Isomoto[1]
[1]Tottori University, Gastroenterology and Nephrology, Yonago, Japan

Contact E-Mail Address: ryoheiogihara@gmail.com

Introduction: The pathogenesis of ulcerative colitis (UC) involves complex immune responses, including Th1, Th2, and Th17 pathways, and is characterized by substantial heterogeneity. Cytokine profiling may contribute to understanding individual disease mechanisms and guiding personalized therapeutic strategies; however, its clinical application remains limited due to technical complexity.

This study aimed to investigate whether endocytoscopic and histopathological findings correlate with mucosal cytokine expression levels and could serve as surrogate markers.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: Thirty-five patients with UC receiving treatment at our institution were enrolled. Endocytoscopy (ultra-magnifying endoscopy) was performed in all patients, and the findings were classified according to the Endocytoscopic Classification system (EC classification: EC-A, EC-B, EC-C, EC-D). Mucosal biopsies were obtained from the most inflamed areas identified during endocytoscopy. Histological evaluation included the Matts histological grade and assessments of neutrophil, eosinophil, and lymphocyte infiltration; goblet cell depletion; crypt distortion; and epithelial damage, each graded on a four-point scale (absent, mild, moderate, severe). mRNA expression levels of cytokines (IFN-γ, TGF-β1, TNF-α, IL-1β, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12, IL-13, IL-17, and IL-23) were quantified using RT-PCR. Statistical analyses were performed to assess correlations between endocytoscopic/histopathological findings and cytokine expression levels.

Results: The median age of participants was 44 years (IQR: 35–57), with 24 males and 11 females. Disease types included pancolitis (n = 16), left-sided colitis (n = 14), and proctitis (n = 5). The median Mayo score was 1 (IQR: 0–5). EC classification scores showed significant positive correlations with the expression levels of IL-1β, IL-6, IL-8, IL-13, IL-17, and IL-23 (Spearman's rank correlation, $p < 0.05$; $r = 0.555$, 0.526, 0.584, 0.441, 0.422, and 0.449, respectively).

Similarly, Matts histological grades were significantly correlated with the expression of IFN-γ, IL-1β, IL-6, IL-8, IL-13, IL-17, and IL-23 ($p < 0.05$; $r = 0.493$, 0.756, 0.692, 0.730, 0.656, 0.623, and 0.448, respectively). Histopathological features—including neutrophil and lymphocyte infiltration, goblet cell depletion, epithelial damage, and crypt distortion—were significantly associated with the expression of IFN-γ, IL-1β, IL-6, IL-8, IL-13, IL-17, and IL-23. Additionally, eosinophil infiltration was positively correlated with the expression levels of IL-1β, IL-5, and IL-13.

Conclusion: This study demonstrates that endocytoscopic and histopathological indicators of inflammation are associated with mucosal expression levels of several cytokines—particularly inflammatory and Th17-related cytokines—in patients with ulcerative colitis (UC). These findings suggest that such evaluations may serve as surrogate markers, potentially improving disease assessment and informing therapeutic decision-making.

Disclosure: Nothing to disclose.

LYSOPHOSPHATIDIC ACID MEDIATED LPAR2 SIGNALING IN MACROPHAGE EXACERBATES INFLAMMATORY BOWEL DISEASE THROUGH REGULATING METABOLIC REPROGRAMMING

S. Liu[1], Q. Zhang[1], S. Zhu[1], Z. Shutian[1]
[1]Beijing Friendship Hospital, Capital Medical University, Beijing, China

Contact E-Mail Address: liusi_scu_319@163.com

Introduction: Lysophosphatidic acid (LPA) is the simplest phospholipid and was indicated to participate in the development of IBD. Macrophage polarization are critically involved in the pathology of inflammatory bowel disease (IBD). However, the function of LPA in IBD is incompletely characterized and it is unclear how LPA regulates macrophage polarization.

Aims & Methods: This study aimed to elucidate the effect and mechanism of LPA in macrophage and IBD. Macrophage-specific lpar2 overexpression mice were constructed by intravenous administration of AAV9-DIO-Lpar2 in Cd11b Cre mice. We crossed Lpar2fl/fl mice with CD11b-Cre mice to induce monocyte-/macrophage-specific lpar2 deletion. Colitis was induced by intrarectally injecting with TNBS or treating DSS dissolved in drinking water for 7 days. Cell lines of Raw264.7 and bone marrow-derived macrophage (BMDM) were used to investigate the role of LPA-Lpar2 in macrophage in vitro. A series of cell and molecular experiments, including RNA sequencing, seahorse XF cell mitostress test, immunostaining, and dual-luciferase reporter assay was conducted to illustrate the mechanism.

Results: We firstly screened the six LPA receptor (Lpar1-Lpar6) expression by analyzing single-cell data from colon biopsies of IBD patients and found that Lpar2 was the only one which elevated in macrophages. In vivo study showed that AAV9-mediated macrophage specific Lpar2 overexpression in mice aggravates the severity of IBD and increased the number of M1 macrophage in the colon of IBD. Inversely, Lpar2 deficiency in macrophage protected mice from colitis.

To further confirmed that the function of LPA-Lpar2 was dependent on macrophage, the macrophages were depleted by Clodronate Liposomes (CLs). And the protective effect of myeloid Lpar2 deficiency in colitis disappeared in the absence of macrophages.

In addition, adoptive transfer of BMDM from CD11b-Lpar2fl/fl mice significantly alleviated DSS and TNBS induced colitis in WT mice. In vitro, treatment with both LPA and Lpar2 agonist (DBIBB) enhances M1 macrophage polarization in Raw264.7 and BMDM with increasing expression of M1 macrophage marker.

Furthermore, the knockdown of Lpar2 by shlpar2 abolished the effect of LPA on macrophage polarization. Next, we analyzed the gene expression profile by RNA-Seq in Raw 264.7 after LPA treatment and Gene ontology analysis showed that genes related to cell energy metabolism were enriched.

The seahorse XF cell mito stress test demonstrated that both LPA and DBIBB increased oxygen consumption rate (OCR). Inhibition of OxPhos abolished the effect of LPA. Mechanism screening demonstrated that LPA downregulated the expression of pyruvate dehydrogenase kinase 2 (PDK2) which is a key mitochondrial enzyme.

Conclusion: Targeting LPA Lpar2 in macrophage might represent a potential therapeutic approach for the treatment of intestinal inflammation

Contact E-Mail Address: laura.restaneo3@gmail.com

Introduction: Growing evidence supports the role of environmental factors, such as diet and lifestyle, in modulating the intestinal microbiota and potentially influencing the symptoms of chronic gastrointestinal disorders.

This study aimed to correlate lifestyle habits with colonic microbiota composition in patients with Inflammatory Bowel Disease (IBD) or Irritable Bowel Syndrome (IBS), compared to healthy controls (HCs).

Aims & Methods: 38 IBD, 44 IBS and 48 HC were recruited. Fecal microbiota composition was analyzed by sequencing the 16S rDNA V3/V4 region using the Illumina platform. Dietary habits and physical activity levels were assessed using a 7-day food diary, a Food Frequency Questionnaire, and the IPAQ. Urinary indican was measured via colorimetric assay and HPLC, fecal zonulin levels were assessed using ELISA, and selected circulating microRNAs were analyzed in plasma and serum by TaqMan-based quantitative Real-Time PCR.

Results: A significant reduction in dietary fiber intake was observed in both IBD and IBS patients compared to healthy controls (HCs) ($p < 0.05$). IBS patients engaged in more moderate physical activity than HCs ($p < 0.05$). Reduced fiber intake was associated with decreased microbial diversity ($p < 0.005$), compared to adequate fiber consumption.

Microbiota analysis revealed a reduction in alpha diversity in IBD patients compared to HCs, particularly in terms of phylogenetic diversity and observed features, while IBS patients showed intermediate values. Beta diversity (weighted and unweighted UniFrac) demonstrated a clear separation among the three groups, with the most pronounced differences observed between IBD and the other conditions. LEfSe analysis identified the highest number of discriminant taxa in HCs, consistent with their greater microbial biodiversity. No clearly pathogenic organisms were identified in either IBD or IBS patients, suggesting that the observed alterations may result from a loss of beneficial commensals rather than the presence of harmful species.

Additionally, greater microbial diversity was found in individuals living in rural areas compared to those in urban environments. IBD and IBS patients not adhering to the Mediterranean Diet (MD) showed significantly higher zonulin levels than those following the MD ($p < 0.001$ and $p = 0.003$, respectively).

Finally, miRNAs involved in inflammatory and epithelial permeability pathways were differentially expressed in both IBD and IBS patients. MiR-24 was significantly dysregulated in IBD ($p = 0.01$), while miR-923 also showed a significant difference in the same group ($p = 0.05$). MiR-221 exhibited a non-significant trend toward upregulation in IBS. These findings suggest a potential role for these miRNAs in the molecular mechanisms underlying inflammatory and functional bowel disorders.

Conclusion: The preliminary results of the present study underlined the impact of lifestyle factors, particularly diet and physical activity, on intestinal microbiota composition and barrier function in IBD and IBS. Microbial and molecular markers may support a more personalized approach to these disorders.

CHRONIC INFLAMMATORY BOWEL DISEASES AND CANCERS

M. Ahamam[1], N. Lagdali[1], F.-Z. Chabib[1], M. Kadiri[1], M. Borahma[1], F.Z. Ajana[1]
[1]Ibn Sina University Hospital, Faculty Of Medicine And Pharmacy Of Rabat, Mohammed V University Rabat, Departement of Medecine C, Rabat, Morocco

Contact E-Mail Address: meryem.ahamam@gmail.com

Introduction: Chronic inflammatory bowel diseases (IBD), such as Crohn's disease and ulcerative colitis, are associated with an increased risk of various cancers, particularly colorectal cancer, but also other types, such as small intestine, biliary tract, or liver cancers. Additionally, certain extra-digestive cancers may also occur in patients with these conditions. These risks vary depending on the duration and severity of inflammation, as well as other factors such as family history or exposure to certain treatments. This work explores the diversity of cancers associated with IBD, their prevalence, and their clinical characteristics, highlighting the importance of considering these risks in the medical management of patients.

Aims & Methods: This is a retrospective and descriptive single-center study conducted within a hepatogastroenterology department, focusing on patients followed for inflammatory bowel diseases (IBD) who developed cancer. The study covers the period from 1990 to 2025.

Results: Out of a total of 1,795 patients followed for IBD (1,200 for Crohn's disease and 595 for ulcerative colitis), 2% (36 patients) developed cancer. The male-to-female sex ratio was 0.38, with a clear female predominance. Among the patients, 69.4% (25) had Crohn's disease, and 30.55% (11) had ulcerative colitis.

The most common location of Crohn's disease was colonic involvement (44%, 11 cases),the predominant phenotype was inflammatory (52%, 13 cases) ,for ulcerative colitis the most frequent location was left-sided colitis (54%, 6 cases) ,the median disease duration before the onset of cancer was 60 months.

Digestive cancers were the most commonly associated with IBD (38.8%, 14 cases), followed by breast cancer in women (30.5%, 11 cases), gynecological cancers (11.1%, 4 cases), prostate adenocarcinoma (5%, 2 cases), skin cancers (5%, 2 cases), and other cancers (5%, 2 cases).

Only 30.5% (11 patients) had risk factors (chronic smoking, family history of cancer, etc.).

Regarding treatment, 33% (12 patients) were on biologic therapy , 30.5% (11) were on azathioprin , 16.6% (6) were on therapeutic abstention , 8.3% (3) were on aminosalicylates, and 5.5% (2) were on corticosteroids.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Treatment was discontinued in 63.8% (23) of patients after the discovery of cancer, and 22% (8) experienced a flare-up which was successfully managed with corticosteroid therapy.

Eighty-three point three percent (83.3%, 30 patients) underwent surgical treatment alone or in combination with radiochemotherapy. Sixteen point six percent (16.6%, 6 patients) were at an advanced stage and had metastases, so they received palliative treatment.

Thirty-six percent (36%, 13 patients) had a good outcome, 30.5% (11) were lost to follow-up, and 2.7% (1) died.

Conclusion: The study shows a 2% cancer incidence in IBD patients, slightly higher than the general population's risk (0.3–0.5% annually), likely due to prolonged inflammation and disease duration. These findings highlight the need for enhanced cancer surveillance and preventive strategies, especially for patients with colonic involvement.

Introduction: Patients with the presence of HLA DQA1-05 have a higher risk of loss of response (mainly secondary) to anti-TNF treatment. Therefore, determining the presence of HLA DQA1-05 could be a valuable tool for selecting the most appropriate biological treatment for each patient. However, one of its limitations is the time and resources required for testing in blood samples, which may hinder in clinical practice.

Aims & Methods: Single-centre retrospective cohort study was conducted. HLA DQA1-05 was determined in saliva to assess its potential impact on therapeutic decision making. In a subset of patients, a blood sample was also collected to assess the concordance between the two tests.

Results: Twenty-one patients with inflammatory bowel disease (IBD) who were considered for a change or initiation of biologic therapy were included in the study. Of these patients, 10 (47.62%) were positive cases observed in saliva. HLA DQA1-05 was also determined in the blood of 11 patients, with 6 (54.55%) being negative and 5 (45.45%) positive. The correlation between saliva and blood samples was 100%. Furthermore, rapid HLA determination in saliva influenced management in 14 (66.67%) of the cases, with 10 (62.5%) of these cases switching to another anti-TNF or another target, with Ustekinumab being the most common. No significant differences were found between positive (6 of 10 [60%]) and negative (8 of 11 [72.73%]) results (p = 0.537). With regard to the decision-making process based on HLA results, the following factors were found not to have a significant influence: the number of previous biologic lines (no influence [33.33%] and yes [66.66%] [p= 0.236]), being naive to anti-TNF (3 cases out of 3 [100%]) or presenting primary or secondary failure (7 out of 18 [38.88%] and yes [61.11%] [0.186]). A higher frequency of HLA-positive cases was observed in patients with pancolitis ulcerative colitis and in patients with Crohn's disease with stenosing phenotype, although this did not reach statistical significance.

Baseline IBD characteristics	Frequency	Percentage
Ulcerative Colitis	6	28.57
Crohn's Disease	15	71.43
E2	4	19.05
E3	2	9.52
L1	4	19.05
L2	1	4.76
L3	7	33.33
L1+L4	3	14.29

Conclusion: In our experience HLA DQA1-05 determination in saliva has the potential to personalise the management of IBD patients treated with anti-TNF. In this study, a perfect HLA DQA1-05 saliva-blood correlation was obtained (100%).

AFIMKIBART (ANTI-TL1A) IS EFFECTIVE IN THE BLOCKADE OF CELLULAR SIGNALING INDUCED BY ACTIVE TL1A

D. Vucic[1], F. Fuh[1,1], A. Nguyen[1], E. Varfolomeev[1], A. Oh[1], G. Merana[1], X. Tao[1], D. Place[1], K. Lasch[2], D. Bojic[3], P. Espie[3], M. Neighbors[1], J. McBride[1], V. Mohanan[1]

Contact E-Mail Address: mohananv@gene.com

Introduction: Tumor necrosis factor-like ligand 1A (TL1A) is a member of the Tumor necrosis factor (TNF) superfamily implicated in the pathogenesis of inflammatory bowel disease (IBD) as a key amplifier of the effector function of several immune cells. TL1A can be expressed by various immune cells, including macrophages, dendritic cells, and some T cell subsets, and exists either as a membrane-bound or as a cleaved soluble trimer. TL1A signals predominantly by activating NF-kB pathway via the only known functional receptor, death receptor 3 (DR3), which has restricted expression mostly on effector T cells and innate lymphoid cells (ILCs). Afimkibart is a fully human anti-TL1A antibody that has shown clinical benefit in Phase 2 clinical studies and specifically blocks the activity of trimeric forms of TL1A. Monomeric TL1A has also been described; however, the relevance of monomeric TL1A in DR3 signaling and disease is unclear. This study aimed to understand the functional characteristics of both monomer and trimer TL1A species in primary cells and cell lines.

Aims & Methods: Immunoassays were used to measure the detection of TL1A species in IBD serum. Recombinant human monomeric and trimeric TL1A proteins were assessed for binding to afimkibart using SPR and in cellular assays using primary immune cells and cell lines for nuclear factor-kappa B (NF-κB) signaling and interferon-gamma (IFNγ) production.

Results: In functional cellular assays with primary immune cells, we demonstrate that trimeric recombinant human TL1A (rhTL1A) protein causes significant NF-κB signaling in human peripheral T lymphocytes, and in the presence of interleukin 12 (IL12) and interleukin 18 (IL18) co-stimulation, a significant increase of IFNγ production by human primary peripheral blood mononuclear cells (PBMCs). In line with the mechanism of action, both the NF-κB signaling and IFNγ production are blocked by afimkibart. In contrast, only high concentrations of monomeric rhTL1A, >100 ng/ml, induced moderate NF-κB signal and demonstrated a minimal increase in IFNγ production above IL12 + IL18 stimulation alone. However, this activity was blocked by afimkibart. Lastly, afimkibart blocks endogenous soluble and membrane-bound TL1A.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Herein, we demonstrate that afimkibart blocks NF-kB signaling and IFNγ production induced by TL1A stimulation. While some signaling activity was observed at high concentrations of monomeric TL1A protein, we hypothesize that any signaling observed with monomeric form is likely due to the formation of trimers, which are efficiently blocked by afimkibart. Overall, any monomeric TL1A present should not be functionally active nor be available as a sink for afimkibart, thus preserving the optimal pharmacokinetic (PK) and pharmacodynamic (PD) properties needed for effective target inhibition.

Contact E-Mail Address: jesus.cosin@uv.es

Introduction: MCL1 immunostaining has been shown in fibroblasts of the fibrotic ileum of CD patients[1] suggesting that senescence of these cells may be a mechanism of fibrosis perpetuation. We aimed to analyse here the expression of senescence markers in murine intestinal fibrosis and to determine the effects, on this process, of galacto-oligosaccharide-functionalized Mesoporous Silica Nanoparticles (NPs) loaded with an anti-MCL1 drug, S63845 (MSN-S63845).

Aims & Methods: MCL1 and β-Galactosidase immunohistochemistry (IHQ) were performed in colons of mice underwent two DSS cycles, obtained from a previous samples collection. C57Bl/6 mice (20–25 g) were drinking DSS at 2% during 2 cycles (a cycle consists in 7 days drinking water with 2% DSS, followed by ten days drinking water). After the first cycle, mice were administered intraperitoneally, 5 days a week, with MSN-S63845 (8 mg/kg), empty MSN, vehicle or S63845 (8 mg/kg), until the end of the experiment. Body weight was monitored daily, and mice were sacrificed 34 days after the beginning of the experiment. A sample from the colon was paraffin embedded for both histological analysis (collagen deposition was quantified by the QuPath software in Syrius Red- stained slides) and MPO IHQ. Other sample was used for RT-PCR studies. The number of CD45, CD3 and Ly6G positive cells in blood was analysed by FACS. Unless other mention, results are expressed as mean±sem.

Results: Both MCL1 and β-galactosidase immunostaining were detected in leukocytes and fibroblasts of the colon of chronic DSS-treated mice. The effects of blocking MCL1, selectively in β-gal positive cells (MSN-S63845), or non-selectively (S63845) did not alter changes in body weight associated to DSS, but significantly increased the colon length (cm) of mice receiving MSN-S63845 (5.9±0.2, P=0.002**) or S63845 (6.2±0.3, P=0,0402*) compared with the respective vehicles (5.1±0.1 or 5.2±0.2, respectively). Treatment of MSN-S63845 compared with empty MSN induced a significant diminution in: a) the thickness of the submucosa (32.4±2.9 vs 51.6±5.9, P = 0,024*), b) the number of MPO positive cells (67±15.7 vs 171.2±15.4, P=0.001**) c) the mRNA expression of inflammatory cytokines *il17* (0.08 (0.02-0.5) vs 1 (0.3-1.6) P=0.03$^{\#}$), *cxcl15* (0.4 (0.2-0.6) vs 0.8 (0.5-3.5) P=0.07) and *cxcl5* (0.1 (0.1-1.2) vs 0.5 (0.5-4.2) P=0.048$^{\#}$) and profibrotic markers, *tgfβ1 (0.5*±0.04 vs 1.03±0.1, P=0.003**). In contrast, treatment with S63845 failed to significantly modify any of these parameters. Mice receiving both MSN-S63845 or S63845 exhibited a similar number of CD45, CD3 and Ly6G positive cells in blood than those receiving the respective vehicles.

$^{\#}$Mann-Whitnney; *t-test

Conclusion: The selective blockade of MCL1 in β-galactosidase positive cells of murine inflamed intestine reduces fibrosis development.

Introduction: A compromised intestinal epithelial barrier plays a central role in inflammatory bowel diseases (IBD) by increasing intestinal permeability and promoting inflammation. Therefore, the restoration of intestinal barrier has become critical in IBD management[1].

Methylxanthine caffeine and its metabolites are widely consumed bioactive compounds that are known to influence various physiological processes[2].

However, their impact on gut health, particularly in modulating inflammation and epithelial permeability, remains underexplored.

Aims & Methods: The aim of this study was to investigate potential effects of caffeine (CAF) and its primary metabolites paraxanthine (PRX), theobromine (TBR) and theophylline (TPHL) on inflammatory responses and barrier integrity in colonic epithelial organoids, providing insights into their potential role in IBD management. Primary screening of different concentrations of CAF (1/2.5/5 mM) and its metabolites PRX (10/50/100 µM), TBR (10/20/50 µM) and TPHL (25/100/500 µM) was performed in Caco-2 cells. Selected metabolites and concentrations were further tested on inflamed 3D intestinal epithelial organoids derived from ulcerative colitis patient (n = 1) and non-IBD individual (n = 1). Both Caco-2 cells and organoids were pre-treated with metabolites for 1 hour before inflammation induction and were further co-treated with TNF-α/IFN-γ cytokine mix (10 ng/ml each) and metabolites for 24 hours.

The effects on inflammation status and epithelial barrier integrity were tested through targeted gene expression analysis using RT-PCR and FITC-Dextran (4kDa) assay, while the effects on generation of reactive oxygen species were investigated by Flow cytometry and DHE assay. The study was approved by the Kaunas Regional Biomedical Research Ethics Committee (protocol no. BE-2-31).

Results: Primary screening revealed that both CAF and its metabolite PRX affected the expression of genes encoding inflammatory cytokines (*TNF, CXCL9*; p ≤ 0.05) and tight junction proteins *(OCLN, TJP1, CLDN1*; p ≤ 0.05) and were selected for further analysis in 3D intestinal organoids. Neither CAF, nor PRX reduced the expression of inflammatory cytokine-encoding genes in inflamed intestinal organoids. However, both CAF and PRX increased expression of tight junction proteins in inflamed intestinal organoids derived from control non-IBD (*TJP1* – 3.16-fold by CAF and 1.33-fold

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

by PRX (p ≤ 0.05); *OCLN* – 1.57-fold by CAF and 1.38-fold by PRX (p ≤ 0.05)) and ulcerative colitis (*TJP1* – 1.32-fold by PRX; OCLN - 1.14-fold by CAF and 1.27-fold by PRX (p ≤ 0.05)) patient-derived organoids. Mean percentages of FITC-Dextran positive organoids were 43 %, 51 %, and 34 % in untreated, inflamed, and inflamed + PRX groups, respectively, revealing a trend in barrier restoration, though it did not reach statistical significance (p = 0.16 in inflamed vs. inflamed + PRX). A tendency of reduction in reactive oxygen species production was also observed after exposure to caffeine or paraxanthine (by 17 % and 11 %, respectively (p > 0.05)).

Conclusion: Methylxanthine paraxanthine might have a positive effect on gut epithelial barrier function through restoration of the expression of tight junction protein-coding genes.

The study was funded by the European Union and the State Secretariat for Education, Research and Innovation (SERI) (project: miGut-Health, grant no. 101095470).

Introduction: Patients with ulcerative colitis (UC) are at increased risk of developing colorectal cancer (CRC), and this is assumed to be due to chronic inflammation of the colorectal mucosa.

Aims & Methods: To identify risk factors for the development of dysplasia or CRC in patients with UC. Retrospective observational cohort study. Clinical data and colonoscopy findings were collected from medical records. A 1:2 Propensity Score Matching (PSM) was performed to balance covariates adjusting for disease extension, age, gender, smoking habit and disease duration. An Andersen-Gill model was used to account for multiple colonoscopies per patient and time-varying risk of dysplasia or CRC, allowing for recurrent events and intra-individual correlation.

Results: A total of 571 UC patients were identified, median age at diagnosis was 39.5 (27.3-54.2), and 304 (53.2%) were men. At diagnosis, 147 (25.7%) had proctitis, 203 (35.6%) left side colitis and 191 (33.5%) extensive colitis. During a median follow-up of 7.1 years (IQR 3.7– 13.3), 51 patients (9.8%) developed dysplasia/CRC. This was more frequent in males (72.9% vs. 27.1%, p=0.004) and in older patients [48.1 years (36.7–60.2) vs. 38.5 years (26.5–53.8), p=0.004].

After PSM adjustment, 123 patients were included, 41 of whom had dysplasia/CRC, with a total of 381 colonoscopies over a follow-up period of 14.6 years (IQR 8.0–22.4). Macroscopic inflammatory activity was present in 283 (74.3%) colonoscopies and microscopic involvement in 5 (1.3%). Older age at diagnosis (aHR 1.03, 95% CI 1.04–1.10, p<0.001) and higher degree of macroscopic inflammation (aHR 1.44, 95% CI 1.02–2.03, p=0.041) were associated with an increased risk of dysplasia/CRC development; advance therapy, family history of CRC, disease extension and microscopic inflammation were not associated with an increased risk.

	Complete cohort				PMS			
	N = 571	No dysplasia/ CRC	Dysplasia/CRC	p	N = 123	No dysplasia/ CRC	Dysplasia/CRC	p

LINKING SERUM BIOMARKERS TO HISTOLOGICAL EVIDENCE OF INFLAMMATION IN IBD: A PILOT STUDY ON EXTRACELLULAR MATRIX AND NEUTROPHIL ACTIVATION FOLLOWING RITLECITINIB TREATMENT

M. Hassanein[1], R.D Ryan[2], Y. Zhao[1], E. Kieras[1], C. Duan[1], A.-C. Bay-Jensen[3], J.H. Mortensen[4], C. Hyde[5], J. Gale[1], E. Peeva[1,6], A. Sapone[7]

Introduction: Extracellular matrix (ECM) remodeling and neutrophil activation are key aspects of the tissue turnover and fibro-inflammation characteristics of IBD pathophysiology. Mucosal damage, which includes ECM changes, affects intestinal barrier integrity, contributes to chronic inflammation, leading to fibrosis and strictures. Understanding the link between ECM remodeling and mucosal damage is key to decoding healing mechanisms that occur in response to IBD treatments. Serum biomarkers may serve as a valuable surrogate for indicating therapeutic response in IBD patients, providing a non-invasive solution.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

This pilot study aims to evaluate the utility of a panel of serum biomarkers for monitoring pharmacodynamic (PD) and histological disease activity response in IBD patients treated with ritlecitinib, a JAK3/TEC inhibitor.

Aims & Methods: Aim: Assess the link between a panel of seven serum biomarkers that reflect ECM turnover and neutrophil activation (CPa9-HNE, PRO-C3, C3M, PRO-C22, C4M, C7M, CTX-III) with endoscopic, and histological responses to ritlecitinib treatment in a pilot study using samples from two Phase 2 UC and CD clinical trials (Vibrato[1] and Pizzicato[2]).

Methods: Longitudinal serum samples were collected from endoscopic responders (R, n=13) and non-responders (NR, n=12) to ritlecitinib 200 mg in patients with moderate to severe UC (8 weeks) and CD (12 weeks) at baseline and at Week 8 for UC or Week 12 for CD. Endoscopic response was defined either as a Mayo Endoscopic subscore of ≤1 at Week 8 for UC, or as a ≥50% reduction in the Simple Endoscopic Score for CD (SES-CD) from baseline at Week 12 for CD. Neo-epitope biomarkers reflecting neutrophil activation (CPa9-HNE), mucosal damage (C3M, C4M, C7M, PRO-C22), fibrogenesis (PRO-C3), and fibrolysis (CTX-III) were measured in serum samples by ELISA.

Correlations between ECM biomarker levels with endoscopic response, and histological parameters were assessed using the Geboes score for UC and the Colonic Global Histologic Activity Score (cGHAS) and Ileal Global Histological Activity Score (iGHAS) for CD to understand the relationship between pharmacodynamic changes and histological disease activity indicies improvement. Changes in histological activity in colon biopsies from UC subjects were assessed using IBD Explore v2.0.0.

Results: Changes from baseline for C7M, CPa9-HNE, and PRO-C22 suggested a response to treatment in the CD-responders group, although these changes were not statistically significant. Neutrophil activation serum biomarker, CPa9-HNE, showed statistically significant correlation with cGHAS at baseline and iGHAS at Week 12 post-treatment. Similarly, serum C7M levels correlated with iGHAS at Week 12.

None of the serum biomarkers tested showed a statistically significant correlation with the Geboes score in the UC cohort. Only UC responders to ritlecitinib demonstrated a consistent decrease in total neutrophil count in both the epithelium and lamina propria (LP) compared to NR. Interestingly, further histological analysis revealed that serum levels of CPa9-HNE were significantly correlated with total neutrophil count in colon tissues, specifically in the epithelium and LP at baseline in UC.

Conclusion: These initial observations suggest that certain blood markers related to mucosal damage and neutrophil activation might be linked to inflammation seen in tissue samples. Larger studies are needed to confirm these results. This highlights the potential of using blood markers to evaluate disease activity in IBD.

Introduction: Altered gut microbiome composition has been implicated in the pathogenesis of inflammatory bowel disease (IBD). However, detailed characterization of microbial diversity differences between IBD subtypes remains incomplete. This study aimed to evaluate gut microbiome alpha diversity in patients with Crohn's disease (CD) and ulcerative colitis (UC) compared to healthy controls using long-read 16S rRNA sequencing technology.

Aims & Methods: Fecal samples were collected from 17 patients with CD, 20 patients with UC, and 192 healthy controls without IBD. DNA was extracted using an SKYAmp stool DNA kit (SkyGen, Russia). Long-read nanopore sequencing of 16S rRNA amplicons was conducted using a MinIon™ sequencer. Taxonomic assignment was performed with EMu software by aligning FASTQ reads to the NCBI 16S database [1]. Alpha-diversity was evaluated at the species level using Chao1 and Shannon indices. Statistical comparisons between groups were conducted using Welch two-sample t-tests with Holm adjustment in R environment and the RStudio software (version 4.4.1).

Results: The Shannon diversity index was significantly lower in the CD group compared to the control group (p=0.01412), while no significant difference was observed between UC and control groups (p=0.15461). Chao1 richness index values were significantly reduced in both CD and UC patient groups compared to controls (p=0.00003 and p=0.03195, respectively), indicating reduced species richness in both IBD conditions.

	Without IBD	CD	UC
Shannon index	3.452 (3.410 - 3.494)	3.165 (2.970 - 3.360)	3.270 (3.016 - 3.524)
Chao1 index	85.750 (84.046 - 87.454)	67.529 (61.087 - 73.972)	74.650 (64.729 - 84.571)

Conclusion: This study demonstrates that both IBD subtypes exhibit reduced microbial richness as measured by the Chao1 index, while significant reduction in Shannon diversity was observed only in CD patients. These findings suggest differential impacts of CD and UC on gut microbiome composition, with CD potentially having more profound effects on overall microbial diversity. Long-read 16S rRNA sequencing provides valuable insights into the microbial signatures associated with different IBD phenotypes, which may contribute to improved diagnostics and personalized treatment approaches.

Introduction: The pathogenesis of autoimmune diseases, such as Crohn's disease (CD), Ulcerative colitis and Spondyloarthritis (SpA) has been linked to imbalanced CD4+ and CD8+ T-cell responses. CD3+CD4-CD8- double-negative (DN) T cells, although constituting a rare subset of peripheral T cells, are gaining interest for their roles in inflammation, immune disease and cancer. However, controversy persists regarding their ontogeny and function.

Aims & Methods: The aim of this study is to evaluate the circulating immune cells involved in response to biological therapy in patients with two concomitant autoimmune disease, in particular $CD3^+$T cells, CD3+CD4-CD8- DN T cells, CD3+CD4+CD8+ *double positive* (DP) T cells and Terminal Effector Memory Re-expressing CD45RA T cells (Temra) identified as CD45RA+CD95+CD197-CD27- CD4+ or CD8+ lymphocytes.

Blood samples were collected from 4 patients affected by CD (disease duration 6-10 years) who developed SpA (ASAS criteria, disease duration 2-7 years)., and after 1 year under stable therapy with one biological drug (anti-TNFalpha therapy: n=3; anti-IL23 therapy: n=1). Cytofluorimetric analysis using the BD FACSLyric Flow Cytometry system was performed for T-cell subpopulations analysis using surface markers including: CD3, CD4, CD8, CD45RA, CC197, CD62L, CD44, CD27 and CD95.

Results: CD45RA+CD197+CD95+ (stem cell memory T cells, Tscm), CD45RA-CD95+CD27+ (central memory T cells, Tcm), CD62low and CD44high (naive Tcells) and CD45RA-CD95+CD27low (effector memory T cells, Tem) were evaluated. Significant differences were found in percentage of CD3+CD4-CD8- DN T cells and CD3+CD4+CD8+ DP T cells: in 3 patients the percentage of CD3+CD4-CD8- DN T cells were significantly higher than CD3+CD4+CD8+ DP T cells. The same patients didn't show significant differences between CD4+ and CD8+Temra cells (respectively, CD4+CD45RA+CD95+CD197-CD27- and CD8+CD45RA+CD95+CD197-CD27- T cells). The only patient, where no significant differences appear between CD3+ DN and CD3+ DP T cells, and where CD4+CD45RA+CD95+CD197-CD27- didn't appear at all, was a difficult to treat patient with uncontrolled intestinal and articular manifestations who subsequently needed double-targeted therapy with anti-TNFalpha plus anti-IL23 biologics.

Conclusion: Our preliminary data suggest that T cell subset distribution could be dysregulated in difficult-to-treat IBD-SpA patients. In particular, DN T cells and Temra could be associated with induction of peripheral immunological tolerance and immunomodulatory activities related to disease control. Further studies are warranted to test this hypothesis and to evaluate the effect of different biological therapy classes on T cells during IBD-SpA.

Disclosure: Nothing to disclose.

"INDEFINITE FOR DISPLASIA" IN INFLAMMATORY BOWEL DISEASE COLITS: OUTCOME IN A 3 YEARS FOLLOW UP STUDY

R. Mancone[1], B. Neri[2], M. Fiorillo[1], E. Wilhelm[3], C. Seghetti[4], E. Lolli[1], I. Marafini[1], E. Calabrese[1], L. Savino[4], L. Biancone[1]

Contact E-Mail Address: roberto.mancone@yahoo.it

Introduction: In Inflammatory Bowel Disease (IBD), histological assessment of colonic biopsies may detect areas "indefinite for dysplasia" (IND). This definition is used when a definite distinction between non-neoplastic changes and neoplasia is not possible(1).

The role of this finding in predicting the endoscopic and histological findings in IBD colitis is currently undefined.

Aims & Methods: Primary aim was to evaluate the outcome of IBD patients(pts) with an initial histological finding of areas IND in random colonic biopsies, followed up for ≥ 3 years. At this purpose, all IBD pts showing areas IND in colonic biopsies taken from March 2018 to March 2022, subsequently followed up for ≥3 years including ≥ 1 control colonoscopy were retrospectively enrolled. All pts were in regular follow up at our referral IBD Unit and underwent colonoscopy with histological assessment in the same center.

Results: The study population included 99 pts with IBD colitis and histological aspects IND detected in random colonic biopsies in 79(79.8%) pts and in target biopsies in 20(20.2%) pts. In the 79 pts, areas IND were detected in random biopsies taken from: rectum in 62(78%), left colon in 29(36%), transverse colon in 6(7.5%), right colon in 5(6.3%), >1 area in 18(22.3%) pts. In the 20 pts with areas IND on target biopsies, these were taken from stenosis (5 pts), polyps (9 pts), lateral spreading tumors (2 pts), flat elevated mucosa (4 pts).

For the aim of the study, only the 79 IBD pts (37 females, 46.8%) showing in random colonic biopsies areas IND were considered.

These 79 IBD pts (69 UC, 9 CD, 1 unclassified colitis) showed median age of 51 [18-79], long-standing IBD in 54(68.4%), family history of CRC in 11(13.9%), concomitant primary sclerosing cholangitis in 1(1.3%) pt. Random biopsies were taken from colonic mucosa proximal to ulcerations in 54(68.4%) pts, erosions in 19(24%) pts and to mild inflammation in 6(7.6%) pts.

The second colonoscopy was performed after a median of 11[1-42] months. In the 79 pts with a first evidence of areas IND on random biopsies, the second colonoscopy detected: dysplasia in 10(12.6%) pts (high grade, HGD in 2[2.5%], low grade dysplasia, LGD in 8[10.1%]pts), areas IND in 12(15.2%) pts, no dysplasia (HGD, LGD or IND) in 38(48.1%) pts, while in the remaining 16(20.3%) pts no reliable histology was available.

LGD at second colonoscopy was detected in random biopsies (4pts) or in target biopsies (4pts). Differently, in both pts with HGD it was detected in target biopsies, including one focal area of adenocarcinoma (CRC) in 1(1.3%) pt. Areas IND confirmed at second colonoscopy were detected in the same colonic segment in 11(13.9%) pts and in a different segment in 1(1.3%) pt.

After the second colonoscopy, 4 out of the 79 IBD pts required IBD-related colonic surgery, and histology of the surgical specimen detected LGD in 1 pt, CRC in 1 pt and areas IND in 2 pts.

During the study period (median 27[2-75] months) 51 out of the 79(64.5%) IBD pts repeated a third colonoscopy detecting: areas IND in 4(7.8%), LGD in 6(11.8%), HGD in 1(2%) pts and no CRC.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. IMMUNE CHECKPOINT INHIBITOR-INDUCED COLITIS IS DEPENDENT ON GRANZYME EXPRESSION

J. Lo[1], Y. Cao[1], X. Zhou[1], N. Powell[1]
[1]Imperial College London, London, United Kingdom

Contact E-Mail Address: j.lo@ic.ac.uk

Introduction: Immune checkpoint inhibitors (CPI) have revolutionised cancer outcomes, but frequently trigger immune related adverse effects, including life-threatening colitis. Tissue resident memory (TRM) T cells are key cells involved in the pathogenesis of CPI-induced colitis (CPI-C), but the mediators they produce to facilitate disease are poorly defined.

Aims & Methods: We utilised our previously published *in vivo* pre-clinical model of CPI-C, which occurs when mice are given combination anti-CTLA4 and anti-PD1 and a proinflammatory microbiota mix, to define the role of the Granzyme A/B cytotoxicity pathway in disease.

Disease was induced in wildtype (WT) and Granzyme A/B double knockout (*GzmAB*$^{-/-}$) mice. Clinical outcomes (colon and spleen mass, histology and infiltrating neutrophils) from these mice were assessed to measure the severity in disease. T cell populations were also analysed using flow cytometry.

Results: *GzmAB*$^{-/-}$ mice showed a significant reduction in disease features compared to WT mice, with reduced colon mass, reduction in infiltrating neutrophils and fewer inflammatory monocytes. Flow cytometry analysis of the T cell compartment revealed a significant reduction in both bulk CD4 and CD8 T cells and also CD4 and CD8 tissue resident memory T cells in both the cLP and IEL in *GzmAB*$^{-/-}$ mice treated with CPI-C in comparison to WT mice treated with CPI-C. *GzmAB*$^{-/-}$ mice treated with CPI-C also had a reduction in IFNγ and TNFα production from both CD4 T cells and CD8 T cells.

These data highlight the importance of granzymes in inducing the disease phenotype in CPI-C. In order to investigate whether CD4 T cells or CD8 T cells were more important, we depleted these cells *in vivo* in WT mice treated with CPI-C at both 1 and 3 weeks.

Here, we found that WT mice with CD4 T cells depleted got significantly worse disease with colon masses increasing and there being increased infiltrating neutrophils. There was an increase in cytotoxic cytokines being produced by CD8 T cells when CD4 T cells were depleted. However, when CD8 T cells were depleted, there was no change in any clinical features or cytokine production from CD4 T cells.

Conclusion: Using *GzmAB*$^{-/-}$ mice we have demonstrated that CPI-colitis is at least partially dependent on the granzyme cytotoxicity pathway. Targeting the cells that produce granzyme in the colon of patients with CPI-colitis might offer an attractive novel treatment option for patients with CPI-colitis.

Introduction: Short bowel syndrome (SBS) is a malabsorptive condition mostly caused by massive surgical resection of the small intestine and is associated with significant morbidity and mortality, reduced quality of life, and high healthcare costs[1].

Crohn's disease (CD) represents a potential cause leading to an increased risk of SBS with considerable clinical consequences[2].

Human microbiota-associated (HMA) mice represent a model to establish human fecal microbiota in preclinical models[3-4].

Here, for the first time, we tried to conduct a "humanized" model of SBS, using faeces from patients affected by this disease.

Aims & Methods: The aim of the current study is to determine the functional role of the gut microbiota of CD patients with or without SBS. A dextran sodium sulphate model of colitis on C57BL/6 mice was employed to assess immune and metabolic signatures following faecal transplantation from patients affected by SBS/IF, CD with high or low risk for SBS/

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. IF. Lymph node samples were collected to examine differences in T cell populations, and disease activity index and bronchoscopy were used to evaluate the activity of the disease.

Results: Fecal microbiota transplantation (FMT) from CD patient with a low risk of SBS/IF was associated with worse disease activity and endoscopic scores in colitis mice.

Additionally, an increase in the percentages of Treg, Tnaive, Th1, and Th17 cells was observed in mice that received FMT from CD patient with a low risk of SBS/IF, compared to controls and those that received FMT from patient with SBS/IF or from CD patient with a high risk of SBS/IF.

Conclusion: Our data underscore the complex interactions between gut microbiota and host immunity and highlight the importance of careful donor selection in FMT applications, particularly for inflammatory conditions. Further research is warranted to characterize specific microbial and immunological factors that drive these effects and to identify microbiota profiles that could potentially confer therapeutic benefits.

Introduction: The BIOSTOP trial is a Norwegian, multicenter study with a prospective, randomized, controlled, and open-label design. The trial was initiated to evaluate the two-year outcomes following the withdrawal of tumor necrosis factor-alpha (anti-TNF) antibodies in patients with ulcerative colitis (UC) who are in sustained clinical and endoscopic remission.

Aims & Methods: The main aim was to identify transcriptomic differences in colon biopsies associated with increased risk of relapse with anti-TNF withdrawal. We also wanted to increase our understanding of the underlying pathological mechanisms of relapse after anti-TNF withdrawal and treatment failure during continued treatment.

Between June 2017 and December 2020, 174 ulcerative colitis patients in confirmed clinical and endoscopic remission were enrolled and randomized, with 86 assigned to continue anti-TNF therapy (control group) and 86 to discontinue treatment (intervention group). Mucosal biopsies were collected at baseline, two-year follow-up, and at point of relaps

Bulk mRNA-sequencing was performed on RNA extracted from rectal biopsies. For patients in remission, samples from baseline and two-year follow-up were analyzed. For those who relapsed or experienced treatment failure, samples from baseline and point of relapse were analyzed. Differential gene expression was performed using DESeq2, and pathway enrichment analysis was assessed with clusterProfiler.

Results: There were no significant differences found at baseline between patients that relapsed (n=45) vs those that stayed in remission (n=41) after anti-TNF withdrawal. In patients that relapsed, the comparison from baseline to point of relapse showed upregulation of key inflammatory genes, including IL1B, STAT3, OSMR, TNF and CXCL10. Pathway enrichment analysis showed that the upregulated genes were associated with an inflammatory response, including TNF-signaling. At two-year follow-up patients who remained in remission also showed upregulation of proinflammatory genes, including genes associated with TNF-signaling. However, the expression levels were lower than in the relapse group. Patients in the control group who experienced treatment failure (n=10) showed a gene expression signature that strongly overlapped with those that relapsed in the intervention group.

Conclusion: We did not detect any transcriptional differences between the relapse and remission group at baseline and after anti-TNF withdrawal the expression of proinflammatory genes including genes involved in TNF-signaling increased in both groups. However, a more pronounced increase was observed in the relapse group, suggesting that those that relapse exhibited reduced immunoregulatory capacity.

Introduction: In the context of inflammatory bowel diseases (IBD), the involvement of brain-gut interaction has been intensely studied in the last decade. Connections between IBD and mental disorders have been previously studied. Psychiatric symptoms, in particular stress, anxiety, and depression, adversely affect a broad range of outcomes in IBD, including increased risk of disease relapse and poorer response to treatment. Although genetic predisposition is crucial for immune-mediated diseases, it seems that environmental factors could have a great impact. Alterations in circulating miRNA levels have been demonstrated both in IBD and psychiatric diseases, but no study has identified a miRNA pattern underlying the crosstalk between IBD and psychiatric symptoms.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Aims & Methods: The aim of this study was to identify a plasma miRNA-based pattern that could be specific to IBD or associated with the complex phenotypes of IBD in conjunction with stress, anxiety, and depression.

A total of 81 individuals were enrolled in this study. All the patients agreed to undergo a psychiatric consultation and have been screened using the following scales: the Hamilton Anxiety Scale (HAM-A), the Becks Depression Inventory (BDI) and the Perceived Stress Scale (PSS).

Based on their IBD diagnosis and psychiatric evaluation, four groups were considered as follows:

i. IBD (patients with IBD with no psychiatric symptoms);

ii. IBD+SAD (patients with IBD presenting stress, and/or anxiety, and/or depressive symptoms);

iii. SAD (patients with a main diagnosis of recurrent depressive disorder);

iv. CTRL (individuals without IBD and without psychiatric disorders).

The levels of 179 miRNAs have been evaluated by qRT-PCR in the plasma from the entire cohort.

Results: More than 40 miRNAs were identified as differentially expressed among the three patient groups in at least one comparison vs CTRL group. The IBD vs CTRL comparison demonstrated the differential expression of four miRNAs (miR-333-3p, miR-1260a, miR-320d, miR-423-5p, and miR-486-5p), whereas the SAD vs CTRL comparison indicated an alteration of 28 miRNA levels. Five miRNAs (miR-223-3p, miR-1260a, miR-320d, miR-423-5p, and miR-486-5p) exhibited differential levels across all comparisons, indicating their potential as markers for the complex phenotype combining IBD and SAD.

Pearson correlation analyses between the level of miRNAs and psychiatric symptoms evaluated by previously mentioned scales were performed, and several significant correlations were found.

Conclusion: In this study we identified a molecular pattern associated with the complex phenotypes of IBD in comorbidity with psychiatric symptoms. Our results might help to develop new tools for predicting disease evolution and also provide new insights into the gut-brain IBD axis.

This investigation received financial support from ICGEB (Contract No.CRP/22/019, ICGEB Ref. No. CRP/ROU21-01)

Contact E-Mail Address: elthes.zsuzsa@med.unideb.hu

Introduction: Inflammatory bowel diseases (IBD) are showing an increasing incidence globally. Despite advanced therapeutic options, many patients still require surgical intervention during their disease course. Timely surgical planning and strategy selection are critical, highlighting the importance of collaborative, multidisciplinary care.

Aims & Methods: To assess the role and outcomes of a multidisciplinary IBD team (involving gastroenterologists, surgeons, and radiologists) in optimizing the management of IBD patients.

In November 2023, a multidisciplinary IBD team was established at our institution. Regular case discussions focused on disease characteristics, treatment history, and therapy outcomes. Patient data were collected retrospectively, including disease type, treatment timeline, surgical interventions, and complications.

Results: Seventy-five patients were reviewed; 40 (53%) underwent surgery. Of these, 38 (95%) had Crohn's disease and 2 (5%) had ulcerative colitis. The male-to-female ratio was 23:17. In Crohn's disease patients: 18% had isolated colonic, 24% ileocecal, 26% upper GI, and 32% both small and large bowel involvement. One UC patient had left-sided colitis, the other pancolitis. The median age was 36 years (IQR 30–48).

Eighty percent received prior immunomodulators, with azathioprine still in use in 5 cases. The median time to initiation of immunomodulatory therapy after diagnosis was 11 months (IQR 4–41). Biological therapy had been used in 75% of patients, with a median initiation time of 63 months post-diagnosis (IQR 22–129); in 12.5%, surgery preceded biological therapy.

Previous bowel resection was noted in 40%, with a median time of 52 months since the last surgery. Balloon dilation had been performed in 15% prior to team discussion. Malignancy was suspected in 3 patients (7.5%) and confirmed in one (2.5%). Six patients (15%) underwent robot-assisted surgery. Fourteen required preoperative hospitalization. Postoperative anastomotic leakage occurred in 2 cases (5%), both with fatal outcomes due to comorbidities.

Conclusion: Multidisciplinary management enables timely and individualized therapeutic decisions in IBD care. Regular team discussions improve surgical planning and patient preparation, reducing complication risks, shortening hospital stays, and enhancing quality of life. Moreover, collaboration fosters mutual understanding and continuous professional development across disciplines.

THERAPEUTIC POTENTIAL OF PROBIOTICS IN DNBS-INDUCED COLITIS: IMMUNOLOGICAL AND MICROBIAL INSIGHTS

P. Rattanachaisit[1], N. Lerttanatum[1], S. Tumwasorn[1], N. Chuaypen[1], T. Dissayabutra[1], D. Werawatganon[1]
[1]Chulalongkorn University, Bangkok, Thailand

Contact E-Mail Address: pakkapon.r@gmail.com

Introduction: Inflammatory bowel disease is a chronic, relapsing condition influenced by genetic, microbial, and environmental factors. This study evaluated the therapeutic potential of multi-strain probiotics in mitigating the severity of experimentally induced colitis in rats, focusing on clinical outcomes, histopathological changes, inflammatory markers, and microbiota changes.

Aims & Methods: Thirty six-week-old male Sprague-Dawley rats were randomly assigned to three groups: Control, Acute Colitis (AC), and Probiotic Treatment (RP; receiving *Lactobacillus rhamnosus* and *Lactobacillus paracasei*). Probiotics were administered orally once daily, beginning three days prior to colitis induction with rectal DNBS and continued for seven days post-induction. On day eight, colon tissues and blood samples were collected for histological and biochemical analysis, and fecal samples were analyzed to assess gut microbiota composition.

Results: The AC group showed significantly elevated TNF-α levels compared to the Control and RP groups ($p < 0.001$), while probiotic treatment significantly reduced TNF-α levels compared to the AC group ($p = 0.002$, $p < 0.001$, respectively). Although the RP group demonstrated increased IL-10 levels and decreased MDA levels, these changes were not statistically significant. Histopathological analysis revealed a lower median Ameho's score in the RP group compared to the AC group, though without statistical significance.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Microbiota analysis showed no significant differences in alpha diversity across groups. However, beta diversity significantly differed in the AC group compared to Control, and after probiotic treatment, the RP group's beta diversity showed a partial shift toward the Control group. Distinct microbial species characterized each group: *Akkermansia spp.* and *Parasutterella spp.* were predominant in distinguishing the Control group from others; *Romboutsia spp.* and *Turicibacter spp.* differentiated the AC group; and *Roseburia spp.* and *Anaerotruncus spp.* were the key species distinguishing the RP group from the others.

	Control	AC	RP
TNF-α (pg/ml)	3240 (2185-3852.5)	10950 (5880-16275)	3505 (2342.5-4762.5)
IL-10 (pg/ml)	313 (170.5-528.25)	199 (111.2-522.75)	324 (248.5-445.25)
MDA (nmol/mg protein)	(1.69-12.84)	9 (2.44-25.54)	4 (2.38-20.78)
IL-17 (pg/ml)	121 (118.25-159.75)	128 (121-151.75)	127 (121.75-129.25)
Ameho's score	0	5 (1-5)	1 (1-3.5)

Conclusion: Multi-strain probiotics reduced TNF-α levels and modulated gut microbiota composition in DNBS-induced colitis. Although changes in IL-10, MDA, and histopathology were not statistically significant, trends favored the probiotic group. Microbial analysis revealed distinct species profiles across groups, with partial restoration of beta diversity and enrichment of beneficial taxa like *Roseburia spp.* in the probiotic group. These findings support the potential of probiotics as a therapeutic adjunct in IBD, highlighting the need for further studies to confirm efficacy and explore underlying mechanisms.

NEUROLOGICAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE: A COHORT-BASED STUDY

D. Darkaoui[1], H. Koulali[1], A. Zazour[1], O. Elmqaddem[1], Z. Ismaili[1], G. Kharrasse[2]
[1]Mohammed VI University Hospital, Hepatogastroenterology, Oujda, Morocco, [2]Faculty of Medicine, Hepatogastroenterology, Oujda, Morocco

Contact E-Mail Address: darkaoui.douaa.8@gmail.com

Introduction: Inflammatory bowel diseases (IBD) are chronic disorders primarily affecting the gastrointestinal tract, but they may also involve other organs through extraintestinal manifestations, including the nervous system. Neurological features can present with a broad spectrum of symptoms, from acute to chronic, involving both the central and peripheral nervous systems.

These manifestations are underdiagnosed and underestimated. Their pathophysiology remains incompletely understood and is thought to be multifactorial.

Neurological complications in IBD are generally divided into two categories:

• Non-drug-induced: directly related to disease activity, immune mechanisms, or nutritional deficiencies.

• Drug-induced: secondary to immunosuppressants or biologics, such as demyelination or neurotoxicity.

Aims & Methods: This study aims to describe the prevalence and spectrum of neurological manifestations in a well-characterized cohort of IBD patients and to identify potential risk factors.

This retrospective descriptive and analytical study was conducted in a tertiary referral center over a nine-year period (January 2016 – March 2025). All included patients had a confirmed diagnosis of IBD, based on clinical, endoscopic, histological, and radiological criteria , with regular follow-up. Disease activity was assessed using the Harvey-Bradshaw Index for CD and the Mayo score for UC. The presence of neurological symptoms assessed by a neurologist. All patients presenting with neurological complaints underwent a complete clinical neurological evaluation, neuroimaging (CT or MRI), laboratory tests, electroencephalography , and electromyography investigations as indicated.

Results: A total of 300 patients with IBD were included, comprising 193 with Crohn's disease and 107 with ulcerative colitis. The mean age was 41 years. Neurological manifestations were identified in 24 patients, accounting for 8% of the cohort. These manifestations were significantly more frequent in patients with UC (14.9%) than in those with CD (4.1%), with a statistically significant difference (p = 0.01).

The sex distribution among patients with neurological symptoms included 13 males (54%) and 11 females (46%), with no significant gender difference observed (p = 0.5). Furthermore, 18 of the 24 patients presenting with neurological involvement had inactive IBD at the time of symptom onset (p = 0.2).

Neurological manifestations were identified and classified based on their presumed etiology.

Drug-induced manifestations were observed in 14 patients. These included 10 cases of paresthesia (3.3%), considered functional or early sensory disturbances, and 4 cases of peripheral neuropathy (1.3%) attributed to medication-related toxicity.

Non–drug-induced manifestations were noted in the remaining patients. These consisted of 7 cases of ischemic stroke (2.3%), 6 cases of migraine (2.0%), 2 cases of epilepsy (0.7%), 2 cases of cerebral venous thrombosis (0.7%), and 1 case of Wernicke's encephalopathy (0.3%).

Notably, no cases of multiple sclerosis or drug-induced demyelinating diseases were reported in this cohort.

Conclusion: This study reveals that neurological involvement in IBD, particularly UC, may be more prevalent than previously appreciated.The low true prevalence or potential underdiagnosis due to lack of targeted screening. A multidisciplinary approach, involving gastroenterologists, neurologists, and other specialists, to prevent long-term morbidity.

Prospective multicenter studies are warranted to better delineate classification criteria, risk factors, and long-term outcomes of neurological EIMs in IBD.

Disclosure: Nothing to disclose.

PP0392

DEVELOPMENT OF AN *IN VIVO* MODEL OF DSS-INDUCED COLITIS FOR DOSE OPTIMIZATION OF ANTI-TNFA, ANTI-INTEGRIN A4B7 AND ANTI-IL23P19 BIOLOGICS AS A BASIS FOR COMBINATION THERAPY STUDIES

F. Suarez-Trujillo[1], M. Orejudo del Río[1], I. Soleto[1], G. Chacon-Calvo[1], M. Baldan Martin[1], P.J Martínez[1], C.H Gordillo-Vélez[2], D. Cibrián[3], J. Gisbert[1], M. Chaparro[1]

Contact E-Mail Address: fabiosuareztr@hotmail.com

Introduction: Current immunotherapy for inflammatory bowel disease (IBD) treatment is based on anti-TNFa, anti-integrin a4b7, anti-IL12/IL23 and anti-IL23 antibodies that have demonstrated to be safe and effective. However, up to two third of patients treated with biologics do not reach complete remission of the disease; this therapeutic ceiling is one of the

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

main challenges we face in the management of patients with IBD. Many *in vivo* models have been developed for research with biologics, but the literature on doses of above-mentioned drugs in *in vivo* IBD models is scarce, highly variable and covers wide ranges.

Aims & Methods: In this work, we aim to find the optimal dose for biologic treatment in a DSS-induced colitis model. C57BL/6 mice were randomized into a control group and treatment groups receiving 3% DSS combined with varying doses of neutralizing antibodies against TNFα, integrin α4β7, and IL-23p19. Treated mice received 3% DSS *ad libitum* for 5 days and clean water for another 3 additional days (5+3 model). Neutralizing antibodies were injected intraperitoneally on days 2 and 5 of the experiment. Doses used for optimization were set for each dose at 100, 250 and 500 µg/mouse for anti-integrin α4β7 and anti-IL23p19 antibodies, and at 10, 25 and 50 µg/mouse for anti-TNFα antibody for covering ranges found in bibliography. Weight loss, fecal consistency and fecal occult blood parameters were measured every day of experiment to elaborate a disease activity index (DAI). Mice were sacrificed at day 8 and the colon was obtained for histological evaluation by H/E staining, and for extraction of lamina propria mononuclear cells (LPMCs). Longitude was also measured. Blood was obtained by intracardiac punction and peripheral blood mononuclear cells (PBMCs) were obtained. Distal and proximal colon sections were fixed in 4% paraformaldehyde and embedded in paraffin. 4 mm sections were hydrated and H/E stained for histological score assessment. Extracted LPMCs and PBMCs were stained for flow cytometry evaluation of inflammation markers.

Results: Proximal and distal colon of mice treated with two doses of 10 µg/mouse of anti-TNFα, 250 µg/mouse of anti-integrin α4β7 and 100 mg/mouse of anti-IL23p19 showed the greatest tissue conservation and repair. In addition, these groups had less weight loss throughout the experiment as well as a reduced DAI. LPMCs and PBMCs inflammatory markers were also decreased in these groups in comparison with the others. Slight differences were found in 250 and 500 µg/mouse anti-integrin α4β7 treated mice.

Conclusion: The optimal treatment doses of neutralizing anti-TNFα, anti-integrin α4β7 and anti-IL23p19 antibodies are set at two doses of 10, 250 and 100 µg/mouse respectively for this 5+3 model of DSS-induced colitis. By establishing precise dosimetry baselines, our work provides a robust framework for combinatorial therapies, which could unlock novel approaches for IBD treatment.

Contact E-Mail Address: kasianeu@gmail.com

Introduction: Inflammatory bowel diseases (IBD), encompassing ulcerative colitis (UC) and Crohn's disease (CD), are chronic gastrointestinal disorders accompanied by psychiatric comorbidities, particularly anxiety and depression. The link between IBD and anxiety and depression remains unclear, but it appears that, among others, it may be explained by altered tryptophan metabolism. Tryptophan, an essential amino acid, is crucial for maintaining mental health and regulating mood through its metabolic processes. It serves as a precursor for several biologically significant compounds, including serotonin, melatonin, and kynurenine metabolites. The interplay between inflammation, tryptophan metabolism, and mental health in IBD remains insufficiently explored.

Aims & Methods: This study aimed to assess the association between metabolites of the tryptophan-kynurenine pathway and depressive symptoms in IBD regarding the disease activity and phenotype. A cohort of 214 patients with IBD (70 with CD and 144 with UC) was included. Disease activity was determined using the Mayo score for UC and SES-CD for CD. Peripheral blood samples were analyzed for selected biomarkers, including metabolites of tryptophan-kynurenine pathway as well as indicators of oxidative stress and inflammation. Depressive symptoms were evaluated using the Beck Depression Inventory (BDI). Statistical analyses included correlation and regression models to explore the relationship between biomarkers and BDI scores, adjusting for clinical and demographic covariates.

Results: The BDI score in the study group ranged from 0 to 52. 31 individuals met the criteria for depression by scoring over 10 points. 137 patients with active disease exhibited significantly higher levels of hsCRP and nitrotyrosine and lower kynurenic acid levels compared to 77 with inactive disease. Kynurenic acid levels were negatively correlated with BDI scores ($r = -0.220$, $p = 0.042$), suggesting an association between tryptophan metabolism and depressive symptoms.

	Active disease	Inactive disease	p
Chlorotyrosine, nM	0.35 ± 0.41	0.26 ± 0.45	0.222
Nitrotyrosine, nM	0.38 ± 0.20	0.26 ± 0.17	0.043
Bromotyrosine, nM	0.05 ± 0.06	0.03 ± 0.03	0.553
L-tryptophan, M	54.67 ± 15.79	60.98 ± 15.34	0.117
L-kynurenine, M	3.53 ± 1.22	3.48 ± 1.01	0.680
5-hydroxy-L-trypthophan, M	0.20 ± 0.15	0.23 ± 0.13	0.233
3-indolepropionic acid, M	0.33 ± 0.57	0.20 ± 0.21	0.723
3-indoleacyrylic acid, M	2.31 ± 0.66	2.46 ± 0.54	0.322
Kynurenic acid, M	0.06 ± 0.04	0.08 ± 0.03	0.035

Table 1. Comparison of selected metabolite levels between individuals with active disease and with inactive disease.
Data expressed as n (%) or mean ± SD.
Significant between-group differences (p < 0.05) are marked in bold.

Additionally, CD patients showed higher serotonin and anthranilic acid levels compared to UC patients (16.67 ± 26.23 vs 6.29 ± 12.55 and 0.35 ± 0.26 vs 0.17 ± 0.17, respectively), though no significant differences in

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. BDI scores were observed between the groups. Biological treatment was more frequent in the active disease group and associated with higher BDI scores, even after adjusting for covariates.

Conclusion: The study revealed significant differences in the tryptophan-kynurenine metabolic pathway among patients with inflammatory bowel disease, which vary based on disease activity. Additionally, variations in the concentrations of certain metabolites are correlated with the severity of depression.

Introduction: Short bowel syndrome (SBS) is a severe complication of extensive small intestinal resection, most commonly occurring in Crohn's disease (CD), a chronic inflammatory disorder defined by transmural immune infiltration. Cytokines and chemokines are central mediators in the immune cascade driving intestinal inflammation and tissue damage[1,2].

Despite advances in care, no biomarkers currently predict SBS onset or progression to intestinal failure (IF). Profiling systemic cytokine and chemokine signatures may thus offer novel insight into disease trajectory and risk stratification.

Aims & Methods: This study investigates circulating inflammatory mediators in patients with established IF/SBS and CD patients at high risk of progression. A total of 150 patients with CD were enrolled and stratified into five groups based on intestinal function and surgical history: A1, SBS with IF requiring parenteral nutrition (PN) or intravenous fluids; A3, SBS without IF and inactive disease; B, high risk of IF with multiple or extensive resections; C1, low risk for IF with no history of resection; and C2, low risk for IF with prior resection. Serum cytokine and chemokine profiles were quantified at baseline (T0) and after six months (T6) using the human 27-PLEX multiplex immunoassay.

Results: Serum cytokines and chemokines profiling at baseline (T0) and after six months (T6) revealed distinct inflammatory patterns across the study groups. Patients with SBS and IF (group A1) showed persistently elevated levels of IP-10, IL-12, MIP-1α, and G-CSF, reflecting sustained immune activation. Whereas, patients at high risk of IF (group B) displayed increased Eotaxin, bFGF, IL-15, and IL-6, indicative of subclinical inflammation and possible tissue remodelling.

A general reduction in cytokine levels was observed at T6, though anti-inflammatory mediators remained minimally modulated, suggesting ongoing low-grade inflammation. Comparisons between groups highlighted divergent cytokine signatures correlating with disease severity and nutritional support requirements.

Conclusion: These findings suggest that specific circulating cytokines may serve as potential biomarkers for early identification of patients at risk of IF. The differential expression patterns observed across groups support their relevance in stratifying disease severity in CD and SBS. Further large-scale studies are needed to validate these preliminary results and to fully establish their prognostic significance.

RISING BURDEN OF INFLAMMATORY BOWEL DISEASE IN PUERTO RICO: A CROSS-SECTIONAL ANALYSIS OF INSURANCE CLAIMS FROM 2018-2022

P. Figueroa Rodríguez[1], E.A. Torres[1], N. Serra Bonett[2]
[1]University of Puerto Rico - Medical Science Camp - School of Medicine, Gastroenterology Research Unit, San Juan, Puerto Rico, [2]Abbvie Corp, San Juan, Puerto Rico

Contact E-Mail Address: patricia.figuerodz@gmail.com

Introduction: The prevalence of IBD is rising in racial and ethnic minorities and in countries with previous low prevalence. There are limited studies of this disease in Latin America and the Caribbean.

Aims & Methods: This cross-sectional, retrospective study used de-identified insurance claims from commercial health insurers in PR. Cases identified had ICD-10 codes for IBD and at least one of the following criteria: 2 hospitalizations for IBD, 4 IBD-related physician visits, one IBD drug claim plus one of the former, or 2 ambulatory center IBD claims plus one of the former .Variables include age, gender, insurance type (Medicare Advantage or commercial insurance), IBD diagnosis, IBD-related physician visits, endoscopies, emergency room visits, hospitalizations and surgery. Point prevalence was defined as a new and pre-existing case during a 12-month period over the average number of insured population for each year of the study period. Estimates are presented as the number of cases per 100,000 insured individuals with 95% confidence intervals (CI) using Poisson regression. The study was approved by the MSC-IRB. We aim to estimate the point prevalence of IBD in an insured population in Puerto Rico (PR) from 2018 to 2022.

Results: The average insured population for the study period was 1,764,543. IBD was identified in 6,293 individuals; 35.6% had Crohn's disease (CD), 61% had ulcerative colitis (UC), and 3.4% were undetermined IBD. The overall prevalence of IBD was 356.6/100,000; prevalence was 127.1/100,000 for CD, and 217.5/100,000 for UC. Yearly prevalence rates showed an upward trend from 2018 to 2021 and a slight decrease in 2022. In 2018, the prevalence was 147.0/100,000 (95% CI: 145.33-148.68), increasing to 175.4/100,000 (95% CI: 173.45-177.35) in 2019 and 188.8/100,000 (95% CI: 186.77-190.89) in 2020. The peak prevalence occurred in 2021 at 215.0/100,000 (95% CI: 212.8-217.23), followed by a decrease to 199.9/100,000 (95% CI: 197.83-201.93) in 2022.

Conclusion: The increase in IBD prevalence in PR from 2018 to 2021, peaking at 215.0/100,000, aligns with previous studies suggesting an increasing disease burden on the island. An analysis for 2013 reported 181.5/100,000 across all insurance types including Medicaid. The peak in 2021 may reflect improved diagnosis, increased disease awareness, or better access following pandemic-related healthcare disruptions. The slight decline in 2022 prevalence may reflect a shift in insurance status, immigration, or a decrease in healthcare access. Continued monitoring of IBD prevalence is essential to track long-term trends, given the considerable rise since the early 2000s. Our findings place PR within the recent rising global trends of this disease and underscores the need for ongoing research and targeted healthcare strategies. The Medicaid insured population is being studied and should provide a more complete vision of IBD in PR.

PARENT PERSPECTIVES ON PEDIATRIC INFLAMMATORY BOWEL DISEASE IN A DEVELOPING NATION: DELAYS IN DIAGNOSIS, TREATMENT RESPONSE, AND PHYSICIAN AWARENESS

P.R. Tripathi[1], V. Mishra[2]
[1]Ankura Hospital for Women and Children, Department of Pediatric Gastroenterology and Hepatology, Hyderabad, India, [2]Ankura Hospital for Women and Children, Hyderabad, India

Contact E-Mail Address: parijattripathi1986@gmail.com

Introduction: Pediatric Inflammatory bowel disease (PIBD) contributes to one-fourth of the total IBD burden. PIBD is rising in developing countries, and it is imperative to diagnose and treat it early due to rapid progression, associated morbidity, and improved quality of life after treatment. Diagnosis is often delayed due to nonspecific symptoms (specifically in Crohn's disease) early in the course of the disease, and less awareness about PIBD amongst primary caregivers and society in developing nations.

Aims & Methods: We aimed to learn from parents and patients suffering from IBD about their real-life experiences during the early disease course, diagnosis, response to treatment, and difficulties associated with it. We included all the confirmed PIBD (disease onset from 0 to 18 years of age) patients under treatment for over three months. The diagnosis was based on standard clinical, endoscopic, imaging, and histopathology criteria. A questionnaire was provided, which was filled out by parents. Symptoms, age at disease onset, diagnosis, any specific reason for delay in diagnosis, and response after treatment were assessed. We also tried to learn from the parents about their assessment of primary pediatricians and dentists about PIBD, as per their experience. Informed consent was taken from all the participants.

Results: Of the total 32 PIBD patients, 25 (Male: 56%) patients who responded to all the questions were included in the study. The mean age at onset of symptoms was 97.6±53.9 (range 10-204) months, the age at diagnosis was 113.7±55.9 (range 16-206) months, and the average duration from onset to diagnosis was 15.8±13.4 (2-46) months. Anaemia, growth failure, abdominal pain, and blood in stool were present in 84%, 80%, 88%, and 56% of patients, respectively. In 72% of patients, the diagnosis was made ≥6 months after the onset of symptoms. 68% of parents felt that delayed diagnosis was mainly due to the unawareness (about IBD) of health care providers. Only 20% (N=5) of patients visited the dentist, and 80% (n=4 of 5) suggested that their dentist was not confident about correlating their oral problem with IBD. Similarly, 72% (n=18) of patients concluded that even after the diagnosis of IBD, their primary healthcare providers are not confident in managing them. In major concerns, 80% of parents felt that there is a poor understanding of the disease in healthcare providers, and 12% (all on biologicals) thought that the cost of treatment is high. Most patients (80%) found it easy to get an appointment and procedures done under a pediatric gastroenterologist.

Age (months)	138.16±60.7 (range 23-252)
Diagnosis (Crohn's/UC/IBD-U, %)	60/40/0
Follow-up (months)	24.4±17.3 (range 3-60)
Biologicals	12%(n=3), all on infliximab
Improvement (clinical, biochemical, and endoscopic)	88% (n=22)

Conclusion: The patient remains the centre of any health care system. This study evaluated parental experiences in managing PIBD, a chronic, progressive condition with increasing incidence and recognition in developing nations. Early diagnosis is the key to altering the disease progression. Patient-reported data indicate a significant deficiency in knowledge and awareness of IBD among healthcare providers, which appears to be a major contributor to diagnostic delays.

These findings underscore the urgent need for targeted educational interventions aimed at healthcare professionals, as well as public health initiatives to raise community awareness. Further epidemiological studies are required to understand the true prevalence and understanding of PIBD in developing countries.

EFFECTIVENESS OF SMOKING CESSATION INTERVENTIONS FOR SMOKERS WITH CROHN'S DISEASE: A SYSTEMATIC REVIEW

S. Nasr[1]

[1]University of Monastir, Preventive Medicine and Epidemiology, Monastir, Tunisia

Contact E-Mail Address: sahar.nasr2508@gmail.com

Introduction: Smoking is the most influential modifiable environmental factor associated with adverse outcomes in Crohn's disease (CD). While smoking cessation (SC) has been shown to mitigate disease activity and surgical recurrence, the actual effectiveness of SC interventions tailored to CD patients remains underexplored.

Aims & Methods: To systematically evaluate the effectiveness of SC interventions in patients with CD and assess their real-world applicability and outcomes.

Following PRISMA guidelines, a systematic search of PubMed, Google Scholar, and Cochrane Library was conducted up to February 2023. Eligible studies included randomized controlled trials (RCTs) and cohort studies assessing SC interventions in adults with confirmed CD. Five studies, including two RCTs and three cohort studies, met the inclusion criteria.

Results: The reviewed interventions ranged from pharmacological treatments (nicotine replacement therapy, bupropion, varenicline) to behavioral and motivational approaches (individual and group counseling, motivational interviewing, Quitline referrals), or a combination of both. SC rates varied widely (14.8–42%), with four studies reporting ≤25% abstinence. The highest SC rate was observed in a pharmacist-led program incorporating behavioral and pharmacological support. However, RCTs showed no statistically significant difference in quit rates between intervention and control groups. Only two studies validated abstinence biochemically. High variability in study design, definitions of smoking/abstinence, intervention modalities, and sample sizes limited direct comparisons. Adherence rates were not systematically assessed, and the influence of socioeconomic factors remained understudied.

Furthermore, the effectiveness of phone-based interventions appeared non-inferior to in-person strategies, highlighting potential avenues for resource-limited settings.

Conclusion: Despite the well-established deleterious impact of smoking on CD prognosis, the evidence base supporting SC interventions in this population remains limited and inconclusive. Current strategies appear less effective in CD patients compared to the general population, underscoring the need for tailored, multifaceted approaches.

Future research should focus on standardized outcome measures, integration of psychological support, real-time adherence monitoring, and equitable access to pharmacological therapies.

MANAGING APPENDICITIS WITHOUT SURGERY: POTENTIAL TO REDUCE THE RISK OF INFLAMMATORY BOWEL DISEASE

L. Lindroos[1,2], P. Arkkila[3], V. Sallinen[4]

[1]University of Helsinki, Helsinki, Finland, [2]Helsinki University Hospital, Helsinki, Finland, [3]Helsinki University Hospital, Gastroenterology, Helsinki, Finland, [4]Helsinki University Hospital / University of Helsinki, Department of Transplantation and Liver Surgery / Abdominal Surgery, Helsinki, Finland

Contact E-Mail Address: lotta.e.lindroos@gmail.com

Introduction: Previous studies have shown that appendectomy protects against the development of Ulcerative Colitis (UC), but the reason for this is not yet known. The risk of Crohn's disease (CD) and Microscopic Colitis (MC) after appendectomy has been studied to a lesser extent. In Finland, the correlation between appendectomy and inflammatory bowel disease (IBD) has not been previously studied.

Aims & Methods: We aim to investigate the risk of developing IBD after appendectomy in the Hospital district of Helsinki and Uusimaa, Finland. In this cohort study the patient material consisted of data from the Hospital district of Helsinki and Uusimaa's patient database from 2005-2020. The analysis included 8,969 patients, who underwent appendectomy, and 20,582 non-appendectomy controls matched by age and sex. The risk of IBD after appendectomy was analyzed by calculating the incidence-rate ratios (IRRs).

Results: In this study, we did not find a significant inverse correlation between appendectomy and UC (IRR 0.88, 95 % CI 0.31-2.15). However, we did find a significantly increased risk of both CD (IRR 7.04, 95 % CI 1.56-53.16) and MC (IRR 3.15, 95 % CI 1.16-8.97) after appendectomy. The increased risk of CD after appendectomy remained significant when the reason for appendectomy was defined as appendicitis and mesenteric lymphadenitis, but did not remain significant for other reasons.

Conclusion: The increased risk of Crohn's disease and Microscopic Colitis after appendectomy suggests that appendectomy as a treatment should be carefully considered if acute appendicitis is suspected. Alternative treatment for uncomplicated appendicitis may include antibiotics or symptomatic treatment.

Disclosure: Nothing to disclose.

PROFILING GUT–BRAIN AXIS PREDICTORS OF CHRONIC ABDOMINAL PAIN IN IBD REMISSION: A UK NATIONAL COHORT STUDY

P. Luthra[1], R. Idrees[1], R. Yehuda-Margalit[1], I. Khwaja[1], M. Parkes[2], C. Norton[3], A.L Hart[4], H. Sokol[5], N. Vergnolle[6], D. Bulmer[7], J.O. Lindsay[8], Q. Aziz[9]

Contact E-Mail Address: pavit12@gmail.com

Introduction: Abdominal pain is a debilitating symptom in Inflammatory Bowel Disease (IBD). 20–50% of patients experience chronic abdominal pain (CAP), even during clinical remission. Emerging evidence suggests CAP in IBD is influenced by bidirectional gut-brain axis dysfunction, encompassing psychological and physiological factors. Identifying these factors is crucial to advancing targeted interventions and improving patient outcomes.

Aims & Methods: We aimed to delineate psychological and physiological determinants of CAP in patients with Ulcerative Colitis (UC) or Crohn's disease (CD) in remission. This cross-sectional study recruited 2525 adults through the UK NIHR IBD-BioResource (December 2022–April 2024). CAP was defined as per Rome IV criteria as recurrent abdominal pain ≥1 day/week in the last 3 months.

Remission was defined as Harvey-Bradshaw Index <5 for CD, and Simple Clinical Colitis Activity Index ≤2 for UC. All subjects completed validated instruments assessing somatic symptom severity (PHQ-15), gastrointestinal (GI) symptom burden (GSR), fatigue and sleep disturbance (PROMIS), anxiety (GAD-7), depression (PHQ-9), cognitive and behavioural responses to pain (CBRQ), personality traits (BFQ), sensory processing sensitivity (HSP-SF), resilience (CD-RISC) and quality of life (EQ-5D-5L). Logistic regression analyses identified independent predictors of CAP.

Results: Among 1,445 patients in remission (mean age 53.06±16 years; 48.3% female), 381 (26.4%) reported CAP. Of these 381, mean age was 49±14.63, 235 had CD (61.7%) and 217 were female (57%).

Patients with CAP had significantly higher mean scores for somatisation, GI symptoms, anxiety, depression, fatigue, sleep disturbance, quality of life, neuroticism, cognitive-behavioural responses and ease of excitation (all p<0.0001), with lower resilience scores (p<0.001) compared to those without CAP.

Multivariable logistic regression identified independent predictors of CAP; younger age, greater somatic symptom severity, symptom focusing, and residual GI symptoms of indigestion and diarrhoea were significant (Table 1).

GSRS abdominal pain was excluded as a predictor. The regression model demonstrated strong discriminatory ability (AUC=0.8260) and explained 31.4% of the variance in CAP.

Predictor	Odds Ratio (95% CI)	p-value
Age (per year increase)	0.97 (0.95–0.99)	0.0029
PHQ-15; somatic symptom severity	1.17 (1.09–1.26)	< 0.0001
CRBQ; symptom focusing	1.15 (1.05–1.26)	0.0025
GSRS indigestion	1.65 (1.24–2.21)	0.0006
GSRS diarrhoea	1.37 (1.11–1.69)	0.004

Table 1. Significant Multivariable Predictors of Chronic Abdominal Pain in IBD Remission

Abbreviations: PHQ-15: Patient Health Questionnaire-15, PHQ-9: Patient Health Questionnaire-9, GAD-7: Generalized Anxiety Disorder Assessment-7, PROMIS: Patient-Reported Outcomes Measurement Information System, PROMIS: Patient-Reported Outcomes Measurement Information System, HSP-SF: Highly Sensitive Person Scale – Short Form, BFQ: Big Five Personality Questionnaire, CD-RISC: Connor-Davidson Resilience Scale.

Conclusion: CAP affects approximately one quarter of IBD patients in clinical remission and is significantly associated with a range of psychological factors. Somatisation, cognitive-behavioural factors including symptom focusing and residual gastrointestinal symptom burden are independent predictors of CAP.

These findings highlight the key role of gut–brain axis dysfunction in CAP and support the need for targeted interventions such as cognitive-behavioural therapy or neuromodulation to alleviate pain and improve quality of life in this population.

Disclosure: Nothing to disclose.

PP0400

PHYSICAL ACTIVITY IS INVERSELY ASSOCIATED WITH CLINICAL EXACERBATION IN PATIENTS WITH CROHN'S DISEASE IN REMISSION - A PROSPECTIVE COHORT STUDY

C. Sarbagili Shabat[1,2], S. Zelber-Sagi[3], N. Fliss-Isakov[1,4], A. Hirsch[1,2], Y. Ron[1], L.S. Grinshpan[5], N.A. Cohen[1], H. Leibovitzh[1], T. Thurm[1,2], N. Maharshak[1,2]

Introduction: Physical activity (PA) is associated with improved quality of life in patients with Crohn's disease (CD). However, there is limited evidence of its impact on the clinical course of the disease and the separate effects of aerobic and anaerobic-resistance PA.

Aims & Methods: We aimed to evaluate the association between PA and the incidence of relapse in patients with CD in clinical remission and to assess the role of PA in patients with CD using patient-reported outcome measures (PROMs), with separate analyses for PA type. A prospective cohort study of adult patients with CD in clinical remission followed for one year or until relapse according to the Harvey Bradshaw Index. At baseline, participants completed a detailed PA questionnaire, nutritional questionnaires, and a patient-reported outcomes measurement information system (PROMIS). Multivariable Cox proportional hazards models were used to assess the association between PA and relapse risk, adjusted for confounders, including dietary factors and fecal calprotectin levels.

Results: A total of 106 patients (mean age 37.9 ± 13.9 years) were included and followed for 9.9±3.2 months, during which 23 (21.7%) experienced clinical relapse. PA at least twice a week was associated with a reduced

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

risk of relapse (HR = 0.26, 95% CI 0.09–0.79). Specifically, only aerobic activity was significantly associated with a reduced risk of relapse (HR = 0.31, 95% CI 0.10-0.95). High-resistance PA was significantly associated with better quality of life parameters, including pain interference (P=0.013), sleep disturbance (P=0.040), better physical function (P=0.029), and enhanced social roles (P=0.020). While aerobic PA showed benefit in physical function (P=0.016).

Conclusion: PA in general and specifically aerobic PA, is associated with a reduced risk of relapse in patients with CD in remission. Additionally, resistance PA is associated with a better quality of life. These findings highlight the importance of incorporating PA into the management of CD in remission state.

Disclosure: None.

BRIDGING ENDOCRINE AND GUT AUTOIMMUNITY: FROM POPULATION TO PROTEOME IN GRAVES' DISEASE–ULCERATIVE COLITIS COMORBIDITY

Y. Zhang[1], J. Zhao[1], J. Fan[1], H. Zhu[1], Y. Xia[1], H. Xu[1]

Contact E-Mail Address: yinmeng23@mails.jlu.edu.cn

Introduction: Graves' disease (GD) and ulcerative colitis (UC) are two distinct autoimmune disorders with increasing evidence of shared pathophysiological mechanisms. While previous epidemiological studies have reported a higher risk of IBD among individuals with GD, the association between GD and UC specifically remains controversial. In particular, the causal direction, genetic liability, and molecular mediators underlying this relationship are not well defined.

Aims & Methods: We conducted a multi-layered investigation to clarify the relationship between GD and UC. First, a large-scale prospective analysis using the UK Biobank cohort was performed to assess the association between GD and subsequent UC risk, with adjustments for demographic, lifestyle, and clinical covariates utilizing COX proportional hazard models. Second, two-sample Mendelian randomization (MR) analyses were conducted using publicly available genome-wide association study (GWAS) datasets to infer potential causal links.

Finally, we performed protein mediation analysis integrating plasma proteomic data to identify potential intermediate proteins and pathways mediating the effect of GD on UC.

Results: Observational analysis revealed that patients with GD had a significantly elevated risk of developing UC. Stratified analysis further revealed that this association was more pronounced among male and obese individuals. The association remained significant even after adjusting for key covariates including medication use, psychological disorders, air pollution exposure, and sunlight exposure. Genetic-level analysis using Mendelian randomization confirmed a potential causal relationship between AITD and UC. This association was independently validated in MR sensitivity analyses. Through mediation analysis based on plasma proteomic data, 28 UC-related proteins were identified as potential mediators of the AITD–UC relationship. Among them, proteins such as Arachidonate 15-lipoxygenase B (ALOX15B) were significantly enriched in the high-risk group. Collectively, six pathways likely represent the core signaling axes through which GD promotes UC pathogenesis, highlighting potential targets for mechanistic and therapeutic exploration.

Conclusion: This study provides robust clinical, genetic, and molecular evidence for a link from GD to UC, mediated through specific immunopathogenic proteins and pathways. These findings offer novel insights into shared autoimmunity and may inform biomarker-driven strategies for early identification and targeted prevention of UC in patients with GD.

Contact E-Mail Address: silviasalvatori23@gmail.com

Introduction: Patients with IBD are at greater risk than the general population of developing frailty, with the negative consequences that this condition determines, such as hospitalizations, post-operative complications, infections and mortality. Since there is no specific score to screen for frailty in IBD patients, studies in literature have used scores validated on cohorts of geriatric patients to date.

Aims & Methods: The aim of this prospective multicenter study is to validate a score specifically designed to detect frailty in IBD patients, the IBD frailty score. Enrolled outpatients were assessed with the IBD frailty score, the Fried frailty phenotype and the Hospital Frailty Risk Score (HFRS) for frailty, with the IBD Disability Index for disability and with the Charlson Comorbidity Index for comorbidities. Differences between qualitative and quantitative variables were evaluated with Chi-square and Mann Whitney U test. We detected test sensitivity and specificity with a ROC curve and to assess the internal consistency we used Spearman correlation coefficients.

Results: From April 2023 to October 2024, we assessed 121 IBD patients with the IBD frailty score at the Policlinico Tor Vergata of Rome. The score showed good test-retest reproducibility on a subgroup of 20 pa-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tients (rho=0.78, p<0.0001), an acceptable mean time of administration (2 minutes and 19 seconds) and correlation with other frailty, disability and comorbidity indexes, with a good performance, AUC = 0.83 (95% CI: 0.75-0.90).

From September 2024 we started the multicenter study, enrolling 149 patients from Policlinico Tor Vergata and 200 patients from Policlinico of Magna Graecia (Catanzaro), with a total of 349 patients with IBD enrolled at this time. Enrollment is still ongoing at the Policlinico Campus Biomedico and the Policlinico Gemelli (Rome). The median age of the validation cohort of patients was 48 years (range: 19-84 years), 185 patients out of 349 (53%) were male, 204 (58.5%) had a diagnosis of UC and 114 (32.7%) had clinically active disease.

The IBD frailty score confirmed an acceptable mean time of administration (2 minutes and 3 seconds) and a positive correlation with the other frailty, disability and comorbidity indexes, except for the HFRS.

Patients with clinically active IBD showed significantly higher scores at the IBD frailty score than patients in remission. Finally, a good performance was confirmed with sensitivity and specificity of 75.8% and 76.6% respectively, with a cut off ≥3 to distinguish frail and not frail IBD patients.

Conclusion: The IBD frailty is the first score to detect frailty specifically designed for patients with IBD. It showed good reproducibility, acceptable time of administration and correlation with other frailty, disability and comorbidity indexes. Data will be validated at the end of the enrollment.

Disclosure: No conflict of interest to declare.

COMPARISON OF THE SEVERITY OF THE CLINICAL MANIFESTATIONS OF PATIENTS WITH CROHN'S DISEASE BASED ON THE AGE OF DIAGNOSIS ACCORDING TO THE MONTREAL CLASSIFICATION

K. Tsitsigiannis[1], D. Piskopou[1], C. Thanos[1], N. Georgakopoulou[1], D. Ntailianas[1], E. Georgiou[1], M. Triantafyllou[1], N. Kalakos[1], G. Michalopoulos[1], A. Striki[1], E. Kotzagiannidou[1], L. Theodoropoulos[1], I. Karoumpalis[1]
[1]G.N.A. "G. Gennimatas", Gastroenterology Clinic, Athens, Greece

Contact E-Mail Address: nicoliageo@gmail.com

Introduction: The aim of the study is to record and compare differences in the severity of the clinical manifestation of Crohn's disease in patients categorized by age at diagnosis according to Montreal classification.

Aims & Methods: The patients included in the study were followed up at the Gastroenterology Clinic of GNA Gennimatas. To assess the severity, the following parameters were recorded for each patient: number of biologic agents used, intensifications of therapy, and the number of surgeries.

The Montreal classification was used, categorizing patients into three groups based on age at diagnosis: A1 (<16), A2 (16-40), and A3 (>40). For the analysis of the data we used the SPSSv23 statistical software.

Results: A total of 465 patients participated in the study, 247 (53.1%) of whom were men, with an average follow-up duration of 14 years. A total of n=42 (9.04%) patients were in the A1 group, n=272 (58.49%) in the A2 group, and n=151 (32.47%) in the A3 group. No statistically significant difference was observed among the three groups in terms of the use of biologic agents (p=0.079).

However, only 9.8% (n=4) of A1 patients had not received a biologic agent, compared to 21.3% (n=58) in A2 and 29.3% (n=44) in A3. In contrast, there was a statistically significant difference regarding surgeries (p<0.001), with A3 patients having significantly fewer surgical interventions than A1 and A2 patients, while A1 patients were more likely to undergo more than one surgical intervention compared to A2 and A3.

Finally, regarding intensification of therapy with biological agents, a statistically significant difference was observed (p=0.05), with A1 patients being more likely to receive at least one intensification.

Conclusion: In summary, differences were observed among patients with Crohn's disease when categorized based on age at diagnosis according to Montreal classification. Specifically, it was found that A3 patients were less likely to undergo surgery.

	A1 (n=42)	A2 (n=272)	A3 (n=151)	Total (n=465)
Gender Male,n(%)	26(61.9)	141 (51,8)	78 (51,7)	247(53,1)
Use of Biologic agents 0, n(%)	4 (9.8)	58 (21.3)	44 (29.3)	
1, n(%)	24 (58.5)	135 (49.6)	58(38.7)	
2, n(%)	9 (22)	49 (18)	33 (22)	
3, n(%)	4 (9.8)	30 (11)	15 (10)	
Intensifications, n(%)	25 (67.6)	102 (47.7)	48(45.3)	
Surgeries, 0, n(%)	28 (66,7)	176(64,7)	125(82,8)	
1, n(%)	8 (19,1)	81(29,8)	22(14,5)	
2, n(%)	6 (14,3)	15(5,5)	4(2,7)	

Additionally, A1 patients showed a higher likelihood of having intensified their treatment and at the same time a lower likelihood of not having received any biological agent.

Disclosure: No disclosures.

Contact E-Mail Address: Olga.nardone@libero.it

Introduction: Disability is a multidimensional concept encompassing physical, psychological, and social limitations that can significantly burden individuals living with inflammatory bowel disease (IBD). However, as disability is shaped by various factors—including cultural, social, and healthcare-related influences that can differ between countries—its prevalence and characteristics may vary globally.

Aims & Methods: We aimed to meta-analyse global data on prevalence of moderate-to-severe disability (MSD) to explore differences in disability prevalence and characteristics by country, IBD subtype, disease activity. MEDLINE EMBASE, EMBASE Classic (from inception to 1st December 2024) to identify cross-sectional and case-control studies reporting the prevalence of MSD based on validated tools (IBD–Disk and IBD-Disability Index) in adult patients (≥18 years) with confirmed IBD. Data were extracted, and pooled prevalence (PP), odds ratios (OR), and 95% confidence intervals (CIs) were calculated.

Results: The search strategy generated 3089 citations. From these, 160 individual articles appeared to be relevant to the study question and 17 fulfilled the eligibility criteria, containing 8225 patients with IBD recruited from 11 different countries. The pooled prevalence of MSD in patients with IBD was 29.6% (95% CI 22.6-37.1%; I^2=98.0%, p<0.01), with no evidence of

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

funnel plot asymmetry (Egger test, p=0.10). The lowest pooled prevalence of MSD was 7.0% in one Dutch study from the Netherlands, and the highest 51% and 52% in two studies from China and Italy, respectively. The pooled prevalence of MSD was higher in patients with IBD with active disease (56.9%, 95% CI 20.3-89.7%, I^2 = 93.0%, p<0.01) compared with those with inactive disease (27.0%, 95% CI 3.3-62.0%, I^2 = 93.0%, p<0.01). Based on three studies that reported MSD prevalence in both active and inactive disease, active IBD increased the odds of MSD more than threefold (odds ratio 3.13, 95% CI 1.74-5.64).

Conclusion: The global prevalence of MSD in the IBD population is 29.6%, and even higher among patients with active disease. These findings underscore the value of incorporating disability assessment into both clinical decision-making and routine therapeutic response —especially in the context of disease modification trials.

Introduction: Prevalence of inflammatory bowel disease (IBD) is increasing worldwide, while incidence is tending to stabilize. Moreover, the use of biological treatments is increasing, some studies suggest that surgeries and hospitalizations are decreasing instead.

Aims & Methods: A population-based, retrospective cohort study was conducted using data from the Catalan Health Surveillance System (CHSS). All patients diagnosed with IBD were included between 2017-2023. Crude incidence and prevalence rates were calculated for all the Catalan population. Data on pharmacological therapy, surgical procedures, hospitalizations, and mortality were analyzed. Trends in age-sex-adjusted rates were also estimated, and logistic regression was used to calculate the adjusted mortality odds ratio (OR). Data for Crohn's disease (CD) and ulcerative colitis (UC) were analyzed separately.

Results: The number of prevalent IBD cases rose from 28,752 in 2017 to 41,423 in 2023. Despite incidence rates remained stable (30.8 in 2017 and 29.9 per 100,000 inhabitants in 2023) prevalence rates increased (386.9 and 510.9 per 100,000 inhabitants respectively). The use of biologics significantly increased (from 13.5% in 2017 to 21.0% in 2023), particularly ustekinumab and vedolizumab. In parallel, a decline in the use of immunosuppressants were observed. IBD-related surgeries and hospitalizations decreased during study period, particularly among CD patients. Mortality remained low but was higher among IBD patients compared to the general population.

Conclusion: Incidence of IBD in Catalonia has stabilized, while its prevalence continues rising, suggesting a transition to Stage 3 (compounding prevalence). The use of biological treatments is increasing steadily, whereas rates of surgeries and hospitalizations are consistently decreasing.

Disclosure: None.

Introduction: Crohn's disease (CD) is a leading cause of short bowel syndrome (SBS) in adults, which can result in intestinal failure (IF) when intravenous nutritional or electrolyte supplementation is required. SBS is frequently associated with sarcopenia, characterized by loss of muscle mass and function, which adversely impacts quality of life and increases the risk of complications.

This study aimed to evaluate differences in body composition and muscle strength among CD patients at varying risk levels for SBS.

Aims & Methods: We conducted a cross-sectional study involving consecutive CD outpatients. The participants were divided into two groups. Group A consisted of CD patients diagnosed with SBS and patients who had undergone two or more bowel resections, or a resection of more than 50 cm. Group B included patients who had never undergone surgery or those who had undergone a resection of less than 50 cm. Body composition was assessed using bioimpedance analysis (BIA), and muscle strength was measured via hand grip testing with a dynamometer, recording the best result of three attempts with the dominant hand. We administered food frequency questionnaire (FFQ) to assess eating habits. Statistical analyses, including t-tests or Mann-Whitney tests, were used as appropriate, with a significance threshold of $p < 0.05$.

Results: The study cohort included 150 patients (mean age 53 years [±19,2]; 24% female). Group A showed an average BMI of 23,7±4 kg/m^2, whereas group B showed an average BMI of 24.6±5 kg/m^2. Muscle strength measured between groups was reduced in group A showing significant dif-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. ferences in hand grip test compared to group B (p-value<0.001). However, no significant differences were observed in BIA parameters, including muscle mass, or in eating habits across the groups.

Conclusion: Our study revealed that SBS patients and CD patients resected two or more times or with a resection greater than 50 cm had reduced muscle strength without a corresponding reduction in muscle mass, indicating impaired muscle function. Further research is needed to better understand the relationship between Crohn's disease-related resections and their impact on both muscle quality and quantity.

Introduction: Inflammatory bowel disease (IBD) is associated with an increased risk of cerebrovascular disease (CVD) and coronary heart disease (CHD). It has been suggested that chronic inflammation may be the mechanism. Previous studies have primarily assessed IBD as a group and not ulcerative colitis (UC) or Crohn's disease (CD) separately.

Aims & Methods: This study aims to determine the relationship between UC and CD and CVD and CHD risk factors/outcomes in a large UK population. General practice electronic medical records were sourced from the United Kingdom (UK) via The Health Improvement Network (THIN). UC and CD risk factors and disease outcomes were identified through Read codes.

Factors	UC Prevalence, n (%) n=3,432	UC Odds Ratio, 95% CI	CD Prevalence, n (%) n=2,831	CD Odds Ratio, 95% CI
Female Sex	1,796 (52.3%)	1.16, 1.09-1.25	1,689 (59.7%)	2.71, 2.08-3.62
Age	43.95 ± 14.4	0.99, 0.99-0.99	45.7 ± 15.7	0.95, 0.94-0.96
Diabetes Type II	417 (12.2%)	1.50, 1.35-1.66	265 (9.4%)	1.12, 0.98-1.27
Dyslipidemia	176 (5.1%)	1.26, 1.08-1.47	112 (4.0%)	0.96, 0.79-1.16
Obesity	7 (0.2%)	0.99, 0.47-2.10	7 (0.3%)	1.21, 0.58-2.55
AMI	113 (3.3%)	1.57, 1.30-1.89	57 (2.0%)	0.95, 0.73-1.23
Ischemic Stroke	47 (1.4%)	1.46, 1.09-1.95	23 (0.8%)	0.86, 0.57-1.30
Intracranial Hemorrhage	15 (0.4%)	1.67, 1.01-2.78	10 (0.4%)	1.35, 0.72-2.51
COPD	31 (0.9%)	1.85, 1.30-2.64	24 (0.9%)	1.74, 1.16-2.59

Results: A total of 1,062,022 unique adult patients were available for analysis. There were 3,432 UC (mean age: 43.95 years, SD=14.4 years; 52% female) and 2,831 CD cases (mean age: 40.9 years, SD=14.06 years; 60% female).

Ulcerative Colitis: Univariate analysis in Table 1. Multiple logistic regression (MLR) of CHD risk factors and outcomes (adjusted in all models for age, sex, diabetes, COPD, dyslipidaemia, obesity, and statins) revealed statistically significant independent CHD risk factors: female sex (OR: 1.19, 95%CI: 1.11-1.28), younger age (OR: 0.98, 95%CI: 0.98-0.99), type 2 diabetes (OR: 1.22, 95%CI: 1.09-1.37), and increased risk of acute myocardial infarction (AMI) (OR: 1.35, 95%CI: 1.11-1.64).

MLR of CVD risk factors and outcomes (adjusted as above plus thrombolytic agents) found statistically significant independent CVD risk factors: female sex (OR: 1.19, 95%CI: 1.10-1.27), younger age (OR: 0.99, 95%CI: 0.98-0.99), diabetes type 2 (OR: 1.20, 95%CI: 1.07-1.34), statin use (OR: 1.13, 95%CI: 1.03-1.25), and any anti-thrombolytic agents (OR: 1.37, 95%CI: 1.25-1.51).

Crohn's Disease: Univariate analysis in Table 1. MLR of CHD risk factors and outcomes (adjusted) revealed statistically significant independent CHD risk factors: female sex (OR: 0.92, 95%CI: 0.85-0.99), younger age (OR: 0.98, 95%CI: 0.97-0.99), statin use (OR: 1.23, 95%CI: 1.11-1.36), and an increased likelihood of death (OR: 1.28, 95%CI: 1.12-1.47).

MLR of CVD risk factors and outcomes (adjusted) revealed statistically significant independent CVD risk factors: female sex (OR: 0.91, 95%CI: 0.84-0.98), younger age (OR: 0.97, 95%CI: 0.96-0.98), anti-thrombolytic agents (OR: 1.71, 95%CI: 1.55-1.90), and an increased likelihood of death (OR: 1.18, 95%CI: 1.03-1.35).

Conclusion: UC cases are more likely to be female, have diabetes, be taking statins, and anti-thrombolytic agents, and have an increased risk of AMI and death. CD cases are less likely to be female, but more likely to be taking statins, anti-thrombolytic agents, and more likely to die.

Contact E-Mail Address: eredondoc@gmail.com

Introduction: This study aimed to assess and compare the incidence, prevalence, and severity of inflammatory bowel disease (IBD) between migrant and native populations in Granada, Spain, over the past decade. We also sought to identify potential epidemiological differences and produce hypotheses regarding factors influencing disease patterns.

Aims & Methods: A retrospective, multicenter observational study was conducted, including patients diagnosed with IBD from 2012 to 2022 in Granada. Data on demographics, disease type, severity, and clinical outcomes were collected and analysed. Migrant and native populations were compared using case-matching based on age, sex, and IBD type. Statistical analyses included logistic regression models to identify risk factors for severe disease.

Results: From 2012 to 2022, 2764 IBD patients were identified, and 144 were analysed: 111 Spaniards (77.08%) and 33 migrants (22.82%). Migrants, mostly from Africa (57.5%), were diagnosed younger than Spaniards (38.85 ± 12.16 vs. 47.67 ± 15.00 years; p = 0.003). Prevalence increased in Spaniards (295 per 100,000 in 2022) but remained stable in migrants (41 per 100,000 in 2022), based on point prevalence calculated at the end of the study period. Incidence was higher in Spaniards (6.49 vs. 1.32 per 10^5 population/year). Severe IBD affected 34.03% of patients, more often Spaniards (37.84%) than migrants (21.21%).

Comparative analysis between Moroccan and Hispanic American patients revealed no statistically significant differences in age (36.0 vs. 34.4 years; p = 0.750) or the number of colonoscopies performed (0.73 vs. 0.56; p = 0.596). Additionally, the distribution of disease phenotypes (Crohn's disease vs. ulcerative colitis) was comparable, as was the use of biological therapies.

Risk factors for severity included Crohn's disease (67.35% vs. 48.42%; p = 0.016) and a fistulizing phenotype (42.42% vs. 25.00%; p = 0.039). Patients with severe IBD were also more likely to have undergone ≥3 colonoscopies (26.5% vs. 6.3%; p = 0.001) and experienced ≥3 hospitalizations (32.7% vs. 5.3%; p = 0.001). Indicators of severity included undergoing ≥3 colonoscopies (OR: 7.016, 95% CI: 2.090–23.556, p = 0.002), experiencing ≥3 hospitalizations (OR: 7.749, 95% CI: 2.347–25.580, p = 0.001), and having Crohn's disease (OR: 2.361, 95% CI: 1.016–5.488, p = 0.046). Spaniard nationality was associated with an increased risk of severe disease (OR: 3.242, 95% CI: 0.101–0.941, p = 0.039).

Conclusion: This study provides valuable insights into the epidemiology of IBD in southern Spain. It revealed no significant increase in the prevalence or incidence of IBD compared to studies conducted in central and northern Europe, nor evidence that migrants experience more severe disease courses. These results highlight the potential protective role of universal healthcare access, regional dietary habits, and advanced therapeutic interventions in mitigating disparities in disease outcomes. Further longitudinal studies are warranted to validate these findings in larger, more diverse cohorts.

Disclosure: Nothing to disclose.

PP0409

INCREASED RISK OF AUTOIMMUNE LIVER DISEASE IN INFLAMMATORY BOWEL DISEASE: A NATIONWIDE DANISH REGISTRY STUDY

S. Kjærsgaard Hansen[1,2], A. Karachalia Sandri[1], S. Saha[3], K. Petrea Bak-Fredslund[2], P. Holland-Fischer[2], T. Jess[1,2], L. Larsen[1,2]

[1]Aalborg University Copenhagen, Center for Molecular Prediction of Inflammatory Bowel Disease, PREDICT; Department Of Clinical Medicine, Hellerup, Denmark, [2]Aalborg University Hospital, Gastroenterology And Hepatology, Aalborg, Denmark, [3]University of California San Diego, Division of Gastroenterology and Hepatology, La Jolla, San Diego, United States of America

Contact E-Mail Address: stine.hansen@rn.dk

Introduction: Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), is a chronic condition with extraintestinal manifestations such as primary sclerosing cholangitis (PSC)[1,2].

It is believed that individuals with IBD have an increased risk of other immune mediated diseases[3,4].

One key area of interest is the gut-liver axis, a bidirectional interaction between the gastrointestinal tract and the liver, which suggests that pathologic conditions of each system can influence each other[5].

In addition to PSC, individuals with IBD may also be predisposed to other autoimmune liver diseases, including autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC). Investigating the relationship between IBD and autoimmune liver disease is critical for identifying individuals at higher risk of liver complications, enabling early detection and targeted interventions to mitigate long-term hepatic damage.

Aims & Methods: This study aims to investigate the risk of autoimmune liver disease among individuals with IBD compared to the general population. We conducted a nationwide, registry-based cohort study using Danish registries to identify individuals diagnosed with IBD and autoimmune liver disease. Diagnoses were based on the International Classification of Diseases, 10th Revision (ICD-10) and the Systematized Nomenclature of Medicine (SNOMED) codes.

All individuals diagnosed with UC or CD from 2000 to 2022 were identified and matched 1:10 with individuals without such diagnosis from the general population based on sex at birth, age and municipality of residence at the time of diagnosis. Matches were assigned their case's IBD diagnosis date as an index date.

Individuals were excluded if they had a diagnosis of hepatocellular carcinoma prior to autoimmune liver disease or had not resided in Denmark for at least five years.

Logistic regression was used to estimate the prevalence odds ratio for autoimmune liver disease among individuals with IBD compared to matched controls up to five years before IBD diagnosis. Standardized incidence rates and time-to-event analysis were used to estimate the risk of autoimmune liver disease, expressed as hazard ratios, after IBD diagnosis or index date, comparing individuals with IBD to matched controls.

All analyses were adjusted for sex, age, subtype of IBD and Charlson Comorbidity Index.

The confidence interval (CI) was 95%, and the significance threshold for the p-value was set at 0.05.

Results: 50,557 individuals with IBD and 505,570 matched controls were included. Autoimmune liver disease was diagnosed in 391 individuals before and in 999 individuals after the IBD diagnosis/index date.

The odds of having a prior diagnosis of autoimmune liver disease were 11.7 times higher (95% CI: 9.5-14.2) among individuals who subsequently received a diagnosis of IBD compared to those who did not. The risk of autoimmune liver disease appeared substantially higher among persons with an IBD diagnosis compared to the those without. The highest

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

risk was observed for PSC, an extraintestinal manifestation of IBD, with an adjusted hazard ratio (aHR) of 45.3 (95% CI: 36.0-57.1). Increased risks were also found for PBC (aHR: 3.1, 95% CI: 2.3-4.0) and AIH (aHR: 4.7, 95% CI: 3.5-6.2) among individuals with IBD compared to those without IBD.

Conclusion: The odds of autoimmune liver disease before IBD diagnosis were increased compared to matched controls. Additionally, an increased risk of PSC, PBC and AIH following IBD diagnosis was observed. These results suggest the importance of monitoring individuals with IBD for autoimmune liver diseases.

Introduction: Inflammatory Bowel Disease (IBD) are multifactorial and debilitating diseases that impact patients' quality of life. A key characteristic of IBD is immune system dysregulation, which contributes to a higher risk of developing additional chronic immune-related disorders, such as chronic rhinosinusitis (CRS). The coexistence of these two conditions can undoubtedly affect patients' life and disease history. This study aims to determine the prevalence of CRS in individuals with IBD and evaluate its impact on their quality of life.

Aims & Methods: We conducted a prospective, observational, single-center pilot study, enrolling consecutive IBD patients. Clinical, demographic, and disease history data were collected. The sino nasal outcome test 22 (SNOT-22) questionnaire was administrated to each patient to assess subjective symptoms of CRS.

Participants were stratified into two groups:

Group 1 (SNOT-22 < 30) indicating no or mild CRS and Group 2 (SNOT-22 > 30) indicating moderate to severe CRS.

Group 2 patients underwent a comprehensive otolaryngological assessment including laboratory testing and a fibrolaryngoscopy to confirm the diagnosis of chronic rhinosinusitis.

Results: We enrolled 100 IBD patients, 43 % were affected by Crohn's Disease and 57% were affected by ulcerative colitis (UC):

- CD patients stratified by disease location:
    1. Ileum: 14 patients (32%)
    2. Colonic: 8 patients (19%)
    3. Ileum-Colonic: 19 patients (44%)
    4. Upper GI: 2 patients (5%)
- RCU patients stratified by disease location:
    1. E1 (proctitis): 8 patients (14%)
    2. E2 (left sided colitis): 20 patients (35%)
    3. E3 (extensive colitis): 26 patients (46%)

Among them, 37% of patients were naive to biological therapy, while 13% had failed at least two lines of biological therapy. Based on the SNOT-22 score, patients were divided in:

- Group 1 with SNOT-22 < 30 (mild symptoms):
    1. CD (43): 26 patients (60%)
    2. RCU (57): 36 patients (63%)
- Group 2 with SNOT-22 > 30 (moderate to severe symptoms):
    1. CD (43): 17 patients (40%)
    1. RCU (57): 21 patients (37%)

Patients with Crohn's disease in Group 2 exhibited higher disease activity, as measured by the Harvey-Bradshaw Index (HBI), compared to those in Group 1 (mean HBI: 3.8 vs. 1.38; p = 0.004). In contrast, no significant difference in disease activity was observed among patients with ulcerative colitis between the two groups.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

At the time of analysis only 15 patients of Group 2 underwent otolaryngological and laboratory evaluation including IgE and eosinophil cationic protein (ECP) and 10 patients showed endoscopic signs of CRS (*See Table 1*).

	CRS (10)	NO CRS (5)	P-VALUE
CD	5	4	
RCU	5	1	
HBI (mean)	4,2	2	0.188
FULL-MAYO (mean)	4,6	3	0,23
ECP (µg/l)	45,1	24,7	0.123
IgE (UI/ml)	120	54.62	0.40

Table 1. *Clinical and biological parameters between CRS and non-CRS patients.*

Conclusion: CRS is frequent among patients with IBD. In line with prior reports, our study identified a CRS prevalence of 10% within IBD patients. Moreover, the higher prevalence of CRS in patients with more severe IBD activity may highlight a potential connection mediated by the gut–lung axis. No significant differences were observed in IgE levels or eosinophil cationic protein values among patients with CRS, suggesting that the pathogenesis of CRS in IBD patients may differ from patients with isolated CRS.
Nonetheless, these findings remain preliminary due to the lack of laboratory analyses and otolaryngological evaluations for additional patients. Comprehensive clinical assessments and advanced laboratory investigations are warranted to further elucidate the underlying mechanisms of the gut–lung axis in this context.
Disclosure: Nothing to disclose.

NO SEASON FOR THE FLARE: A RETROSPECTIVE STUDY OF IBD EXACERBATIONS OVER 15 YEARS

A. Kasniewska-Kosinska[1], P. Kłos[1], P. Urynowicz[2], K. Płoszka[2], A. Fabisiak[1], E. Małecka-Wojciesko[1]
[1]Medical University of Lodz, Department of Digestive Tract Diseases, Łódź, Poland, [2]Medical University of Lodz, Department of Biostatistics and Translational Medicine, Lodz, Poland

Contact E-Mail Address: Alicja.kasniewska@stud.umed.lodz.pl
Introduction: Inflammatory bowel diseases (IBD), comprising two main disorders, Crohn's disease (CD) and ulcerative colitis (UC) are chronic conditions characterized by a fluctuating disease course. Symptoms vary depending on disease activity, localization, and behavior. The etiopathogenesis of IBD is complex and environmental factors play a key role in developing intestinal inflammation. We hypothesized that seasonal changes may influence the severity and frequency of exacerbations.
Aims & Methods: The goal of the study was to determine the impact of seasonal changes on the onset and clinical presentation of IBD. As the normal distribution was violated the Kruskall-Wallis test was utilized. Results are presented as median with interquartile range (IQR). p-values <0.05 were considered statistically significant.
We retrospectively assessed cases of IBD exacerbations requiring hospitalization in the Department of Digestive Tract Diseases, Medical University of Lodz, Lodz, Poland between 2010 and 2025. A total of 563 patients were analyzed (207 with CD and 365 with UC).
Additional data, such as age of onset, disease duration, and disease severity were extracted from the medical records where possible.
Results: The median age was 43 years (IQR: 35.00-55.00) for CD patients and 43.5 years (IQR: 34.50-62.50) for UC patients. Median age at diagnosis was 27 years (IQR: 20.00-41.00) for CD patients and 29 years (IQR: 22.00-45.00) for UC patients. Median disease duration was 5 years (IQR: 1.00-11.00) for CD and 3 years (IQR: 0.00-9.00) for UC. No statistically significant seasonal variation in exacerbation rates was observed for either CD or UC patients (p = 0.509). There were also no significant seasonal differences in age (CD: p = 0.866; UC: p = 0.340), age at diagnosis (CD: p = 0.576; UC: p = 0.571), disease duration (CD: p = 0.434; UC: p = 0.244), or disease severity (Total Mayo Score: p = 0.619; Partial Mayo Score: p = 0.790; Harvey-Bradshaw Index: p = 0.540).

	Median (IQR)			
	Spring	Summer	Autumn	Winter
Age of CD diagnosis	26.00 (20.00 – 42.00)	30.50 (19.75 – 38.50)	27.00 (21.50 – 39.50)	26.50 (19.00 – 39.00)
Age of UC diagnosis	29.50 (20.50 – 45.50)	28.00 (20.00 - 46.00)	32.00 (24.00 – 49.00)	29.00 (22.00 – 40.00)
CD duration	6.00 (2.00 – 14.25)	4.00 (1.00 – 9.50)	4.00 (1.00 – 9.50)	5.00 (1.00 – 10.00)
UC duration	3.00 (0.00 – 8.00)	4.50 (0.00 – 11.00)	1.00 (0.00 – 9.00)	2.00 (0.00 – 7.00)
TMS	10.00 (9.00 – 11.00)	10.00 (8.00 – 11.00)	10.00 (9.00 - 11.00)	10.00 (8.00 – 11.00)
PMS	7.00 (6.00 - 8.00)	7.00 (6.00 – 8.00)	7.50 (6.00 – 8.00)	7.00 (5.00 – 8.00)
HBI	12.00 (9.00 – 15.00)	11.00 (8.00 – 14.50)	10.00 (7.00 – 13.00)	11.00 (8.00 – 14.00)

Conclusion: Despite anecdotal claims of seasonal patterns in IBD exacerbations, our 15-year retrospective analysis found no significant seasonal variation in hospitalization rates or clinical parameters. These findings challenge the presumed role of seasonal factors in IBD flare-ups. Further studies are warranted to validate these results in broader populations, including exacerbation managed in outpatient clinics.
Disclosure: Nothing to disclose.

Contact E-Mail Address: davrib_1998@yahoo.com
Introduction: Crohn's disease (CD) is an Inflammatory Bowel Disease (IBD) with a multifactorial etiology that is not yet fully understood. It affects the intestinal wall in a transmural and segmental manner, with a preferential location in the distal ileum and right colon. Approximately 20% of CD patients develop perianal involvement (pCD), where the most common manifestations are fistulas and abscesses, followed by fissures and strictures. Patients with pCD represent a more severe disease phenotype, characterized by a reduced quality of life. Dysregulation of cytokine activity may influence the onset and severity of CD symptoms: several studies in patients with chronic inflammatory disorders (e.g., neoplasms or asthma) have shown that polymorphisms in pro- and anti-inflammatory genes can affect clinical outcomes.
Given the prominent role of altered inflammatory processes in the pathogenesis and severity of CD, the cytokine-mediated inflammatory pathway is of particular importance for predicting the potential development of pCD in patients with CD.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Aims & Methods: The aim of this study was to evaluate whether there is a significant association between the presence of a specific genotype of polymorphisms (in CD patients) in the cytokine pathway and an increased, or decreased, likelihood of developing pCD. The polymorphisms analyzed in this study were: TNF-α (-308 G>A), IL-6 (-174 G>C), IL-6 (-597 G>A), IL-10 (-1082 G>A), IL-10 (-3575 T>A), TGF-β (cod10 T>C), RAS (-4343 G>A), RAF-1 (-931 T>C), ERK (-966 T>C).

These polymorphisms were analyzed in the biological samples of 204 CD patients, 34 of whom had pCD, followed at the gastroenterology outpatient clinics of the AOU "Città della Salute e della Scienza di Torino," whose biological samples are stored in a biobank. For the statistical analysis, the significance of the association was evaluated using the chi-square test by calculating the p-value; in cases where the p-value was significant, logistic regression was performed to calculate the OR and CI 95%. Statistical significance was assumed for p-values < 0.05.

Results: Only a few studies in the literature have analyzed the correlation between cytokine polymorphisms and pCD, and among those, none have found a significant association between the polymorphisms analyzed here and the development of pCD.

In this study, we demonstrate a statistically significant association between the IL-6 (-597 G>A) polymorphism and the development of pCD: carrying the -GG genotype showed a protective effect (OR = 0.46, 95% CI = 0.22–0.995; 13 out of 111 patients [11.7%] with the -GG genotype developed pCD, compared with 20 out of 90 [22.2%] with the -GA and -AA genotypes) against the development of pCD in CD patients (p-value = 0.049).

This finding is consistent with some data in the literature that analyzed the correlation between the -A genotype of the IL-6 (-597 G>A) polymorphism and increased serum levels of IL-6 expression.

Conclusion: This study therefore demonstrates, for the first time, in CD patients, a significant correlation between the IL-6 (-597 G>A) polymorphism and the development of pCD, paving the way for further future studies that could ideally confirm this association in a larger cohort. Potential genetic sequencing at the time of CD diagnosis could allow for the prediction of the risk of developing pCD, suggesting a more aggressive therapeutic approach for these patients right from diagnosis.

Disclosure: Nothing to disclose.

CHANGES IN GENE EXPRESSION IN MULTIPLEX IBD FAMILIES, CONSEQUENCES OF SHARED HOUSEHOLD: A MULTIPLEX IBD FAMILY STUDY

T.B. Aabrekk[1,2], G. Aamodt[3], T.E. Detlie[4], M.L. Høivik[5,1], V.A. Kristensen[1,5], P. Ricanek[6], B. Bai[7], T.M. Tannæs[7], Y. Böttcher[8,7], M.-B. Bengtson[2]

Contact E-Mail Address: tbaabrekk@msn.com

Introduction: The highest risk factor of inflammatory bowel disease (IBD) is having a first-degree relative (FDR) with IBD. However, genetic variation accounts for only a small proportion of IBD heritability. Evidence from family and twin studies underscores the role of shared environment for the development of IBD. In a recent study based on two population-based IBD cohorts from South-Eastern Norway, thirty years apart, we reported a substantial increase in the rate of familial IBD (1).

Aims & Methods: This study investigates the potential underlying mechanisms for the increased rate of familial IBD in South-Eastern Norway.

We examine the association between shared environment and gene expression across IBD phenotypes [Crohn's disease (CD) and ulcerative colitis (UC)] and four comparison groups:

(I) multiplex IBD familial patients (≥3 FDRs with IBD),

(II) healthy relatives in multiplex IBD families,

(III) sporadic IBD patients, and;

(IV) symptomatic non-IBD controls.

Expression analyses focus on four candidate genes, FKBP5, BCL3, VMP1, and TRAIL, previously identified as differentially methylated in IBD compared to controls (2,3). Blood samples were collected from 15 multiplex IBD families in South-Eastern Norway, between April 2023 and January 2024. For comparison, blood samples from 50 sporadic IBD patients and 50 symptomatic controls (SC) were obtained from the IBSEN III cohort (4). RNA was extracted from PAXgene blood samples of the multiplex families at EpiGen, Akershus University Hospital, Norway, while RNA extractions from the sporadic IBD patients and SCs were performed at The Institute of Clinical Molecular Biology, Kiel, Germany. All cDNA synthesis were carried out at EpiGen. Gene expression was measured using RT-qPCR on cDNA with target-specific primers. Relative quantification was performed using GAPDH and ACTB as housekeeping genes.

Simple t-tests were conducted to compare the mean gene expression between the four comparison groups and across IBD phenotypes.

Results: The multiplex IBD family study included 62 individuals, 41 IBD patients, 25 patients with UC, 16 with CD, and 21 healthy family members, 13 FDR and 8 spouses. The results for the differences in mean fold changes between the four groups, including CD and UC for each of the four candidate genes, are presented in Table 1. The gene expression analysis revealed differences in mean fold changes between the four groups and across CD and UC.

The relative quantification of gene expressions for the four candidate genes revealed no significant differences in gene expression among the IBD patients vs healthy members of multiplex families.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Significant differences were observed for all candidate genes among familial IBD vs sporadic IBD and between healthy multiplex family members vs symptomatic controls, except for BCL3 and TRAIL, respectively. (p<0.005).

	FamIBD vs Fam healthy		FamUC vs Fam healthy		FamCD vs Fam healthy		FamIBD vs sporadic IBD		FamUC vs sporadic UC		FamCD vs sporadic CD		Fam Healthy vs SC	
Gene	Diff 95% CI	p	Diff 95% CI	p	Diff 95% CI	p	Diff 95% CI	p	Diff 95% CI	p	Diff 95% CI	p	Diff 95% CI	p

TRAIL	0.03 -0.13 -0.19	0.716	0.02 -0.16 -0.2	0,821	0.04 -0.19- 0.27	0.724	-0.23 -0.36 --0.09	0.001	-0.21 -0.38 --0.04	0.018	-0.3 -0.55 --0.04	0.023	-0.04 -0.17- 0.09	0.578

Conclusion: Our results reveal associations between the expression levels of IBD candidate genes and shared family environment, suggesting that epigenetic mechanisms may contribute to the development of familial IBD. Further methylation studies are warranted to clarify the underlying mechanisms of changed gene expression.

Introduction: Ulcerative colitis (UC) is a chronic, invalidating condition with a multifactorial aetiology. Several medications are available[1]; however, few data exist on predictors of response to such therapies. Genetics plays a pivotal role in disease predisposition and prognosis. OCTN1, an organic cation transporter, has been investigated as a modulator of intestinal inflammation. Genetic polymorphisms of OCTN1 have been linked to an increased susceptibility to IBD, but their role in predicting treatment response remains unclear[2,3].

In mice with colitis, *Octn1 -/-* is associated with a less severe course of disease and a higher percentage of Treg in comparison to wild-type mice.[4]

Aims & Methods: AIM: To investigate the association between *Octn1* genotypes and clinical response to anti-TNFα treatment in patients with ulcerative colitis.

We conducted a retrospective, single-center observational study at Policlinico Universitario "A. Gemelli" IRCCS, Rome. We enrolled adult patients diagnosed with ulcerative colitis and candidates to start treatment with anti-TNFα agents (infliximab, adalimumab, or golimumab). Individuals with known antibodies against infliximab or adalimumab and patients with a documented allergic reaction to these medications were excluded.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. Clinical and endoscopic data were collected at baseline and at 12 months of therapy. Patients were genotyped for the Octn1 SNP 1050152 (c1672t), and classified as wild-type (503L), heterozygous, or homozygous mutant (503F). 1 year therapy persistence, endoscopic response (defined as an improvement in endoscopic Mayo score) sustained clinical improvement in the absence of corticosteroid use over the previous 12 weeks) were assessed as clinical endpoints

Results: Of the 105 patients enrolled, 22 were homozygous for the 503F variant, 49 were heterozygous , and 34 presented two wild-type alleles. No statistically significant differences were observed between the patient groups with regard to gender, age at diagnosis, age and Mayo Endoscopic Score at initiation of therapy, duration of disease, or extent of diagnosis.*Octn1* mutated patients (503F) patients displayed greater rates of steroid-free clinical remission (OR=4.86, 95% CI 1.45 - 16.3; p= 0.010) and endoscopic improvement (OR= 6.52, 95% CI 1.93- 22.0; p = 0.003) after one year of therapy. Both the results were confirmed at the multivariable analysis (OR= 4.82 for steroid free clinical remission and OR= 7.94 for endoscopic response). Statistical significance was found for the mere therapy persistence (OR= 16.58, p = 0.009).

	N=105	CC (n=34)	CT (n=49)	TT (n=22)	p trend
Age (years.) at enrollment	40 (25-49)	41 (30-52)	40 (23-51)	36.5 (23-44)	0.536
Age at diagnosis (years.)	31 (20-44)	32 (20-46)	31 (20-42)	32 (19-41)	0.771
Sex (male / female)	57 (54.3) / 48 (45.7)	20 (58.8) / 14 (41.2)	25 (51.0) / 24 (49.0)	12 (54.5) / 10 (45.5)	0.738
Disease duration (years.)	4 (1-8)	4.5 (2-9)	4 (2-8)	4 (1-7)	0.768
Disease extension at diagnosis (Left sided colitis / Pancolitis)	44 (44) / 56 (56)	16 (48.5) / 17 (51.5)	20 (44.4) / 25 (55.6)	8 (36.4) / 14 (63.6)	0.680
1 year Therapy Persistence (yes)	74 (70.5)	19 (55.9)	34 (69.4)	21 (95.5)	0.004
1 year Steroid Free Remission (yes)	52 (49.5)	14 (41.2)	21 (42.9)	17 (77.3)	0.014
Endoscopic Response (yes)	51 (50.5)	9 (29.0)	26 (54.2)	16 (72.7)	0.006

Conclusion: Homozygosity for the rs1050152 c/t *Octn1* polymorphism appears to predict a more favorable clinical response to anti-TNFα therapy in ulcerative colitis, as evidenced by improved endoscopic outcomes and reduced need for corticosteroids after one year.

Introduction: The inflammatory bowel disease (IBD) subgroup classification of Crohn's disease (CD) and ulcerative colitis (UC) is based on clinical, endoscopic, histological and radiological findings. A non-invasive serological tool to aid the diagnosis of IBD is currently lacking. Extracellular matrix (ECM) proteins have been proposed as promising biomarkers of inflammatory activity, mucosal damage, and fibrosis development in IBD and may have diagnostic utility.

Aims & Methods: We aimed to investigate the diagnostic accuracy of 13 serum ECM protein epitopes representing inflammation and collagen formation and degradation. Serum from 518 newly diagnosed and treat-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ment-naïve adult IBD patients (180 CD, 338 UC) and 205 symptomatic controls (SC) from the IBSEN III cohort (discovery cohort) were collected at diagnosis. The serum was analysed for a panel of ECM protein epitopes (C4M, C6M, C7M, PROC3, PROC4, PROC5, PROC6, PROC11, PROC16, PROC22, VICM, CTXIII, and CPa9HNE) using enzyme-linked immunosorbent assay (ELISA).

We used log2-transformed protein concentrations to fit logistic models for IBD vs SC, CD vs SC, UC vs SC, and CD vs UC. We fitted models for each individual protein and for all 13 proteins combined. Backward regression with the Bayesian information criterion, starting from the full model with 13 proteins, identified models with three to four proteins.

The models fitted to the discovery cohort were validated in the independent NORDTREAT cohort of 130 newly diagnosed IBD patients (56 CD, 74 UC) and 103 SC using the area under the curve (AUC) of the receiver operating characteristic (ROC) curve.

Results: The coefficients of models fitted to the discovery cohort identified C6M, C7M, C4M, PRO-C3, and PRO-C6 as the most important proteins for separating disease from controls. In the validation cohort, the combination of C6M, C7M and PRO-C3 reached the highest AUC of 0.65 for distinguishing IBD from SC. When fitting the model to differentiate CD from SC, the collagen VI epitope C6M was superior, reaching an AUC of 0.65 and increasing to 0.70 when combined with C7M, PRO-C3, and PRO-C6. A model with all 13 markers gave an AUC of 0.71 for CD vs SC. Only C4M showed capacity of differentiating between UC and CD with

an AUC 0.66. Lastly, differentiation of UC from SC using only C6M had an AUC of 0.62, increasing to 0.64 when adding C7M and PRO-C3 to the model.

Conclusion: This study revealed a moderate diagnostic accuracy of predicting IBD versus SC. However, the ability to separate patients with CD from SC was promising, motivating further exploration of biomarker utility for CD subgroup distinctions.

SERUM LEVELS OF ANTI-TNF ALPHA AGENTS AND THEIR CORRELATION WITH TRANSMURAL HEALING ASSESSED BY MAGNETIC RESONANCE ENTEROGRAPHY AND ENDOSCOPIC HEALING IN PATIENTS WITH CROHN'S DISEASE

R.Q.M.d. Mendonça[1], V.V. Ricci[1], D.F.M. Vieira[1], J. Elias Jr[2], O. Feres[3], R. Parra[3], S. Da Costa Ferreira[1]

[1]Ribeirao Preto Medical School, University of São Paulo, Dept. of Hepatogastroenterology, Ribeirão Preto, Brazil, [2]Ribeirao Preto Medical School, University of São Paulo, Radiology, Ribeirao Preto, Brazil, [3]Ribeirao Preto Medical School, University of São Paulo, Surgery and Anatomy, Ribeirao Preto, Brazil

Introduction: In recent years, magnetic resonance enterography (MRE) has emerged as a novel tool for assessing disease activity in patients with Crohn's disease (CD). It is well known that anti-TNF agent trough levels (TLs) are associated with endoscopic healing (EH) in CD. However, limited data exist regarding the correlation between transmural healing (TH) and TLs in CD.

Aims & Methods: This study aimed to evaluate the correlation between anti-TNF TLs and TH, as well as mucosal healing (MH). We conducted a single-center cross-sectional study including CD patients on maintenance therapy with infliximab (IFX) or adalimumab (ADA) for at least one year. All patients underwent ileocolonoscopy and MRE at baseline and between one and two years after initiating anti-TNF therapy. TH was assessed using the simplified Magnetic Resonance Index of Activity (MARIAs) and was defined as the absence of inflammatory signs in the terminal ileum and all colonic segments. IFX and ADA TLs were measured using the Quantum Blue® assay (BÜHLMANN, Schönenbuch, Switzerland). EH was defined as a Simple Endoscopic Score for Crohn's Disease (SES-CD) of <3 points on colonoscopy. The correlation between IFX or ADA TLs, TH, and MH was analyzed using receiver operating characteristic (ROC) curve analysis.

Results: A total of 52 consecutive patients with active CD were included (55.8% male; median age, 37.04±15.49 years). Among them, 37 (71.15%) were on IFX and 15 (28.85%) on ADA. The mean TL values were 7 mg/dL for IFX and 15 mg/dL for ADA. An improvement in the MARIAs score after initiating anti-TNF therapy was observed in 54% of cases (p=0.02), regardless of the biologic agent used. Regarding SES-CD, an average decrease of 85% for ADA (p<0.01) and 82% for IFX (p<0.01) was observed.

Mean TL values >2.25 mg/dL for IFX and >14.45 mg/dL for ADA were associated with TH according to the MARIAs score; however, the correlation was weak [AUC: 0.6 (0.43–0.77)]

Conclusion: Satisfactory trough levels of IFX and ADA were associated with a significant decrease in MARIAs and SES-CD scores. However, no clear correlation between TLs and TH was demonstrated. Further studies investigating long-term TH and proactive dosing strategies based on therapeutic drug monitoring may help clarify whether an association between anti-TNF TLs and TH exists.

Disclosure: Nothing to disclose.

Introduction: The intestinal mucosa undergoes constant renewal, with epithelial and immune cells routinely shed into the gut lumen. Recent findings suggest that these shed cells remain viable and retain transcriptomic signatures relevant to bowel pathology. Analysis of luminal content obtained during colonoscopy indicates that Fecal Host Transcriptomes (FHT) mirror histologic inflammation in IBD.

This study aimed to evaluate whether sequencing of stool samples can noninvasively reflect the presence of intestinal inflammation in patients with IBD, predict the location of inflammation within the bowel and distinguish between IBD type; Crohn's Disease and Ulcerative Colitis.

Aims & Methods: Our aim was to investigate whether transcriptomic analysis of stool samples that are taken ambulatory or at home could reveal the inflammation signature of inflamed IBD patients.

Bulk RNA sequencing of stool samples from 71 IBD patients and healthy controls was used to generate FHTs. Each sample was paired with an endoscopic assessment and clinical data to capture a time-matched view of intestinal inflammation.

Three random forest classifiers were trained to:

1. Distinguish active inflammation from remission;
2. Predict inflammation location in Crohn's disease (colon vs. small intestine). and;
3. Classifier based on gene modules expression was used to differ between CD and UC in patients with active inflammation.

Results: Fecal RNA quality was high, with a median of 2,140 human genes detected per sample. The FHT test demonstrated robust performance across all tested applications. The first model, designed to distinguish active inflammation from remission (n = 71), achieved a sensitivity of 85% and a specificity of 92%. The second model, which predicted the location of inflammation in Crohn's disease patients (n = 21), achieved 100% sensitivity and 100% specificity. The third model, aimed at differentiating Crohn's Disease from Ulcerative Colitis (n = 35), reached a sensitivity of 83% and a specificity of 100%. These findings underscore the potential of FHTs as a non-invasive tool for comprehensive inflammation profiling in IBD.

Conclusion: Fecal shed cell transcriptomics offers a novel, non-invasive approach for assessing mucosal inflammation at the endoscopic level in IBD patients. This approach enables differentiation between disease activity states, anatomical localization of inflammation, and IBD subtype classification. Ongoing studies aim to evaluate its utility in grading inflammation severity and predicting therapeutic response.

Introduction: Accurate and timely endoscopic evaluation is critical for the management of postoperative Crohn's disease (CD). Although numerous established and novel indices exist, their relative operating properties and the optimal instrument for routine use in clinical and research settings are unknown.

Aims & Methods: We characterised the reliability and responsiveness of both historical and novel endoscopic indices using centrally assessed ileocolonoscopy videos from a randomised controlled trial comparing infliximab versus placebo for preventing postoperative CD (PREVENT; NCT01190839). Three blinded central readers independently assessed 70 videos from the PREVENT trial using the Rutgeerts and modified Rutgeerts scores, POCER index, REMIND score, Simple Endoscopic Score for CD (SES-CD), and the CD Endoscopic Index of Severity (CDEIS). Indices were scored separately for the neoterminal ileum, the anastomosis (including the blind loop of a side-to-side anastomosis), and the distal colonic segment. Intra- and inter-rater reliability was quantified using the intraclass cor-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. relation coefficient (ICC) and was interpreted using the Landis and Koch benchmarks.[1] Responsiveness was quantified using the win probability (WinP), defined as the probability of a patient receiving infliximab having a better endoscopic score than a patient receiving placebo, and interpreted using Cohen's benchmarks.[2]

Results: Inter-rater reliability was substantial for the Rutgeerts (ICC 0.74 [95% CI: 0.62-0.83]) and modified Rutgeerts scores (0.79 [0.68-0.86]), ileal REMIND score (0.79 [0.67-0.87]), SES-CD (0.79 [0.70-0.86]), and CDEIS (0.80 [0.72-0.86]). Inter-rater reliability was moderate for the POCER index (ICC 0.49 [0.26-0.64]) and fair for the anastomotic REMIND score (0.30 [0.14-0.47]). Intra-rater reliability was almost perfect for all indices (ICC≥0.81) (Table 1). The Rutgeerts (WinP 0.77 [95% CI: 0.65-0.86]) and modified Rutgeerts scores (WinP 0.81 [0.69-0.89]), ileal REMIND score (WinP 0.83 [0.72-0.91]), SES-CD (WinP 0.80 [0.66-0.89]), and CDEIS (WinP 0.75 [0.61-0.86]) demonstrated a large degree of responsiveness when treatment assignment was the criterion for change. The POCER index (WinP 0.54 [0.43-0.65]) and the anastomotic REMIND score (WinP 0.53 [0.42-0.64]) had a small degree of responsiveness. The reliability and responsiveness of all indices were consistently lower when assessed at the anastomosis or distal colon compared to the neoterminal ileum.

Index	Inter-rater ICC (95% CI)[a]	Intra-rater ICC (95% CI)[a]	WinP (95% CI)[b,c]	WinP (95% CI)[b,d]
Rutgeerts score	0.74 (0.62, 0.83)	0.90 (0.85, 0.94)	0.77 (0.65, 0.86)	0.72 (0.57, 0.83)
Modified Rutgeerts score	0.79 (0.68, 0.86)	0.92 (0.88, 0.96)	0.81 (0.69, 0.89)	0.68 (0.52, 0.81)
POCER index	0.49 (0.26, 0.64)	0.89 (0.78, 0.95)	0.54 (0.43, 0.65)	0.61 (0.46, 0.74)
REMIND - Ileal	0.79 (0.67, 0.87)	0.91 (0.85, 0.96)	0.83 (0.72, 0.91)	0.71 (0.55, 0.83)
REMIND - Anastomotic	0.30 (0.14, 0.47)	0.81 (0.71, 0.89)	0.53 (0.42, 0.64)	0.62 (0.47, 0.75)
SES-CD	0.79 (0.70, 0.86)	0.93 (0.87, 0.96)	0.80 (0.66, 0.89)	0.70 (0.54, 0.82)
CDEIS	0.80 (0.72, 0.86)	0.91 (0.86, 0.95)	0.75 (0.61, 0.86)	0.70 (0.56, 0.81)
Overall VAS	0.81 (0.72, 0.87)	0.90 (0.84, 0.94)	0.80 (0.67, 0.88)	0.71 (0.55, 0.83)

[a] Interpreted according to the Landis and Koch benchmarks[1]: poor = <0; slight = 0.0–0.20; fair = 0.21–0.40; moderate = 0.41–0.60; substantial = 0.61–0.80; and almost perfect = 0.81–1.00.
[b] WinPs of 0.56, 0.64, and 0.71 correspond to Cohen's effect sizes of 0.2, 0.5, and 0.8, which are the benchmarks for „small", „moderate", and „large" effects, respectively.[2]
[c] Using treatment assignment as the criterion for change.
[d] Using clinical recurrence as the criterion for change.
Abbreviations: WinP, Win probability; CDEIS, Crohn's Disease Endoscopic Index of Severity; CI, confidence interval; ICC, intraclass correlation coefficient; POCER, Postoperative Crohn's endoscopic recurrence; SES-CD, Simple Endoscopic Score for Crohn's Disease; VAS, visual analogue scale.

Table 1. Reliability and responsiveness of endoscopic scores

Conclusion: Existing endoscopic indices are reliable and responsive for assessing postoperative CD activity in the neoterminal ileum but are suboptimal for assessing the anastomosis or distal colon.

Contact E-Mail Address: bacsurp@gmail.com

Introduction: High-quality endoscopy in IBD is associated with better clinical outcomes, while quality measurement supports effective quality control. The European Society of Gastrointestinal Endoscopy recommends using nine performance measures, depending on the indication for endoscopic examination in IBD.

Aims & Methods: Our study aimed to compare colonoscopy quality between tertiary and secondary referral centers for IBD patients, based on endoscopic reports. In this cross-sectional study, colonoscopy reports of IBD patients were analyzed.

At our tertiary center, we consecutively enrolled patients over 18 years old with established IBD between July and October 2024, using their available colonoscopy reports. The secondary care group included patients referred to our tertiary center, with the last existing report from secondary care used for analysis, while the tertiary care group consisted of our patients whose most recent report was similarly used.

Nine key performance measures (indication, bowel preparation, photo documentation, ileal intubation, biopsy, endoscopic activity score, high-definition and chromoendoscopy use, and neoplasia detection) were evaluated based on colonoscopy reports.

Patients were stratified by procedure indication (diagnostic, activity assessment, or surveillance) as well. Descriptive statistics, Welch's, and Fisher's exact tests were used to compare groups, with p-values <0.05 considered significant.

Results: Overall, 207 colonoscopy reports were assessed, of which 68/207 were performed at secondary care level. A total of 78/207 patients were diagnosed with Crohn's disease, while unclassified diagnoses were noted only at secondary centers. Activity control (88% vs. 38%, p<0.001) and surveillance (8% vs. 0%, p=0.02) examinations were more common at the tertiary level. Bowel preparation was better at tertiary centers (Boston Bowel Preparation Scale [BBPS] 8.3±2.3 vs. 7.2±1.2; p=0.003), and use of BBPS was more frequent at higher levels of care (p<0.001).

Disease activity scores were more commonly used at the tertiary level during activity control examinations (51.2% vs. 19.2%, p=0.004), while ileal intubation was also more frequent at the tertiary level (53% vs. 28%; p<0.001). Procedure and withdrawal times did not differ between levels in diagnostic or activity control examinations. Neoplasia detection was low, and biopsy rates were similar.

Variables	Secondary care (n = 68)	Tertiary care (n = 139)	Sig.
Diagnosis, n (%)			
CD	24 (35.3)	54 (38.8)	
UC	25 (36.8)	85 (61.2)	<0.001
IBD-U	19 (27.9)	0 (0)	
Examination time, mean (±SD)	20.2 (9.0)	16.2 (3.5)	0.004
Withdrawal time, mean (±SD)	10.4 (6.5)	8.2 (2.3)	0.008
Ileal intubation, n (%)	19 (27.9)	71 (51.1)	0.005
Disease activity score use, n (%)	7 (10.3)	71 (51.1)	<0.001
Neoplasia detected, n (%)	2 (2.9)	17 (12.2)	0.038

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Quality indicator targets were met in neither secondary nor tertiary centers; however, wider investigation is needed to verify these results. Broad education can help to improve the quality of colonoscopy in IBD care.

Disclosure: Nothing to disclose.

PP0420

EVALUATION OF TRANSFER IN INFLAMMATORY BOWEL DISEASE PATIENTS FROM PEDIATRIC TO ADULT CLINIC IN STOCKHOLM COUNTY. A QUALITATIVE STUDY

Introduction: In Sweden some 300 patients with inflammatory bowel disease (IBD) are annually transitioned from pediatric to adult care. Patients with childhood-onset IBD more often presents with severe disease phenotypes and are at increased risks of low school performance, later psychiatric disorders, and low attachment to the labour market. The transition to adult care can be challenging for both patients and parents, as it involves changes in care routines and relationships with healthcare providers.

Aims & Methods: This qualitative study explored experiences of IBD patients about to transfer and already transferred and their parents in Stockholm County. Semi-structured interviews were conducted with 15 patients (9 pre- and 6 post-transfer) and 8 parents. All interviews where transcribed verbatim and thematic analysis was employed to analyse the interview material.

Results: The key themes both for parents and patients were autonomy, preparations, worries, relationships and possible improvements.

Patients highlighted the increased responsibility post-transfer, expressing both readiness and challenges in gaining autonomy. Parents worried about losing oversight and felt concern that their children would receive less emotional support and lower quality care compared to the pediatric clinic. Both groups stressed the emotional and practical adjustments required, including establishing relationships with new healthcare providers. Pre-transfer patients expressed worry about leaving familiar pediatric settings, while post-transfer patients reported satisfaction with the adult care system despite initial concerns. Recommendations for improvement from the informants included enhanced communication, written materials, and knowledge about the difference between adult and pediatric care.

Conclusion: The transition from pediatric to adult care for IBD patients involves emotional, practical, and relational challenges for both patients and parents.

The study shows that there is a need for a clear structure and information of how the process works and that there is an effective communication between the pediatric and adult clinics. In the process, it is essential to acknowledge and address factors such as the child's developing autonomy, considerations regarding separation from familiar caregivers, and to deal with the patients concerns about the future in a patient centred way. The fact that most patients and parents post-transfer was very satisfied with current process could indicate that a crucial factor in a successful transition is a motivated and committed health care personnel at both ends of the transfer. From a patient perspective, there are other more effective improvements to the transition process than joint visits.

This study highlights the importance of patient-centred strategies to optimize transitional care in Sweden.

Contact E-Mail Address: caron.benedicte@hotmail.fr

Introduction: Ulcerative proctitis (also called isolated proctitis) affects approximately 30% of patients with ulcerative colitis , yet achieving disease control remains challenging. Controlling the disease is essential to preventing disability and disease progression. Backbone therapy includes topical and oral 5-aminosalicylic acid (5-ASA) and steroids. One third of patients with ulcerative proctitis are refractory to conventional therapy with 5-ASA and steroids.

Aims & Methods: The aim of this study was to investigate current practice on isolated proctitis management across the globe.

Physicians with experience in treating inflammatory bowel diseases (IBD) were invited to participate in an anonymous, multiple-choice survey between January and February 2025. The survey addressed various aspects of patient care including clinical practice and attitudes towards isolated proctitis identification, disease activity measurement attitudes, and current treatment of isolated proctitis, including the use of advanced therapies.

Results: The survey included 460 physicians from 66 countries. Gastroenterologists were the most represented specialists (89.0%), followed by surgeons (6.3%), and internal medicine doctors (3.5%). Three quarters of participants (74.6%) had > 10 years of experience in IBD.

The majority of participants (87.9%) assessed clinical activity of isolated proctitis within 3 months of treatment initiation, 75.9% used fecal calprotectin, and 67.1% used C-reactive protein (CRP) to measure disease ac-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tivity. Endoscopic assessment was performed 3 to 6 months (34.2%) or 6 to 12 months (48.4%) after treatment induction. For patients in clinical remission, the participants assessed clinical and biological disease activity every 6 months (54% and 59% respectively), and endoscopic evaluation every 5+ years (rectosigmoidoscopy: 27% and colonoscopy: 31%).

In this survey, 49% of participants were more reluctant to begin an advanced therapy in patients with isolated proctitis compared to pancolitis or left sided colitis. Infliximab (mean 6.55/10; SD: 2.64), vedolizumab (mean 5.64/10; SD: 2.98), upadacitinib (mean 4.88/10; SD: 2.91), and ustekinumab (mean 4.81/10; SD: 2.90) were preferred in refractory proctitis. Two thirds of participants (61.0%) were less likely to use biologics in combination with immunosuppressants in isolated proctitis compared to left sided or pancolitis. Anti-TNF (tumor necrosis factor) (48.4%) was the preferred choice in first line advanced therapy after failing conventional treatment.

Conclusion: This study highlighted differences in management of isolated proctitis compared to left sided colitis or pancolitis. This is likely explained by the fact that isolated proctitis patients were historically excluded from clinical trials, therefore management relied on extrapolation of data from studies on more extensive disease. To date, a single advanced therapy (etrasimod) has demonstrated efficacy in isolated proctitis patients through a double blinded, randomized clinical trial . Future clinical trials on advanced therapies for this frequent and disabling condition are eagerly awaited.

COMPARISON OF TWO FATIGUE QUESTIONNAIRES FOR PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD)

S. Wurm[1], R. Rosania[1], V. Keitel-Anselmino[1], U. von Arnim[1]
[1]University Hospital Magdeburg, Gastroenterology, Hepatology and Infectious Diseases, Magdeburg, Germany

Contact E-Mail Address: sophie.wurm@st.ovgu.de

Introduction: Fatigue is a common but rarely diagnosed symptom in patients with inflammatory bowel disease (IBD). The IBD-specific fatigue questionnaire Inflammatory Bowel Disease Fatigue (IBD-F) was validated in German in 2022. It assesses the severity and frequency of fatigue (Section 1) as well as its impact on daily life (Section 2). The Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) also measures the impact of fatigue on daily life. While the FACIT-F has been validated in English for IBD, it has not yet been validated in German, although it is frequently used in IBD studies.

Aims & Methods: This study compared the IBD-F and FACIT-F in a German-speaking IBD cohort. IBD patients and a healthy control group (HC) completed both the IBD-F and FACIT-F questionnaires. Disease activity in IBD patients was assessed using the partial Mayo Score (pMS for ulcerative colitis; UC) or the Harvey Bradshaw Severity Index (HBSI for Crohn's disease; CD). Internal consistency was calculated using Cronbach's α. To assess acceptance, the number of fully completed questionnaires was analyzed. Spearman correlation was used to compare IBD-F and FACIT-F scores in both IBD patients and healthy controls.

Results: A total of 382 IBD patients (CD n = 240; 98 male; age 43.1 ± 13.9; UC n = 142; 72 male; age 43.2 ± 12.6) and 130 healthy controls (HC; 61 male; age 40.2 ± 16.5) participated. 75% (286/382) of the patients reported fatigue in IBD-F Section 1 and were included in further analyses.

Internal consistency was rated as excellent for IBD-F Section 1 (α = 0.930), Section 2 (α = 0.979), and FACIT-F (α = 0.936), as indicated by Cronbach's alpha. Acceptance decreased with increasing number of items (IBD-F Section 1 94.4%; Section 2 80.1%; FACIT-F 90.9%). A significant negative correlation was observed between the FACIT-F and IBD-F Section 1 in both the IBD group (r_s = -0.751, p < 0.01) and controls (r_s = -0.361, p < 0.01), as well as between the FACIT-F and IBD-F Section 2 (IBD: r_s = -0.862, p < 0.01; HC: r_s = -0.463, p < 0.01).

Patients in remission (59% (168/286)) reported lower fatigue scores in IBD-F Section 1 and 2 and FACIT-F than patients with active disease (36% (104/286)), but higher fatigue scores than HC. HC showed higher fatigue scores in the FACIT-F than in the IBD-F (see Table 1).

Questionnaire	IBD/Controls	N	Mdn (IQR)
IBD-F Section 1 - Total Score	Control	130	0.0 (2.0)
	IBD - Total	286	8.0 (5.0)
	- Remission[a]	168	6.0 (5.0)
	- Active disease[a]	104	10.0 (6.8)
IBD-F Section 2 - Total Score	Control	130	0.0 (2.3)
	IBD - Total	286	21.0 (28.9)
	- Remission[a]	168	18.0 (19.0)
	- Active disease[a]	104	30.0 (35.4)
FACIT-F - Total Score	Control	130	48.0 (7.3)
	IBD - Total	286	35.0 (16.7)
	- Remission[a]	168	37.5 (16.0)
	- Active disease[a]	104	29.6 (19.8)

Mdn = Median; IQR = Interquartile range. [a] Due to missing data, the pMS and the HBSI could not be calculated for 14 patients.
Higher scores in Sections 1 and 2 of the IBD-F, as well as lower scores in the FACIT-F, indicate greater fatigue. IBD-F Section 1 Total Score range: 0–20. IBD-F Section 2 Total Score range: 0–120. FACIT-F Total Score range: 0–52.

Table 1: Descriptive statistics of IBD-F and FACIT-F.

Conclusion: Both the IBD-F and FACIT-F are effective tools for assessing fatigue in IBD patients. The IBD-F, however, appears to better distinguish healthy individuals without fatigue.

Disclosure: Nothing to disclose.

PP0423

CLINICAL AND PHENOTYPIC CHARACTERISTICS OF EARLY-ONSET INFLAMMATORY BOWEL DISEASE IN CHILDREN UNDER 6 YEARS OF AGE: A SINGLE-CENTER COHORT STUDY

I. Samolygo[1], S. Erdes[1], E. Yablokova[1], M. Manina[1], A. Antishin[1], A. Pestova[1]
[1]Moscow Sechenov Medical University, Paediatrics, Moscow, Russian Federation

Contact E-Mail Address: ivan.samolygo.03@bk.ru

Introduction: Early-onset inflammatory bowel disease (EO-IBD), defined as disease onset before the age of 6 years, represents a distinct subgroup of pediatric IBD. It is associated with extensive colonic involvement, resistance to standard therapy, and a higher risk of complications, including extraintestinal manifestations (EIMs).

Aims & Methods: The purpose of our study was to analyze the clinical features of EO-IBD in children of a large gastroenterological center in the Russian Federation. This retrospective single-center cohort study included 37 children diagnosed with EO-IBD between 2019 and 2024. Clinical and demographic data were collected from outpatient records. Intestinal symptoms (abdominal pain, stool frequency and consistency, pathological impurities) and EIMs were assessed. Special attention was given to the timing of EIM onset relative to intestinal symptoms.

Results: The study included 37 patients — 17 with Crohn's disease (CD) and 20 with ulcerative colitis (UC) — all of whom were diagnosed before or at the age of 6. The median (Me) age at diagnosis was 5 years for both UC (IQR 3 – 6) and CD (IQR 4 – 6). The groups were comparable in terms of sex (p = 0.56) and age (p = 0.81). The median time from symptom onset to diagnosis was 10 months for UC (IQR 6.25 – 18) and 8.5 months for CD (IQR 5.5 – 15.8), with no significant difference between the groups (p = 0.74). Growth retardation (SDS < –2) was observed in four boys with CD at age 6. The most common symptoms in CD were abdominal pain (64.7% vs 60% in UC; OR 0.82; CI 0.22 – 3.12; p = 0.77) and weight loss (29.4% vs 7.1%; p = 0.019). Fever occurred exclusively in the CD group (35.3%). In contrast, UC was more frequently associated with diarrhea (90% vs 70.6% in CD; OR 3.75; CI 0.62 – 22.6; p = 0.13) and blood in stool (85% vs 64.7%; OR 0.32; CI 0.067 – 1.57; p = 0.15). EIMs were observed in 7 of 20 (35%) UC patients and 7 of 17 (41.2%) CD patients. The most frequent EIM in both groups was peripheral arthritis – found in 3 UC patients (10%) and 5 CD patients (29.4%) (p = 0.29). Peripheral arthritis was significantly more likely to occur after the onset of intestinal symptoms (p < 0.001). In two patients of each group, an EIM was the first manifestation of disease. In 43.2% of patients, an accurate diagnosis was not possible at disease onset, and they were initially classified as having IBD-unclassified (IBD-U). During follow-up, the time to establish a definitive diagnosis was measured. The median time to UC diagnosis was 24 weeks (IQR 20 – 48), and for CD it was 40 weeks (IQR 30–45.5) (p = 0.56).

Conclusion: EO-IBD in young children presents with specific phenotypic traits and a high rate of EIMs. Delayed diagnosis is common, particularly in cases initially classified as IBD-U. Our findings emphasize the need for early recognition and accurate differentiation of IBD subtypes in this challenging age group.

CORRELATION BETWEEN PATIENT-REPORTED DISEASE ACTIVITY, PHYSICIAN'S GLOBAL ASSESSMENT AND QUALITY OF LIFE IN INFLAMMATORY BOWEL DISEASE

S. Ramos Lopes[1], M. Teixeira[1], D. Tomás[1], A. Bastos[1], C. Sequeira[2], C. Teixeira[1], E. Gamito[1], A.L. Alves[1]

Contact E-Mail Address: saramarlopes@gmail.com

Introduction: As a chronic disease, patients' perspectives on their disease status and quality of life is an essential part of inflammatory bowel disease (IBD) management[1]. Patient-reported outcomes should be the standard of measure for signs and symptoms evaluation[2].

Aims & Methods: We aimed to evaluate the correlation between patients' self-assessment of disease activity, activity scores and the physician's global assessment.

A unicentric cross-sectional study was conducted. The Short Inflammatory Bowel Disease Questionnaire (SIBDQ)[3] was administered to consecutively evaluated IBD patients in the outpatient setting. Additionally, a pilot questionnaire addressing perceived disease activity was completed by both patients and their attending physician.

Disease activity was categorized as remission, mild, moderate, or severe. Remission was defined as Harvey Bradshaw Index (HBI) ≤ 4 for Crohn's disease or Mayo Clinic Subscore (MCS) ≤ 2 for ulcerative colitis.

Spearman's rank correlation coefficient was used to assess correlations between patient-reported disease activity, physician global assessment, disease activity scores, and quality of life.

Results: A total of 105 patients were included (female: 52%; mean age: 44±15 years), of whom 68% had Crohn's disease. 71% percent of patients were receiving advanced therapy (Table 1).

Female gender, % (N)	**52% (55)**
Age, mean ± standard deviation (SD), years	44.1 ± 15.0
Type of IBD, % (N)	
CD	68% (71)
UC	32% (34)
History of IBD-related surgery, % (n)	25% (26)
History of IBD-related hospitalization, % (n)	39% (41)
Current medical therapy, % (n)	
5-Aminosalicylates monotherapy	19% (20)
Immunomodulators (mono or combo therapy)	31% (32)
Advanced therapy	71% (74)
Disease activity indices, mean ± SD	
HBI	2.5 ± 6.5
MCS	3.4 ± 4.0
Patient-reported disease activity, % (N)	
Remission	27% (28)

SIBDQ-PT	50.7 ± 12.1

Table 1.

A quarter of the patients (27%, n=28) perceived their disease to be in remission, of whom 56% were indeed in deep remission and 19% in endoscopic remission (table 1). A statistically significant positive correlation was observed between patient self-assessment and HBI scores (mean=2.5±6.5 points, r=0.400, p=0.001) and MCS scores (mean=3.4±4.0 points, r=0.574, p<0.001).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among patients who did not consider themselves in remission, 42% rated the activity of their disease as mild, 23% as moderate, and 9% as severe. The attending physician assessed 26% with mild disease, 22% with moderate disease, and 18% with severe disease (table 1). There was a statistically significant positive correlation between patient and physician assessments (r=0.374; p<0.001).

The mean SIBDQ score was 50.7 ± 12.1 points (table 1), and a statistically significant negative correlation was found between patient self-assessment of disease activity and the SIBDQ (r=-0.417, p<0.001).

Conclusion: These observational data suggest a weak correlation between patient-reported disease activity and the physician's global assessment. Divergent perceptions of disease activity between patients and physicians may compromise patient-engagement. Furthermore, the moderate correlation observed with overall quality of life supports the importance of alignment patients and physicians to improve the quality of care provided.

Contact E-Mail Address: takatomo@koto.kpu-m.ac.jp

Introduction: Linked Color Imaging (LCI) is an endoscopic system that emphasizes the red mucosal color to identify subtle areas of inflammation. Endoscopic imaging, including LCI classification and LCI index, has been reported as a predictor of histological healing (HH) in ulcerative colitis (UC). Endoscopic changes (LCI classification, LCI index) in vedolizumab treatment have not been reported to date.

Aims & Methods: This study aimed to evaluate endoscopic remission and HH using LCI endoscopy at week 22 of vedolizumab treatment in patients with moderate to severe UC. This was a phase 4, multicenter, open-label, single-arm, prospective study involving 12 patients with moderately to severely active UC receiving vedolizumab. Vedolizumab was administered for 54 weeks. Endoscopy and mucosal sampling from most inflamed sites or the patient's rectum when all sites had equal endoscopic severity were performed at weeks 0, 22, and 54 to assess the LCI index, LCI classification, Mayo endoscopic score (MES), Nancy score (If MES = 0, it was collected from the rectum). This study was also evaluated a variety of possible factors such as fecal calprotectin, serum vedolizumab concentration and mucosal gene expression associated with changes induced by vedolizumab. LCI index was numerically evaluated for the redness of a 40-pixel square area within the LCI image. LCI classification was defined by assigning one of the three categories (A, no redness; B, redness with visible vessels; C, intense redness without visible vessels). HH was defined as a Nancy score ≤1, and clinical outcomes were compared between HH and non-HH groups. Correlation coefficients between LCI endoscopy and other clinical markers (MES, Nancy score, fecal calprotectin and vedolizumab concentration) were analyzed at weeks 0, 22, and 54. Gene expression analysis was performed on 374 genes, comparing HH (n=8) vs. non-HH (n=3) and LCI classification A (n=5) vs. LCI classification B and C (n=6) at week 22. Biomarkers common to HH and LCI-A were identified as LCI-Deep remission (L-DR) markers.

The study was registered with the Japan Clinical Trial Registry (Identifier: UMIN000042855).

Results: At week 22, 66.7% (8/12) achieved histological healing (HH), while 50.0% (6/12) met LCI classification A criteria. The LCI index change from baseline showed a statistically significant difference between HH and non-HH (week 22: p=0.021; week 54: p=0.011).Correlation analysis demonstrated that LCI index was significantly associated with: MES (week 22: ρ=0.729, week 54: ρ=0.789), Nancy score (week 22: ρ=0.695, week 54: ρ=0.725), fecal calprotectin (week 22: ρ=0.555, week 54: ρ=0.783), vedolizumab concentration (week 22: ρ=0.758, week 54: ρ=-0.418). Gene expression analysis identified IL1B, CXCL11, CD38, CSF2RB, PTPN6, CD86, NFKB2, IFNAR2, STAT1, GNAI2, FES and IRF9 as L-DR markers, as they were commonly associated with both HH and LCI classification A. There are genes involved in NF-κB signaling pathway and JAK-STAT signaling pathway associated with UC. HH and LCI endoscopy have been found to correlate well but do not perfectly align.

In this study, we proposed a definition of L-DR, which encompasses both HH and LCI endoscopic remission.

Conclusion: This study introduces L-DR as a novel definition for combined endoscopic (LCI-A) and HH (Nancy score ≤1) in UC patients receiving vedolizumab. Additionally, we identified candidate L-DR biomarkers that may serve as potential indicators of deep remission.

PREDICTING INFLAMMATORY BOWEL DISEASE-ASSOCIATED LIVER DISEASE FROM ROUTINE BIOMARKERS USING LARGE LANGUAGE MODEL–REFINED CLINICAL DATA

Z. Green[1,2], A. Kadhim[1], L. Win[1], G. Czanner[3], S. Ennis[1,4], RM. Beattie[2], J. Ashton[1,2]

Introduction: Hepatobiliary disorders are recognised extraintestinal manifestations in inflammatory bowel disease (IBD). Up to 30% of patients exhibit abnormal liver function tests and 5% will develop chronic liver disease (1). IBD-associated liver diseases (IBDALD), comprising primary sclerosing cholangitis (PSC), autoimmune hepatitis (AIH) and AIH/PSC overlap syndrome carry significant morbidity through progressive hepatobiliary damage and increased cancer risk.

Early recognition is challenging due to non-specific biochemical derangement and heterogeneous presentation. No validated stratification tools exist for prospective risk identification.

This study investigated whether routinely collected biomarkers convey predictive value for IBDALD, leveraging large-language model (LLM) refined phenotyping.

Aims & Methods: We analysed 1,571 paediatric and adult-onset IBD patients recruited to the "Genetics of IBD" study (Southampton, UK; 2010–). IBDALD cases were identified through LLM-assisted (Llama 3.1-70B-Instruct) structuring of 32,041 free-text imaging and histopathology reports, followed by clinician verification (2). Participants diagnosed with IBDALD prior to IBD were excluded from further analysis.

Examined biomarkers included ALT, ALT and ESR (n=335,605 datapoints for the examined cohort). For each biomarker, patient-level medians were calculated from all available results within ±6 months of IBD diagnosis. A 1:4 individual matched case-control design was applied (matched on age at IBD diagnosis, gender, and IBD subtype) in *R*.

Conditional logistic regression models assessed associations between IBDALD and biomarker values, treated as both continuous (patient-level medians) and binary – normal versus abnormal - (age- and sex-adjusted lab range flags) variables. Longitudinal biomarker trajectories were explored using LOESS and linear mixed-effects models.

Results: Thirty-five cases of IBDALD were identified (27 post-IBD diagnosis). Median follow-up duration was 11.5 (0.5–59.5) years and median 4.5 years (0.4–39.1) from IBD diagnosis to liver disease onset. In whole cohort analyses, ALT, ALP, and ESR were significantly elevated in IBDALD at diagnosis of IBD ($p < 0.01$). In matched case-control models, higher median ALT (OR = 1.04 per U/L increase, 95% CI: 1.01–1.07, p = 0.012), ALP (OR = 1.01, 95% CI: 1.00–1.02, p = 0.014), and ESR (OR = 1.05, 95% CI: 1.00–1.09, p = 0.034) were each associated with IBDALD. In a combined model including all three biomarkers, none retained statistical significance. When analysed as binary (normal/abnormal) variables, ALT and ALP remained significantly associated with IBDALD (ALT: OR = 5.10, 95% CI: 1.57–16.59, p<0.01; ALP: OR = 15.33, 95% CI: 1.87–125.77, p<0.05). ESR did not reach significance (OR = 3.71, 95% CI: 0.75-18.32 p=0.107).

Longitudinal modelling supported distinct ALT and ALP trajectories in the IBDALD group and distinct trends over time were visualised for ALT, ALP and ESR in LOESS scatterplots.

Conclusion: These data suggest that routinely measured biomarkers may carry early predictive signals for IBD-associated liver disease, identifiable at the time of IBD diagnosis. The use of LLM-assisted phenotyping enabled high-fidelity case definition within real-world data. These findings should be interpreted cautiously given the rarity of IBDALD and potential overfitting in multivariable models. Future prospective studies are warranted to validate predictive models and support integration into IBD care pathways.

ACCEPTABILITY OF FECAL CALPROTECTIN IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: IMPACT OF AN ALTERNATIVE COLLECTION DEVICE FOR STOOL SAMPLING (THE ACCALMI STUDY)

G. Pasi[1], A. Antari[2], D. Masson[2], H. Caillon[2], T. Dejoie[2], M.A. Vibet[3], M. Collins[1], A. Bourreille[1], C. Le Berre[1]

Contact E-Mail Address: giuliapasi05@gmail.com

Introduction: Fecal calprotectin (FC) is a key non-invasive biomarker used to monitor inflammatory bowel disease (IBD). Despite its clear clinical value, patient adherence to the test remains suboptimal, mainly due to reluctance related to stool collection.

The objective of the ACCALMI study was to compare the acceptability of a new stool collection device, similar to the one used for fecal immunochemical tests (FIT), with a standard stool container, and to evaluate its impact on patient compliance.

Aims & Methods: In this prospective, single-center study, 156 patients with an established diagnosis of IBD and who had been prescribed an FC test as part of their routine care, were randomly assigned to either the standard container group or the alternative device group (Procise Stool Collection Device™), which includes a collection tube with a thin spiral-shaped probe facilitating stool collection. Acceptability was assessed using a 4-category ordinal scale (from "poor" to "very good") and a visual analog scale (VAS, from 0 to 10). Analyses were conducted in both per-protocol and intention-to-treat (ITT) populations, with missing data handled using the maximum bias method. Factors associated with improved FC acceptability, and compliance with FC testing, were analyzed.

Results: The alternative collection device significantly improved acceptability as measured by the ordinal scale (odds ratio [OR] 2.69; $p < 0.001$). In the alternative group, acceptability ratings were significantly higher with only 1.4% versus 7.0% rating it as 'poor', 12.5% versus 46.6% as 'average', 66.7% versus 40.8% as 'good', and 19.4% versus 5.6% as 'very good'. Measured using the VAS, the average acceptability was 7.9/10 in the group using the alternative device compared to 6.1/10 in the standard group, with a significant difference of 30.4% (95% CI [19.7 - 44.7%], $p < 0.001$), although it did not reach the threshold of 30% that was set *a priori*. The ITT analysis led to the same conclusions. Among the patients who had already undergone FC testing and were randomized to the "alternative device" group,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

55% indicated a preference for the alternative device, compared to 7.2% for the conventional device, while 37.7% found them similar. Embarrassment and discomfort associated with the standard container were alleviated by the alternative device. A long home-to-hospital distance (> 50 km) and the use of the alternative device were the only factors associated with better acceptability in the multivariate analysis. Compliance was similar between both groups and remarkably high (92%).

Conclusion: The ACCALMI study demonstrated that the alternative stool collection device, similar to the one used in FIT for colorectal cancer screening, is more accepted by IBD patients than the standard container, thus improving the acceptability of FC testing. These findings support the integration of patient-centered innovations in diagnostic and follow-up testing to improve the monitoring of IBD.

Introduction: Recurrence of Crohn's disease (CD) lesions after surgery remains high. Identifying patients at high risk of recurrence who may benefit from prophylactic therapy would be relevant. However, data on specific preoperative risk factors remain scarce, while onset and severity of Post Operative Recurrence (POR) are assessed with the Rutgeerts score (RS)(1). Still, the value of early endoscopic lesions, and RSi2, to predict the later course of the disease and the risk of late (from 1 to 10 years) POR in any individual patient is unclear. Non-invasive Small Intestine Contrast Ultrasonography (SICUS) assesses intramural extension of CD lesions, their progression, and is as effective as RS in detecting early POR lesions (2).

Aims & Methods: 1. To develop a risk score based on pre-operative clinical predictors to estimate POR likelihood;

2. to identify predictors of severity of mucosal lesion according to RS;

3. to assess the overtime progression of transmural lesion.

Prospective cohort study (1998-2022). CD patients were evaluated at ileo-colonic surgery and every 6-12 months thereafter. Sex, age at diagnosis/surgery, active smoking, CD behaviour (B)/location (L), perianal disease (PD), length of resected bowel, steroids, immunosuppressants/biologics therapy use, and CD duration before surgery were analysed using multivariable proportional hazards regression. Cumulative POR rates and risk score were calculated with Poisson models, taking for each predictor the integer part of the Poisson model parameter.

Results: Over a median follow-up of 7.6 years (IQR 4.1–12), 78 patients (32 F; median age 30 years; 60% smokers) were analysed. CD characteristics: B1 8%; B2 67%; B3 25%; L1 63%; L3 36%; PD 22%; immunosuppressive/biologics 17%; median CD duration pre-surgery 4.7 years; median resected bowel length 28 cm.

Cumulative POR rates were 51.8% (IQR,41%-63.4%), 65.2% (54.4%-75.7%), 69% (58.6%-79%), 75.9% (65.8% -84.8%), 78.9% (69.0%-87.3%), at 1, 2, 3, 4, and 5 years. POR risk factors included active smoking, age ≥35 years at surgery, and marginally B1 (Table).

Predictors of RS were PD (HR=3.39; 95% CI 1.12-10.26; p=0.03 and CD duration ≥5 years pre-surgery (3.45; 1.15–10.32; p=0.03). The estimated cumulative probability of POR increased with higher risk scores (from 1 to 3) being 22%, 58%, 83% and, respectively, 43%, 80% and 100% at 1 and 4 years. Lesion length at POR varied by RS (median, IQR): RSi1 (32%): 0.5 cm (0.5-0.5), RSi2 (35%): 4 cm (0.5-7), RSi3 (15%): 15 cm (8.5-21.5), RSi4 (5%): 16 cm (9.5-23.5). Lesions remained stable in patients with RSi1 and RSi3 (45%) but fluctuated in those with RSi2 and RSi4 (31% increased, 24% decreased).

		Univariate analysis				Multivariate analysis				Cumulative Risk Score
Variable		HR	95% CI		p	HR	95% CI		p	contribution
Age at surgery (years)	≥35 vs. <35	1.84	1.10	3.10	0.02	1.82	1.07	3.07	0.03	0.60
Sex	Female vs. Male	1.24	0.74	2.08	0.42	1.59	0.90	2.79	0.11	0.46
Active smoking	Yes vs. No	1.50	0.88	2.55	0.14	1.99	1.06	3.75	0.03	0.69
Disease behaviour	B2 vs. B1	2.28	0.81	6.44	0.12	2.53	0.89	7.19	0.08	0.93
	B3 vs. B1	2.01	0.66	6.09	0.22	3.01	0.94	9.61	0.06	1.10
Disease duration (years)	≥5 vs. <5	1.18	0.71	1.98	0.52	NI	NI	NI	NI	NI
Length of resection (cm)	≤ 25 vs. >25	1.15	0.69	1.92	0.60	NI	NI	NI	NI	NI
PD	Yes vs. No	1.10	0.63	1.92	0.74	NI	NI	NI	NI	NI

*HR:hazard ratio;CI: confidence interval;*time dependent covariates;*
NI:not included in the final model selected through a backward selection (p<0.2)

Conclusion: The present score based on preoperative factors predicts the risk of postoperative recurrence. Patients with preoperative higher risk scores or RSi2 at recurrence would require early and close monitoring due to significant transmural lesion progression.

DIAGNOSTIC ACCURACY OF THE FECAL IMMUNOCHEMICAL TEST FOR ASSESSING ENDOSCOPIC ACTIVITY IN INFLAMMATORY BOWEL DISEASE

V. G. Pintor[1], M. Chaparro[1], J. P. Gisbert[1]

[1]Hospital Universitario de La Princesa, Instituto de Investigación Sanitaria Princesa (IIS-Princesa), Universidad Autónoma de Madrid (UAM), Gastroenterología, y Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain

Contact E-Mail Address: vigonpi@gmail.com

Introduction: Fecal immunochemical test (FIT), widely used in colorectal cancer screening, has emerged as a potential biomarker of endoscopic activity in inflammatory bowel disease (IBD). Compared to fecal calprotectin, FIT offers greater standardization, automation and availability, with simpler handling and potentially better adherence. Its implementation could streamline non-invasive monitoring, but its diagnostic accuracy in IBD remains unclear. We therefore conducted a systematic review and meta-analysis to evaluate its performance.

Aims & Methods: Selection of studies: assessing the accuracy of FIT to estimate endoscopic activity in IBD patients. Search strategy: electronic bibliographical searches. Data synthesis: meta-analyses of the FIT were performed combining the sensitivity (Se), specificity (Sp), likelihood ratios (LRs), and area under de curve (AUC) values of summary receiver operating characteristic (ROC) curves of the individual studies. Heterogeneity among the studies was assessed by the I-squared (I^2) statistic.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Eighteen studies (Table 1) met the inclusion criteria: 12 focused on ulcerative colitis (UC), 4 on both UC and Crohn's disease (CD), and 2 on CD alone. Twelve studies employed the standard cut-off for FIT provided by the manufacturer or used the same cut-off as for colorectal cancer screening (usually considered the common threshold), while 6 studies estimated their optimal cut-off values. When we considered all studies (including 1,812 patients and 2,137 assessments), the accuracy of FIT for the diagnosis of endoscopic activity was (pooled values): Se: 0.66, Sp: 0.83, LR+: 4.96, and LR-: 0.38, respectively, with an AUC of 0.86.
Significant heterogeneity was found among the Se (I^2 89%) and Sp (I^2 86%) of different studies. Most of the available studies were based exclusively on patients with UC (including 1,554 patients and 1,904 assessments), so we performed a subgroup analysis including only this type of IBD, finding a pooled Se, Sp, LR+ and LR- of 0.69, 0.82, 5.35 and 0.31 respectively, with an AUC of 0.88. On the other hand, in patients with CD (327 patients, 302 assessments), the corresponding values were 0.55, 0.85, 3.2 and 0.58, with an AUC of 0.73. ROC curve analysis showed that FIT had a higher diagnostic performance in UC patients.

Takahara	2024	Standard (>100 ng/mL)	MES >0	UC 63	63	93%	100%	52	0	4	7

TP: True positives; FP: False positives; FN: False negatives; TN: True negatives; UC: Ulcerative colitis; CD: Crohn's disease; MES: Mayo endoscopic score; SES-CD: Simple endoscopic score for Crohn's disease; UCEIS: Ulcerative colitis endoscopic index of severity.

Table 1. Studies evaluating the accuracy of fecal immunochemical test (FIT) for estimating endoscopic activity in inflammatory bowel disease.

Conclusion: FIT demonstrates moderate-to-high diagnostic accuracy for detecting endoscopic activity in IBD, particularly in UC. Therefore, FIT may represent a promising non-invasive tool for assessing IBD disease activity. However, significant heterogeneity among studies underscores the need for further research to optimize cut-off values and define the role of FIT in routine IBD monitoring.

Contact E-Mail Address: e.visser6@franciscus.nl

Introduction: In the southwest Netherlands, hospitals collaborate to provide high quality, uniform care for inflammatory bowel disease (IBD). To achieve this, a care pathway (CP) was implemented for treating IBD with biologics and small molecules (1). The CP consists of protocols addressing different stages in IBD treatment, such as initiation and switching of therapy, frequency and type of follow-up.
This study assessed the adherence to the CP and identified barriers and facilitators to its implementation.
Aims & Methods: A mixed-methods study was conducted. Quantitative data was used to evaluate the adherence to different protocols of the CP and was collected retrospectively from electronic health records (EHRs) from December 2020 until March 2023. Surveys and semi-structured interviews were used to identify barriers and facilitators, using the Extended Normalisation Theory. Surveys were sent to all healthcare providers and interviews were conducted with gastroenterologists, IBD-nurses, healthcare assistants, and IT-personnel.
Results: A total of 299 patients were included. Adherence to the CP regarding the documentation of travel plans and vaccination status improved after implementing the CP (15% pre-implementation vs. 33% post-implementation), as well as written communication with general practitioners (31% vs. 83%) and body weight registration (12% vs. 50%). Among patients switching medication, 25% had a repeated screening for HIV, tuberculosis, and hepatitis B and C documented if prior tests were over a year old. Post-implementation, scheduling outpatient visits were more closely aligned with CP recommendations across CP protocols (57% vs. 100%), as did blood test ordering (10% vs. 44%). Disease activity scoring with validated questionnaires remained low (7% vs. 21%). Adherence to registering medication adherence, current smoking status, and side effects during annual outpatient visits remained low (18% vs. 40%).
Of 85 surveys, 42 were completed, and 11 interviews were conducted. Facilitators were improving collaboration between healthcare providers and the potential to standardise care. Barriers included the complexity of the use in EHRs, difficulty for healthcare providers to change their current routine, and the heterogeneity of IBD.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: A CP for the treatment of IBD with biologics and small molecules has been implemented to improve IBD care, however, adherence appears to be challenging, partially contributed to the difficulty healthcare providers experience in changing their behaviour. The gradual improvement indicates that increased familiarity with the CP may enhance adoption. Discrepancies between performed and documented tasks in EHRs may also contribute to lower adherence rates, which could be improved by audit and feedback sessions.

Contact E-Mail Address: e.visser6@franciscus.nl

Introduction: Eight hospitals in the southwest of the Netherlands collaborate to improve inflammatory bowel disease (IBD) care. To achieve this, a care pathway (CP) was developed for treating IBD with biologics and small molecules. This CP addresses initiation and switching of therapy, as well as diagnostic testing and treatment follow-up (1).

Aims & Methods: This study aimed to estimate the causal effect of the CP on costs and quality of life, and to evaluate whether the CP is cost-effective.

A cost-effectiveness analysis was conducted from a societal perspective. The CP was implemented in six hospitals, with two control hospitals. Costs were assessed during a baseline period (December 2020–December 2021) and an intervention period (March 2022–March 2023). Quality-adjusted life years (QALYs) were derived from the EQ-5D-5L. A difference-in-differences (DiD) analysis was conducted and the incremental cost-effectiveness ratio (ICER) was calculated.

Results: A total of 1,173 patients were included (intervention n=841, control n=332). Baseline costs per patient were €23,259.96 in intervention hospitals, and €22,837.93 in control hospitals. During the intervention period costs decreased to €20,959.76 in intervention hospitals. This reduction was not observed in control hospitals (€22,191.21). The DiD-analysis showed cost savings of €-1,653.48. QALYs did not change. The ICER was located in the southeast quadrant of the cost-effectiveness plane, with a high probability of achieving a net monetary benefit exceeding €0 compared to standard care.

Conclusion: The implementation of a CP for the treatment of IBD with biologics and small molecules is cost-effective, it reduces healthcare costs while maintaining quality of life. Therefore, adoption of care pathways in care for complex diseases should be considered.

Introduction: Metabolomics in ulcerative colitis (UC) research offers promising insights into disease mechanisms and activity monitoring. Nuclear magnetic resonance (NMR) spectroscopy enables serum metabolite profiling which can include inflammatory markers such as glycoprotein A (GlycA) and B (GlycB). The supramolecular phospholipid composite (SPC) is derived from phospholipids found on lipoproteins. The Glyc/SPC ratio shows NMR signals of glycoproteins and phospholipids. Lipoprotein levels are influenced by systemic inflammation and altered lipid profiles are

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

seen in inflammatory bowel disease (IBD) patients[1]. While GlycA is linked to IBD activity[2], Glyc/SPC is yet unexplored in IBD. Methionine, an amino acid associated with inflammation, has not been extensively studied in IBD. In this study, we hypothesize that the serological metabolite profile differentiates between UC patients with active disease and those in remission.

Aims & Methods: This study aimed to determine whether UC patients exhibit distinct serological metabolite profiles depending on disease activity. Serum samples were collected from healthy subjects (HS), UC patients in remission (UCR), and UC patients with active disease (UCA), and analyzed using NMR spectroscopy.

A targeted metabolomic panel was applied to quantify 157 metabolites. Statistical significance was assessed using two-sample *t*-tests followed by False Discovery Rate correction using the Benjamini-Hochberg method, with $q < 0.05$ considered significant. Orthogonal partial least squares discriminant analysis (OPLS-DA) was conducted to evaluate metabolic differences between groups.

Model validations were performed using Cross-Validated ANOVA, with $p < 0.05$ considered significant, as well as permutation testing (n = 100) to assess robustness. Variable Importance in Projection (VIP) analysis was conducted to identify the metabolites that contributed most to the model.

Results: Serum samples from 50 HS (41 females), 54 UCR (26 females), and 15 UCA (6 females) were analyzed. A total of 67 metabolites differed in HS vs. UCA, 39 in UCR vs. UCA, and 17 in HS vs. UCR. The OPLS-DA models discriminated between UCR and UCA and between UCA and HS, but not UCR and HS. Further analysis focused on the UCR vs. UCA comparison. The OPLS-DA model showed separation between UCR and UCA (R2Y = 0.838, Q2 = 0.599, p < 0.0001), without indications of overfitting from permutation testing. The top three discriminant metabolites, based on VIP scores, were methionine (q = 0.0004), Glyc/SPC (q = 0.001), and V4CH (VLDL subclass, q = 0.007) (Table 1).

Group	Methionine (mM)	Glyc/SPC (p.d.u.)	V4CH (mg/dL)
HS	0.080 ±0.019	0.49 ± 0.12	3.13 ±2.00
UCR	0.077 ±0.016	0.58 ± 0.12	3.57 ±1.87
UCA	0.046 ± 0.029	0.80 ± 0.27	6.40 ± 2.31

Table 1. Serological metabolite levels of the top three discriminant metabolites. Values are presented as mean ± standard deviation. p.d.u = procedure-defined units.

Conclusion: Shifts in Glyc/SPC, lipoprotein, and amino acid levels were observed in UCA, suggesting metabolomic differences compared to UCR. This indicates that NMR metabolomics holds promise as a tool for disease activity monitoring in UC. However, further analysis, including validation in a separate cohort and comparison with established biomarkers, is needed to evaluate accuracy and diagnostic value.

Contact E-Mail Address: gottfried.novacek@meduniwien.ac.at

Introduction: The Health Outcome Observatory (H2O) project aims to standardize and facilitate the collection of patient-reported outcomes (PROs) as well as clinical outcomes by a Core Outcome Set (COS) defined for patients with inflammatory bowel disease (IBD).[1]

The present study describes preliminary data on the PROMIS®-10 questionnaire (Patient-Reported Outcomes Measurement Information System) – a generic health-related quality of life measure - in IBD patients.

Aims & Methods: This is a real-world interim analysis of IBD patients included in the H2O project at the Medical University of Vienna, Austria. The variables analyzed were part of the COS. PROMIS®-10 was evaluated, including Global Physical Health and Global Mental Health scores. Higher scores indicate better health and a score between 40 and 59 was defined as normal range.

A descriptive analysis and a correlation analysis, including sex, age, age at diagnosis, disease duration, IBD_Disk_managing_defecation_day and night, IBD_urge, PRO-2 for CD (number of liquid or very soft stools and abdominal pain score) and UC (rectal bleeding score and stool frequency score) were performed.

Results: 691 patients (46% females) were included in the analysis. 460 were diagnosed with Crohn's disease (CD), 220 with ulcerative colitis (UC), and 11 with IBD unclassified (IBDU). The PROMIS scores were similar in CD and UC. The mean PROMIS Global Physical Health score was 41.5 (SD 5.3) in CD and 41.9 (SD 4.5) in UC, respectively. The mean PROMIS Global Mental score was 46.9 (SD 8.8) in CD and 48.4 (SD 8.3) in UC. 223 patients had a PROMIS Global Physical Health score < 40, and no patient had a score > 59. 89 patients had a PROMIS Global Mental Health score < 40, and 32 patients had a score > 59. The PROMIS Global Physical Health score correlated with the Mental score (r=0.23; p<0.001), sex (male r=0.13; p=0.003), PRO-2 for CD number of liquid or very soft stools (r=-0.11; p=0.01) and abdominal pain score (r=0.14; p=0.002). The PROMIS Global Mental Health score correlated with sex (male r=0.13; p=0.004), the IBD_Disk_managing_defecation_day (r=-0.32; p<001) and night (r=-0.31; p<0.001), IBD_urge (r=-0.33; p<0.001), PRO-2 for CD number of liquid or very soft stools (r=-0.34; p<0.001) and abdominal pain score (r=-0.49; p<0.001), and PRO-2 for UC rectal bleeding score (r=-0.13; p=0.004) and stool frequency score (r=-0.35; p<0.001).

Conclusion: About one third of the patients had a PROMIS Global Physical Health score below the normal range. The majority of the IBD patients had a PROMIS Global Mental Health score within the normal range, which correlated with the severity of gastrointestinal symptoms, including urgency and incontinence.

Introduction: Inflammatory bowel disease (IBD) is associated with a 2-3-fold risk of venous thromboembolic complications. This risk is further increased by disease flare. However, there is a lack of studies systematically searching for these events and identifying other risk factors in IBD patients.

Aims & Methods: The aim of a prospective cohort study was to evaluate the occurrence of perfusion disorders in the pulmonary circulation in patients with acute severe ulcerative colitis (ASUC). A cohort of patients from a single tertiary IBD centre hospitalized with an episode of ASUC was recruited from January 2023 to April 2025. Ventilation-perfusion (V/P) SPECT was performed in all patients after hospital discharge. In case of detection of primary perfusion defect, anticoagulation treatment was initiated in patients not yet anticoagulated.

Results: Fifty four patients with relapse of UC requiring hospital stay due to disease activity in the past 24 months in whom V/P SPECT was performed were identified. None of the patients had clinical symptoms of pulmonary embolism. Mean age of the cohort was 37.0±13.4 years (min-max 19-76 years). Of them 53.7% (29/54) were males. Mean disease duration at the time of V/P SPECT was 7.1±7.1 years (1-35 years). Disease extension included 25.9% patients with left-sided colitis and 74.1% with pancolitis. Active smoking was present in 13.0% of patients and history of using JAK inhibitors was positive in 63.0% of patients. Mean time elapsed between last hospital stay due to UC activity and V/P SPECT was 239.6±216.4 days (12-745). Presence of a perfusion defect was found in 16.7% (9/54) of patients. There were no significant differences in baseline patient and disease characteristics including smoking and JAKi history between positive and negative group. None of the positive patients had previous history of known thrombotic event.

Conclusion: We have identified 16.7% of patients with severe UC relapse in the past 2 years to have signs of perfusion defect on V/P SPECT warranting further research to identify potential risk factors and probability of developing perfusion disorders of pulmonary circulation in patients with ASUC.

MANAGING PREGNANCY IN INFLAMMATORY BOWEL DISEASE- DO WE MEET ECCO STANDARDS?

R. Kemp[1], K. Kemp[2], F. Leslie[2]

[1]University of Manchester, Medical School, Manchester, United Kingdom, [2]Manchester University NHS Foundation Trust, Gastroenterology, Manchester, United Kingdom

Contact E-Mail Address: robert.kemp@student.manchester.ac.uk

Introduction: Inflammatory bowel disease (IBD) has a high incidence in young people directly impacting their reproductive years. In 2023, ECCO produced guidelines on sexuality, fertility, pregnancy & lactation to support healthcare professionals in managing patients considering, and throughout pregnancy. This audit undertaken as 3rd year medical student project.

Aims & Methods: The study aimed to evaluate the extent to which ECCO standards on are being met at a tertiary hospital and look at disease activity and adherence to advice.The IBD service was benchmarked against the ECCO guidelines. The women received antenatal care at our linked women's Hospital. Patients are offered monthly appointments with the IBD team during pregnancy. Data was collected from electronic patient records (EPIC©) of patients under the care of the IBD team. The data were analysed in SPSS using statistical tests, including Mann-Whitney U test.

Results: The study included patients who became pregnant or gave birth between April 1, 2023 - March 31, 2024. The results included 56 women, of whom 28 had already given birth. Thirty women (53.6%) had Crohn's Disease and 26 (46.4%) had ulcerative colitis. Ages ranged from 20 to 42 years. Forty-eight women (85%) were receiving active treatment, with 23 (41%) on advanced therapies and of these of the 23 people on biologics, 13 (56.6%) continued taking the biologic throughout pregnancy, 6 (26.1%) stopped taking the biologic before the third trimester. 71.4% of women had a documented & individualized care plan. Documentation was noted to be poor around advice re lactation (12.5%).

IBD activity improved between pre-conception and during pregnancy, as indicated by faecal calprotectin levels decreasing on average from 392.7 (SD 630) pre-conception to 104.2 (SD 142.7) during pregnancy. Women with active disease generally give birth earlier than those without active disease, and those with active disease were more likely to have a preterm birth with 25% of the active disease group giving birth prematurely, i.e. before 37 weeks, although this did not meet statistical significance. 50% had a spontaneous vaginal delivery, while 32.2% had a caesarean section. There was no significant difference in the baby's birth weight between mothers on biologic treatment and those not on biologic treatment.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The audit identified areas where the ECCO standards were not fully met, such as documenting advice around medications and lactation. The IBD team has developed an action plan to address the findings of the audit. We also demonstrated reduced disease activity during pregnancy in this cohort of women and in keeping with previous studies saw that patients with active IBD were more likely to deliver before 37 weeks.

Contact E-Mail Address: AGNESEFAVALE@ICLOUD.COM

Introduction: Inflammatory Bowel Disease (IBD) patients carry a high risk of malnutrition, independently of disease activity. Screening for malnutrition in IBD is currently recommended since malnutrition, as well as low Fat-Free Mass Index (FFMI), have been associated to poor disease outcomes. However, due to a non-universal definition of malnutrition, most Nutritional Screening Tools (NSTs) have been validated compared to different reference methods and do not consider patients' body composition. Moreover, the ability of most NSTs to predict malnutrition over time has not been explored.

Aims & Methods: The aim of this study was to compare the efficacy of different NSTs to predict malnutrition, as defined by the ESPEN 2015 and GLIM criteria, and a low FFMI in a cohort of inactive/mildly active IBD patients.

This is a prospective, single center, cohort study enrolling Crohn's disease (CD) and ulcerative colitis (UC) patients in clinical remission or with mildly active disease as defined by Harvey-Bradshaw Index and partial Mayo Score, respectively. MUST, MIRT, MNA, NRS-2002 and SaskIBD-NR questionnaires and Bioelectrical Impedance Analysis (BIA) were performed at baseline and after six months follow-up. A low FFMI was defined as <18 kg/m2 in males and <15 kg/m2 in females. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and the accuracy of the different NSTs for the detection of malnutrition and low FFMI at six months were calculated.

Results: Sixty-six (CD: 32; UC: 34) IBD patients were enrolled. Median age was 55.5 years (IQR 34-62.8), median disease duration was 10 years (IQR 6-17). At baseline, all CD and 30/34 (88%) UC patients were in clinical remission; median C-reactive protein was 0.8 mg/L (IQR 0-3.8), median fecal calprotectin was 55.2 mcg/g (IQR 12.9-326). Of the entire cohort, 6/66 (9%) and 17/66 (26%) patients were malnourished according to GLIM and ESPEN criteria, respectively, [(GLIM CD:3, UC: 3)(ESPEN: CD: 3; UC:14)] and 5/66 (8%) had low FFMI (CD:1; UC: 4). At 6 months follow-up, all CD and 31/34 (91%) UC patients were in clinical remission. Ten out of 66 (15%) and 32/66 (48%) patients were malnourished according to GLIM and ESPEN criteria, respectively [(GLIM CD:5, UC: 5)(ESPEN: CD: 15; UC:17)], 11/66 (17%) patients had low FFMI (CD: 3; UC: 8). Baseline MIRT showed the highest sensitivity for the diagnosis of both ESPEN and GLIM-defined malnutrition at 6 months (ESPEN: 40.5%; GLIM: 50%). For ESPEN, MIRT and NRS2002 were the most accurate NSTs (MIRT: 50%, NRS2002: 51.5%), while SaskIBD (75.8%) showed the highest accuracy in detecting GLIM-malnourished patients at 6 months follow up. Among all NSTs, baseline MIRT, MNA and NRS2002 had the highest sensitivity for the detection of low FFMI at six months (MIRT, MNA, NRS2002: 45.5%), while SaskIBD_NR was the most accurate (80.3%).

Conclusion: MIRT might be the NSTs of choice to predict defined malnutrition and low Fat-Free Mass Index at 6 months follow-up in a cohort of inactive/mildly active IBD patients.

REAL WORLD EFFICACY OF STEP-UP APPROACH IN ACHIEVING STRIDE-II RECOMMENDED TREAT-TO-TARGET GOALS IN CASES OF INFLAMMATORY BOWEL DISEASE – EXPERIENCE FROM INDIA

V. Wagle[1], B. Tantry[1], S. Gopal[1], S. Shenoy[1], A. Shetty[1]
[1]Kasturba Medical College Hospital, Manipal Academy of Higher Education (MAHE), Manipal, Medical Gastroenterology, Mangalore, India

Introduction: Inflammatory Bowel Disease (IBD), including Ulcerative Colitis (UC) and Crohn's Disease (CD), is a chronic gastrointestinal disorder marked by progressive inflammation. Recent therapies focus on a treat-to-target (T2T) strategy, as per STRIDE-II guidelines, aiming for defined short-term, intermediate-term, and long-term goals. While Western countries favor a top-down approach, emerging nations still largely follow the step-up method. Our study assesses the real-world effectiveness of the step-up strategy in meeting these targets at a tertiary care hospital in South India.

Aims & Methods: To study the short-term, intermediate-term and long-term treat-to-target goals (as per STRIDE-II recommendations) met, based on the current medical therapy in cases of Ulcerative Colitis and Crohn's disease in a real world setting.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

This study included 122 IBD patients (61 UC, 61 CD) treated with step-up approach of medical therapy over 18 months. Targets assessed included clinical response (short-term) at 4-8 weeks, biomarker normalization and clinical remission (intermediate-term) at 3 months, endoscopic remission and improvement in quality of life (long-term) at 6-9 months. Data on patient demographics, disease characteristics, therapeutic regimens, and adverse events were analysed using statistical methods.

Results: Short-term clinical response was achieved in 91.8% of UC patients and 86.9% of CD patients. Clinical remission was seen in 80.3% of UC and 70.5% of CD cases at 3 months. Biomarker normalisation was seen in 78.68% of UC and 68.85% of CD patients. Mucosal healing was observed in 31.2% of UC and 36.1% of CD patients at 6-9 months. Quality of life goals were met by 66% of UC and 67% of CD patients. Deep remission (clinical along with endoscopic remission) was achieved in 29.5% of UC and 32.8% of CD cases. Biologics and non-biologics showed no significant difference in achieving therapy goals. Baseline severity impacted outcomes, with severe UC patients struggling more to meet both short-term and long-term targets compared to those with milder forms ($p<0.05$).

Similarly, mild and moderate CD patients achieved clinical remission better than severe CD patients ($p<0.05$). Multivariate analysis with logistical regression showed that in Crohn's disease, baseline CDAI score predicted the likelihood of clinical remission ($p=0.011$). Baseline SES-CD score predicted the likelihood of achieving mucosal healing ($p=0.045$). Colonic CD was more likely to achieve mucosal healing than other sub-types ($p=0.02$). Sub-group analysis showed that elderly and pediatric populations, did not show statistically significant variations in treatment success.

Conclusion: Findings from our study suggest that the step-up approach can achieve outcomes that are broadly comparable to those reported in top-down studies from Western settings. While the top-down strategy is traditionally associated with early disease control, our results highlight that a carefully monitored and timely step-up approach can also be effective, particularly in real-world, resource-limited environments. These insights support the need for individualised treatment strategies that consider both disease severity and contextual healthcare factors.

Introduction: Active ulcerative colitis (UC) is typically assessed through clinical manifestations, laboratory examinations, and colonoscopy, which also determine the disease's severity.

An easy-to-use and patient-friendly technique for early clinical suspicion confirmation is intestinal ultrasonography (IUS). Ancillary technologies such as elastographic techniques have recently become available and can be used in conjunction with traditional IUS.

Aims & Methods: The study aim was to assess the accuracy and reproducibility of intestinal 2D-shear Wave Elastography (2D-SWE) as a predictor of disease's activity and mucosal healing (MH). 2D-SWE was performed in 34 consecutive patients with active disease confirmed by colonoscopy. The 2D-SWE measurements (n. 10 with IQR/Med < 30%) was taken in the sigmoid colon by two independent operators at basal and 3 months after the starting of a new treatment regimen. The correlation between 2D-SWE and the Mayo endoscopic score (MES) was investigated along with clinical and conventional ultrasound parameters such as Bowel Wall Thickness (BWT) and Limberg score (LS).

Results: 2D-SWE values (kPa) positively correlated with MES with a statistically significant difference between mucosal healing (MH) and active disease groups ($p = 0.003$). The AUROC (95% CI) for assessing mucosal healing by 2D-SWE was 0.84 (95% CI: 0.70-0.97). Using a cut off value of 21.5 kPa, sensibility and the specificity for mucosal healing were 0.62 and 0.99, respectively. The median 2D-SWE values obtained by the two independent operators were 19.7 kPa (IQR 16.2-26.8) and 17.7 kPa (IQR 14.4-23.7) respectively. 2D-SWE was also positively correlated with rectal bleeding, LS and BWT (r 0.38 $p=0.027$; r 0.43 $p=0.014$; r 0.33 $p=0.057$) but not with fecal calprotectin and C-reactive protein.

No significant correlation was found between 2D-SWE values and clinical remission (Partial Mayo Score ≤ 2) after 3 months of a new treatment regimen ($p = 0.491$).

Conclusion: This study demonstrated the feasibility of 2D-SWE technique with an excellent inter-observer repeatability. The technique showed good accuracy in predicting mucosal healing, with increasing values correlating with disease severity. In the future, 2D-SWE could help reduce the number of colonoscopies and improve clinical decision making.

Introduction: Eight hospitals in the southwest of the Netherlands collaborate to provide high quality, uniform care for inflammatory bowel disease (IBD). To achieve this, a care pathway (CP) was implemented for treating IBD with biologics and small molecules (1).

The CP is a decision-support tool that provides guidelines for medication prescribing, procedures, treatment adjustments, and recommendations for follow-up.

Aims & Methods: This study aimed to evaluate the effect of a CP on patient outcomes and healthcare utilization.

A longitudinal multicentre non-randomised cohort study with a baseline observation period (December 2020 – December 2021) and a follow-up period (March 2022 – March 2023) was conducted, in which adult patients with IBD treated with biologics or small molecules were included. Outcomes were collected according to the International Consortium for Health Outcomes Measurement (ICHOM) standard set from electronic health records or through validated questionnaires. Missing data were handled using single imputation nested within a bootstrap procedure. Effect of the CP on these outcomes were analysed with case-mix adjusted (generalized) linear mixed models.

Results: A total of 1,173 patients participated in the study, with the majority being female (55%) and a median age of 45 years (IQR 33-58). Most patients had Crohn's disease (64%). The CP was associated with a 0.22 increase on the ibd-control-8 score (β=0.22, p=0.28), and an increase on the probability of achieving endoscopic/radiologic (β=0.14, p=0.29), biochemical (β=0.18, p=0.22) and patient-reported remission (β=0.19, p=0.21). Probability of clinician-reported remission decreased slightly (β=-0.09, p=0.59). Emergency room visits (β=-0.36, p=0.13), hospital admissions (β=-0.41, p=0.10), and length of stay (β=-0.09, p=0.56) reduced, although these associations were not significant. The CP had no effect on quality of life (β=0.00, p=0.83), anaemia probability (β=-0.01, p=0.95) or on nutritional status (β=-0.01, p=0.34).

Conclusion: A CP for the management of IBD with biologicals and small molecules has clinically significant potential to reduce healthcare utilization, while improving patient-reported disease control, and disease remission. These results emphasize that clinical care pathways can improve care and reduce healthcare utilisation for complex diseases. However, the adherence to the CP and whether these results lead to a reduction in healthcare costs should be further investigated.

FECAL CALPROTECTIN AND FECAL ALPHA-1 ANTITRYPSIN – IS THERE A CORRELATION BETWEEN THESE TWO INFLAMMATORY MARKERS?

T.T. Perets[1,2], Y. Huta[1], O. Ashorov[1], R. Gingold-Belfer[3], R. Dickman[3]

[1]Rabin Medical Center - Beilinson Hospital, Gastroenterology Laboratory, Petah Tikva, Israel, [2]Holon Institute of Technology, Department of Digital Medical Technologies, Holon, Israel, [3]Rabin Medical Center - Beilinson Hospital, Division of Gastroenterology, Petah Tikva, Israel

Contact E-Mail Address: kaiser1974@gmail.com

Introduction: The biomarker fecal calprotectin (FC) is an efficacious tool for evaluating the level of disease activity in Crohn's and Ulcerative colitis, as well as for discriminating between inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS). Fecal Alpha-1 Antitrypsin (A1AT) is an excellent marker for intestinal protein loss and for an increased mucosal permeability.

Aims & Methods: The aim of this investigation was to determine the relationship between these two inflammatory fecal markers.

The study was performed retrospectively. We've collected test results for both markers between 2018 and 2022 from 459 patients who performed both tests (67.4% females; mean age 35.1±22.7). Linear correlation evaluation between FC and A1At was performed using the Pearson Correlation Coefficient (PCC).

Results: Out of the 459 patients, 274 were diagnosed with IBD, 61 with IBS and the rest with other, non-GI disorders. Out of these, 37.7% were positive for both markers, 45.3% were negative for both markers, 7.6% were positive for A1AT and not FC and 9.4% were positive for FC and not A1AT. Linear correlation between the two markers using six categories for data scoring, was found to be significant by PCC test (R=0.83, P values < 0.001) and sensitivity and sensitivity, specificity and accuracy were 80.1%, 85.6% and 83.0% respectively. Out of the 274 patients in the IBD group, 39.2% were positive for both markers, 45.8% were negative for both markers, 5.4% were positive for A1AT and not FC and 7.6% were positive for FC and not A1AT. Linear correlation between the two markers was found to be significant by PCC test (R=0.87, P values < 0.0001) and sensitivity, specificity and accuracy were 83.7%, 89.8% and 86.9% respectively.

Conclusion: Our study demonstrates that FC had a significant relationship with A1AT in patients with IBD and IBS. Furthermore, A1AT might be used as a surrogate marker for FC in the diagnosis of IBD, IBS-IBD discrimination and disease severity and treatment follow up. In addition to that, both markers used together may be used as a new clinical score for the assessment of IBD and IBS severity.

Disclosure: Nothing to disclose.

EVALUATING SARCOPENIA IN ACUTE HOSPITALIZED IBD PATIENTS: A PROSPECTIVE OBSERVATIONAL STUDY

F. Adel Elshahat Ibrahim[1], A. Penas Castro[2], S. Sebastian[1]
[1]Hull University Teaching Hospitals NHS Trust, IBD Unit, Hull, United Kingdom, [2]Hull University Teaching Hospitals NHS Trust, Gastrointestinal Dietitics, Hull, United Kingdom

Contact E-Mail Address: fadwa_alex@yahoo.com

Introduction: Sarcopenia, defined as the loss of skeletal muscle mass (SMM) with a decrease in functional strength, has been increasingly linked to adverse disease outcomes in chronic conditions such as malignancy and hepatic disease. However, the prevalence of sarcopenia and its role in influencing outcomes in inflammatory bowel disease (IBD) remains understudied particularly in hospitalized patients with acute flares. In our study we intended to assess for sarcopenia prevalence in IBD inpatients using functional measures (Hand grip Strength) and CT evaluation of skeletal muscle index.

Aims & Methods: IBD patients were prospectively assessed during their admission with IBD flares. Sarcopenia was assessed via Hand Grip Strength using Jamar digital dynamometer. Skeletal muscle index (SMI) was assessed in patients who had CT scans using Mirada software. Other anthropometric measurements were also collected including BMI, calf circumference and waist circumference. Routine clinical scores and blood tests were monitored. Outcomes were evaluated including need for biologic treatment and risk of IBD-related surgery. Statistics was done via R V (4.5.0).

Results: 49 IBD patients were included. 21/49(43%) were CD, 27/49(55%) and one patient had IBD-U. The median age was 37(27-55). Females were 24/49(49%). The median BMI was 23.5 kg/m^2 (20.6-27.9) for whole cohort (Female = 22.7 kg/m^2 (20.3-28), Male = 24 kg/m^2(20.9-25.8)).The median calf circumference for females was 35 (30-39) and for males was 36(32.5-38.5). The median hand grip strength was 18.8 kg (16.5-23.9) for females and 35 kg (27.5-42) for males. 61.2% (30/49) of patients had low hand grip strength (below the 25th centile for their age according to PENG guidance). 22.4% (11/49) were sarcopenic according to the ESWOP2 criteria including 5 females and 6 males.. 35 patients had CT scans done including 19/24(79.1%) females and 16/25(64%) males. 65.7%(23/35 (13 females and 10 males)) had a low BMI-adjusted SMI at L3 on their CT. 71.4% (35/49) patients received biologics during admission. 6.1% (3/49) patients had surgery during admission including 2 subtotal colectomies and 1 diversion ileostomy.

Conclusion: Sarcopenia is prevalent in acutely hospitalized IBD patients, with 61% showing low hand grip strength and 66% exhibiting low SMI on CT. These findings highlight the need for routine screening for sarcopenia and early intervention. Further research is required to assess the impact of sarcopenia on clinical outcomes and explore targeted nutritional and rehabilitation strategies

Disclosure: Nothing to disclose.

PP0442

A DIFFERENT WAY TO DETECT THE ADDED VALUE OF PROACTIVE TDM IN DECISION MAKING FOR IBD PATIENTS TREATED WITH IV INFLIXIMAB

E. Athanasiadou[1], G. Axiaris[1], K. Soufleris[1], G. Georgiadou[1], D. Lazou[2], G. Lazaraki[1], I Diamanti[1], D. Tzilves[1]
[1]Theagenio Anticancer Hospital, Gastroenterology, Thessaloniki, Greece, [2]424 Military Hospital of Thessaloniki, Thessaloniki, Greece

Contact E-Mail Address: eftychiaath1@gmail.com

Introduction: The clinical benefit of Proactive Therapeutic Drug Monitoring (TDM) for infliximab and other monoclonal antibodies in Inflammatory Bowel Disease (IBD) remains a subject of ongoing debate. This study aimed to assess the real-world impact of broadly applying proactive TDM in unselected, consecutive IBD patients receiving infliximab infusions (both induction and maintenance). We compared TDM-guided management decisions to those made by an IBD expert blinded to TDM results but fully informed otherwise.

Aims & Methods: Infliximab trough levels and anti-drug antibodies were assessed using a validated ELISA assay; Through levels above 10 mg/ml were considered therapeutic. Infliximab levels and antibodies were measured in 55 IBD patients (34 with Crohn's Disease, 21 with Ulcerative Colitis) in 77 occasions: median age 42 years, median disease duration 8.5 years, mostly bio-exposed (58%) and mostly already on dose-escalated regimens (90%). Crohn's Disease patients had mostly complicated (stricturing or penetrating) disease (74%), half had prior surgery (44%), 50% were smokers and 20% had perianal disease. Management decisions based on TDM were compared to those of a blinded expert. Patients were followed prospectively for clinical, biochemical, and endoscopic response, with endoscopic data available in 39 cases.

Results: Therapeutic infliximab levels were observed in 80% of samples and anti-drug antibodies were detected in only one patient. Following TDM-based adjustment showed most patients had clinical (80%), biologic (89%) and endoscopic (61%) improvement compared to baseline assessment. Concordance in decision making was achieved in 58% of occasions. Therapy was discontinued in 11 patients (blinded expert concurred in 3/11,27%), the same dose was maintained in 53 patients (agreement occurred in 36/53, 68%), and dose modification in 13 patients (agreement was seen in 6/13, 46%).

Conclusion: Excellent results were achieved in this difficult to treat group of IBD patients treated with iv infliximab, possibly aided by proactive TDM. Without proactive TDM a small but significant percentage of them would risk undertreatment, either by not optimizing or by staying on redundant therapy. Discrepancies between TDM-based decisions and expert clinical judgment suggest that TDM provides distinct and actionable information that may prevent both under- and overtreatment. Future studies should estimate the impact of proactive TDM in different clinical scenarios, mostly in patients with severe disease.

Disclosure: Nothing to disclose.

PP0443

ALEXITHYMIA IN IBD: A NEW MANAGEMENT TOOL FOR MULTIDISCIPLINARY TARGETED CARE

S. Di Cola[1], A. Trombetta[1], M. Barletta[1], G. Scalese[2], C. Severi[1], M. Merli[1], E. Ribichini[1]
[1]Sapienza University of Rome, Translational and Precision Medicine, Rome, Italy, [2]Sapienza University of Rome, Translation and Precision Medicine, Rome, Italy

Contact E-Mail Address: simone.dicola@uniroma1.it

Introduction: Psychological comorbidities such as anxiety and depression are common in patients with inflammatory bowel disease (IBD). Alexithymia, defined by difficulty in identifying and describing emotions, may increase symptom perception and impact disease outcomes. Its relationship with psychological distress and clinical activity remains unclear, particularly across IBD phenotypes.

Aims & Methods: This study aimed to explore the correlations between alexithymia, clinical variables, and psychopathological symptoms in patients with inflammatory bowel disease (IBD), and to compare profiles between Crohn's disease (CD) and ulcerative colitis (UC). Patients aged 18–70 years with confirmed CD or UC were recruited from outpatient and day-hospital settings. Exclusion criteria included diagnosed psychiatric or neurological disorders, malignancy, or recent head trauma. Participants completed the Toronto Alexithymia Scale (TAS- 20), the Symptom Checklist-90-Revised (SCL-90-R) for psychological distress, and the Hospital Anxiety and Depression Scale (HADS), including both anxiety (HADS-A) and depression (HADS-D) subscales. A cut-off score of ≥51 on the TAS-20 was used to define the presence of alexithymia. Clinical and demographic data were collected, including disease activity indices, disease phenotype, endoscopic findings, extraintestinal manifestations, and current therapies. Descriptive statistics were reported as mean ± standard deviation. Analyses included t-tests, Pearson correlations, ANCOVA, and multivariate linear regression. $p<0.05$ considered significant.

Results: A total of 103 patients with IBD were included (CD = 45; UC = 58). The mean TAS-20 score was 45.0 ± 11.0 in CD and 42.7 ± 10.4 in UC, with no significant difference between groups. The overall prevalence of alexithymia (TAS-20 ≥ 51) was 24.3%, with comparable rates in CD (22.2%) and UC (25.9%, $p = 0.845$). In CD, TAS-20 scores were significantly correlated with endoscopic disease activity (CDEIS: $r = 0.35$, $p = 0.023$) and with the presence of fistulas or abscesses ($r = 0.38$, $p = 0.042$). No significant correlations were observed with CDAI, disease phenotype, or perianal disease alone. In UC, clinical disease activity independently predicted alexithymia (SCCAI: $\beta = 7.29$, $p = 0.023$). With regard to psychological symptoms, TAS-20 scores were significantly correlated in CD with HADS-D ($r = 0.58$, $p < 0.001$), HADS-A ($r = 0.34$, $p = 0.021$), SCL-90 GSI ($r = 0.37$, $p = 0.012$), and paranoid ideation ($r = 0.43$, $p = 0.003$). In UC, significant correlations were also observed with HADS-A ($r = 0.52$), HADS-D ($r = 0.39$), and SCL-90 GSI ($r = 0.45$), all with $p < 0.005$. In multivariate analysis, the SCL-90 GSI score independently predicted alexithymia in UC ($\beta = 11.78$, $p < 0.001$). The effect of diagnosis (CD vs UC) on TAS-20 scores was not significant ($p = 0.079$) after adjusting for anxiety and depression.

Conclusion: Alexithymia is a common trait in IBD, with comparable prevalence in CD and UC. In CD, it is associated with endoscopic disease severity and fistulizing complications, while in UC, with clinical activity. In both groups, psychological distress, especially depression, is a key correlate. These findings underscore the value of assessing emotional processing in patients with active or complicated IBD to support more targeted multidisciplinary care.

Introduction: Regulatory guidance recommends the endoscopy subscore as the index to assess the endoscopic component of the primary endpoint in ulcerative colitis (UC) trials[1]. Inter-reader variability in assessments may impact the reliability of trial results[2,3]. Currently, there is no metric in place to assess the certainty by which a reader is assigning an endoscopy subscore. Machine learning (ML) provides an opportunity to assess the endoscopy subscore and provide a measurement of its certainty in a standardized manner. Artificial Intelligence Assessment of Endoscopic Severity (AI-ES) accurately assesses the endoscopy subscore[4].

The objective of this study is to evaluate the calibration of AI-ES - how well its predicted probabilities reflect true likelihoods - to assess the reliability of its measurement of certainty in endoscopy subscore assessments in UC trials.

Aims & Methods: AI-ES is a deep learning algorithm that assesses the endoscopy subscore in UC endoscopic videos. AI-ES measures probability for the four ordinal endoscopy subscore classes. The endoscopy subscore with the highest probability is assigned as the final score by AI-ES. We assessed calibration on a holdout test set of 639 videos (~25%) from the Phase 3 induction trial for mirikizumab in UC (NCT03518086). Videos had a 2+1 centrally read endoscopy subscore, randomly selected from week 0 and 12 with a distribution of endoscopic severity similar to the overall study population. Calibration plots were generated across endoscopy subscore classes with probabilities grouped into septiles (~100 videos per group) for primary analysis and deciles for confirmation. Brier scores, ranging from 0 (perfect calibration) to 1 (worst calibration), were calculated, with values <0.25 considered informative[5].

Results: AI-ES demonstrated strong calibration, with Brier scores below <0.25 for each endoscopy subscore (0: 0.037, 1: 0.082, 2: 0.162, 3: 0.112). The Brier score for evaluation of endoscopic improvement (0,1 vs 2,3) also showed excellent calibration (0.066). Findings were consistent when assessing probabilities by deciles.

Assessment	Brier Score
Ordinal endoscopy subscore	
Endoscopy subscore 0	0.037
Endoscopy subscore 1	0.082
Endoscopy subscore 2	0.162
Endoscopy subscore 3	0.112
Endoscopic improvement	
Endoscopy subscore 0, 1 vs 2, 3	0.066

Conclusion: Whereas data on the certainty of human readers in endoscopy subscore assessments are elusive, AI-ES is calibrated across all endoscopy subscore classes, providing reliable data on score probabilities. This novel measurement of certainty by AI-ES added to the score assessment may enable novel AI-based multi-reader or consensus workflows in trials, potentially improving the reliability of UC endpoint assessments.

Introduction: The IBD-Disk is a widely used, self-administered visual analogue tool for measuring disability in patients with inflammatory bowel disease (IBD). However, it does not capture key aspects of daily life, particularly diet and nutrition, which are critical for IBD patients and may significantly influence disability.
Aims & Methods: This cross-sectional study explored the prevalence of moderate to severe disability in young adults with IBD and evaluated the use of a modified IBD-Disk (mIBD-Disk) to screen for eating disorders and food avoidance. Patients previously diagnosed with IBD during childhood and adolescence (<18 years old), and currently followed at two adult IBD academic centers, were consecutively enrolled.
All participants were assessed for disability and screened for eating disorders (ED) and avoidant restrictive food intake disorder (ARFID). Restrictive eating behaviours were evaluated using the Nine Item ARFID Screen (NIAS), which assesses three domains: picky eating, low appetite, and food-related fear with a score >23 suggesting probable ARFID. The Eating Attitudes Test (EAT-26) was used to screen for ED, with a score ≥20 indicating a positive result. Disability was measured using the IBD-Disk with a score >40 indicating moderate to severe disability) and the modified IBD-Disk (mIBD-Disk)[1], which consisted of the original 10 items plus an additional question on dietary habits, for a total of 11 items
Results: A total of 144 patients (50.7% with Crohn's disease) were included, with a median age of 24 years (range: 21–28), and 54.2% were female. One-third (34.7%) had clinically active disease, and the median BMI was 21.8 (range: 20.1–24.2). Moderate to severe disability, as assessed by the IBD-Disk, was observed in 38.9% (56/144) of the cohort, and the median mIBD-Disk score was 33 (IQR: 16–61).
ARFID risk was identified in 24 participants (16.7%), with food-related fear being the most frequent domain (13.2%). The median EAT-26 score was 5 (range: 3–12), with ED present in 17 patients (11.8%).
In both univariate and multivariate analyses, moderate to severe disability (OR: 4.03; 95% CI: 1.23–13.17; p = 0.02) and a score greater than 4 on question 11 of the mIBD-Disk related to dietary habits (OR: 3.49; 95% CI: 1.06–11.47; p = 0.04) were independently associated with ARFID risk. ROC curve analysis showed that the mIBD-Disk Q11 had an 82% diagnostic accuracy (95% CI: 0.73-0.91) for predicting ARFID.
Conclusion: Patients diagnosed with IBD in childhood and adolescence have an increased prevalence of moderate to severe disability. Integrating the mIBD-Disk into clinical practice could provide an effective tool to identify patients at risk for eating behaviours and food avoidance, supporting timely referrals for nutritional and psychological interventions

Introduction: Crohn's disease (CD) is increasing worldwide. Medical treatment and endoscopic techniques have reduced the need for surgery to some extent. Recommendation for postoperative surveillance is colonoscopy after six months. Since colonoscopy is invasive and resource-demanding, it is appealing to add or replace it with other methods to risk stratify the patients for recurrence. Examining the proximal or distal resection margin, mainly for plexitis, has been reported to predict a higher risk of recurrence. Eosinophils reside to an increased degree in the mucosa of CD patients, communicating with mast cells and nerve endings, contributing to increased inflammation, affected barrier function and fibrosis. Also, the staining methodology is readily available for eosinophilic plexitis.
Aims & Methods: The aim was to examine the correlation between eosinophils in the myenteric or submucosal plexa and endoscopic, clinical and surgical recurrence. From a larger cohort of CD patients who had an ileocecal resection (n=244), a smaller group who also had a follow-up

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with endoscopy was selected for a closer examination (n=20). Non-IBD-patients (colon cancer) served as controls (n=6). Fresh slides were stained with an enhanced hematoxylin-eosin staining for eosinophils combined with immunohistochemistry for S100 to visualise plexa. Eosinophilic plexitis was defined as eosinophils inside the plexus or in its direct proximity. The plexa were identified and defined as a cluster of 3 or more neurons and glia cells, submucosal or myenteric. The quantification of eosinophils was done in light microscope at 40x magnification. Statistics were done using Mann-Whitney U-test.

Results: In this pilot study, 20 CD patients were examined: 9 with endoscopic recurrence and 11 without. Six control patients were included. During follow-up, 10 patients had clinical recurrence and 4 patients had surgical recurrence. Five patients were lost to follow-up. Eosinophilic plexitis in either myenteric or submucosal plexa in the proximal resection margin was correlated with increased endoscopic recurrence, p=0.05. It was also a significant difference between patients with endoscopic recurrence compared with controls, p=0.004.

Conclusion: In this small pilot study, we found a correlation between eosinophilic plexitis in the proximal resection margin and endoscopic recurrence. Eosinophilic plexitis could be a prognostic tool for risk assessment of recurrence in the larger cohort.

Introduction: Short bowel syndrome (SBS) is a critical clinical condition that occurs when, following multiple intestinal resections, the residual small bowel in continuity is ≤200 cm. SBS is associated with intestinal failure (IF) when the intestinal absorptive function is impaired, requiring intravenous administration of nutritional or electrolyte supplements. Crohn's disease (CD) is one of the most frequent causes of SBS in adults

Aims & Methods: This study aimed to identify clinical predictive factors of SBS in CD patients (pts). We conducted a prospective study, enrolling consecutive outpatients with CD. Statistical univariate comparison for the primary outcome was assessed for continuous variables by the Mann-Whitney U and the Kruskal-Wallis ANOVA tests. Categorical variables were compared using the chi-square test. We also evaluated a multivariate logistic regression model to identify independent predictors of SBS.

Results: We enrolled 169 pts with CD (47.3% male, mean age 43.5 years [±14.1]). 45.5% of them were smokers; extraintestinal manifestations (EIMs) were present in 45.5% of pts, and 67.5% of pts had bowel resections (26.6% of them with more than one surgery). The median disease duration and median time between diagnosis and the first resection were 9 years (IQR 4-17) and 6.5 years (IQR 1-13), respectively. At baseline, 101 pts were on anti-TNF therapy, and considering the course of the disease, 20.1% of the pts were exposed to ≥3 biologics. 10% of pts had SBS and 5.3% IF.

In univariate analysis, comparing patients with and without SBS, the following variables were statistically different: disease duration (p=0.000), upper gastrointestinal disease location (p=0.001), ileocolonic location (p=0.008), stenosing behavior (p=0.040), perianal disease (p=0.000) and time from CD diagnosis to initiation of biological therapy (p=0.002). At multivariate analysis, disease duration (OR 1.2, 95% CI 1.12-1.42, p=0.000) and perianal disease (OR 4.3, 95% CI 0.99-19.27, p=0.050) resulted independently associated with the development of SBS.

Conversely, the time from diagnosis of CD to start biological therapy resulted in an inverse association with the onset of SBS (OR 0.8, 95% CI 0.74-0.97, p=0.016). This latter finding could be due to the late use of biological therapy in patients with less severe disease.

Conclusion: Our data identify clinical characteristics allowing gastroenterologists to predict the risk of developing SBS in a cohort of pts with CD. Further studies would be needed to confirm our results.

Contact E-Mail Address: melekbalamir.md@gmail.com

Introduction: Intestinal ultrasound (IUS) is a non-invasive modality for monitoring disease activity in inflammatory bowel disease (IBD). While widely used for long-term assessment, its utility in early response evaluation following biologic therapy initiation or modification remains underexplored.

Aims & Methods: This prospective study aimed to assess early ultrasonographic response at week 6 in ulcerative colitis (UC) and Crohn's disease (CD) patients undergoing induction, dose escalation, or switching of biologic therapy. A total of 24 patients (mean age: 40.1 ± 12.8 years; 54.2% female) were included. Fourteen patients (58.3%) were initiating biologic treatment, 4 (16.7%) underwent dose escalation, and 6 (25%) were switched to another biologic agent. Biologic therapies included infliximab (70.8%), adalimumab (16.7%), and others (12.5%). IUS examination was performed at baseline and at week 6.

The following parameters were assessed: bowel wall thickness (BWT), wall stratification, color doppler signal activity and mesenteric fat inflammation. IUS remission was defined as bowel wall thickness less than 3 mm and no color doppler signal. IUS improvement was defined as more than 25% decrease in bowel wall thickness without increase in color doppler signal. IUS activity assesment was performed at the same segment of the bowel at the 6th weeks.

Results: A total of 24 patients were included in the study, with a mean age of 40.1 ± 12.8 years; 13 (54.2%) were female. Seven patients (29.2%) had ulcerative colitis (UC), and 17 (70.8%) had Crohn's disease (CD). Fourteen patients (58.3%) had newly initiated biologic therapy, 4 (16.7%) underwent dose escalation, and 6 (25%) were switched to a different biologic agent. Anti-TNF agents were used in 21 patients (87.5%), including infliximab in 17 (70.8%) and adalimumab in 4 (16.7%). The remaining 3 patients (12.5%) were treated with other biologic agents. At baseline, the most active intestinal segment on IUS was the terminal ileum in CD patients (9 patients, 52.9%) and the sigmoid colon in UC patients (4 patients, 57.1%) (p = 0.021). At week 6, 11 patients (45.8%) showed ultrasonographic improvement, 9 patients (37.5%) had no change, and 4 patients (16.7%) showed worsening. The baseline mean bowel wall thickness (BWT) of the most active segment was 5.5 ± 1.3 mm, which decreased to 4.4 ± 1.7 mm at week 6. A reduction in BWT was observed in 18 patients (75%), while an increase was seen in 6 patients (25%) (p = 0.002). In multivariate regression analysis, higher baseline bowel wall thickness was identified as an independent predictor of ultrasonographic improvement at week 6 (OR: 3.137; 95% CI: 1.005–9.790; p = 0.04).

In patients who showed improvement, bowel wall thickness significantly decreased from baseline 6.2 ± 1.5 mm to 3.7 ± 1.6 mm at week 6 (to; p = 0.003), whereas in patients who worsened, an increase in wall thickness was observed (5.3 ± 1.0 mm to 6.7 ± 1.7 mm; p = 0.068). By disease group, 5 of the UC patients (71.4%) showed ultrasonographic improvement, 1 (14.3%) remained unchanged, and 1 (14.3%) worsened. Among CD patients, 6 (35.3%) showed improvement, 8 (47.1%) had no change, and 3 (17.6%) worsened. However, there was no statistically significant difference in response patterns between the UC and CD groups (p = 0.244).

Conclusion: Intestinal ultrasound at week 6 effectively detected early treatment response, with baseline bowel wall thickness emerging as a predictor of improvement. These results support its use in routine early monitoring of IBD patients on biologic therapy.

FECAL CALPROTECTIN IN SMALL BOWEL CROHN'S DISEASE: IS IT A RELIABLE TOOL?

M. Souto[1,2], A.I. Ferreira[1,2], J. Carlos Goncalves[1,2], C. Arieira[1,2], F. Dias de Castro[1,2], V. Macedo Silva[1,2], B. Rosa[1,2], J. Berkeley Cotter[1,2]

Contact E-Mail Address: mariana.souto9@gmail.com

Introduction: The correlation between fecal calprotectin (FC) levels and small bowel (SB) inflammation in patients with Crohn's Disease (CD) remains a subject of debate.

Aims & Methods: This study aims to investigate the relationship between FC levels and SB inflammatory activity in patients diagnosed with SB CD. We conducted a retrospective cohort study involving patients with SB CD who underwent small bowel capsule endoscopy (SBCE) and FC testing. Patients with colon inflammation were excluded.

Participants were categorized into four groups based on their SB inflammatory status: no inflammation (all three SB tertiles showed Lewis Score (LS) <135); proximal SB inflammation (first and/or second SB tertiles had LS ≥ 135, with no inflammation in the third SB tertile); distal SB inflammation (third SB tertile had LS ≥ 135, with no inflammation in the proximal SB); pan-SB inflammation (both proximal and distal SB with inflammation).

Results: A total of 87 patients were included in the study, with a median age of 35 years, 75.9% being female. The distribution of inflammation among the patients was as follows: no inflammation in 21.8%; proximal inflammation in 4.6%; distal inflammation in 33.3%; pan-SB inflammation in 40.4%.

FC median values exhibited an ascending trend along the SB axis: no inflammation 58 µg/g (33-180); proximal SB inflammation 65 µg/g (30-128); distal SB inflammation 122 µg/g (42-507); pan-SB inflammation 400 µg/g (205-852).

Statistically significant differences in FC levels were observed between pan-SB inflammation *vs.* isolated proximal inflammation (p = 0.014), and isolated distal inflammation (p = 0.012).

Additionally, FC showed a positive correlation with LS in the second (r = 0.464, p<0.001) and third tertiles (r = 0.435, p<0.001), but no correlation was noted in the first tertile.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

FC demonstrated good predictive capacity for identifying inflammation in the distal SB and pan-SB *vs.* no inflammation and proximal inflammation, with an area under the curve of 0.790 ($p < 0.001$) and an optimal cutoff value of 228 µg/g.

Conclusion: FC levels correlate positively with the presence of SB lesions in the second and third tertiles of the small bowel. However, it is not a reliable marker for detecting inflammation in the first tertile, highlighting the importance of conducting a SBCE in these patients.

PERCEPTION AND EXPERIENCE OF PREGNANCY IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Ncir[1], M. Ayari[1], S. Ben azouz[1], A. Chehaider[1], M.H. Douggui[1], T. Jomni[1]
[1]Internal Security Forces Hospital La Marsa, Gastroenterology, Tunis, Tunisia

Contact E-Mail Address: ayari.myriam@hotmail.fr

Introduction: Inflammatory bowel diseases (IBD) often affect women of childbearing age, complicating pregnancy management. These patients face medical and psychological challenges.

Aims & Methods: The aim of our study was to investigate the perception and the experience of pregnancy in IBD patients. A cross-sectional study was conducted between August and September 2024. A structured questionnaire was distributed through the national Tunisian association of IBD patients. It aimed to assess the impact of pregnancy in Tunisian women with IBD, focusing on complications, treatment adjustments and psychological effects.

Results: In total, 63 patients with IBD (Crohn Disease: 47.6 %, ulcerative colitis: 52.4%) responded to the questionnaire. Demographically, 1.6% were aged 18-25, 49.2% were 26-35, 31.7% were 36-45 and 17.5% were over 45 years old. In terms of educational level, 71.4% had completed university studies. Disease duration was over 10 years for 49.2% of the patients, 5-10 years for 27%, and less than 5 years for 23.8%. Pregnancy was planned in 68.3% of the cases.

A significant proportion of patients 76.2% were afraid that IBD may lead to a complicated pregnancy and 60.3% worried about pregnancy's impact on disease. To address these concerns, 74.6% sought information through internet and social media.

Complications occurred in 55.6% of patients, mainly disease flares (34.9%), nutritional deficiencies (15.9%) and prematurity (14.3%). Colonoscopies were required in 20.6% of the pregnant patients. Regarding treatment, 46% were on aminosalicylates, 17.5% on azathioprine, 7.9% on anti-TNF, 3.2% on corticosteroids and 25.4% received no treatment during pregnancy.

Therapeutic adjustment was made in 39.7% of the patients and a good compliance was reported in 54%. Concerns about treatment side effects affected 69.8% of the participants and 73% sought more information on treatment risks. Patients evaluated pregnancy's impact on quality of life as low in 47.6% of cases, moderate in 33.3% and high in 19%.

Disease perception improved in 30.2% of the participants, remained unchanged in 49.2% and worsened in 20.6%. In terms of mental health, 49.2% of the patients had anxiety, 11.1% had depression, and 28.6% reported general well-being.

Patients with history of surgical treatment were more likely to have planned pregnancy (p=0.013). Individual research over the disease was significantly associated with long disease course (p=0.011) and high educational level (p=0.014). Low adherence to treatment was significantly higher in patients with high concerns about side effects (p=0.013). Regarding expectations, 63.5% of the patients expressed a desire for better collaborative care between obstetricians and gastroenterologists and 52.4 % would like to have psychological support.

Conclusion: This study highlights the need for holistic care to improve the management and quality of life for pregnant women with IBD.

Disclosure: Nothing to disclose.

GAPS IN DISEASE-SPECIFIC KNOWLEDGE IN INFLAMMATORY BOWEL DISEASE PATIENTS AT A TERTIARY CARE CENTER

L. Stechel[1], T.G. Le Thi[2], L. Koletzko[1], R. Wimmer[1], B. Misselwitz[1], S. Koletzko[2], N.G. Rossen[3], H. Török[1]
[1]LMU University Hospital, Ludwig-Maximilians University, Munich, Internal Medicine II, Munich, Germany, [2]Dr. von Hauner Children's Hospital, LMU University Hospital of Munich, Pediatric Gastroenterology and Hepatology, Munich, Germany, [3]Amsterdam University Medical Centre, Gastroenterology and Hepatology, Amsterdam, Netherlands

Contact E-Mail Address: helga.toeroek@med.uni-muenchen.de

Introduction: Disease-specific knowledge plays a central role in chronic disease management. In patients with inflammatory bowel disease (IBD), limited knowledge is linked to poorer perceived health and increased discomfort (1).

Aims & Methods: This study assessed disease-specific knowledge among adult patients with IBD at a tertiary center and defined existing knowledge gaps. Factors associated with higher or lower levels of knowledge were explored.

The retrospective cohort study included 392 IBD patients who completed a comprehensive questionnaire between March 2020 and April 2021 (2). Questionnaire responses were analyzed alongside clinical records to quantify disease-specific knowledge. A scoring system was developed to quantify disease-specific knowledge (0–8 points), based on correct diagnosis, Montreal classification, complications, and current therapies. Scores were categorized as low (0–5) or high (6–8) knowledge levels. Associations between knowledge levels and disease-related, sociodemographic, and psychosocial factors were analyzed using logistic regression analysis.

Results: While most patients correctly identified their diagnosis (kappa: 0.863, CI: 0.816–0.905, $p < 0.001$) and advanced treatment (e.g. infliximab: kappa: 0.959, CI: 0.925–0.983, $p < 0.001$), knowledge gaps were observed regarding disease location (e.g. isolated proctitis in ulcerative colitis: kappa: 0.101, CI: –0.051–0.341, $p = 0.128$), complications, comorbidities, and certain other medications. In the univariate analysis a higher knowledge level was found in patients with Crohn's disease, younger age at diagnosis, in patients with no disease activity, and treatment with biologics, in those receiving disability pension and in patients with a high Perceived Stress Questionnaire (PSQ) score for worries (table).

Items (reference variable/dummy variable)	Overall knowledge level, OR (95% CI), p value
Diagnosis (CD/UC)	0.243 (0.133-0.445), p<0.001
Age at diagnosis	0.969 (0.950-0.989), p=0.002
Physician global assessment (no activity/moderate activity)	0.125 (0.047-0.333), p<0.001
Self-assessment (no activity/moderate activity)	0.269 (0.125-0.579), p<0.001
Treatment includes any biologics (no/yes)	2.381 (1.331-4.259), p=0.003
PSQ-Score worries	1.013(1.004-1.022), p=0.008
Receiving disability pension (no/ yes)	0.088 (0.020-0.382), p=0.001

Table: Univariate logistic regression analysis for items significantly associated with higher knowledge levels.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

A younger age at diagnosis ($p = 0.028$) and having Crohn's disease ($p < 0.001$) were independently associated with higher knowledge levels whereas active disease was associated with lower disease-specific knowledge.

Conclusion: Significant disease-specific knowledge gaps were identified, particularly concerning disease location, complications, and comorbidities. Targeted patient education should focus on addressing these specific deficits in susceptible groups.

PREDICTORS OF INDETERMINATE QUANTIFERON-TB AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE

H. AbdulMoniem Yousef[1], M. Alraddadi[1], G. Almasri[2], A.G.M. Alghamdi[1], B. Khaled Al Ibrahim[1], M. Alahmari[1], M. Alshowair[1]

[1]King Fahad Medical City, Gastroenterology and Hepatology Department, Riyadh, Saudi Arabia, [2]AlFaisal University, Riyadh, Saudi Arabia

Contact E-Mail Address: Hamidsincara@gmail.com

Introduction: QuantiFERON-TB is replacing the tuberculin skin test for latent TB screening in IBD patients before starting biologic therapy(1). Indeterminate results may cause delays in treatment initiation and necessitate further evaluation(2).

Aims & Methods: This is a retrospective chart review study conducted at King Fahad Medical City, Riyadh , Saudi Arabia, to investigate factors associated with indeterminate QuantiFERON-TB results in patients with inflammatory bowel disease (IBD).

Results: A total of 300 participants were included, with 53.2% diagnosed with Crohn's disease (CD) and 46.8% with ulcerative colitis (UC). Indeterminate QuantiFERON-TB results were observed in 4.7% of cases. None of these patients showed positive seroconversion or developed active tuberculosis during the follow-up period up to the study's completion.

Factor	Positive Association	p-value
Geographical Region	Northern region of Saudi Arabia (14.3% indeterminate)	0.021
Chest X-ray Findings	Abnormal X-ray (higher likelihood of indeterminate results)	<0.001
White Blood Cell Count	Elevated WBC (31.8% indeterminate)	<0.001
Albumin Levels	Hypoalbuminemia (17.4% indeterminate)	<0.001
C-Reactive Protein (CRP)	Elevated CRP (8.3% indeterminate)	0.008
Steroid Use	Steroid use (3.7-fold increased risk of indeterminate results)	0.008
IBD Subtypes	UC pancolitis (highest proportion of indeterminate results)	0.834

Conclusion: Indeterminate QuantiFERON-TB results were significantly associated with factors like geographical region, elevated WBC, hypoalbuminemia, elevated CRP, and steroid use, highlighting the need to consider these variables in latent TB screening for IBD patients. Importantly, none of the patients developed active TB or showed positive seroconversion.

Introduction: The therapeutic landscape of ulcerative colitis (UC) has expanded significantly in recent years, yet real-world data are still needed to guide optimal treatment sequencing and improve short and long-term outcomes. Mucosal healing (MH) is a well-established therapeutic goal in UC management, closely associated with improved long-term prognosis.

Aims & Methods: The aim of this study was to describe real-life treatment sequences in UC patients receiving biological therapies at a tertiary referral center. This retrospective analysis included UC patients treated with biological therapies between 2019 and 2023. Patients received infliximab, adalimumab, vedolizumab, ustekinumab, or other advanced therapies across up to six treatment lines. Biological treatment pathways prior to achieve MH were visualized using a Sankey diagram.

Endoscopic outcomes were evaluated one year after each biological therapy. MH, the primary outcome, was defined as endoscopic remission (Mayo UC score 0–1).

Results: Among 98 patients treated with biologics, MH was achieved in 46% (n = 45). Infliximab was used as the first-line agent in 55 patients (56%), adalimumab in 12 (12%), vedolizumab in 25 (25%), and golimumab in 3 (3%). Thirty-five patients (36%) achieved MH after the first-line therapy (n = 20 with infliximab; n = 2 with adalimumab; n = 12 with vedolizumab; n = 2 with golimumab). MH rates declined with each additional line of therapy: 17.4% after second-line treatment and no patients beyond the third line. The median time to achieve MH was 24.5 months (range 6–180). Treatment sequencing analysis revealed a progressive shift toward vedolizumab and ustekinumab in later lines, with infliximab remaining the most frequent first-line agent.

Conclusion: This study highlights a progressive decline in MH rates with successive lines of biological therapy in UC in a real-life cohort of patients. These findings emphasize the need for predictive tools to personalize treatment strategies in routine clinical practice.

OVERWEIGHT IS ASSOCIATED WITH LOW ADHERENCE TO THE MEDITERRANEAN DIET AND INCREASED DISABILITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

O.M. Nardone[1], C. Leo[2], A.D. Guarino[2], G. Calabrese[2], M. Petolicchio[2], F. Imoletti[2], L. Bonacci[2], A. Testa[2], A. Rispo[2], F. Castiglione[2]

Introduction: The prevalence of obesity in inflammatory bowel disease (IBD) has risen, with 15–40% of adults classified as obese and an additional 20–40% as overweight[1]. Poor dietary habits and sedentary lifestyles contribute to overweight and sarcopenia, potentially worsening IBD-related disability.

Aims & Methods: This cross-sectional study aimed to evaluate the relationships between nutritional status, adherence to the Mediterranean diet, sarcopenia and disability in IBD patients. Patients with IBD attending the outpatient clinic or infusion unit of an academic tertiary center between 2023 and 2024 were consecutively enrolled. Bioelectrical impedance analysis (BIA) was used to estimate the fat-free mass index (FFMI), a recognized measure of skeletal muscle mass. Physical function was assessed via gait speed (time to walk 6 meters), and handgrip strength (HGS) measured using a Jamar dynamometer. Sarcopenia was diagnosed based on FFMI, HGS, and walking speed. Disability was evaluated using the IBD-Disk questionnaire, with scores ≥40 indicating moderate-to-severe disability. Adherence to the Mediterranean diet was assessed using the Medi-Lite score, with scores <9 reflecting low adherence. Demographic, clinical, and disease related data were collected.

Results: A total of 95 IBD patients (58% with Crohn's disease, CD), 57.8% female, with a median age of 42 years (IQR 26-58) were included. Clinical activity ,measured with the Harvey-Bradshaw index (HBI), had a median score of 6 (IQR 4–7) for CD, while the median pMayo score for ulcerative colitis (UC) was 4 (IQR 2–6).

The median BMI was 23.60 (IQR 21-27). Overweight prevalence was 43.2% (41/95). Low adherence to the Mediterranean diet was significantly more frequent in overweight patients compared to nonoverweight patients ($p<0.001$). Overweight was also associated with increased age ($p < 0.001$). Sarcopenia prevalence was 7% (7/95) and was more common in non-overweight patients than in overweight patients ($p = 0.002$). The median BMI among sarcopenic patients was 20.6 (18.5–25.3). The mean IBD-Disk score was 41 ± 23.2, with 46.3% of patients reporting moderate-to-severe disability. Overweight patients were more likely to experience moderate-to-severe disability compared to non-overweight patients [27 (65.9%) vs. 23 (42.6%), $p =0.02$]. No significant association was found between sarcopenia and moderate-to-severe disability ($p = 0.44$).

Conclusion: Overweight is associated with low adherence to the Mediterranean diet and increased disability in IBD patients. Targeted interventions to improve adherence to the Mediterranean diet and manage overweight could potentially reduce disability in IBD patients.

SEQUENCE TREATMENT PATHWAYS AND TRANSMURAL HEALING IN CROHN'S DISEASE

E. Calabrese[1], L. Basile[1], F. Zorzi[1], A. Colella[1], J. Vesely[1], S. Calderone[1], L. Doni[1], E. Cuccagna[1], G. Monteleone[1], E. De Cristofaro[1]

Contact E-Mail Address: emma.calabrese@uniroma2.it

Introduction: There is an increasing diversification in the treatment landscape for Crohn's disease (CD) driven by heterogeneity of individual phenotypes, disease courses and previous treatments. This complexity makes universal evidence-based algorithms challenging. A "treat-to-target approach" with tight inflammation monitoring after starting biologics or small molecules therapy is recommended. Intestinal ultrasound (IUS) has proven effective in monitoring treatment response in large CD cohorts. Transmural healing (TH) is a robust but puzzling endpoint that can be achieved in about one-fourth of patients treated with biological therapy and few prognostic indicators to predict it were analyzed.

Aims & Methods: We aimed to describe treatment patterns and effective therapeutic sequences to achieve TH. Secondary aim was to identify prognostic factors to predict TH. This retrospective analysis included CD patients treated with biological and small molecules therapies according to the ECCO recommendations. Patients received biological and small molecules therapies across up to four treatment lines. Biological and small molecules treatment pathways prior to achieve TH were visualized using a Sankey diagram. IUS outcomes were evaluated one year after each biological and small molecules therapy. Logistic regression analysis was performed to identify clinical predictive factors of TH, that was defined as bowel wall thickness <3 mm and no vascularization at IUS.

Results: Among 139 patients treated with biological and small molecules therapies, TH was achieved in 25.9% (n = 36). Infliximab was used as the first-line agent in 55 patients (39.6 %), adalimumab in 69 (49.6%), vedolizumab in 6 (4.4%), certolizumab pegol in 1 (0.7%), Ustekinumab in 8 (5.7%). Twenty-five patients (20%) achieved TH after the first-line therapy (n=10 with infliximab; n=9 with adalimumab; n=3 with vedolizumab; n=3 with ustekinumab). TH rates declined with each additional line of therapy. The median time to achieve TH was 25.6 months (range 12–60).

Treatment sequencing analysis revealed a progressive shift toward ustekinumab in later lines, with anti-TNFs remaining the most frequent first-line agents. Multivariate analysis showed that colonic lesion and early treatment (within 2 years from diagnosis) were associated with a higher likelihood of achieving TH [OR = 7.76, $p<0.001$; OR 6.705, $p<0.001$, respectively], while perianal disease was associated with a lower likelihood of TH [OR 0.151, $p=0.02$].

Conclusion: This study highlights a progressive decline in TH rates with successive lines of biological and small molecule therapies in CD patients and identifies several clinical factors that influence this outcome. Long-term follow-up and prospective studies specifically designed to evaluate sequencing in patients exposed to anti-TNFs are needed to guide challenging decisions.

Disclosure: Nothing to disclose.

Contact E-Mail Address: kajari.lilian@gmail.com

Introduction: Inflammatory Bowel Diseases (IBD) require lifelong treatment and patient monitoring. Current predictors of relapse and therapeutic success have limitations, mostly invasive, time-consuming, and expensive. The faecal biomarker can help to monitor the disease activity and therapeutic response by simple and non-invasively. Faecal Calprotectin (FC) is the gold-standard, but it has many disadvantages.

We previously described that the correlation between the faecal Plasminogen activator inhibitor type 1 (PAI-1) (FP) level and the endoscopic activity and therapeutic response promote that it could be used as a novel non-invasive faecal biomarker in IBD diagnosis. Moreover, the faecal PAI-1 protein level is stable at room temperature and 4°C.

Aims & Methods: To observe the exact faecal biomarker potential, we aimed to define the FP level of IBD patients and subjects with other gastrointestinal (GI) diseases and compare it with the FC. Faecal samples were collected from 128 patients with IBD (CD-active: 18, CD-inactive: 10, UC-active: 20, UC-inactive: 10) and other GI diseases [colorectal cancer (CRC): 20, diverticulosis [DIV]: 21, irritable bowel syndrome [IBS]: 10, adenoma: 10) and 9 healthy subjects. ELISA method was applied to define FP level, and it was validated for stool samples by us and 0.5 ng/g PAI-1 level was defined as the cut-off value. For FC observation diagnostic FC ELISA kit (Orgentec) was used. 50 mg/g cut-off value was applied at FC. Confusion matrix analysis was utilized to define Youden-index, positive predictive value (PPV), negative predictive value (NPV), accuracy, specificity, and sensitivity of the measured values.

Results: FP level was significantly higher in patients with active IBD compared to inactive and non-IBD subjects (0.64 vs 0.0 ng/g, p<0.0001). No significant differences were observed between CD-active and UC-active groups (0.46 vs 0.79 ng/g, p=0.65). In addition, FP concentrations were significantly increased in active IBD (0.76 pg/g) patients compared to inactive IBD (0.0 pg/g, p=0.0001), CRC (0.11 ng/g, p=0.02), DIV (0.05 ng/g, p=0.001), IBS (0.0 ng/g, p<0.0001), adenoma (0.0 ng/g, p<0.0001), and healthy (0.0 ng/g, p=0.0002) subjects.

However, FC showed the same pattern as FP, except at the CRC, adenoma and DIV. In these groups, there were no significant differences compared to the active IBD (487.4 mg/g) subjects (vs CRC: 147.1 mg/g, p=0.09; p=; adenoma: 159.8, p=0.056. Confusion matrix analysis defined high specificity (83.5%) and moderate sensitivity (57.9%) values (TP: 22, FP: 14, FN: 17, TN: 71, PPV: 0.61, NPV: 0.816) at the FP measurements. Nevertheless, at FC levels 35.3% specificity and 94.7% sensitivity were measured (TP: 36, FP: 55, FN: 2, TN: 30, PPV: 0.396, NPV: 0.938). Calculated Youden-index was higher at the FP (0.41) compared to the FC (0.3). On the other hand, the accuracy of the FP is 75.6% and the FC is 53.6%. Based on the results of all FP levels measured (N=299) so far, the calculated values were specificity: 78%, sensitivity: 62%, PPV: 0.63, NPV: 0.78, Youden-index: 0.4, accuracy: 72.3%.

Conclusion: Our results suggest that the FP level selectively increased in the active IBD and discriminated more specifically from the other GI diseases compared to the FC. However, the sensitivity was lower, but it was improved by the increasing patient numbers at the pooled FP levels. Thus, the FP level could be useful in the diagnosis of IBD independently or combined with FC.

Introduction: Bowel urgency is one of the most bothersome symptoms of ulcerative colitis (UC) and have a great impact on quality of life and psychosocial function. The Urgency Numerical Rating Scale (U-NRS) is desinged to ojectify this subjective symptom. It measures the degree of faecal urgency experienced over the past 24 hours by patients with UC on a scale of 0-10. We assumed that the scale has a large variance, as patients evaluate their own symptoms differently, the urge may be different quality for two patients with the same score.

Aims & Methods: The objective of our study was to investigate the possible components of urgency and refine the assessment of urgency. Patients with UC older than 18 years treated at our departments for at least 3 months and having complaints were enrolled in our study. The patients filled out our non-validated questionnaire with questions about fecal urgency (U-NRS), pain level, speed of urge, incontinence and lifestyle characteristics associated with incontinence. Statistical analysis was performed using STATA 18 program.

Results: 263 patients were enrolled, median age was 39.5 years, the mean of disease duration was 11.7±9.2 years. The mean U-NRS score was 3.2±3.2, 32% (84/263) had 0 score and 3% (9/263) has 10 score. 12% of the patients (n=31) felt most difficult to hold mucus, 37% (n=97) stool and 29%

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(n=76) other secretions. 8% (n=22) had urge with every stool in the last 24 hours, 36% (n=95) had less than half of defecations. The speed of urge defined more the level of urgency than the pain level (R2=0.798 p<0.001, β=0.894 vs R^2=0.805, p<0.001, β=0.117). The duration of faeces holding in the last 7 days had significant connection to U-NRS (R^2=0.211, p<0.001, β=-0.46). Patients using public restroom at least once during the last week had significantly higher score on U-NRS than other patients (4.6±3.1 vs 2.4±3 p<0.001). 12% (31/263) used diaper.

The usage of diapers was also significantly more often in patients with higher U-RNS score (5.2±3.2 vs 2.9±3.1,p<0.0001). Faecal leakage both during the day and night was significiantly higher with higher U-NRS score (p<0.001 for both). Patient reported outcome (PRO2) had a weak correlation with U-NRS (R^2=0.14).

However if we examine bloody stool, the stool number and difficulty of faecas holding seperately we got a significant and better correlation with urgency (R^2=0.43). Patients with moderately severe-severe disease (PRO2 > 5) had a higher chance to have urgency (AUC=0.9). The possibility was higher to have urgency among patients with painful defecation (R^2=0.41). The level of urgency, duration of faeces holding and the frequency of faeces holding problems had the strongest correlation with U-NRS (R^2=0.83). Patients defined urgency with these parameters according to this result. We created score with them, level of urgency points + half of duration points + frequency, which showed a good model to refine the definition of urgency (R^2=0.83).

Conclusion: Bowel urgency affects UC patients' lives and is associated with more severe disability. Bowel urgency is common in UC affecting about two-third of patients and associates with more severe activity of UC. Fecal urgency can characterize with the level of urgency, duration of faeces holding and the frequence of stool more accurately than a single, subjective numeric scale. A new scoring system is needed to more accurately assess patients' complaints in this area and to objectify severity.

Disclosure: The authors have no potential conflict of interest to disclose.

Introduction: Although several therapeutic strategies exist for the treatment of ulcerative colitis (UC), their efficacy is still far from optimal. The JAK/STAT signalling pathway has emerged as a promising therapeutic target. Tofacitinib (TOFA), an oral JAK inhibitor, is the first approved small molecule for induction and maintenance of remission in moderate-severe UC. However, potential predictive markers for therapeutic response to TOFA are currently lacking.

Aims & Methods: Therefore, we aimed to assess the mucosal expression of JAK/STAT and cytokine levels in UC patients treated with TOFA to identify potential predictive markers of therapeutic response. This prospective study included UC patients initiating TOFA therapy. Clinical indices, laboratory parameters, and colonoscopy were evaluated at baseline and after a 12-week treatment period. RNA and total protein were isolated from colonic biopsies. qRT-PCR analysis was applied for the following targets: STAT1, STAT3, JAK1, JAK2, JAK3 and TYK2. Mucosal protein levels of TNF-a, IL-6, IL-1b, IL-4, IL-17A, IFN-g, and PAI-1 were determined by multiplex ELISA.

Results: A total of 49 UC patients were enrolled, and 75.5 % completed the 12-week follow-up. Of these, 63.3 % of the patients responded to TOFA. Clinical and endoscopic remission rates were 69.4% and 32.6%, respectively. Primary non-response was observed in 24.5% of the patients and loss of response in 36.7%. In responders, serum C-reactive protein (CRP) level, partial Mayo (pMayo), and endoscopic Mayo (eMayo) scores significantly decreased. TOFA responders showed a significant reduction in STAT1 and JAK2 gene expression. The mucosal protein levels of IL-6, IL-1b, IFN-g, IL-17A, and PAI-1 were also significantly decreased in patients who responded to TOFA.

Importantly, baseline levels of IL-6, IL-4, and PAI-1 were significantly lower in responders. Patients achieving steroid-free remission had significantly reduced baseline levels of IL-1b, IL-4 and PAI-1.

In contrast, elevated level of IL-1b was significantly higher in patients with loss of response. Moderate correlations were observed between pMayo scores and TNF-a, IL-6, IL-1b, and IL-17A levels. Weaker correlations were seen between eMayo scores and the examined cytokine concentrations.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

However, the strongest correlations were found between mucosal PAI-1 level and pMayo (r=0.55) and eMayo (r=0.52) scores. Serum CRP level showed moderate correlations with cytokine concentrations.

Conclusion: TOFA treatment was effective in more than 60% of patients and clinical remission was achieved in nearly 70%. Lower baseline mucosal protein level of IL-1b, IL-6, IL-4 and especially PAI-1 may serve as potential predictive markers of treatment response. Among these, PAI-1 demonstrated the strongest correlation with both clinical and endoscopic disease activity, underscoring its potential as a predictive and monitoring biomarker in UC.

IMPACT OF DISEASE ACTIVITY ON PREGNANCY OUTCOMES IN WOMEN WITH INFLAMMATORY BOWEL DISEASE

K. Shah[1], M. Kaler[1], G. Parkes[1], J.O. Lindsay[2], K.B. Kok[1]
[1]Barts Health NHS Trust, Gastroenterology, London, United Kingdom, [2]Digestive Disorders Clinical Academic Unit, BARTS & THE LONDON SCHOOL OF MEDICINE, Dept. of Digestive Diseases, London, United Kingdom

Contact E-Mail Address: krishna.shah2@nhs.net

Introduction: Active inflammatory bowel disease in pregnancy is associated with an increased risk of adverse maternal and neonatal outcomes. Understanding patterns of disease activity may inform strategies for improving outcomes.

Aims & Methods: A retrospective cohort study was conducted of pregnancies managed through an IBD–antenatal clinic between August 2020 and January 2025. Patients were stratified into 2 groups based on disease activity during pregnancy. Active disease was defined using the Physician Global Assessment, symptoms, and biomarkers (CRP and/or FCP). Disease flare was defined by an increase in symptoms and/or biomarkers from their baseline. Disease activity was assessed pre-conception (within 6 months before pregnancy) during pregnancy and post-partum (up to 6 months post birth).

Results: Of 209 pregnancies (Table 1), 76.3% (n=158) were in remission and 23.7% (n=49) had active disease pre-conception. Among those with active disease, 81.6% (n=40) remained active into pregnancy, while 18.4% (n=9) achieved remission. Of those in remission at pre-conception, 73.4% (n=116) stayed in remission during pregnancy, and 24.7% (n=39) flared. 2 patients with no pre-conception data were active in pregnancy.

Of 125 patients in remission during pregnancy, 73.6% (n=92) stayed in remission post-partum and 12.0% (n=15) flared. Among 81 patients with active disease in pregnancy, 39.5% (n=32) remained active, and 53.0% (n=43) achieved remission post-partum.

Patients in remission through pregnancy had a higher mean BMI (24.5 vs 23.0 kg/m^2, p=0.027), were more likely to be of white ethnicity compared to minority ethnic groups (61.0% vs 38.4% p=0.0026), have a diagnosis of Crohn's disease (58.6% vs 37.0%, p=0.0088), and be nulliparous (51.2% vs 35.0%, p=0.0414).

At conception, approximately 30% of patients in both groups were not receiving any treatment. During pregnancy, this proportion fell to 8.6% in the active group, reflecting therapy escalation. Use of biologics increased from 22.2% to 38.2% in the active group and remained stable at 36.0% in the remission group. Corticosteroid use was exclusive to the active disease cohort (6.2% at conception; 23.5% during pregnancy).

Active disease in pregnancy was associated with higher rates of adverse outcomes: gestational diabetes (12.3% vs 8.0%, p=0.001), fetal growth restriction (4.9% vs 0%, p=0.044), and low birth weight (<2500g: 14.6% vs 2.4%, p=0.015). While rates of small for gestational age infants were higher in the active group (9.9% vs 4.0%), this was not statistically significant.

Emergency c-sections were more common in the active group (29.9% vs 15.0%, p=0.03), while elective c-sections were more frequent in the remission group (27.5% vs 13.4%, p = 0.03).

Women in remission more often had an intact perineum (63.6% vs 54.7%), while episiotomy was more frequent in those with active disease (18.8% vs 11.7%); both did not reach statistical significance.

	Pre-conception % of available data (n)	Pregnancy % of available data (n)	Post-partum % of available data (n)
Active disease	23.7% (49)	39.3% (81)	25.2% (47)
Remission	76.3% (158)	60.7% (125)	74.2% (135)
Excluded (pregnancy loss)	0	3	3
Missing data points	2	0	24

Conclusion: This study underscores the impact of active IBD on maternal and neonatal outcomes.

Nearly 1 in 4 women in remission at preconception flared during pregnancy. This highlights the need for effective pre-conception counselling, access to disease monitoring tools, multidisciplinary management and timely treatment optimisation to sustain remission during pregnancy.

Disclosure: No disclosures.

COMPARISON OF REMIMAZOLAM AND MIDAZOLAM FOR SEDATION DURING COLONOSCOPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: PATIENT SATISFACTION, RECOVERY TIME, AND SAFETY

C. Bezzio[1], G. Franchellucci[1,2], R. Gabbiadini[1], A. Dal Buono[1], L. Loy[1], G. Migliorisi[1], B. Masoni[1], S. Ferretti[1], P. Bertoli[1], C. Ferrari[3], R. Monzani[3], C. Hassan[2], A. Repici[2], A. Armuzzi[1]

Contact E-Mail Address: gianlucafranchellucci94@gmail.com

Introduction: Endoscopy is a crucial tool in the management of inflammatory bowel disease (IBD). Recently, Remimazolam a novel, ultra-short-acting benzodiazepine has been approved for procedural sedation. Although propofol provides superior sedation compared to midazolam, its use in Italy is limited due to the requirement for anesthesiologist supervision, higher costs, and a shortage of specialists. To date, no real-world studies have compared midazolam, remimazolam, in IBD patients.

Aims & Methods: This prospective, single-center study enrolled consecutive IBD patients undergoing outpatient colonoscopy at a tertiary care center. Patients were randomized in a 1:1 ratio to receive either remimazolam or midazolam for sedation. All procedures included continuous vital sign monitoring, and both sedatives were administered directly by the endoscopist.

The primary objective was to evaluate the feasibility of patient discharge from the endoscopy unit. Secondary objectives included comparing the safety profile of remimazolam versus midazolam and assessing patient-reported satisfaction with the procedure.

Discharge readiness was assessed using the Post-Anaesthetic Discharge Scoring System (PADSS), which evaluates six criteria: vital signs, ambulation, nausea/vomiting, pain, bleeding, and voiding. A PADSS score of ≥9 at

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

10 and 20 minutes post-procedure was considered indicative of discharge readiness. Patient satisfaction was measured using a four-point scale: not satisfied, not yet satisfied, satisfied, and very satisfied.

Results: A total of 200 patients were enrolled, with 100 in each group. 90 patinets were affected by Crohn's disease and 108 by ulcerative colitis. Baseline characteristics, including age, disease duration, BMI, gender, and history of abdominal surgery,were comparable between the groups. All colonoscopies were completed successful, the time of colonscopy was 22.51 minutes(CI 20.85-24.16) in the midazolm group and 21.08 minutes (CI:21.08-23.69) in the remimazolam group (p: 0.911, CI -2.232-1.99). At 10 minutes post-procedure, 68 patients (68%) in the remimazolam group achieved a PADSS score ≥9, compared to 25 patients (25%) in the midazolam group ($p < 0.001$). At 20 minutes, 96 patients (96%) in the remimazolam group met the discharge criteria, versus 69 patients (69%) in the midazolam group ($p < 0.001$). In patients who had previously undergone colonoscopy (n=189), high satisfaction was reported by 64 patients in the remimazolam group and 39 in the midazolam group ($p < 0.001$). Among those with a history of abdominal surgery, 30 out of 46 (68.2%) patients in the remimazolam group reported high satisfaction, compared to 15 out of 44 (35.7%) in the midazolam group ($p = 0.003$). No severe adverse events were reported. Two patients in the remimazolam group experienced transient bradycardia, while two patients in the midazolam group required supplemental oxygen during the procedure.

Conclusion: This prospective study suggests that remimazolam enables faster discharge from the endoscopy unit compared to midazolam, with a high level of patient satisfaction and a favorable safety profile.

Introduction: While inflammatory bowel disease (IBD), which includes Crohn's disease (CD) and ulcerative colitis (UC), affects people of all sexes, potential disparities in the diagnostic process—such as differences in symptom onset, symptom reporting, and time to diagnosis—have not been systematically investigated in depth to date.

Aims & Methods: This analysis aims to explore potential sex differences in the pre-diagnostic symptom presentation and the diagnostic pathway of IBD, spanning from the onset of first symptoms to the eventual clinical diagnosis. In this interim analysis of a multicenter cross-sectional study, data of 1180 participants with IBD (women: n=770, men: n=410) from 42 recruiting units all over Germany were included.

A comprehensive set of demographic data was collected via an online survey, encompassing the following variables: the IBD entity, sex and gender identity, age, the initial symptoms of IBD, the time from symptom onset to first consultation, the time from first consultation to referral, and the time to diagnosis. In addition, the respective physician's sex was documented. Moreover, the distinct disease-related and therapeutic histories have been collected. Inclusion criteria were a minimum age of 18 years and a confirmed diagnosis of UC or CD for a minimum of three months.

Results: No significant sex differences were observed in the median time to initial physician consultation for either CD or UC (CD: women 3 months [IQR: 1–12], men 3 months [IQR: 0.5–10], p=0.567, g=0.1; UC: women 2 months [IQR: 0.8–5], men 1.3 months [IQR: 0.5–4], p=0.091, g=0.1). Similarly, the median time from first consultation to referral did not differ significantly between sexes (CD: women 1.5 months [IQR: 0.5–5], men 1 month [IQR: 0.5–6], p=0.154, g=0.1; UC: women 0.8 months [IQR: 0.3–3], men 0.5 months [IQR: 0.2–1], p=0.113, g=0.2).

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

However, women experienced significantly longer median time from symptom onset to final IBD diagnosis compared to men (CD: women 12 months [IQR: 5–48], men 6.5 months [IQR: 2.5–24], p=0.002, g=0.3; UC: women 5 months [IQR: 2–14.5], men 3 months [IQR: 1.3–8], p=0.006, g=0.2). The misdiagnosis rate was found to be significantly higher in women with IBD than in men (IBD women: n=311 (40.4%); IBD men: n=141 (34.4%); p=0.044). Furthermore, sex-specific differences in the initial presentation of symptoms were observed. Women with CD were more likely to present with diarrhea (p=0.005, ϕ =0), nausea (p=0.013, ϕ=0), or arthralgia (p=0.012, ϕ =0) compared to CD men. In UC, women were more likely to initially experience fever (p < 0.001, ϕ = 0) or abdominal pain (p = 0.004, ϕ = 0) compared to men.

Conclusion: Despite similar timelines for initial physician contact and referral, women with IBD experienced significantly longer diagnostic delays and higher rates of misdiagnoses than men. Sex-specific differences in initial symptom presentation were observed, suggesting that diagnostic disparities may be partly driven by variations in symptom profiles and their interpretation. These challenges call for a broader, global perspective and increased awareness to improve the overall care of individuals with IBD on an international scale.

Contact E-Mail Address: claire.tan@mohh.com.sg

Introduction: Personalizing biologic therapies in inflammatory bowel disease (IBD) remains a critical unmet need. Here, we investigated circulating and stool microRNAs (miRNAs) as prognostic markers for treatment response across three biologics - anti-TNF, vedolizumab (VEDO), and ustekinumab (UST) - and explored their relationship with gut microbiome to uncover potential host-microbe predictors of response.

Aims & Methods: This study included 43 IBD patients (mean age 40.4 years, 25.6% female, 20.1% with ulcerative colitis) enrolled in the ILEITIS cohort at National University Hospital, Singapore. The majority had received anti-TNF (n=35), whilst others were given VEDO (n=9), or UST (n=15) therapies. Clinical non-response was defined as disease flare within 48 weeks post-induction, indicated by C-reactive protein >5 mg/L, fecal calprotectin >150 µg/g, or moderate to severe endoscopic inflammation. Baseline serum and stool samples were collected and isolated for miRNA profiling by the ID3EAL™ PanoramiR microRNA Knowledge Panel (MiRXES) via the QuantStudio5-384-well qPCR system (Applied Biosystems). Fecal microbial communities were assessed via shotgun metagenomic sequencing. Differential expression analysis and Spearman correlation with false discovery rate (FDR) adjustment were performed to explore miRNA–microbe associations and treatment response patterns.

Results: Among 376 paired serum and stool miRNAs analyzed, only six exhibited significant positive correlations, indicating largely compartment-specific expression patterns. Stool miRNAs demonstrated stronger and more numerous correlations with gut microbial taxa (11 significant pairs, FDR < 0.05), whereas serum miRNAs showed no strong associations. Biologic-specific miRNA signatures were identified.

Predictive modelling identified top-ranked miRNA with high discriminative performance for treatment response; serum miR-296 and stool miR-134 perfectly predicted VEDO response (AUROC = 1.0); serum miR-146 predicted UST response (AUROC = 1.0); and stool miR-302 robustly predicted anti-TNF response (AUROC = 0.897). Correlation analysis between biologic-responsive miRNA and microbial taxa revealed 12 significant correlations for stool-derived miRNA and 14 for serum-derived miRNA.

Notable microbial species involved in these associations include *Bacteroides uniformis, Parabacteroides distasonis, Phocaeicola dorei, Clostridium scindens, Streptococcus sanguinis, Bilophila wadsworthia, Hungatella hathewayi,* and *Clostridium leptum*, all taxa implicated in IBD-associated dysbiosis, showed significant correlations (FDR < 0.05).

Conclusion: Stool- and serum-derived miRNAs capture non-overlapping but complementary dimensions of host response to biologic therapy in IBD. There are significant overlaps between host miRNAs and microbiome readouts suggesting plausible links between key microbial responders to therapy and host regulatory miRNAs, especially in the luminal compartment. Our findings highlight the value of integrating compartment-specific miRNA and microbiome profiling to improve precision medicine approaches in IBD.

Disclosure: Nothing to disclose.

Introduction: Abnormal hepatobiliary biochemistry is frequently observed in patients with inflammatory bowel diseases (IBD), encompassing ulcerative colitis (UC) and Crohn's disease (CD). However, its prevalence and clinical implications in IBD remain unclear.

Aims & Methods: We aimed to determine the occurrence and clinical impact of abnormal hepatobiliary biochemistry in patients with newly diagnosed IBD.

Between May 1, 2021, and April 30, 2023, all adult and pediatric patients with incident IBD within a catchment area covering 20% of Denmark were enrolled in the prospective, population-based Copenhagen IBD Inception Cohort. Herein, all adult patients underwent hepatobiliary blood tests (alanine aminotransferase (ALT), alkaline phosphatase (ALP), bilirubin,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and INR) at IBD diagnosis. Multivariate Cox proportional hazard analyses adjusting for age, sex, smoking, and disease phenotype were performed (adjusted HR, aHR, 95% confidence interval).

Results: A total of 527 patients (UC: 326; CD: 201) were included in the cohort, with 290 (89.0%) and 189 (94.0%) undergoing blood tests, respectively, within a median of two days (interquartile range: -14 - 6) before IBD diagnosis. No demographic or clinical phenotypical differences were observed between patients who underwent blood test and those untested.

Abnormal hepatobiliary biochemistry was found in 49 (16.7%) and 46 (24.3%, p<0.01) patients with UC and CD, respectively, primarily driven by higher median ALP levels in CD (80 U/L [IQR 69-97]) versus UC (74 U/L [IQR 61-90], p<0.01). No associations were observed between abnormal hepatobiliary biochemistry and sex, age, initial extent or location of IBD, or disease activity. However, stricturing or penetrating CD was significantly associated with abnormal hepatobiliary biochemistry (adjusted OR = 4.62 [1.70; 12.54]). During a follow-up of 2.1 years (IQR 1.6-2.6), abnormal hepatobiliary biochemistry was not associated with the initial course of UC; however, an increased risk of requiring resective surgery for CD was observed (aHR= 3.27 [1.04-10.24], Table 1).

	Disease activity (worsening or flare)	Systemic steroid	IBD-related hospitalization	Colectomy or resective surgery	Immunomodulators	Biological therapy	Surgery or biological treatment
	Hazard ratio (95% confidence interval) adjusted for disease phenotype, sex, age, and smoking						
Ulcerative colitis	1.09 (0.35-3.34)	0.95 (0.42-2.14)	1.06 (0.38-2.94)	1.82 (0.34-9.70)	0.61 (0.21-1.75)	1.82 (0.83-3.98)	1.14 (0.35-3.70)
Crohn's disease	0.46 (0.05-3.95)	1.04 (0.48-2.28)	1.21 (0.43-3.35)	3.27 (1.04-10.24)	1.24 (0.57-2.70)	1.34 (0.64-2.83)	1.60 (0.75-3.39)

Table 1: Impact of abnormal hepatobiliary biochemistry on the initial course of inflammatory bowel diseases.

Conclusion: In this prospective, population-based cohort, abnormal hepatobiliary biochemistry was present in approximately one in six patients with UC and one in four patients with CD at diagnosis, with no association with IBD disease activity. Although it did not correlate with the initial course of UC, these findings underscore the need for increased attention to hepatobiliary biochemistry in patients with CD.

Introduction: Sexual dysfunction is an underrecognized concern among patients with inflammatory bowel diseases (IBD).

Aims & Methods: This study aimed to assess the prevalence and associated risk factors of sexual dysfunction at IBD diagnosis.

All adult patients with newly diagnosed ulcerative colitis (UC) or Crohn's disease (CD) within a defined region of Copenhagen, Denmark, were prospectively enrolled from the Copenhagen IBD Inception Cohort (May 2021–May 2023).

Sexual dysfunction was defined using patient-reported IBD-specific Memorial Symptom Assessment Scale (MSAS), with frequent dysfunction categorized as occurring "sometimes" or more often. Multivariable logistic regression analysis were adjusted for age, sex, and phenotype.

	Frequent sexual dysfunction Adjusted odds ratio [95% confidence interval]	
	Ulcerative colitis	Crohn's disease
Elderly-onset IBD (age≥60 vs. <60 years)	0.95 [0.25;3.60]	1.29 [0.23;7.12]
Female sex	1.53 [0.58;4.07]	2.66 [0.72;9.83]
Diagnostic delay (>26 weeks vs. less)	1.25 [0.39;3.98]	0.33 [0.06;1.79]
Obesity	0.52 [0.06;4.53]	1.30 [0.22;7.69]
Active smoking (ref: never)	1.52 [0.45;5.08]	3.10 [0.47;20.42]
Disease classification (ref: L1, E1, or B1)		
L2 / E2	1.46 [0.58;3.69]	1.91 [0.52;6.93]
L3 / E3	1.11 [0.44;2.77]	1.68 [0.44;6.35]
B2 or B3		2.54 [0.43;14.92]
Perianal vs. none	0.80 [0.31;2.08]	0.82 [0.09;7.75]
Extra-intestinal manifestations (yes vs. no)		2.88 [0.51;16.13]
IBD activity (moderate-to-severe vs. mild)		
SCCAI ≥ 6 or HBI ≥ 8	1.17 [0.43;3.20]	0.74 [0.17;3.29]
C-reactive protein > 10 mg/L	0.34 [0.08;1.38]	3.79 [0.86;16.77]
Fecal calprotectin > 1800 mg/L	0.55 [0.18;1.68]	1.66 [0.38;7.29]
MES ≥ 2 or SES-CD ≥ 7	0.68 [0.22;2.03]	NA
Initial disease course		
Need for hospitalization	1.15 [0.30;4.32]	4.43 [1.14;17.26]
Need for biologics	0.86 [0.16;4.75]	1.34 [0.29;6.14]
Need for surgery	NA	0.76 [0.08;7.42]
Moderate to severe impairment of PROs		
EQ-5D-5L, problems in 4 of 5 domains	1.78 [0.47;6.77]	5.38 [1.23;23.57]
SIBDQ < 60	2.76 [0.73;10.48]	NA
IBD-DI > 20	6.93 [1.58;30.37]	7.83 [0.72;84.54]
FACIT-F < 35	2.55 [0.90;7.20]	4.02 [1.05;15.40]
Symptoms in modified MSAS questionnaire		
Abdominal pain	5.23 [0.62;44.24]	1.98 [0.48;8.12]
Mucus on stool	0.90 [0.20;4.06]	NA
Blood on stool	0.53 [0.08;3.71]	1.00 [0.11;8.95]
Feeling bloated	2.80 [0.70;11.19]	NA
Weight loss	1.76 [0.60;5.17]	6.60 [0.54;80.24
Reduced appetite	5.23 [1.53;17.89]	NA
Stool urgency	3.16 [1.06;9.45]	0.69 [0.18;2.60]

Table 1: Predictors of frequent sexual dysfunction.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 383 included patients (UC: 182; CD: 107), frequent sexual dysfunction was reported by 29.4% of females and 17.5% of males with UC, and by 22.7% of females and 25.0% of males with CD. In UC, sexual dysfunction was associated with moderate-to-severe disability (IBD Disability Index; adjusted odds ratio (aOR) =6.93; 95% CI: 1.58–30.37) and bowel urgency (aOR=3.16; 1.06–9.45). In CD, it was linked with CD-related hospitalization (aOR=4.43; 1.14–17.26), impaired quality of life (EQ-5D-5L; aOR=5.38; 1.23–23.57), and fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue; aOR=4.02; 1.05–15.40). Sexual dysfunction was not associated with age, sex, disease activity, endoscopic severity, biochemical markers, or initial treatment.

Adjusted for age, sex, and disease phenotype (presence of extensive colitis in UC or ileal disease in CD). In CD, symptoms were only adjusted for disease phenotype due to sample size. Severe disease was defined by the need for glucocorticoids, immunomodulators, biologics, or surgery within three months of diagnosis.

Conclusion: Sexual dysfunction is common and often present at IBD diagnosis, independent of objective disease severity. Early recognition of sexual dysfunction is essential for comprehensive, patient-centered IBD care.

HOSPITAL ADMISSIONS DURING PREGNANCY IN WOMEN WITH INFLAMMATORY BOWEL DISEASE: AN 11-YEAR SINGLE-CENTER OBSERVATIONAL STUDY

S. Rellou[1], K. Rosiou[2], T. Glanville[3], C. Selinger[2]
[1]General Oncology Hospital of Kifisia Oi Agioi Anargyroi, Gastroenterology Department, Athens, Greece, [2]St James's University Hospital, Leeds Teaching Hospitals NHS Trust, Gastroenterology Department, Leeds, United Kingdom, [3]St James's University Hospital, Leeds Teaching Hospitals NHS Trust, Maternity Department, Leeds, United Kingdom

Contact E-Mail Address: s_r_1235@hotmail.com

Introduction: Pregnancy in women with Inflammatory Bowel Disease (IBD) is associated with increased risk of complications, particularly when disease activity is uncontrolled. Antenatal hospital admissions may reflect underlying disease activity or pregnancy-related complications and may adversely affect pregnancy outcomes.

Aims & Methods: The aim of this retrospective observational study was to describe the causes and outcomes of hospital admissions during pregnancy in women with IBD.We included completed pregnancies in women with a confirmed diagnosis of Crohn's disease (CD), ulcerative colitis (UC), or IBD-unclassified (IBD-U), followed between May 2014 and March 2025, who had at least one hospital admission during pregnancy. Data were collected on IBD history, disease activity, assessed according to the Global Physician Assessment (GPA), treatment, reasons for admission, investigations, and pregnancy outcomes.

Results: Of 57 pregnant women that were included (mean age: 32 years; 27 CD, 27 UC, 3 IBD-U), 6 patients (10.52%) were diagnosed during pregnancy. Prior to pregnancy, 20 patients (35.08%) had undergone IBD-related surgery, and 10 of these had a stoma. Among CD patients, 14.28% (n=4) had a history of previously active perianal disease, and 21.43% (n=6) had active perianal disease during pregnancy. Disease activity, before conception, was as follows: 66.67% (n=37) in remission, 12.28% (n=7) with mild disease, 7.02% (n=4) with moderate disease, and 1.75% (n=1) with severe disease. During pregnancy, 73.68% (n=42) remained in remission, while 12.28% (n=7) had moderate disease, 8.77% (n=5) mild disease, and 5.26% (n=3) severe disease. Regarding maintenance therapy during pregnancy, 38.6% (n=22) received aminosalicylates, 29.82% (n=17) thiopurines, and 36.84% (n=21) biologics. 13 patients (22.8%) remained on no maintenance therapy. Steroids were used at least once during pregnancy in 36.84% (n=21). In total, 64.91% (n=37) of admissions were IBD-related (n=19 flare, n=7 stoma complications, n=6 abdominal pain in the absence of active IBD, n=2 perianal complications, n=2 gastrointestinal bleeding, n=1 perforation). Among non-IBD-related admissions, 45% (n=9) were due to obstetric complications, 15% (n=3) due to infections, 30% (n=6; biliary sepsis, cholestasis, migraine, suspected venous thromboembolism ,hemoptysis and suspected pulmonary embolism) due to other causes, and 10% (n=2) due to undocumented reasons. Radiological investigations were performed in 38.6% (n=22) of patients, 21.05% (n=12) underwent endoscopic evaluation, and 10.52% (n=6) required surgical intervention. Pre-eclampsia or eclampsia was documented in 4 patients (7.01%), and gestational diabetes was observed in 5 patients (8.77%). Delivery outcomes included 61.4% vaginal births (n=25 spontaneous vaginal deliveries; n=10 assisted vaginal deliveries) and 36.84% caesarean sections (n=11 elective; n=9 emergency). Two stillbirths were recorded. The mean birth weight was 3,135 grams and 49.12% (n=28) of mothers initiated breastfeeding. Preterm delivery, defined as birth before 37 weeks of gestation, occurred in 14.03% (n=8) of cases.

Conclusion: Hospital admissions in pregnant women with IBD often reflect disease flares, stoma complications or abdominal pain. Most pregnancies complicated by IBD hospital admissions had favorable outcomes. These findings underline the importance of multidisciplinary care and close monitoring to manage both IBD-related issues and pregnancy-specific complications.

Introduction: In Crohn's disease (CD), a comprehensive approach to care is increasingly advocated, incorporating various factors that may impact patients' quality of life, including sexual dysfunction (SD). However, data on sexual health in this population remain scarce.

Aims & Methods: The aim of this study was to assess the prevalence and risk factors of sexual dysfunction, as well as its impact on quality of life in patients with CD.

We conducted a cross-sectional study including all patients with a confirmed diagnosis of CD who attended follow-up consultations over the six months preceding the study. Sexual function was assessed using the Female Sexual Function Index (FSFI) for women and the International Index of Erectile Function (IIEF) for men. SD was defined by a total FSFI score <26 for women and an IIEF score <26 for men. Disease activity was evaluated using the Harvey-Bradshaw Index (HBI), and quality of life was assessed via the short version of the Inflammatory Bowel Disease Questionnaire (S-IBDQ).

Results: A total of 102 patients were enrolled (mean age: 40.35 ± 15.07 years), with a male predominance (M/F sex ratio = 1.61). Active smoking was reported in 32.3% of patients. Disease location was ileal (47.1%), colonic (20.6%), and ileocolonic (32.4%). The predominant disease phenotype was both stricturing and penetrating in 41.2% of cases. Perianal involvement was present in 38.2%. Severe disease activity was noted in 20.6% of patients. Nearly half (47.0%) underwent at least one surgical procedure during follow-up, with 12% undergoing total colectomy. At the time of the study, 23.5% were receiving systemic corticosteroids, 23.5% azathioprine, and 53.0% anti-TNFα therapy.

The mean IIEF score was 17.22 ± 9.65 and the mean FSFI score was 21.56 ± 7.18. SD was identified in 38.5% of women and 28.6% of men, with no statistically significant difference (p = 0.78). Severe sexual dysfunction (IIEF score 5–10) was observed in 17.6% of male participants. Both disease activity and active smoking were significantly associated with SD (p = 0.001 and p = 0.024, respectively). No significant association was found between SD and perianal disease or history of intestinal surgery.

The mean S-IBDQ score was 45.06 (range: 17–67), with 41.2% of patients scoring <40, indicating a major impact of CD on quality of life. SD was strongly correlated with poorer quality of life, as shown by lower S-IBDQ scores in both men (p = 0.002, r = 0.01) and women (p = 0.008, r = 0.01). Notably, 73.5% of patients expressed a desire to discuss sexual health with their gastroenterologists.

Conclusion: This study highlights a substantial prevalence of sexual dysfunction in patients with Crohn's disease, with significant repercussions on quality of life. These findings emphasize the importance of systematically addressing sexual health in clinical practice to optimize patient-centered care.

Disclosure: Nothing to disclose.

Introduction: Histologic remission is not a formal target in the management of patients with ulcerative colitis (UC). In clinical practice, medical therapy escalation is reserved for patients with MES ≥2. Currently, there is no evidence on outcomes of patients with MES 1 stratified by histology.

Aims & Methods: We conducted a retrospective cohort study to compare long-term outcomes of UC patients with a MES of 1, stratified by histological activity according to the Nancy Histological Index (NHI), and those with MES 2 after 12 months of advanced therapy. We included all consecutive adult patients (≥ 18 years) with a confirmed diagnosis of UC initiating any advanced therapy with at least 12 months of follow-up. Only patients with MES 1 or 2 after 6-12 months from the start of therapy and availability of histological report with NHI were eligible. The primary endpoint was the rate of a composite outcome including medical therapy escalation, hospitalization, and surgery among patients with MES 1 and histological activity (NHI 2-4) versus those with MES 2. A multivariate logistic regression was performed to identify independent predictors of the composite outcome. In addition, Spearman correlation was used to assess associations between histologic activity and individual outcome components.

Results: A total of 159 patients with UC were included (82 males, 51.6%), with a mean age of 44 ± 15 years. At baseline, 76 patients (47.8%) were naïve to advanced therapies. Most patients had MES 3 at baseline (51.6%). The most commonly used drug was infliximab (50, 31.4%), followed by ustekinumab (46, 29.0%), vedolizumab (35, 22.0%), tofacitinib (13, 8.2%), upadacitinib (8, 5.0%) adalimumab (6; 3.8%), and filgotinib (1, 0.6%). Concomitant therapy with systemic corticosteroids or azathioprine was adopted in 22 (13.8%) and 38 patients (23.9%), respectively. At 12-months, 90 (56.6%) patients had MES 1 and 69 (43.4%) had MES 2. Histological activity was observed in 36 individuals with MES 1 (40.0%) and in 60 patients (87.9%) with MES 2. The mean follow-up was 21.5 ±8.2 months. When stratified by histological activity, no significant difference was observed in the composite endpoint between patients with MES 1 and histological activity and MES 2 (33% vs 73%; $\rho = -0.25$; $p > 0.05$).

Similarly, no statistically significant differences were found in the rates of hospitalization (1.6% with MES 1 vs 2.8% with MES 2, $\rho = -0.02$; $p > 0.05$), medical therapy escalation (30.5% with MES 1 vs 75% with MES 2, $\rho = -0.32$; $p > 0.05$). Interestingly, the need for a change in advanced therapy (13.8% vs 28.9%, $\rho = -0.25$; $p > 0.05$) and treatment optimization (18.3% vs 13.4%, $\rho = -0.04$; $p > 0.05$) did not differ significantly between patients with MES 1 and histological activity and MES 2.

Conclusion: UC patients with MES 1 and histological activity have similar adverse long-term outcomes to those with MES 2. These findings support consideration of treatment intensification in patients with MES 1 who exhibit histologic inflammation, reinforcing the prognostic value of histologic assessment beyond endoscopic findings.

Disclosure: Nothing to disclose.

PP0468

MICRONUTRIENT AND NUTRITIONAL STATUS OF IBD PATIENTS IN REMISSION REFERRED TO A SPECIALIST DIETITIAN CLINIC

P. Murphy[1], K. Klimova[1], J. Gulliver[2]
[1]University Hospital Plymouth NHS Trust, Gastroenterology, Plymouth, United Kingdom, [2]University Hospitals Plymouth, Gastroenterology, Plymouth, United Kingdom

Contact E-Mail Address: paula.murphy2@nhs.net

Introduction: Nutritional deficiencies are common in IBD patients and have been widely reported in Crohn's disease (CD) patients in particular. Nonetheless micronutrient screening is not routine in all centres in the UK. Body Mass Index (BMI) is widely used for detecting malnutrition in clinical practice but it is not sensitive marker of muscle mass. Hand grip strength (HGS) is quick to perform and may be an effective parameter to predict muscle function and health in IBD patients in busy outpatient settings. Different cut points are used in clinical practice to determine muscle weakness and may yield different results.

Aims & Methods: The aims of this study were (1) To examine micronutrient status (2) To establish the incidence of over- and under-weight and (3) To measure hand grip strength to determine the frequency of dynapenia in stable patients with IBD referred to specialist dietitian clinic for advice. A baseline micronutrient screen including 9 vitamin and minerals (Vitamins A,D, E, folate, B12, ferritin, selenium, copper and zinc as well as haemoglobin) was performed on all consenting patients at initial dietitian appointment. Inflammatory marker, C reactive protein, was also checked. Patients with raised CRP, were excluded from the micronutrient analysis. All patients were weighed, height measured and BMI calculated. Hand grip strength was measured using Marsden hand grip dynamometer. The maximum result of 6 trials was recorded and its corresponding percentile (1). Dynapenia was defined as HGS<16kg for females and <27kg for males (2) . Results of Ulcerative colitis (UC) and Crohn's disease (CD) patients were compared.

Results: A total of 292 consecutive patients, (108m, 184 f) referred for dietitian input from April 2023 to March 2025 were included. Mean age was 45 years (SD18). 201 patients with CD and 91 with UC were included. Results are presented in Table 1. No difference in micronutrient status was found between CD and UC patients apart from vitamin D where a higher incidence of deficiency was found in UC compared with CD patients (p=0.045) . Contrary to widespread belief incidence of underweight was low in both CD and UC with a higher incidence of obesity in both groups than underweight. Over a quarter of the IBD population had muscle weakness defined by both Dodds et al (2014) and Cruz-Jentofft et al (2019) which is concerning (1,2).

NUTRITIONAL STATUS	CD	UC
BMI kg/m2	Mean (SD) 24.8 (6.1) <18.5 kg/m^2 n=19 (9.5%) >30kg/m^2 n=33 (16.4%)	Mean (SD) 25.5 (6.5) <18.5kg/m^2 n=6 (6.7%) >30 Kg/m^2 n= 19 (21%)
HAND GRIP STRENGTH maximum (kg)	38.5 (11.3) M 21.4 (7) F <16kg n=20 (28%) <27kg n=11(20%) <10TH Percentile n=48 (37.5%)	40.2 (9.1)M 22.3 (6.6)F <16kg n=3 (9%) <27kg n=3 (11%) <10th percentile n=18 (30%)
VITAMIN D	77%	68%*
FOLATE	12.8%	17.9%
B12	5.6%	4.8%
SELENIUM	10.7%	3.4%
ZINC	31.5%	34.9%
FERRITIN	23.2%	15.4%
LOW HAEMOGLOBIN	31.0% (M) 20.3% (F)	35.4%(M) 22.6% (F)

Conclusion: Vitamin D status in particular should be monitored in all stable patients with IBD. A high proportion of both UC and CD patients were found to have weak muscle strength. HGS is a readily obtainable measure quick to perform and could be easily incorporated into routine clinical practice. Further research is needed to establish its clinical significance for stable IBD patients.

Contact E-Mail Address: lasswediness@gmail.com

Introduction: Inflammatory Bowel Disease (IBD), including ulcerative colitis and Crohn's disease, is a chronic condition that requires patients to be well-informed about their disease for effective self-management. Knowledge of triggers, treatment options, and lifestyle adjustments is essential for managing symptoms, reducing flare-ups, and improving quality of life.

This study explores knowledge gaps among IBD patients and evaluates predictive factors associated with a high level of disease-related knowledge.

Aims & Methods: We conducted a monocentric cross-sectional study including IBD patients. All individuals completed the IBD-Know score which is a validated 24-item questionnaire covering various IBD-related aspects, including anatomy, function, epidemiology, diet/lifestyle, general knowledge, medication, complications, surgery, reproduction, and vaccination.

In this study, the IBD-Know score was administered to IBD patients in our gastroenterology department. Each correct response was awarded one point, with higher scores indicating greater knowledge levels. While the IBD-Know score does not have universal cutoff points, scores above the median were interpreted in this study as reflecting high to excellent knowledge. Factors potentially influencing the level of IBD-related knowledge were also analyzed.

Results: A total of 69 patients with IBD (38 with Crohn's disease and 31 with ulcerative colitis) completed the IBD-Know questionnaire. The median age was 38 years, with a male-to-female ratio of 1.56. The median disease duration was 52 months (range: 6-156 months). Regarding lifestyle

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and medical history, 28 patients were current smokers, 48 had a history of IBD-related hospitalization, 28 had undergone IBD-related surgery, and 15 reported a family history of IBD.

Medication histories varied: all patients had used immunomodulators and corticosteroids, 38 had taken 5-aminosalicylates, and 35 were on biologics. Educational attainment was diverse, with 41 patients having completed college or university, while the remaining participants had a high school education or less.

The overall mean IBD-Know score was 13.8, with a mean correct answer rate of 40.8% across all 24 items. The lowest correct answer rate was in the reproduction domain (31.2%), with a subgroup analysis revealing lower accuracy among men (28.7%) compared to women (52%). The highest correct response rate was for the question on smoking in Crohn's disease (80.4%), while the lowest was for the indication of biologics (19%).

Univariate analysis identified several factors significantly associated with a higher IBD-Know score: disease duration over five years (p=0.02), history of IBD-related hospitalization (p=0.01), higher education level (college/university or greater) (p=0.002), family history of IBD (p=0.03), and biologics treatment (p=0.03). In multivariate analysis, hospitalization history (odds ratio [OR]: 2.525, 95% confidence interval [CI]: 1.280-4.705; p=0.002) and higher education level (OR: 2.692, 95% CI: 1.380-5.206; p=0.02) remained significant predictors of a high IBD-Know score after adjusting for other variables.

Conclusion: This study identifies significant knowledge gaps among patients with IBD, particularly regarding reproduction. Factors such as disease duration, hospitalization history, and education level correlate with higher knowledge scores. Addressing these gaps through targeted educational initiatives is essential to empower patients and enhance their self-management, ultimately improving their quality of life.

Introduction: During their lifetime, patients with Crohn's disease (CD) frequently develop strictures as a complication, where various degrees of inflammation and fibrosis coexist. Distinguishing between inflammatory and fibrotic strictures is crucial for deciding on surgery or treatment changes, yet it is currently challenging in clinical practice. Cross-sectional imaging techniques (e.g. magnetic resonance imaging MRI) provide a reasonably accurate estimate of bowel wall fibrosis. However, only histopathological examination can determine its true extent. Radiomics uses artificial intelligence to analyze quantitative features from diagnostic images and can predict clinical outcomes.

Aims & Methods: This study aims to assess the role of radiomics in classifying patients according to the degree (no/mild vs severe) of intestinal fibrosis in a cohort of CD patients who underwent surgery for strictures disease. We retrospectively selected 48 CD patients who underwent MR-enterography and subsequent surgery within 4 months between 2017-2023. An expert pathologist evaluated the degree of fibrosis in histopathological specimens from surgical samples using the Chiorean scoring system from 0 (no fibrosis) to 2 (severe fibrosis), and the degree of inflammation using Geboes score. For each MR-enterography, typical lesions of CD were searched by an expert radiologist on T2-weighted axial images generating a region of interest (ROI) segmentation for each lesion. We extracted 100 radiomic features from each ROI of the pre-processed MRI images using Pyradiomics. Feature selection included univariate analysis (Wilcoxon-Mann-Whitney test) and Spearmann correlation to exclude highly correlated features. A logistic regression model with stepwise regression was built with the selected features and evaluated by computing the area under the curve (AUC) of the receiver operating characteristic (ROC) curve. Model's sensitivity and specificity were calculated using the best cut-off according to the Youden index method.

Results: Among the 48 patients, 48% (n=23) showed severe fibrosis on the surgical specimen, whereas 52% (n=25) had either no or mild fibrosis. Two radiomic features were selected and resulted statistically significant in the fitted logistic regression model($p < 0.05$): original_shape_Maximum2DDiameterColumn and original_firstorder_90Percentile. Results with their 95%CI were: AUC 0.79 (0.64-0-90), sensitivity 0.69(0.50-0.75) and specificity 0.84(0.66-0.94). Bootstrap corrected (mean optimism) values of AUC and metrics were: AUC 0.77 (0.02), sensitivity 0.68(0.01), specificity 0.81(0.02).

Conclusion: Our study suggests that MRI-based radiomics modeling could help predict the degree of intestinal fibrosis. Future research will confirm these findings in a larger cohort.

Contact E-Mail Address: Mina.ayadxx@gmail.com

Introduction: Inflammatory bowel disease (IBD) is associated with an increased risk of psychological disorders; however, no prior study has systematically identified clinical predictors for their onset.

Aims & Methods: This study aimed to identify key clinical factors that can predict the development of psychiatric disorders in IBD patients.. We analyzed data from 7,069 IBD patients in the UK Biobank to predict the

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. onset of 13 psychiatric disorders in this population. Predictors including 16 socio-demographic variables, 8 surgical procedures, 8 disease location, 6 inflammation-related biomarkers, and medication usage were included to identify potential predictors of psychiatric diseases in IBD patients. The SHAP (SHapley Additive exPlanations) method was applied to rank the importance of all the predictors. A LightGBM (LGBM) model was then developed to predict the occurrence of psychiatric disorders in IBD patients after IBD diagnosis.

Results: Of all the 38 clinical factors evaluated, 15 factors that ranked top by importance were chosen to form a 15-predictors panel. The panel demonstrated strong performance (AUC = 0.72) in predicting the onset of psychiatric disorders 25 years before onset in patients of Crohn disease, and an AUC of 0.68 in Ulcerative Colitis (UC) patients. Besides, for patients with Crohn Disease, the model for predicting mental and behavioral disorders due to psychoactive substance use performs outstandingly (AUC = 0.87).

Conclusion: The LGBM model accurately predicted the occurrence of psychological diseases in IBD patients offering a valuable tool for clinicians. SHAP enhanced understanding of key factors enabling better treatment strategies and potentially improving the risk of developing psychological diseases.

IMPACT OF INTESTINAL ULTRASOUND (IUS) IMPLEMENTATION ON COLONOSCOPY UTILIZATION IN IBD PATIENTS: A RETROSPECTIVE STUDY FROM A TERTIARY HOSPITAL

C. Thanos[1], N. Georgakopoulou[1], D. Ntailianas[1], D. Piskopou[1], E. Georgiou[1], M. Triantafyllou[1], K. Tsitsigiannis[1], N. Kalakos[1], G. Michalopoulos[1], A. Striki[1], A. Braimakis[1], T. Argyropoulos[1], I. Karoumpalis[1]

Contact E-Mail Address: charalampos.a.thanos@gmail.com

Introduction: The management of inflammatory bowel disease (IBD) often relies on colonoscopy to evaluate disease activity and detect complications. However, intestinal ultrasound (IUS) has emerged as a non-invasive, accurate alternative, endorsed by ECCO-ESGAR guidelines for use in both Crohn's disease and ulcerative colitis.

This study aimed to evaluate the impact of IUS implementation on the frequency of colonoscopies performed in IBD patients at a tertiary care hospital.

Aims & Methods: We conducted a retrospective analysis comparing two time periods: before IUS implementation (2021–2022) and after its introduction (2023–2024). The number of colonoscopies performed for IBD management in each period was recorded. Screening colonoscopies in IBD patients were not included in the analysis; therefore, the data reflect colonoscopies performed specifically for the clinical management of the disease. The percentage change in colonoscopy utilization was calculated to assess the effect of IUS integration into routine clinical practice.

Results: In the pre-IUS period (2021–2022), a total of 340 colonoscopies were performed for the management of patients with IBD. After the introduction of IUS in 2023, the number of colonoscopies over the subsequent two years decreased to 280, reflecting a 17.6% reduction. This decline suggests a meaningful shift towards non-invasive monitoring facilitated by IUS.

Conclusion: The integration of IUS into the endoscopic workflow was associated with a notable decrease in colonoscopy use among IBD patients. These findings reinforce the role of IUS as a valuable, non-invasive modality for disease monitoring, with the potential to optimize resource utilization and support faster clinical decision-making. Prospective studies are needed to further assess the long-term benefits and cost-effectiveness of widespread IUS adoption in IBD care.

Introduction: Intestinal point-of-care ultrasound, as standardized by the International Bowel Ultrasound Group (IBUS), has emerged as a valuable tool for diagnosing, monitoring, and managing patients with Inflammatory Bowel Disease (IBD). While IBUS emphasizes a structured intestinal assessment, some European centers adopt a more comprehensive approach, combining intestinal ultrasound with a complete abdominal examination.

The Karolinska Centre for Digestive Health, a tertiary referral institution providing specialized care to approximately 4,500 patients with IBD, established a dedicated Gastrointestinal Ultrasound Unit in October 2023. This unit offers advanced diagnostic services to both hospitalized patients and those treated on an outpatient basis.

Aims & Methods: This retrospective study aimed to assess the prevalence of secondary extraintestinal findings in IBD patients undergoing comprehensive abdominal ultrasound between October 4, 2023, and March 4,

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. 2025. All patients underwent ultrasound assessments that included both intestinal and abdominal imaging. Patients referred for indications unrelated to intestinal ultrasound (IUS), as well as those undergoing repeat examinations, were excluded from the analysis to ensure data consistency. All examinations were performed by a single gastroenterologist with 25 years of ultrasound experience. In cases where secondary extraintestinal findings were identified, patients' electronic medical records were reviewed to determine whether these findings represented new diagnoses or previously known conditions.

Results: The study included 348 patients with IBD, 201 *(58%)* females and 147 *(42%)* males, with a mean age of 42.4 years. Among these, 260 *(75%)* were referred internally by our IBD Outpatient Clinic, 47 *(13%)* by the Gastroenterology Ward, 33 *(10%)* by private outpatient clinics, and the remainder from other healthcare sites. IUS revealed evidence of intestinal inflammation in 144 patients *(42%)*, while findings were normal in 204 patients *(58%)*.

Furthermore, 150 patients presented with a total of 195 secondary extraintestinal findings, of which 113 *(58%)* represented newly identified pathologies. Among all secondary findings, the majority, 104 *(53%),* were related to the hepatobiliary system, including 33 newly diagnosed cases of hepatic steatosis and 17 new cases of cholecystolithiasis. One patient demonstrated ultrasound features suggestive of primary sclerosing cholangitis (PSC) and is currently undergoing further evaluation. Additional findings involved the reproductive system (29/*15%*), urinary system (15/*7%*), spleen (32/*16%*), and pancreas (5/*2%*). Various other intra-abdominal findings were also identified (37/*18%*). Notably, one patient presented with a suspicious mass in the right iliac fossa, and another demonstrated ultrasound findings suggestive of a prostatic tumor; both cases were referred for further oncologic evaluation.

Additionally, three patients were newly diagnosed with intraductal papillary mucinous neoplasm (IPMN), which was subsequently confirmed via magnetic resonance imaging, and all were enrolled in the national IPMN surveillance protocol.

Conclusion: A considerable proportion of patients with IBD were found to have previously unknown extraintestinal abdominal pathologies, underscoring the essential role of comprehensive ultrasound examination that combines both intestinal and abdominal assessment. Fortunately, only a minority of these findings resulted in changes to patient management.

Contact E-Mail Address: Sarraelfss@gmail.com

Introduction: Intestinal ultrasound is a noninvasive and inexpensive tool to assess disease activity in patients with inflammatory bowel disease, such as Crohn's and ulcerative colitis by monitoring the disease activity in real time.

Aims & Methods: Intestinal ultrasound is a non-invasive, cost-effective imaging tool for routine clinical evaluations. This study examines its role in monitoring Crohn's disease, comparing it with CT Enterography.

This is a prospective, descriptive, comparative study including patients with crohn's disease aged over 16, between March 2023 and March 2024. Every patient had a colonoscopy, enteroscan, and digestive ultrasonography; the delay between each test was limited to one month by the same operator. Patients with ileal or recto-colic resections or pregnant women were not included. We develope a form to collect clinical, therapeutic, and epidemiological informations as well as the outcomes of CT, colonoscopy, and ultrasounds. Between ultrasound, CT scan and colonoscopy, we asked our patients to choose the most widely accepted para-clinical test. Ultrasonography's sensitivity (Se) and specificity (Sp) were determined, and data from enteroscanner and ultrasound were analyzed, with a focus on the wall's thickness, vascularization, damage extent, and peridigestive environment. The statistical study was carried out using SPSS 21.0 software. Quantitative variables were expressed as medians and qualitative variables as numbers and percentages. The McNemar test and the Wilcoxon test for associated samples were applied. The significance level was set at 0.05.

Results: Forty-nine patients were included, with a male-to-female ratio of 0.53 and a median age of 32 years. US detected digestive thickening in 81.6% of cases, mainly in the terminal ileum. CT Enterography detected thickening in the proximal small bowel and rectum in 2.2% of cases, which US missed. US sensitivity was 84.4%, with specificity of 50%. No significant difference was found between US and CT for thickening detection. Mesenteric infiltration detected by US was similar to CT (Se = 86.5%, Sp = 100%). For adenopathy, Se was 75% (Sp = 97%). US showed a 60% sensitivity for detecting complications, with a significant difference compared to CT (p = 0.002). There was no correlation between thickening on US and ulcers on endoscopy.

Conclusion: Despite limitations in examining the proximal intestine and rectum, intestinal ultrasonography is a sensitive, accessible method for monitoring Crohn's disease and detecting complications.

Disclosure: Nothing to disclose.

LEVERAGING GLOBAL VIDEO CONTEXT TO AUTOMATE COLON SECTION IDENTIFICATION IN ULCERATIVE COLITIS ENDOSCOPY

A. Gomariz[1], P. Szostak[1], R. Girycki[1], B. Stimpel[1], S. Abbasi-Sureshjani[1], S. Levitte[2], T. Karrer[1]
[1]Roche, Basel, Switzerland, [2]Genentech, South San Francisco, United States of America

Contact E-Mail Address: alvaro.gomariz@roche.com

Introduction: Our previously developed UC-SCALE algorithm[1] predicts UC severity at the colon-section level by assigning a Mayo Clinic Endoscopic Subscore (MCES) to the rectum, sigmoid, or descending colon. Yet, manually annotating anatomical sections—especially after the procedure—is exceedingly challenging for expert readers and is typically not part of clinical practice. To streamline UC-SCALE usage and reduce manual labeling, we propose an AI algorithm that automatically identifies each frame's anatomical location in colonoscopy videos.

Aims & Methods: We used the same five phase-III etrolizumab clinical trial datasets underlying UC-SCALE: three trials (3028 videos, 1309 patients, 391 sites) for training, one trial (692 videos, 327 patients, 80 sites) for validation, and one trial (607 videos, 317 patients, 83 sites) for testing. We tuned model hyperparameters by comparing multiple training runs and selected the best-performing configuration on the validation set for final testing. For each frame, we extracted "embedding vectors" generated by our internal IBD foundation model (adapted from DINO[2]), which condenses frame image content into relevant features.

For comparison, these two models were trained to classify each frame as rectum, sigmoid, or descending colon:

- Frame-Only Model (no video context): Predicts anatomic location using only the single-frame embedding.
- Full Video-Context Model: Uses a transformer-based architecture, similar to the one proposed by Mobadersany et al [3], that incorporates the entire video's sequence of embeddings, mimicking how clinicians view videos in context.

Results: The Frame-Only Model yielded modest performance (AUC=0.71, F1=0.59), confirming the difficulty of labeling isolated frames. By contrast, the Context-Aware Model significantly improved metrics (AUC=0.93, F1=0.82), highlighting the value of incorporating sequential information—similar to real-time endoscopic navigation.

Model	AUC	F1-score
Frame-Only	0.71	0.59
Full Video-Context	0.93	0.82

Table 1. Performance of the two section classification models.

Conclusion: Incorporating video-wide context remarkably enhances frame-by-frame anatomical labeling of UC colonoscopy. This approach can be coupled with UC-SCALE's section-level severity scoring to automate both localization and disease severity estimation, reducing the need for manual section annotation.

Future work will validate performance across diverse datasets, potentially lowering trial costs and broadening clinical adoption of IBD AI-based algorithms.

KINETICS OF TRANSMURAL HEALING IN PATIENTS WITH CROHN'S DISEASE TREATED WITH ANTI-TNF THERAPY

A. Buisson[1], C. Hordonneau[1], B. Pereira[1]
[1]CHU Estaing Clermont-Ferrand, IBD Unit, Clermont-Ferrand, France

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: Transmural healing is a promising target in Crohns' disease (CD) that is associated with more favorable outcomes than endoscopic remission, especially lower risk of bowel damage progression. C-score has been recently developed and validated to assess transmural healing in patients with CD. However, the best time to assess transmural healing remains to be determined.

Aims & Methods: We aimed to evaluate the kinetics of transmural healing in patients with CD treated with anti-TNF therapy.

From a prospective database of patients with CD performing MRI for luminal CD, we analyzed the kinetics of transmural healing among CD patients older than 18 years-old receiving anti-TNF therapy, with objective sign of inflammation on morphological evaluation (cross-sectional imaging) before starting the treatment, who underwent at least one MRI examination to assess therapeutic efficacy within 12 months. Patients treated with anti-TNF agents for treat isolated perianal lesions were excluded.

We used a statistical model based on imputation according the last observation carry forward and clinical relevance. Transmural healing was then assessed every month during the first year. For segmental analysis, we used the same division into segments than recommended for Lemann Index calculation. Transmural healing was defined as C-score < 0.5 in each segment. C-score was calculated as previously published (0.2 x (bowel thickness in mm – 3) + 2 if ulcer + 1.5 if enlarged lymph nodes).

Results: Overall, 123 patients were included. Among them, 90 were female (73.1%), 48 (39.9%) were current smokers and 53 (43.0%) had prior intestinal resection. The median CD duration at baseline was 7.6 years [1.4-15.2]. At baseline, 41 patients (33.3%) were anti-TNF-naïve. At baseline, 67 patients (55.3%), 53 patients (43.8%) and 1 patient (0.8%) were treated with infliximab, adalimumab and golimumab, respectively with concomitant immunosuppressant in 94 patients (79.0%).

At baseline, 220 segments were considered as active (C-score > 0.5) including 100 in the terminal ileum and 120 in the colon/rectum.

According per-segment analysis (N=220), the rate of transmural healing was 6.4% at M1, 6.4% at M2, 10.0% at M3, 10.1% at M4, 14.6% at M5, 18.0% at M6, 23.2% at M7, 24.5% at M8, 26.0% at M9, 26.8% at M10, 29.1% at M11 and 30.4% at M12.

Among terminal ileum segments (n=100), the rate of transmural healing was 2.0% at M1, 2.0% at M2, 5.0% at M3, 5.0% at M4, 9.0% at M5, 12.9% at M6, 16.0% at M7, 17.0% at M8, 18.0% at M9, 19.0% at M10, 20.0% at M11 and 20.0% at M12.

Among colorectal segments (n=120), the rate of transmural healing was 6.4% at M1, 6.4% at M2, 13.8% at M3, 13.8% at M4, 15.6% at M5, 22.0% at M6, 28.4% at M7, 28.6% at M8, 28.6% at M9, 28.6% at M10, 32.8% at M11 and 34.4% at M12.

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among the 123 patients with CD, in multivariable analyses, absence of transmural healing (C-score > 0.5) within the first year was associated with increased risk of surgery (HR=3.37 [1.30-8.68]; p=0.012), drug discontinuation (HR=2.31 [1.29-4.14]; p=0.005), and bowel damage progression (p <0.001) while we observed a trend for higher risk of CD-related hospitalization (HR=1.92 [0.85-4.36]; p=0.11).

Conclusion: Transmural healing is achievable in more than 30.0% of active segments in patients with CD treated with anti-TNF therapy within the first year. The best time to assess transmural healing was between 6 and 12 months after starting anti-TNF therapy with higher rate of transmural healing for colorectal versus ileal segments. Transmural healing defined as C-score < 0.5 is associated with long-term improved outcomes in patients with CD.

Introduction: Perianal abscesses are a frequent and serious complication of Crohn's disease (CD), requiring timely and accurate diagnosis to guide appropriate treatment. Transperineal ultrasound (TPUS), especially when combined with contrast-enhanced ultrasound (CEUS), may offer a promising, real-time, bedside alternative.

Aims & Methods: This study aimed to evaluate the diagnostic performance and inter/intra-observer reliability of CEUS versus conventional TPUS B-mode in differentiating abscesses from inflammatory masses in CD patients with acute perianal symptoms.

We retrospectively analyzed 52 examinations performed on 37 adult Crohn's disease (CD) patients who underwent transperineal ultrasound (TPUS) at a tertiary IBD center between 2012 and 2021 for acute or painful perianal symptoms and suspected septic complications.

Patients were included if TPUS identified perianal lesions or masses suggestive of abscesses, warranting further evaluation with contrast-enhanced ultrasound (CEUS) to better characterize the lesion. Exclusion criteria included contraindications to CEUS (e.g., congestive heart failure), the presence of simple fistulas, or large, clearly identifiable abscesses (>3 cm) with evident fluctuating fluid content already visible on B-mode imaging. TPUS B-mode and CEUS examinations were performed using standardized protocols, with intravenous administration of 4.8 mL of contrast agent (SonoVue®).

All examinations were recorded, and three expert reviewers independently assessed anonymized video cases in two phases—B-mode followed by CEUS—randomized and blinded to clinical data. Lesions were classified as abscesses, inflammatory masses, or phlegmons. Intra- and inter-observer agreement was evaluated for maximum lesion size, maximum size of fluid content, and final diagnosis using intraclass correlation coefficients (ICC) and Cohen's kappa (κ).

Results: On TPUS B-mode, 17 abscesses, 32 inflammatory masses, and 3 phlegmons were identified; CEUS reclassified several of these lesions, ultimately detecting 16 abscesses, 31 inflammatory masses, and 5 phlegmons. Among the 17 abscesses diagnosed on B-mode, only 4 were confirmed by CEUS, while 11 were reclassified as inflammatory masses and 2 as phlegmons. Conversely, 11 lesions initially classified as inflammatory masses on B-mode were reclassified as abscesses by CEUS.

Intra-observer agreement for B-mode was excellent in assessing lesion size (ICC 0.853) and fluid content (ICC 0.897), but only fair to substantial for final diagnosis (κ = 0.55). CEUS demonstrated superior reliability, with nearly perfect intra-observer agreement for diagnosis (κ = 0.95).

Inter-observer agreement for TPUS B-mode was moderate to good for lesion size (ICC 0.798) and fluid content (ICC 0.736), but poor for final diagnosis (κ = 0.31, 95% CI 0.00–0.78), mainly due to the limited reliability of most sonographic features (echogenicity, gaseous artifacts, vascularity), except for posterior echo enhancement (κ = 0.54, 95% CI 0.36–0.82). In contrast, inter-observer agreement for CEUS was good for lesion size (ICC 0.847, 95% CI 0.76–0.91), fluid collection size (ICC 0.925, 95% CI 0.88–0.96) and for final diagnosis (κ = 0.83, 95% CI 0.79–0.95).

Conclusion: Contrast-enhanced TPUS significantly improves diagnostic reliability in identifying perianal abscesses in Crohn's disease, outperforming conventional B-mode TPUS in both intra- and inter-observer assessments. CEUS provides a valuable, accessible imaging modality for real-time evaluation of perianal complications, particularly in urgent clinical scenarios or when MRI is not feasible.

THERAPEUTIC EFFICACY OF FECAL MICROBIOTA TRANSPLANTATION IN ULCERATIVE COLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

H. Khizar[1], K. Ali[1], J. Wang[1], J. Yang[2]
[1]The Fourth Affiliated Hospital of School of Medicine, and International School of Medicine, International Institutes of Medicine, Zhejiang University, Surgery, Yiwu, China, [2]Hang Zhou First People's Hospital, gastroenterology, Hangzhou, China

Introduction: Ulcerative colitis (UC) is a persistent inflammatory bowel disease characterised by alteration in the gut microbiota. Fecal microbiota transplantation (FMT) is a potential treatment for UC, aimed at restoring the balance of microorganisms in the intestines. This study evaluated efficacy of FMT for treating patients with UC.

Aims & Methods: A comprehensive electronic literature search was conducted for published studies in PubMed, Embase, and Scopus from their inception until April 2024. The analysis included randomized control trials (RCTs) that met the inclusion criteria. A random-effects model was applied to calculate odds ratios (ORs) and 95% confidence intervals (95%CIs) to evaluate the efficacy of the outcomes.

Results: This meta-analysis included a total of 19 RCTs, reporting the data from 932 patients diagnosed with UC. The OR showed a significantly higher clinical remission (2.67, 95% CI: 1.92, 3.71, $p < 0.00001$) and endoscopic remission (1.92, 95% CI: 1.19, 3.11, $p = 0.008$) among patients receiving FMT compared to the control group. Subgroup analyses of the primary outcome suggest that various factors, such as the method of FMT administration, donor characteristics, FMT dosage, and whether FMT is used alone or in combination, could slightly influence treatment outcomes. The OR of 1.18 (95% CI 0.75, 1.86, $p = 0.48$) indicated that both groups experienced similar adverse events.

Conclusion: These findings suggest that applying FMT is a safe and highly effective approach for treating UC, with adverse events comparable to those in the control group. This highlights the necessity for a better understanding of microbiota's role in UC management.

Introduction: Aim: To report on the efficacy and safety of elective switching from intravenously (IV) to subcutaneously (SC) administered Vedolizumab in Inflammatory Bowel Disease (IBD) patients in clinical remission.

Aims & Methods: Methods: Retrospective analysis of IBD patients in clinical remission who were receiving Vedolizumab IV for treatment of their disease in a single tertiary center and were switched to SC, based on their physician's choice. The primary endpoint was disease deterioration during the follow-up period, according to the disease specific composite measures. In CD, clinical remission was defined as Crohn's Disease Activity Index (CDAI) <150 and in UC as Simple Clinical Colitis Activity Index (SCCAI) <2.

Results: Results: Between December 2023 and February 2025, 86 patients (Crohn's disease = 17, Ulcerative colitis = 69) were consulted in order to switch from IV to SC vedolizumab administration. Five patients (5,8%) did not want to change and therefore, 81 patients (94,2%) were finally switched. All patients were in clinical remission. After a mean (SD) follow up period of 8 (4) months, 9 patients (11,1%) experienced worsening of their disease, and were either switched back to IV VDZ (n=4, 4,9%) or to another agent (n=5, 6,2%). The remaining 72 patients (88,8%) showed favorable response, none of them requested an unscheduled visit, or developed an adverse event (clinical or laboratory) or needed escalation of treatment.

Conclusion: Conclusion: Elective switching from IV to SC Vedolizumab seems to be an effective and safe approach in real-world every day clinical practice in IBD patients in clinical remission.

Introduction: The British Society of Gastroenterology {1} recommend the use of structured transition programmes to improve control of chronic GI disease in adolescents. Although research is limited structured transition programmes have been shown to improve disease outcomes in IBD.

Aims & Methods: We performed a retrospective multicentre study. Data was collected on patients prior to transition and post-transition to adult IBD services across Ireland over a 5-year period. Patients were grouped into those who attended a structured transition programme and those who received standard care transitioned with a referral letter to the adult gastroenterologist.

Our aim was to look at the impact of attending a structured transition programme on engagement of patients with IBD services and disease outcomes including change in medications, biologic failure and need for steroids.

Results: In total 282 patients were included. 155 patients attended a structured transition programme and 127 patients were in our standard care group. No significant differences were seen in basic demographics, median FCP levels or biologic use between either group at the time of transition.

Patients who took part in a structured transition programme had significantly better engagement with adult IBD services with significantly lower rates of non-attendance at outpatient clinics in the 1st year post-transition (11.6% versus 27.2%, $p = 0.04$) and significantly lower rates of disen-

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

gagement with services (4.2% versus 13.1%, p = 0.015)(Table 1). Patients who attended a structured transition programme had significantly lower rates of change in medication therapy post-transition to adult services (p =0.045) (Table 1).

There was no significant difference seen in rates of biologic failure, need for steroid or median FCP levels between either group. The only factor on regression analysis that negatively impacted rates of non-attendance at outpatient clinics or disengagement with IBD services was attending a structured transition programme.

	Structured Transition Programme	Standard Care	P value
Clinic non-attendance	12.3%	27.2%	0.002
Lost to follow-up	2.7%	19.15%	<0.001
Change in medications	37.5%	50.0%	0.045
Failure of biologic therapy	15.8%	25.7%	0.08
Need for steroids	26.4%	22.4%	0.28
Need for surgery	9.7%	14.7%	0.15
Disease flares	32.6%	34.5%	0.79

Conclusion: Structured transition programmes in IBD improve engagement of patients with IBD services with significantly lower rates of non-attendance at clinics and disengagement with IBD services. More research and funding is required in the field of transition services in IBD to improve care for this cohort of vulnerable patients.

Introduction: No data exist on the relationship between serum and tissue infliximab (IFX) concentrations and outcomes in acute severe ulcerative colitis (ASUC).

Aims & Methods: In hospitalized patients (pts) with ASUC treated with IFX rescue therapy, we assessed relationships between longitudinal serum and tissue IFX concentrations and pt outcomes. In an open-label, prospective study, hospitalized ASUC pts treated with IFX rescue therapy were followed for 22 weeks (wks) at 2 centers. Inclusion criteria:

(A) hospitalized ASUC (partial Mayo score [PMS] > 7, baseline Mayo endoscopic score [MES] ≥ 2 and met Truelove/Witts criteria)

(B) receiving either standard or accelerated rescue IFX.

From IFX initiation until wk 22, clinical scores (PMS) and serum sampling were performed at multiple induction and maintenance timepoints (hospital/outpatient).

Colonoscopy scores (MES) and biopsies were collected on day 2-5 post first infusion (early inpatient) and wk 16-22 (maintenance).

Outcomes: Median area under the curve (AUC) of serum IFX concentration during early induction (wk 0-2), induction (wk 0-14) and maintenance (wk 15-22) were compared between wk 22 endoscopic remitters (ERs) (MES 0 or 1 without UC-related hospitalization or colectomy) and non-remitters (NRs). Tissue IFX concentrations were compared between groups.

Results: 110 serum samples over 22 wks (mean 7.9 samples/pt) with 54 samples between wk 0- 2 (mean= 3.9/pt) were collected. Biopsies at early inpatient (n=17) and maintenance colonoscopies (n=15) were collected from 14 pts. Mean age was 38 years, 50% were female, mean disease duration was 7.8 years and 69% had pancolitis. One NR needed colectomy and another was re-hospitalized. 50% achieved endoscopic remission at wk 22. ERs had numerically higher baseline CRP (49 [±28] vs. 31 [±24] mg/dL), immunomodulator use (71% vs. 43%) and clinical response (86% vs. 43%) to NRs, while albumin (3.3 [±0.9] vs. 2.9 [±0.6] g/dL) and total IFX dose between wk 0-2 (16 [±1] vs. 12 [±6] mg/kg) were more similar. Mean BMI was 23.8 kg/m^2. Between wk 0-2, the mean number of IFX infusions per pt

20506414, 2025, S8, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ueg2.70036 by Cochrane Colombia, Wiley Online Library on [15/10/2026]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

was 1.5 (±0.7), and median dose per infusion was 11.4 mg/kg (IQR 25-75: 11-19). Median serum IFX concentration AUC was higher in ERs than NRs in early induction (wk 0-2: 568 ug*day/mL [528-1627] vs. 293 [145- 423], p=0.004), all induction (wk 0-14: 3036 [2742-3199] vs. 1768 [1375-2468] p=0.004) and in maintenance (wk 15-22: 841 [309-3295] vs. 405 [295-718] p=0.002). Findings were similar for dose normalized AUC.

Peak concentration 2 hrs post first infusion was numerically higher in ERs vs. NRs (median 365 ug/mL [200-484] vs. 187 [140-355] p=0.15) overall and dose-adjusted. Anti- IFX antibodies were detected in one NR maintenance sample. Baseline clearance inversely correlated with AUC (r=-0.7, p=0.03) or dose-normalized induction AUC (r=-0.8, p=0.01).

Tissue IFX concentrations were similar in inflamed/non-inflamed tissue and were similar between ERs/NRs in early induction (median 104 ng/mg [89-114] vs. 107 [76-133], p=1.0), and maintenance (10 [4-69] vs. 26 [3-87], p=0.99). Percent of drug in tissue vs. serum was similar between ERs/NRs (induction: median 7% vs 8%; maintenance: 8% vs 6%).

Conclusion: Intense serum and tissue sampling of ASUC pts receiving IFX showed higher serum drug exposure at all timepoints in endoscopic remitters whereas tissue concentrations were similar regardless of outcome. Tissue IFX may be required but not sufficient for achievement of outcomes in ASUC.

TISSUE DRUG LEVELS ARE SIGNIFICANTLY HIGHER AND POSITIVELY CORRELATED WITH SERUM LEVELS IN IBD PATIENTS UNDER SUBCUTANEOUS COMPARED WITH INTRAVENOUS INFLIXIMAB MAINTENANCE THERAPY

X. Roblin[1], S. Nancey[2], G. Duru[1], A.-S. Peaucelle[1], G. Boschetti[2], L. Bastide[1], M. Barrau[1], F. Mechi[3,3], S. Paul[4]

Introduction: Previous studies reported a positive correlation between serum and tissue drug levels in IBD receiving intravenous (IV) infliximab (IFX) therapy, except in those with severely inflamed tissue (1). Tissue drug levels in patients with IBD receiving SC IFX have not yet been investigated. We aimed to compare both the serum and tissue drug levels between SC and IV IFX maintenance therapy in IBD patients.

Aims & Methods: Any IBD patients under maintenance therapy with SC or IV stable doses IFX who underwent a colonoscopy for routine follow-up were eligible. Patient and disease characteristics, as well as clinical and endoscopic activity were recorded. Clinical activity was defined by high activity score (CDAI or pMAYO score) with at least one elevated biomarker (fecal calprotectin >250 mg/g, serum CRP >5 mg/L). Endoscopic disease activity was categorized as absent (normal), low (mild inflammation), moderate (friability, aphthoid lesions), or severe (ulcerations), as reported by the endoscopist blinded to the results of serum and tissue drug levels. Two biopsies were taken from the same location (either the most active area or randomly if no endoscopic lesion), and tissue and serum IFX levels were measured simultaneously in a centralized manner blinded to clinical and endoscopic disease activity. Frozen biopsy specimens were treated with the Bio-Plex® Cell Lysis Kit after tissue cutting and homogenates were sonicated at 4°C (Omni Ruptor 205). Tissue extracts were then frozen at -80°C prior drug measurements (iTrack10; Theradiag).
